Methods: To investigate if miR-143/145 gene cluster could promote PM fibrosis, all these immortal HPMCs were characterized by fibrosis related markers and tested the expression of miRNA-143/145 cluster and tropomyosin4 (TPM4) by real time PCR or Western blot. We also used PD dialysis rat model to observe the response of PM to miR-143/145 gene cluster and their possible target.

Results: Here, we found that miR-143/145 gene cluster, which are examined to be highly expressed in HG-induced HPMCs (HG, 60 mmol/L) and in PD animal model, TPM4 were found significantly lower expression in HG-induced HPMCs. So our study showed that high glucose from PD fluid could promote the expression of miR-143/145 of HPMCs and reduce the expression of TPM4, compared with normal glucose-cultured HPMCs. Reporter assays further supported that TPM4 were post-transcriptionally regulated together by miR-143/145 gene cluster. Collectively, these data suggested that TPM4 was a potential target of miR-143/145 gene cluster. Re-expression of miR-143/145 gene cluster by miR-143 or miR-145 mimics led to cell deformation, and reduced cell adhesion, following the down-regulating expression of TPM4 and E-cadherin, but up-regulating expression of α-SMA, CTGF, collagen and fibronectin which might increase PM fibrosis.

Conclusions: Our data suggested that miR-143/145 gene cluster might contribute to the cell deformation of HPMCs and the progressive PM fibrosis during PD.

Mitochondrial DNA Copy Number Is Associated with Peritoneal Dialysis Failure in Younger and Metabolically Healthier Peritoneal Dialysis Patients

Jae Eun Um,1 Jong Hyun Jhee,2 Kyoungh Sook Park,3 Chang-Yun Yoon,4 Mi Jung Lee,2 Jung Tak Park,5 Shin-Wook Kang,1 Taehyun Yoo.1,2

1Samsung Biomedical Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Insulin resistance and inflammation are known to be closely related to adverse outcomes in peritoneal dialysis (PD) patients. Recently, mitochondrial function has been reported to play a key role in glucose metabolism as well as systemic inflammation in various populations. However, the clinical consequences of mitochondrial function in PD patients are not well known. Therefore, this study was aimed to investigate the relationship of mitochondrial DNA (mtDNA) copy number and clinical outcome in PD patients.

Methods: A total of 120 prevalent PD patients were recruited. mtDNA copy number was counted by a PCR based method. Primary outcome was PD catheter removal due to ultrafiltration failure. Metabolic syndrome was defined using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Cox proportional hazard analysis was performed to determine the independent association of mtDNA copy number with primary outcome.

Results: The mean age was 52.3 years and 52 patients (42.5%) were male. The mean mtDNA copy number was 29.1±14.9. During a mean follow-up duration of 59.4±39.3 months, primary outcome was observed in 54 patients (45.0%). There were no significant differences in baseline characteristics between non-PD and PD failure group except for serum adiponectin levels (20.5±7.3 vs. 17.5±7.3 mg/mL, P=0.028). mtDNA copy number was significantly associated with PD failure in multivariate Cox analysis (hazard ratio (HR)=0.995, 95% confidence interval (CI)=0.976-1.015, P=0.634). However, a subgroup analysis revealed that mtDNA copy number was an independent predictor of PD failure in patients younger than 55 years without metabolic syndrome (HR=0.819, 95% CI=0.692-0.970, P=0.029) after adjustment for confounding factors.

Conclusions: mtDNA copy number may be associated with ultrafiltration failure in younger and metabolically healthier patients treated with PD.

Background: Vascular endothelial growth factor (VEGF) has been implicated in peritoneal angiogenesis and membrane remoulding in peritoneal dialysis (PD). Human peritoneal mesothelial cells (HPMC) have been identified as a major source of VEGF in the peritoneum. However, the exact mechanism of VEGF induction in HPMC is unclear. Since IL-6 concentrations in the drained dialysate correlate with VEGF levels, the link between the two has been suggested. While HPMC do not bear classical IL-6 receptor, they can respond to IL-6 trans-signalling that involves soluble IL-6 receptor (sIL-6R). Here, we have examined whether this mechanism can underlie VEGF synthesis by HPMC.

Methods: HPMC were isolated from normal omentum. Dialysate effluent was obtained from stable PD patients and peritonitis. VEGF mRNA and protein levels were measured by RT-qPCR and ELISA, respectively. The involvement of transcriptional factors was assessed by EMSA, transient transfections with VEGF promoter constructs, and siRNA silencing.

Results: IL-6 and sIL-6R alone had no effect on VEGF release by HPMC. However, the exposure to IL-6+sIL-6R resulted in a time- and dose-dependent induction of VEGF mRNA and protein. The combination of IL-6+sIL-6R activated the VEGF promoter region that contained high affinity binding sites for the transcription factor SP4. Specific mutation of the SP4 binding site eliminated VEGF promoter activation. In turn, the induction of SP4 was controlled by STZ 3. Exposure of HPMC to dialysate effluent obtained during acute peritonitis and containing increased levels of IL-6 and sIL-6R resulted in a dose-dependent VEGF induction. This effect was significantly attenuated in cells treated with siRNAs for either SP4 or STAZ.

Conclusions: Dialysate IL-6 and sIL-6R act through the trans-signalling pathway controlled by the STAT3-SP4 axis to up-regulate mesothelial VEGF production during peritonitis.

Funding: Government Support - Non-U.S.

Background: Conventional culture methods for microbes are inherently slow and inefficient. Treatment of bacterial (BP) and fungal peritonitis (FP) are different and quick differentiation is needed. Presently, there is no biomarker to predict relapsing and inefficient treatment of bacterial (BP) and fungal peritonitis (FP). We aimed to validate the potential use of soluble IL-6 receptor (sIL-6R) and IL-6 to differentiate bacterial peritonitis from fungal peritonitis.

Methods: Five unused PD fluid, 13 effluent from normal PD and 45 effluents from 15 patients at baseline (1 week and 2 weeks of therapy) with BP including 3 who relapsed and 3 FP were included. Half of each was subjected to total and differential WBC count and culture; and half was frozen at -80°C for NMR analysis. BP and FP was diagnosed based on identification of organism. RP was defined as per standard definition. High Resolution NMR spectra were recorded at 29.7 T on a Bruker Avance III 800 MHz spectrometer. Standard 1D 1H NMR spectra were acquired using the Carr– Purcell–Meiboom– Gill (CPMG) pulse sequence. To confirm the assignment of marker peak, two-dimensional (2D) 1H-1H TOCSY and 1H-13C HSQC spectra were also acquired.

Results: Five unused and 15 normal PD effluents after 6 hours of dwell did not show any marker peak at NMR spectra at 0.67 ppm while 15 cases of BP showed marker peak; however marker peak disappeared after resolution of peritonitis at 1 week and 2 weeks of antibacterial therapy except for 3 cases who relapsed in whom marker peak was persisting despite absence of clinical peritonitis. The 3 cases of FP did not show any such marker peak differentiating it from BP. Marker signal represent trans-methylene protons of cyclopropene ring moiety as reported earlier and depicted in Figure 1.

Conclusions: The cyclopropane signal at 0.67 ppm can be marker signal to differentiate BP and FP and persistence of this signal at 2 weeks after clinical resolution of peritonitis predicts RP.

Background: Vascular endothelial growth factor (VEGF) has been implicated in peritoneal angiogenesis and membrane remoulding in peritoneal dialysis (PD). Human peritoneal mesothelial cells (HPMC) have been identified as a major source of VEGF in the peritoneum. However, the exact mechanism of VEGF induction in HPMC is unclear. Since IL-6 concentrations in the drained dialysate correlate with VEGF levels, the link between the two has been suggested. While HPMC do not bear classical IL-6 receptor, they can respond to IL-6 trans-signalling that involves soluble IL-6 receptor (sIL-6R). Here, we have examined whether this mechanism can underlie VEGF synthesis by HPMC.

Methods: HPMC were isolated from normal omentum. Dialysate effluent was obtained from stable PD patients and peritonitis. VEGF mRNA and protein levels were measured by RT-qPCR and ELISA, respectively. The involvement of transcriptional factors was assessed by EMSA, transient transfections with VEGF promoter constructs, and siRNA silencing.

Results: IL-6 and sIL-6R alone had no effect on VEGF release by HPMC. However, the exposure to IL-6+sIL-6R resulted in a time- and dose-dependent induction of VEGF mRNA and protein. The combination of IL-6+sIL-6R activated the VEGF promoter region that contained high affinity binding sites for the transcription factor SP4. Specific mutation of the SP4 binding site eliminated VEGF promoter activation. In turn, the induction of SP4 was controlled by STZ 3. Exposure of HPMC to dialysate effluent obtained during acute peritonitis and containing increased levels of IL-6 and sIL-6R resulted in a dose-dependent VEGF induction. This effect was significantly attenuated in cells treated with siRNAs for either SP4 or STAZ.

Conclusions: Dialysate IL-6 and sIL-6R act through the trans-signalling pathway controlled by the STAT3-SP4 axis to up-regulate mesothelial VEGF production during peritonitis.

Correlation Between Fibroblast Growth Factor-23, Endothelial Dysfunction, and Inflammatory Markers in Chronic Peritoneal Dialysis Patients and Their Response to Antioxidant Therapy

Mital Bora, Nephrology, Ayur Sandra Super Specialty Hospital, Guwahati, Assam.

Background: Cardiovascular disease (CVD) is the major cause of morbidity and mortality in dialysis patients. Various non-traditional factors like inflammation, acute phase reactants and endothelial dysfunction have been proposed for this increased incidence of
CVD. Increased intact parathyroid hormone and FGF-23 levels are associated with the progression of chronic kidney disease in peritoneal dialysis (PD) patients. N-AcetylcySTEine (NAC) acts on atherosclerosis and also improves the endothelial functions. This study was designed to evaluate the correlation between FGF-23, endothelial dysfunction and markers of inflammation in chronic PD patients and to evaluate the effect of three months of NAC on these parameters.

Methods: All patients underwent Doppler studies to assess endothelial function by the flow mediated dilatation (FMD) of the brachial artery and carotid intima media thickness (CIMT).BRachial artery was imaged during reactive hyperemia (endothelium-dependent, glyceryl trinitrate mediated dilatation (nitroglycerine-mediated dilatation, NMD, endothelium-independent) in all PD patients. NAC was given in the dose of 1200 mg in two divided doses for a period of three months.

The associations between different parameter were analyzed using Spearman correlation. The parameters were repeated after three months of therapy with NAC.

Results: A total of 73 chronic PD patients were enrolled in this study. FGF-23 showed strong positive correlation with serum homocysteine level (r=0.97, p<0.001), hsCRP (R=0.77, P<0.001), Endothelium Dependent Dilatation (EDD) (r = 0.968, P < 0.001) and CIMT (r = 0.994, P < 0.001), but negatively correlated with Endothelium Independent Dilatation (EID) and Vitamin D level. All these parameters including FGF-23, hsCRP, homocysteine, CIMT and EDD were significantly reduced after three months of therapy with NAC.

Conclusions: FGF-23 correlated well with inflammatory markers and endothelial function. With three months of therapy, NAC significantly reduces the CIMT, inflammatory markers and improves the endothelial function in chronic PD patients.

SRF Enhances Cell Adhesion, Migration and Peritenal Fibrosis via Modulating miRNA-199a/214 Cluster in Human Peritoneal Mesothelial Cells
Ljie He, Shiren Sun.
Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: Our previous work showed that serum response factor (SRF) was involved in fibrosis of peritoneal membrane, but the exact underlying mechanism were still unclear. Here we further study the role of miR-199a-214 cluster and the relationship of SRF in peritoneal fibrosis.

Methods: We isolated HPMCs from the effluents of end-stage renal disease (ESRD) patients with peritoneal dialysis (PD), and also used PD dialysate rats model to observe the response of PM to miR-199a-214 cluster and the predicted target CDH1 and CLDN2.

Results: In this study, we found that miR-199a-214 cluster, which was examined to be highly expressed in HG-induced HPMCs by real time PCR, was directly regulated by SRF after HG stimulation. All these HG induced immortal HPMCs became scatter, to be highly expressed in HG-induced HPMCs by real time PCR, was directly regulated the response of PM to miR-199a/214 cluster and the predicted target CDH1 and CLDN2.

Conclusions: Together, this study reveals a new SRF-miR-199a-214 cluster CDH1/CLDN2 EMT axis which highlights the potential damage of HG and fibrosis in PD. Funding: Government Support - Non-U.S.

Therapeutic Targeting of EGFR Protects against Peritoneal Fibrosis in Rats
Li Wang, 1 Na Liu, 1 Andong Qu, 2 Shougang Zhaung, 1 Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; 2Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown Univ, Providence, RI.

Background: Long-term PD leads to peritoneal damage and subsequently to peritoneal fibrosis that is characterized by fibroblast activation, collagen fibril accumulation, inflammation, and angiogenesis, but there is still no available treatment for peritoneal fibrosis thus far.

Methods: In the current study, we explored the therapeutic effect of gefitinib, a specific inhibitor of the epidermal growth factor receptor (EGFR), on the development and progression of peritoneal fibrosis induced by chlorhexidine gluconate (CG) and high-glucose dialysis fluid in rats.

Results: Daily intraperitoneal injections of CG or high-glucose dialysis fluid induced a progressive and severe peritoneal fibrosis as indicated by the thickening of the submesothelial area, increased fibril accumulation of collagen fibrils and activation of myofibroblasts. This was accompanied by time-dependent EGFR phosphorylation. Administration of gefitinib, a specific EGFR inhibitor, immediately after injury prevented the onset of peritoneal fibrosis, and delayed treatment until a certain degree of peritoneal fibrosis has occurred halted the progression of fibrosis development. Gefitinib treatment attenuated the phosphorylation of EGFR, Smad3,STAT3 and nuclear factor (NF)-κB during peritoneal fibrosis. Gefitinib also inhibited overproduction of transforming growth factor-β1 and multiple proinflammatory cytokines as well as infiltration of macrophages to the injured peritoneum. Moreover, gefitinib significantly reduced peritoneal increase of CD31 (blood vessels and vascular endothelial growth factor (+)) cells after injury.

Conclusions: These results demonstrate that EGFR contributes to peritoneal fibrosis, inflammation and angiogenesis and suggest that EGFR inhibitors may have therapeutic potential in peritoneal fibrosis.

Effects of Alanyl-Glutamine Addition in Peritoneal Dialysis Fluid on Peritoneal Immune Modulation – A Pilot Clinical Trial
Klaus Kratchochwi1,2 Rebecca Herzog,1,2 Manoj K. Bhasin,1 Seth L. Alper,1 Andreas Vychytil,1 Christoph Aufricht.1
1Medical Univ of Vienna, Vienna, Austria; 2Zytopenrotec GmbH, Vienna, Austria; 2Beth Israel Deaconess Med. Ctr., Harvard Medical School, Boston, MA.

Background: Low peritoneal glutamine levels may contribute to reduced immune defense and increased inflammation in the peritoneal cavity. As a pilot clinical trial, PD patients were treated with PD fluid supplemented with 8 mM alanyl-glutamine (AlaGln) and the effect on peritoneal cell immunocompetence was studied by functional assays and transcriptomics using RNA-sequencing (RNAseq) and microRNA (miRNA) profiling of cells derived from PD effluents.

Methods: In an open-label, randomized, crossover clinical trial at the Medical University of Vienna (EudraCT-2012-00404-36), 6 stable PD patients received either standard PD fluid (Physioneal40 3.86%, Baxter) or AlaGln-supplemented PD fluid for an overnight dwell followed by a 4 h peritoneal equilibration test. Cytokine release from ex vivo isolated effluent cells was assessed as a measure of immuno-competence. Cells were also analyzed by RNAseq (TruSeq Single-end mRNA, Illumina) and miRNA microarray analysis (Affymetrix) using an integrated bioinformatics workflow developed in the Bhasin Lab.

Results: AlaGln treatment significantly increased cytokine release following ex-vivo stimulation, consistent with restoration of previously suppressed peritoneal immunocompetence. Peritoneal effluent cell transcripts of 9,797 genes were identified. Unsupervised clustering and principal component analysis revealed partial separation between the treatments. Supervised analysis using the paired approach identified 13 differentially expressed miRNAs and 41 differentially expressed genes with >1.5-fold change (P<0.01). Functional enrichment analysis of these genes indicated pathways linked to immune response and modulation.

Conclusions: In summary, AlaGln-mediated improvement in peritoneal leukocyte immunocompetence was correlated with changes in peritoneal leukocyte transcriptional status in well-described clinical samples. To strengthen these promising data, larger numbers of patients will be treated with AlaGln for a prolonged period in an international multi-center RCT.

Choice of Dialysis Modality for Children with End Stage Renal Disease
Julien Hoste,1,2 Cecile Coirieux3,2,4 Pediatric Nephrology, Robert Debou E Thiers, Tours, France; 3REIN Registry, Agence de la Biomedecine, La Plaine Saint Denis, France.

Background: Despite many studies that aim to assess the best modality of dialysis, results remain conflicting both in adults and in children. This lack of medical evidence leads commentateurs to emphasize the importance of patients’ choice in the decision process. Thus, we try to assess factors that impact the choice of the dialysis modality in children and to determine which from medical factors, center practices or patients’ wishes plays the major role.

Methods: All incident patients <20 years old at start of dialysis, recorded in the French ESRD registry between 2002 and 2013 were included. We used multivariate hierarchical logistic regression models to study patients and centers characteristics associated with the probability of starting with peritoneal dialysis (PD). The effect of centers was assessed by including centers as a random effect.

Results: Among 806 patients treated in 177 centers, 601 (74.6%) started with hemodialysis (HD) and 205 (25.4%) with PD. A higher probability of PD was found in younger patients while starting HD as emergency was associated with a low use of PD. PD and low high educational level of the town of residence were both associated with less probability of PD when compared with average educational level. There was a significant variability between centers, that was not explained by patients’ case-mix. Being treated in specialized pediatric centers was associated with less probability of PD, while the probability of PD was proportional to the rate of PD in the center.

Conclusions: Although little evidence exists to favor a dialysis modality over the other in children, HD remains the predominant modality in France. PD is still mostly offered to the youngest children while it remains underused in patients starting RRT in emergency. However, we found that besides medical factors, centers practices play a major role in the choice of dialysis modality. This raise concerns about the place left to patients’ and families’ choices and to what extend doctors may influence the final decision. Further pediatric studies focusing on children and parents’ wishes are needed in order to provide cares as close as possible to there expectations.

Clinical Course of Children Born with Chronic Kidney Disease – A Single Centre Experience
Christina Taylan,1 Bernd Hoppe,2 Eva Maria Hafner,2 Lutz Thorsten Weber.1 1Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; 2Pediatric Nephrology, Univ of Bonn, Bonn, Germany.

Background: The number of babies born alive suffering from chronic kidney disease (CKD) is constantly increasing.

Methods: We analyzed the outcome of infants with CKD and renal replacement therapy (RRT) started within their first year of life. Between 2007 and 2013 17 infants (11 male; 6 female) developed end-stage renal disease resulting in RRT in our department.

Results: All of them received peritoneal dialysis (PD) initially at a median age of 34 [31-334] d. During follow up 10 children underwent renal transplantation (RTx), 1 child was still on PD at last follow up, 1 child had to go back to hemodialysis after graft loss and 2 had a recovery of renal function. 3 out of 17 children died during the PD period. Causes of death were severe sepsis twice and one cerebral bleeding. The mean GFR at last follow up (22.0±7.3 years) of patients who went RTx was 105±22.8 ml/min/1.73 m². In the other 6 patients with mean age at transplantation was 29.2±14.2 months. Mental development was measured by Mental Development Index T1 (Bayley Scales of infant development BSID-II) at an average age of 12 [9-16] months and showed developmental delay at the motor, mental and behaviour rating scale. At time of transplantation 6/10 infants had tube feeding, 9/10 were <3 percentile of height, 3/10 were <3 percentile of weight.

Conclusions: RRT started in the first year of life was associated with reasonable outcome and should be offered to all infants with end stage renal disease. It is, however, associated with a high risk of developmental delay. This work emphasizes the great importance of transplantation 6/10 infants had tube feeding, 9/10 were <3 percentile of height, 3/10 were <3 percentile of weight.

Altered Myogenesis and Oxidative Stress in a Rat Model of Chronic Kidney Disease
Keith Ayin,1 Neal X. Chen,2 Jason M. Organ,3 Kalilah O’Neill,4 Sharon M. Moe.5,4 1Dept Physical Therapy, Indiana Univ, Indianapolis, IN; 2Div of Nephrology, Indiana Univ, Indianapolis, IN; 3Dept of Anatomy, Indiana Univ, Indianapolis, IN; 4YMC, Indianapolis, IN.

Background: Skeletal muscle atrophy and impaired muscle function are associated with lower quality of life, and greater disability and mortality risk in those with chronic kidney disease (CKD). However, the pathogenesis of atrophy is unknown.

Methods: We used a slowly, progressively, naturally occurring, CKD rat model (Cyrrat) and its normal littermate (NL). At 35 weeks, we tested muscle strength, sacrificed and collected tissues and blood. RNA and protein were isolated from skeletal muscle and real time PCR and western blotting performed.

Results: CKD rats developed sarcopenia evident by reduced cross sectional area (p<0.05), increased connective tissue deposition on histology (p<0.05), and impaired strength (p<0.05). Strength was defined as the maximal amount of force produced during maximal, electrically stimulated dorsiflexion. These findings of atrophy can be explained by reduced regeneration, increased catabolism, or differentiation of muscle stem cells toward myofibroblasts. By PCR, there was increased activation and differentiation of muscle stem cells (reduced Pax-7, increased MyoD and myogenin (p<0.05)) and increased proteolytic machinery (Ac-activated caspase-1 and Mrf4-1 (p<0.05). Fibrosis was enhanced via decreased miR-29b (p<0.05) and increased Wnt5a (p<0.01). Finally myostatin was increased in blood and muscle RNA expression yet no difference in the activin type IIb. The long term consequences of the impaired balance of increased proteolysis and inadequate regeneration is further supported by mitochondrial derangement (electron microscopy) and increased mitochondrial complex IV (p<0.05) despite increased expression of the antioxidant nuclear erythroid 2-related factor 2 (p<0.05).

Conclusions: In a rat model of CKD, sarcopenia was present despite the activation of myogenic factors. The atrophy is due to a combination of factors including increased myostatin, increased expression of atrogin, and the presence of oxidative damage. Augmentation of the myogenic and antioxidative responses through treatments may prevent progressive sarcopenia in CKD.

Can Calcitriol and Calcidiol to Regulate Toll Like Receptors 7, 9 and IL-6 Expression on Leukocytes from Chronic Dialysis Patients
Maria Dalboni,1,2,3 Jose Tarcisio Giffoni,1 Silvia Regina Manfredi,1 Carolina Cristina Grubiosa,1 Edgar Maquigussa,1 Danilo Takashi Aoike,1 Miguel Cendororgo Neto,2,1 Jose Tarcisio Giffoni,1 1Div of Nephrology, Univ Federal de Sao Paulo, Sao Paulo, Brazil; 2Medicine, Tufts-New England Medical Center, Boston; 3Medicine, Univ Nove de Julio, Sao Paulo, Brazil.

Background: Toll-like receptors (TLR) are involved in immunologic response. The TLR2 and TLR4 expression on neutrophils and monocytes from CKD patients is unclear. To evaluate TLR-2, TLR-4, TNF-α, IL-6 and IL-10 expression in neutrophils (PMN) and monocytes (MN) from Hemodialysis (HD) and Pre-dialysis (PD) patients.

Methods: Blood samples from 43 hemodialysis (HD) patients (collect before the beginning of the second week of each hemodialysis session), 46 pre-dialysis (PD) estimated by Modification of Diet in Renal Disease (MDRD) and 70 age and gender-matched healthy volunteers (CONT) were analyzed for TLR2 and TLR4 expression on PMN and MN by Flow cytometry. The TNF-α, IL-6 and IL-10 cytokines were analyzed by ELISA.

Results: The expression of TLR2 and TLR4 on neutrophils from HD patients was higher than PD and CONT patients (p<0.001). In monocytes, TLR-2 expression was higher in HD patients compared to others groups (p<0.001) and TLR4 expression was higher in PD patients compared to the CONT and HD patients (p<0.001). Regarding to cytokines, we observed a significant correlation between TLR2 and TLR4 and IL-6 levels compared to CONT (4.6±5.3 vs 1.9±1.3 and 6.0±3.2 vs 2.5±2.1; p=0.001, respectively) and IL-10 levels in HD patients were higher than PD and CONT patients (115±166 vs 36±82 and 27±62, respectively). We also observed a significant correlation between TLR2 and TLR4 and IL-10 expression on monocytes (r = 0.30, p = 0.02 and r = 0.34, p = 0.01, respectively). In respect to monocytes, only TLR2 had correlation with TNF-α and IL-6 (r = 0.30; p = 0.02 and r = 0.24; p = 0.03, respectively).

Conclusions: It is possible that the deregulation of TLR2 and TLR4 expression on leukocytes may be caused by uremic toxins in CKD population. Besides, the high expression of TLR2 and TLR4 in these cells resulted in an increase of TNF-α and IL-6 levels, suggesting that TLRs are associated with inflammatory mechanisms in uremic patients.

Can Calcitriol and Calcidiol to Regulate Toll Like Receptors 7, 9 and IFN-γ Expression on Leukocytes Incubated with Uremic Serum
Maria Dalboni,1,2,3 Nils Marquiss,1,2,3 Jose Tarcisio Giffoni,1,2,3 Nuno Vale,1,2,3 Silvia Regina Manfredi,1 Edgar Maquigussa,1 Danilo Takashi Aoike,1 Miguel Cendororgo Neto,2,1 Jose Tarcisio Giffoni,1 1Div of Nephrology, Univ Federal de Sao Paulo, Sao Paulo, Brazil; 2Medicine, Tufts-New England Medical Center, Boston; 3Medicine, Univ Nove de Julio, Sao Paulo, Brazil.

Background: Vitamin D deficiency is highly prevalent among patients in all stages of CKD. Studies have reported that the Vitamin D deficiency is associated with mortality and morbidity in CKD patients and may modulate TLRs that are involved in inflammatory responses. Thus, the purpose was the evaluate the effect of calcitriol on IL-6, IFN-γ TLR-7 and TLR-9 expression in leukocytes B and T on patients on dialysis with vitamin D hipovitaminosis.

Methods: In a randomized, placebo-controlled, double-blind study, we investigated the effect of calcitriol (100,000 UI once per week or placebo) for 3 months, in patients on chronic dialysis, who had nutritional vitamin D deficiency. The 25(OH)D detection was performed by quimioluminescence and IL-6, IFN-γ, TLR-7, TLR-9, VDR, CYP27 and CYP24 expression by flow cytometry on lymphocytes and B T.

Results: After 3 months of treatment, Calcitriol increased 25(OH)D, levels (16.0±8.4 vs 42.8±15.0; p<0.01) and reduced PTH levels (525.3 (128-1775) vs 484.8 (262-1120); p=0.002), but have no effect on CYP24 (39±3 vs 40±3; p=0.97). As an additional experiment, we observed a significant increase of TLR7 (305±78 vs 252±45; p<0.01), TLR9 (1864±700 vs 1084±370; p=0.001 and CYP24 (264±136 vs 200±86; p=0.01), and increased of VDR (739±60 vs 945±440; p=0.006) and CYP27 (245±38 vs 44±380; p=0.04) expression.

Conclusions: Calcitriol treatment increased TLR7 expression in patients showed to be efficient to correct hipovitaminosis D. In addition, we observed impact of 25(OH)D, repletion on expression of the TLR7, TLR9, IFN-γ and improve of regulatory mechanisms.
associated with intracellular production of vitamin D on lymphocytes from CKD patients. These results suggest that selenium treatment play an important role on TLR4 expression as an anti-inflammatory and that this may contributed to a better systemic inflammation response in CKD patients.

FR-PO844

The Effect of Selenium Deficiency on Thyroid Hormone and Cardiovascular Diseases in Hemodialysis Patients  
So Mi Kim,1 Eun Kyong Lee,2 Yun Jung Oh,3 Ja Soon Kim.4 1Div of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju National Univ School of Medicine, Jeju, Jejudo, Republic of Korea; 2Div of Nephrology, Dept of Internal Medicine, Dankook Univ Hospital, Cheonan, Chungnam, Republic of Korea; 3Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Jejudo; 4Div of Nephrology, Dept of Internal Medicine, Incheon sarang Hospital, Incheon, Kyoungkido, Republic of Korea.

Background: Selenium deficiency is known to associate with impairment of thyroid hormone and cardiovascular diseases such as ischemic heart disease (IHD), cardiomyopathy or sudden death. In hemodialysis (HD) patients, various causes may contribute to selenium deficiency, including malabsorption, alteration of metabolism, and removal through dialysis itself. Therefore, we tried to investigate the effect of selenium deficiency on thyroid hormone and cardiovascular diseases in HD patients.

Methods: This cross-sectional study enrolled 83 HD patients. They were divided into two groups based on serum selenium levels: 62 patients were normal level and 22 patients were selenium deficient (serum selenium < 100 μg/L). HD patients were divided into age groups: group A (≤59 yrs) and group B (≥60 yrs). Cardiovascular diseases, including IHD, heart failure, and cardiomyopathy, were evaluated. Results: Thyroid hormone impairment, including hypothyroidism and subclinical hypothyroidism, showed higher tendency in selenium deficient group than that in non-selenium deficient group (27% vs 10% P=0.06). The prevalence of IHD was significantly higher in selenium deficient group than that in the non-selenium deficient group. (59% vs 21 %, p=0.04) But there was no difference in heart failure and cardiomyopathy. The patients with thyroid hormone impairment showed high prevalence of IHD, and the coincidence of thyroid hormone impairment and IHD was also significantly higher than that in selenium deficient group than that in non-selenium deficient group. (18% vs 4%, p=0.014).

Conclusions: This study showed the significant high prevalence of thyroid hormone impairment and IHD in HD patients with selenium deficiency. Selenium deficiency may affect heart disease, associating with thyroid hormone impairment.

FR-PO845

Associations of Prelude (Pre-ESRD) BMI and Weight Change with Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study  
Flani Stepa,1 Melissa Soodho,1 Joline L.T. Chen,1 Amanda R. Torторici,1 Jennie Jing,1 Danh V. Nguyen,1 Csaba P. Kovessy,1 Kamyar Kalantar-Zadeh,1 1UC Irvine; 1UTHSC.

Background: In end stage renal disease (ESRD) lower body mass index (BMI) portends a higher risk of mortality while obesity is protective, so-called obesity paradox. However, the association of BMI and change in BMI over time in the pre-ESRD period and early post-ESRD mortality is unknown. We hypothesized that lower and decreasing BMI prior to transition to ESRD may be associated with higher early dialysis death.

Methods: In a cohort of 22,716 US veterans who transitioned to dialysis between 10/2007 and 9/2011 with available BMI values within the last 2 year prelude period (prior to transition to ESRD), we examined the association of 6 month average BMI and 2 year BMI slope as continuous predictors of all-cause mortality in the first 3 months after transition, using restricted cubic spline analyses and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region. In the models of BMI slope, we also adjusted for BMI level at the time of transition.

Results: The mean±SD age was 69±11 yrs, 27% were African-American, 7% Hispanic, and 49% diabetic. There was a reverse U-shaped association between BMI and mortality, where patients with BMI <27 kg/m2 were at higher risk of death (Figure A). When examining changes in weight over the 2-year prelude there was a U-shaped association where patients with little to no change in BMI (-1 to +1 kg/m2/yr) exhibited the best survival (Figure B).

Conclusions: Among veterans transitioning to dialysis, obese patients and those patients with little to no weight change in the last 2 years prior to ESRD have the greatest survival in the first 3 months post transition. Weight change in late stages of pre-dialysis CKD, possibly due to uric acid and fluid gain, portend poor outcomes, and could be used to identify at-risk patients.

Nutritional Assessment for Incident Dialysis Patients  
Kuto Masakane,1 Yuya Sakai,2 Miho Suzuki,3 1Yabuki Hospital, Nephrology, Yamagata, Japan; 2Yabuki Hospital, Dept of Health and Nutrition.

Background: Nutritional status is one of the most powerful predictors of patient survival in chronic dialysis patients especially in elderly. It is generally accepted that aging itself is one of the risk factors of malnutrition. Recently the patients who started dialysis have become older and older as the average age of incident dialysis patients in Japan is nearly 70 years old. It is very meaningful to evaluate the status of malnutrition in new elderly dialysis patients, its time-course and to establish strategies for preventing progression of malnutrition.

Methods: The nutritional status of 257 incident dialysis patients in YHG was retrospectively evaluated by MIS. The nutritional status on 37 patients out of the 257 patients has been followed for 3 years. The “malnutrition” was diagnosed as “moderate-severe” in MIS and fulfill of the diagnosis of PEW. Patients greater than 75 years old were categorized as Elder and patients under 75 years old as Non-elder. The statistical significance of time-dependent changes in nutritional status was evaluated by paired-T test.

Results: The prevalence of malnutrition at the point of dialysis initiation by MIS in average was 7%, 12% in Elder and 5% in Non-elder. The nutritional status had been improved in the non-elder but not in the elder. The lean body mass had decreased in the first year of dialysis vintages in both groups and had remained the same in the following 2 years. Body fat mass had increased consistently for 3 years in non-elderly. It had increased for the first 2 years but had began to decrease in the third year in the elder. Protein and energy intake per ideal body weight were lower in elder dialysis patients.

Conclusions: Malnutrition in elder dialysis patients was often accompanied by the initiation of chronic dialysis therapy and would gradually develop in the maintenance period. In order to protect the progression of malnutrition several proposals were addressed as the proper timing of the initiation of dialysis before the deterioration of daily activities; nutritional education for sufficient energy and protein intake, exercise education and sufficient dialysis prescription with biocompatible dialysis membranes.

FR-PO847

Uric Acid Is a Determinant of Glomerular Filtration Rate in Inflammatory Conditions  
Shad Ma Hannoow, Issa Al Salmi. Medicine, The Ministry of Health, Dubai, United Arab Emirates; The Renal Medicine Dept, The Royal Hospital, Muscat, Oman.

Background: The presence of gout or a baseline serum uric acid in the upper range are possibly stronger predictors of first CV events than some traditional CV risk factors or parameters of inflammation. Presence study analysis UA determinants in relation to GFR.

Methods: Patients attending the only centre of MOH in Dubai were studied during their OPD visit from January to December 2011. Many laboratory tests including UA were performed. MDRD formula was used to get eGFR. Simple statistical and regression models were performed. Variables that normally distributed being log transformed.

Results: 79 (88.6%, 11.4%) were recruited with mean age 46.4(13.4) years. Mean UA w 249.8 (84.4, eGFR137: 150 159.6, 306.)

Regression analysis found a negative relationship between UA and GFR (P=0.001,-0.004,-0.002) and positive relationship between uric acid and age (p=0.032, 0.001-0.011), urea (p=0.001,41-0.137), microalbuminuria (p=0.006,0.000-0.001), microalbumin/cr (0.001-0.013), SBP(0.014,0.001-0.009), DBP(0.025,0.001-0.014), age at DX RA (P=0.028,0.001-0.010), monocytew% (0.009,0.013-0.088), monocyte count (p=0.003,0.015-0.776) TG (p=0.034,0.009-0.216), BUT also negative with cholesterol (p=0.033,-0.148,-0.007).

Uric acid multiple model has maintained a strong correlation with eGFR (p=0.005), monocytew count (0.009), cholesterol (p=0.007),microalbuminuria(p=0.01), after adjustment for all the above mentioned variables.

Conclusions: UA is determined by eGFR and other renal parameters in inflammatory condition. On the other hand, uric acid increase the risk of renal impairment and CVD in inflammatory condition. Thus, uric acid level might be an elemental key factor that result in renal impairment and CVD in inflammatory condition. UA may be just an innocent bystander but may be an active player in the pathogenesis of renal disease by causing endothelial dysfunction, intravascular renal disease and renal impairment in inflammatory conditions.

FR-PO848

Does Nutritional Status and Serum Electrolytes Change when Dialysis Patients Reduce Their Fluid Overload?  
Penny Faith Sheppard,1 Suzette Thompson,2 Laura Rosales,3 Nathan W. Levin,1 Peter Kotanko,1 Fansan Zhu.1 1Renal Research Inst, New York, NY; 1Fresenius Vascular Care, New York, New York.

Background: Electrolyte balance between the intracellular (ICV) and extracellular (ECV) fluid compartment is essential in the control of normal physiological functions. Nutritional status is mainly reflected by ICV. In hemodialysis (HD) patients the relationship between control of fluid and management of fluid balance is not completely understood. We aimed to evaluated whether the degree of reduction of fluid overload affects the measurement of ICV, and concentrations of serum albumin (Alb), sodium, potassium, and calcium.

Methods: Fifty six HD patients were studied. At baseline (BL), the fluid status was evaluated by calf bioimpedance spectroscopy (cBIS). If patient’s dry weight (DW) was not reached by criteria of cBIS DW, the post target weight was gradually reduced (Zhu et al, 1999).
Physiol Meas, 29;S530-S516, 2008). At six months follow up, the patients either reached DW or did not (NDW) due to difficulty in prolonging treatment time. ECV and ICV, weight and systolic blood pressure (SBP) were measured pre and post HD. Comparison of all parameters between BL and follow up were made using student t test.

Results: Thirty one patients reached DW and 25 did not. Weight and ECV were significantly reduced during follow up. However, ICV, electrolytes and Alb concentrations did not change between different fluid statuses. Post HD SBP significantly decreased from BL to the end of the study in DW but not in NDW groups.

Conclusions: Although extracellular fluid (ECV) was largely reduced, the ICV and serum concentrations of sodium, potassium, and calcium did not differ significantly. This implies that there is no fluid or mass shift from ICV to ECV, suggesting over all isotonic removal of sodium and that nutritional status is not changed by attainment of dry weight.

Trends in Weight Change During the First Two Years of Transition to Hemodialysis Treatment
Vivian Ngo,1 Elani Streja,1 Anna Mathew,2 Tae Hee Kim,3 Yoshitsugu Obi,3 Connie Rhee,1 Csaba P. Kovetsky,3 Kamyar Kalantar-Zadeh,1 UC Irvine,1 Hofstra North Shore LIJ Health System,2 UTHSC.3

Background: Some hemodialysis patients may undergo rapid weight loss in the first few months of starting dialysis, but the nature of this trend has not yet been characterized in large nationally representative studies. We hypothesized the trajectory of weight change during the first 24 months of hemodialysis therapy may differ by baseline body mass index (BMI).

Methods: We examined percent post-dialysis weight (kg) change from baseline in 37,759 incident hemodialysis patients who initiated dialysis in a large US dialysis organization in calendar years 2007-2011 and who survived the first 2 years of hemodialysis. Trends of percent weight change over time were analyzed using crude and case-mix adjusted mixed effects models. Baseline BMI was categorized into 8 categories (18.5, 18.5-20, 20-22, 22-25, 25-30, 30-35, 35-40, 40+ kg/m²).

Results: Patients were 60±14 years old, 64% diabetics, 44% female, and had an average starting weight of 82±22 kilograms. Patients reached a nadir of weight at the 5th month of dialysis with an average 2% weight loss from baseline. At 14 months, patients’ weight stabilized at an average of 1% drop from baseline. However, trends differed across groups of baseline BMI groups. Underweight (BMI <18.5) did not experience weight loss but instead gained approximately 6% of their weight by the 24th month. Obese patients (BMI >40) did not reach a nadir and lost approximately 6% of their weight by the 24th month.

Conclusions: Baseline BMI can affect the trajectory of weight change over the first two years in hemodialysis patients. Further studies are needed to better understand the cause of these differences and their impact on clinical outcomes.

FR-PO850
Significance of Renal Autonomic Nerves in the Reduction of Body Weight by SGLT2 Inhibitors
Aika Hagiwara, Kazutoshi Miyashita, Masaaki Sato, Hiroyuki Inoue, Kentaro Fujii, Masanori Tamaki, Hiroshi Itoh. Nephrology, Endocrinology and Metabolism, School of Medicine, Keio Univ, Shinjuku, Tokyo, Japan.

Background: Sodium-glucose co-transporter (SGLT) 2 inhibitors decrease not only serum glucose level but also body weight significantly. Similarly, it is reported that renal denervation (RDN) decreases body weight, in addition to blood pressure. The urinary glucose might have a relationship with sympathetic activation that controls body weight, however, the relationship has not been elucidated.

Methods: The present study examined the roles for renal autonomic nerves in the weight reduction by SGLT2 inhibitors through performing RDN on mice fed on a high-fat diet. The C57BL/6 mice fed on a high-fat diet were divided into 4 groups; control group, RDN group, SGLT2 inhibitor group and SGLT2 inhibitor with RDN group. The body weight, glucose tolerance, tissue weights, tissue hormone sensitive lipase (HSL) activity and noradrenalin concentration were examined. The SGLT2 inhibitor (tologliflozin 50 mg/kg pellet) was administered to mice from 8 weeks old mixing it in the high-fat diet (60 Kcal% fat). RDN was performed at 7 weeks old by surgically stripping the renal arteries and coating the vessels with a solution of 10% phenol in ethanol.

Results: The body weight at 16 weeks old significantly decreased in the SGLT2 inhibitor group. In that group, the catecholamine levels in subcutaneous fat and the activity of HSL which was measured by the phosphorylation level were increased. On the other hand, RDN with SGLT2 inhibitor group significantly weakened the degree of the reduction of body weight by the SGLT2 inhibitor associated with suppression of the catecholamine levels and the activity of HSL in the adipose tissue. In RDN without SGLT2 inhibitor group, the body weight significantly decreased; however, HSL in the adipose tissue was not activated.

Conclusions: These results indicate that HSL activation in the adipose tissue mediated by the renal autonomic nerves was involved in the mechanism of weight reduction by SGLT2 inhibitors. The renal autonomic nerves were suggested to have a role in the control of tissue HSL activity and body weight.

FR-PO851
The Combination of Walking Exercise and Branched Chain Amino Acid Recovered Response of Protein Synthesis in Low Protein Diet Fed Chronic Kidney Disease Model Rats

Background: Low protein diet (LPD) protects progression of renal injury in patients with chronic kidney disease (CKD). However, LPD may accelerate muscle wasting in these patients. The exercise and branched chain amino acid (BCAA) are known to increase the muscle synthesis by activating mTOR signaling pathway. The aim of this study is to investigate whether walking exercise and BCAA would increase muscle protein synthesis in LPD fed CKD (5/6 nephrectomized) rats.

Methods: CKD rats were fed LPD or LPD fortified with BCAA diet (BD), and about half of the each group were loaded with the walking exercise (7 weeks of treadmill, 15 m/min, 1 hour/day, 5 days/week). After 7 weeks, the kidney and the soleus muscle were collected to evaluate the renal fibrosis and the muscle protein synthesis, respectively.

Results: The renal function and fibrosis were not different between LPD and BD fed CKD rats, and the walking exercise did not accelerate renal damage in both LPD and BD fed CKD groups. The walking exercise increased the phosphorylation of p70s6kinase, a biomarker of mammalian target of rapamycin complex 1 activity, in soleus muscle of LPD and BD fed CKD rats. However, the phosphorylation of p70s6kinase was lower in LPD fed CKD rats when compared with sham-operated groups and BD fed CKD group. Conclusions: CKD reduces activation of muscle protein synthesis. Combination of walking exercise and BCAA recovered the muscle protein synthesis in CKD rats. These results suggest combination of walking exercise and BCAA may be beneficial to improve the muscle protein synthesis in CKD.

Unacyl-Ghrelin: A Key Molecule in Uraemic Cachexia in Children and Animal Models
Alice Monzani1, Michella Perrone,2 Sara Testa,2 Fabio Pauglialonga,2 Silvia Consolo,2 Gianlugi Ardissino,2 Francesca Tel,2 Marta Lepore,2 Stefani Rotondo,2 Antonietta Biasuzzi,2 Luciana Ghio,2 Gian Boni,2 Albert Edefonti.2

1 Div of Pediatrics, Univ del Piemonte Orientale, Novara, Italy; 2Pediatric Nephrology Unit, Fondazione IRCCS Ca granda Ospedale Maggiore Policlinico, Milan, Italy.

Background: Cachexia and poor growth are common in children with chronic kidney disease (CKD). Several mechanisms are involved, including loss of appetite and poor food intake. Unacyl-ghrelin (UAG) is known to produce an inhibitory effect on feeding. We measured UAG levels in children and adolescents with CKD stage II-IV on conservative treatment (CKD-CT), on haemodialysis (CKD-HD) and after transplantation (Tx), compared to healthy controls, in relation to biochemical and anthropometric parameters.

Methods: Plasma UAG levels were measured by ELISA in 43 CKD-CT, 20 CKD-HD, 48 Tx and 43 healthy children. Urea and creatinine levels were measured in all the subjects and GFR was calculated by Schwartz formula. Weight, height and bicipital, tricipital, subscapular and suprailliac folds were measured, and BMI z-score, fat-mass and fat-free mass pro body weight (FM/BB and FFM/BB, respectively) were calculated.
FR-PO853

Visceral Fat Area Is Associated with Renal and Cardiac Function in a Population with Normal or Mildly Impaired Renal Function

Sung Jun Kim,1 Yunju Nam,1 Hyeon Seok Hwang,1 Seok Soon Shin,2 Hye Eun Yoon.1,2 Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; 1Internal Medicine, Incheon St. Mary’s Hospital, Incheon, Korea.

Background: Visceral fat is involved in the development of metabolic and cardiovascular diseases. This study was to evaluate the association between visceral fat area (VFA) and renal and cardiac function and arterial stiffness in a population with normal cardiovascular diseases. This study was to evaluate the association between visceral fat area (VFA) and renal and cardiac function and arterial stiffness in a population with normal or mildly impaired renal function. Measuring VFA may predict risks of renal factors. In contrast, total body fat was not associated with eGFR.

Methods: This cross-sectional study included 719 middle-aged adults who underwent a voluntary health check-up program. Participants with estimated glomerular filtration rate (eGFR) below 60 mL/min/1.73 m2 were excluded. VFA was measured using bioimpedance analysis. Subjects were divided into tertiles according to their VFA. The associations between VFA and eGFR, brachial-ankle aortic pulse wave velocity (baPWV), and echocardiographic parameters were investigated.

Results: Across the tertiles of VFA, there was a significant trend for decline in eGFR (P<0.001), increase in baPWV (P=0.001) and left ventricular mass index (LVMI, P<0.001), and decrease in the ratio of early mitral inflow velocity to peak mitral annulus velocity (E/E'). VFA showed significant correlations with eGFR (r = -0.15, P=0.001), baPWV (r = -0.28, P<0.001), LVMI (r = -0.31, P=0.001), and E/E' (r = -0.21, P=0.001). In multivariate analysis, VFA was linearly associated with eGFR (β = -0.06, 95% confidence interval [CI] 0.11 - 0.01, P=0.02), LVMI (β = -0.08, 95% CI 0.06 - 0.10, P=0.001), and E/E' (β = 0.01, 95% CI 0.006 - -0.019, P=0.01), after adjustments for cardiovascular risk factors. In contrast, total body fat was not associated with eGFR.

Conclusions: VFA is associated with renal and cardiac function in middle-aged adults with normal or mildly impaired renal function. Measuring VFA may predict risks of renal and cardiac diseases.

Serum Ferritin <70 µg/L Predicts Functional Iron Deficiency in Patients with Chronic Kidney Disease

Neha Garg, Mrinalini Kotru, Om Prakash Kalra, Meera Sikka. Pathology, UCMS and GTBH, Delhi, New Delhi, India.

Background: Chronic Kidney Disease (CKD) is a major public health problem with anemia occurring early in the course of disease. Its most common cause is erythropoietin deficiency which can be effectively treated with erythropoietin stimulating agents. However most of the patients do not respond adequately due to development of Functional Iron Deficiency (FID). The current diagnostic criteria for FID as recommended by KDOQI 2006 tend to miss the diagnosis of FID. The study was conducted to explore the role of hsCRP and Interleukin-6 (IL-6) along with Serum Ferritin (SF) in improving the efficacy of this criteria.

Methods: 77 clinically diagnosed patients of CKD (Stage 3, 4 and 5) of either sex, age >18 years with Hb <11 g/dL were included in the study. Complete clinical history and physical examination was done. Complete hemogram with peripheral smear, serum iron, total iron binding capacity, Transferrin Saturation (TSAT), SF, transferrin receptors (TfR), hsCRP, IL-6, ESR were estimated.

Results: stBR/log ferritin (taken as gold standard) detected 31/77 patients as having iron deficient erythropoiesis. Out of these 31 patients, 12 patients had SF <12 µg/L indicating absent iron stores. Remaining 19 patients had SF in these, TSAT <20% and SF <100 µg/L detected FID in only 2 patients with a sensitivity of 6.45%. SF at a cut-off <70 µg/L showed the best sensitivity (83.87%) and specificity (73.91%) in detecting FID in these patients. hsCRP identified 7 patients who were missed by SF test in detecting FID among these 12 patients. hsCRP in the absence of raised hsCRP, SF <70 µg/L had very good sensitivity (100%). However, in the presence of raised hsCRP sensitivity was reduced (79.16%).

Conclusions: TSAT <20% and SF <100 µg/L had a sensitivity of only 6.45%. However, SF <70 µg/L emerged as the most sensitive and specific in identification of iron deficient erythropoiesis. SF <12 µg/L - SF <70 µg/L was able to identify 14/19 cases of FID. Also, hsCRP could be used to stratify the CKD group in which FID could be detected with high sensitivity and specificity.

FR-PO855

Chronic Inflammation Is Associated with Poor Clinical Outcomes Independent of Mineral Metabolism Abnormalities in the HEMO Study

Anna Jeentea Jovanovich,1,2 Eugene J. Nuccio,3 Alfred K. Cheung,1,3 Tom Greene,1 Michel Chonchol,4 Kristen L. Nowak,2 1Denver VA Medical Center; 2Univ of Colorado Denver; 3VA Salt Lake City; 4Univ of Utah.

Background: Epidemiological studies show a high prevalence of chronic inflammation, vitamin D deficiency, and fibroblast growth factor 23 (FGF23) excess in hemodialysis patients. Whether the relationships of high circulating C-reactive protein (CRP) and interleukin-6 (IL-6) with all-cause mortality and cardiac and infectious events are attenuated in the presence of circulating markers of mineral metabolism is unknown.

Methods: We studied the association of inflammatory markers (CRP and IL-6) with all-cause mortality, cardiovascular diseases and arterial stiffness in a population of 1340 subjects from the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial. Cox regression models adjusted for important confounding variables: demographics, comorbidities, Kt/V, dialyzer, smoking, albumin, and mineral metabolism markers including serum calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D, and FGF23.

Results: Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) CRP and IL-6 levels were 6.1 (2.6-15.2) mg/L and 3.2 (1.7-6.9) pg/mL, respectively. Over mean 2.8±4 years follow-up, there were 582 deaths, 514 cardiovascular events, and 495 infectious events. Among subjects with levels in the highest quartile compared to the lowest quartile, both CRP and IL-6 were significantly associated with all-cause mortality in adjusted analyses, odds ratio (OR) 1.96 (95% CI, 1.27-3.02) and OR 1.51 (95% CI, 1.02-2.23), respectively. However, only CRP, was associated with cardiovascular disease events (OR 1.90, 95% CI 1.04-3.44) and infectious events (OR 3.84; 95% CI 1.37-10.74) among subjects with levels in the highest quartile compared to the lowest quartile.

Conclusions: CRP and IL-6, were significantly associated with all-cause mortality independent of metabolic abnormalities. Only CRP was significantly associated with cardiovascular disease and infectious disease events independent of mineral metabolism abnormalities among subjects in the HEMO trial.

FR-PO856

Assessment of Protein-Energy Wasting: Comparing a New PEW Score and the MIS in Chronic HD Patients

Camiel LM de Roij van Zuidewijn,1 Muriel P. Grooteman,2 Peter J. Blankestijn,1 Menso Jan Nubè,1 Pieter M. Ter Wec.1 1Nephrology, Univ of Medical Center, Amsterdam, Netherlands; 2Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands.

Background: the assessment of protein-energy wasting, a syndrome of decreased bodily protein and energy fuels, remains debated. Recently, a French group introduced a new PEW score, encompassing BMI, serum creatinine, nPNA and serum albumin. In a cohort of chronic hemodialysis patients, we compared the predictive value of this score with the Malnutrition Inflammation Score (MIS) using all-cause mortality as end point. Furthermore, we investigated which of these scores correlates best with quality of life (QOL).

Methods: from data of the CONnective TRAnsport Study (CONTRAST), the new PEW score and the MIS were determined at baseline. QOL was measured with the Kidney Disease QOL-Short Form 36, which results in 2 general and 12 kidney-disease specific domains of QOL. Discrimination and calibration for mortality were tested by Harrell’s C statistic and calibration of Framingham Scores, respectively. Spearman’s rank correlation coefficient ρ was used to determine correlations between a test and the various QOL domains.

Results: 489 out of 714 patients were analyzed. 183 died during follow-up (mean 3.8±2.5 years). Discrimination for mortality was higher for MIS than the new PEW score (Harrell’s C statistic 68.0 [95% CI 65.7-69.8] and 61.0 [95%CI 59.0-63.3], respectively). Furthermore, mortality calibration was adequate for MIS (p=0.65), but not for the new PEW score (p=0.03). Lastly, MIS correlated with 13 domains of QOL (ρ’s between -0.47 and -0.12), whereas the new PEW score only correlated with the physical component score (ρ=0.18).

Conclusions: both the MIS and the new PEW discriminate for mortality, but the MIS performs better. Furthermore, only the MIS is properly calibrated. Third, the MIS correlates with more QOL domains with higher correlation coefficients. Therefore, we conclude that MIS is preferred over the new PEW score in assessing PEW.

FR-PO857

Change in MIS Over 1 Year Is Not Associated with Mortality in Chronic Hemodialysis Patients

Camiel LM de Roij van Zuidewijn,1 Muriel P. Grooteman,1 Menso Jan Nubè,1 Peter J. Blankestijn,1 Menso Jan Nubè,1 Pieter M. Ter Wec.1 1Nephrology, Univ of Medical Center, Amsterdam, Netherlands; 2Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands.

Background: protein-energy wasting, a state of decreased bodily protein and energy fuels, has been associated with increased mortality as measured by the Malnutrition Inflammation Score (MIS), a composite, clinical, nutrition-related score. Longitudinal data on this score, however, are limited. We checked whether a change in MIS over 1 year of follow-up is associated with mortality.

Methods: data from CONTRAST were used, a well-defined cohort of end-stage kidney disease patients. Patients were selected for analysis if MIS was available at baseline (M0) and at 12 months (M12). Delta (Δ) MIS was calculated as MIS (M12) – MIS (M0). As the

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 561A
association between ∆MIS and mortality was not linear; patients were divided into quartiles of ∆MIS. Cox proportional hazards models, crude and adjusted for potential confounders, were used to calculate hazard ratios (HRs) of patients with severe deteriorating MIS (increase >2 points), mild deteriorating MIS (increase of 1 or 2 points), stable MIS versus patients with an improving MIS.

Results: 404 patients were available for analysis. Mean age was 63.0±13.5 and 62.4% were male. During follow-up (median 3.1 years), 135 patients died. Median ∆MIS was 1.0 (IQR -1.0 to 3.0). Survival curves are shown in fig 1. HR of patients with a mild deteriorating or stable MIS versus patients with an improving MIS was 0.85 (95%CI 0.53-1.39) and 0.97 (95%CI 0.56-1.67), respectively; for patients with a severe deteriorating MIS, HR was 1.63 (95%CI 1.02-2.51). After correction for age, sex, dialysis vintage and dialysis modality, this association did not remain significant (p=0.1).

Conclusions: a change in MIS over 1 year is not associated with mortality in a multivariable survival analysis.

FR-PO858
Soluble CD14, a Marker of Endotoxemia, Associates with Survival and Cardiovascular Disease in CKD Patients Ruben Poesen,1 Ian Barrows,2 Ali Ramezani,3 Pieter Evenepoel,4 Kathleen Claes,1 Bjorn Meijers,1 Dominic S. Raj,2 Sajda Poesen,1 Nephrology, Univ Hospitals Leuven, Belgium; 1Renal Diseases and Hypertension, George Washington Univ.

Background: CKD goes along with gut microbial dysbiosis and gut barrier dysfunction, possibly contributing to endotoxin translocation. Subsequent binding of endotoxin to toll-like receptor-4 and its co-receptor CD14 activates the innate immune system. As half-life of systemic endotoxin is very short, soluble CD14 (sCD14) has been proposed as better marker of endotoxin exposure. Whether sCD14 relates to adverse outcome in CKD patients not yet on dialysis is unknown.

Methods: We performed a prospective study in CKD patients stage 1-5. Plasma sCD14 was determined with ELISA. Determinants of sCD14 were examined with regression analysis. The relationship between sCD14, survival and cardiovascular disease (CVD) was explored using Kaplan Meier and Cox PH analysis.

Results: 495 CKD patients were followed from 2005 until 2010. Median plasma sCD14 was 3.72±4.40. Lower eGFR and higher CRP were the strongest determinants of higher sCD14 (both P<0.0001). During follow-up, we observed 53 deaths (Tertile 1/2/3: 12/17/24 events, log rank P 0.02, see figure). In Cox PH analysis, sCD14 remained a significant predictor of death (univariate HR per SD increase of 1.809 (1.356–2.413), P=0.0001), even after adjustment for renal function, Framingham risk factors, CRP and albumin (HR 1.899 (1.316–2.739), P=0.0006). We also noted 78 CV events (Tertile 1/2/3: 18/29/31 events, P=0.01). This association remained borderline significant in the fully adjusted model (HR 1.299 (0.999–1.689), P=0.05).

Conclusions: Plasma sCD14 is elevated in patients with advanced CKD, suggesting increased endotoxin exposure. sCD14 is independently associated with survival and CVD, pointing to a role of endotoxemia as a driving force behind adverse outcome in CKD.

FR-PO860
Microbiota Derived Phenylacetylglutamine Associates with Survival and Cardiovascular Disease in CKD Patients Ruben Poesen, Pieter Evenepoel, Bjorn Meijers. Nephrology, Univ Hospitals Leuven, Belgium.

Background: Lately, there is increasing interest in gut microbiota derived uremic retention solutes as driving force behind adverse outcome in CKD. p-cresyl sulfate and indoxyl sulfate are considered representatives of this group, also commonly referred as to protein-bound solutes due to their high protein binding and dependence on active tubular secretion for renal clearance. Phenylacetylglutamine is another microbial metabolite subjected to high tubular secretion, although protein binding is rather low. We questioned whether this solute also relates to adverse outcome in CKD patients not yet on dialysis.

Methods: We performed a prospective study in CKD patients stage 1-5. Serum levels of phenylacetylglutamine were determined using LC-MS. Correlation between eGFR and serum phenylacetylglutamine was explored using Spearman’s rank correlation analysis. The relationship between phenylacetylglutamine, survival and cardiovascular disease was examined using Cox proportional hazard analysis.

Results: 488 CKD patients were followed from November 2005 until December 2010. Median serum level of TMAO was 11.6 µM (IQR 5.7 – 21.8). We observed a highly significant inverse correlation between eGFR and serum TMAO (rho -0.71, P < 0.0001). During follow-up, we noted a total of 51 deaths and 75 cardiovascular events. In univariate Cox proportional hazard analysis, TMAO was a significant predictor of mortality (HR 1.521 (1.183 – 1.956), P=0.001) and cardiovascular disease (HR 1.570 (1.283 – 1.921), P < 0.0001). However, significance was lost after adjustment for eGFR for overall mortality (HR 1.126 (0.795 – 1.595), P=0.50), as well as for cardiovascular events (HR 1.256 (0.958 – 1.647), P=0.10).

Conclusions: Serum levels of TMAO rise in parallel to a declining renal function and further analysis of 24h urine samples is ongoing to elucidate its renal handling. In this European cohort of CKD patients, we were not able to find an association between TMAO and adverse outcome that is beyond renal function, which is in contrast to previous observations in US populations, both general and CKD. This may question the validity of TMAO as a universal biomarker for cardiovascular disease, possibly due to population-specific differences in diet and/or microbial metabolism.

Sarcopenia Among Prevalent Hemodialysis Patients: Weighing the Evidence

Piyawan Kittikulcharn, 1 Juan Jesus Carrero, 1 Glenn Matthew Chertow, 1 George A. Kayser, 1 Kirsten L. Johansen, 1 UCSI, 2 Karolinska Inst, 1 Stanford Univ; 1 UC Davis.

Background: There is no consensus on the best way to define sarcopenia in ESRD. Use of muscle/height(Ht) is suggested by geriatric societies but may underestimate sarcopenia, particularly in the setting of excess adiposity. We compared three definitions of sarcopenia in a prevalent HD cohort.

Methods: ACTIVE/ADPOSE enrolled HD patients from San Francisco and Atlanta from 6/09 to 8/11. Bioelectrical impedance spectroscopy was performed before a midweek dialysis session (n=645), and total-body muscle mass was estimated using an equation containing age, sex, body weight (BW), and intracellular water. We defined sarcopenia as muscle mass 2SD below sex-specific means for adults aged 18-49 y from NHANES data indexed to Ht, %BW, and body surface area (BSA) by DuBois formula. We compared the prevalence of low muscle mass among the three methods and assessed their correlation with handgrip strength.

Results: Mean age was 57±14 years, 41% were women, 61% black. The prevalence of sarcopenia was 8% by muscle/Ht, 25% by muscle/%BW and 32% by muscle/BSA. Most sarcopenic patients by muscle/BSA method had normal muscle mass, while >50% of sarcopenic patients by %BW were obese. Almost none of the overweight or obese patients were defined as sarcopenic by muscle/Ht.

Conclusions: Muscle mass/BSA and muscle mass/height may underestimate the prevalence of sarcopenia, particularly in overweight HD patients. Detection of sarcopenia among overweight/obese patients requires adjustment for body size or adiposity.

Does a Probiotic Supplementation Alter the Indoxyl Sulfate Levels in Non-Dialysis Chronic Kidney Disease Patients? A Randomized Placebo-Controlled Clinical Trial

Denise Maia, 1 Natalia Alvarenga Borges, 1 Milena Barcea Stockler-Pinto, 2 Denis Fouque, 1 Amanda F. Barros, 1 Medical Sciences Graduate Program, Federal Univ Fluminense, Rio de Janeiro, Brazil; 1 Cardiovascular Sciences Graduate Program, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil; 1 Post Graduate Program in Dentistry, Estacio de Sá Univ, Rio de Janeiro, RJ, Brazil; 1 Dept of Nephrology, Centre Hospitalier Lyon Sud, Univ Claude Bernard, Lyon, France; 1 Graduate Program in Science Applied to Health Products, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil; 1 Medicine Faculty, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil.

Background: The imbalance in gut microbiota associated with alterations in colonic epithelium contributes to the accumulation of gut-derived uremic toxins in chronic kidney disease (CKD) patients. Therapeutic strategies like probiotic supplementation may modulate the gut microbiota and reduce the toxins levels. The effect of the probiotics supplementation on indoxyl sulfate (IS) plasma levels in non-dialysis CKD patients.

Methods: In this double-blind, placebo-controlled trial, 29 non-diagnosis CKD patients were recruited. Patients were randomized to receive probiotic (1 capsule, containing 30 billion of colony forming units - S. thermophilus, L. acidophilus, and B. longum, n= 17) place and placebo (n= 12) for 3 months. IS plasma levels were quantified by HPLC, calprotectin and protein C reactive were analyzed by immunoenzymatic assay. Five patients in probiotic group and three in placebo were lost to follow-up.

Results: Plasma IS increased significantly in patients who received probiotics whereas the other parameters did not change.

Conclusions: Our results suggest that administration of probiotics alone may increase plasma IS levels in non-dialysis CKD patients. These findings support the need for more studies with probiotics in CKD patients.

Prevention of the Progression of Both Renal Dysfunction and the Atherosclerotic Change in Chronic Kidney Disease (CKD) Stage 3-4 Patients due to Benign Nephrosclerosis

Yoshikiko Inoue, Tomoaki Miyazaki, Shinya Omiya, Kiyoko Inui, Daisuke Komukai, Ashio Yoshinura. Div of Nephrology, Showa Univ Fujigaoka Hospital, Yokohama, Kanagawa, Japan.

Background: Effect of EPA for CKD patients is not fully known. We studied the efficacy of EPA to prevent the progression of both renal impairment and atherosclerosis in CKD stage 3-4 patients due to benign nephrosclerosis (BNS).

Methods: 31 CKD stage 3-4 patients due to BNS with dyslipidemia were followed for 3 years after the start of EPA treatment. The dosage of 1800 mg/day of EPA was newly prescribed. T-cho, LDL-cho, Triglycerides (TG), eGFR, the amount of proteinuria, EPA, arachidonic acid (AA), Dihomo-gamma-linolenic acid (DGLA) and docosahexaenoic acid (DHA) were studied. Both right and left (RL) brachial-ankle pulse wave velocity (baPWV), RL maximum carotid intima-media thickness (max IMT), RL maximum carotid plaque thickness and RL ankle-brachial index (ABI) were evaluated at before treatment (baseline), after 1 year and at the end of the study (3-year).

Results: EPA, EPA/AA ratio, TG, RL baPWV, RL max IMT and eGFR showed significant improvement at 3-year (table 1).

FR-PO864
Atherosclerotic Change in Chronic Kidney Disease (CKD) Stage 3-4 Patients

Masahira Hattori, 1, 2 Yoko Tateoka, 1 Yoshiharu Itoh, 1 Wataru Suda, 2, 3 Masahira Kikuchi, 1 Yoshiharu Itoh, 1, 2, 3 Mami Kikuchi. 1 Kyoto Prefectural University of Medicine, Kyoto, Japan; 1 Keio Univ, Tokyo, Japan; 2 Waseda University, Tokyo, Japan.

Background: Gut microbiota is known to function in producing uremic toxins (UTs) and their precursors, such as indoles, phenols and so on. However the relationships between gut microbiota and UTs in CKD patients were not clear. To elucidate the production of UTs by gut microbiota, we collected blood, urine and feces samples in normal rats, rats subjected to 5/6 renal removal. AST-120, a spherical carbon adsorbent of intestinal small-molecular-weight UTs and/or their precursors, was used to evaluate the effects of AST-120 on gut microbiota.

Methods: Serum and urine levels of UTs were quantified by SRC of LCE/MS/MS. Gut microbiota from feces were analyzed using 454-pyrosequencing of a hypervariable V1-V2 region of the 16S rRNA gene in combination with barcode sequences. We used the GLSEARCH program and self-build 16S sequences database and genome database to determine the closest species. We identified the indole and/or phenol producing species using BLASTX.

Results: In CKD rats, urinary excretion and serum concentrations of UTs, such as indoxyl sulfate and phenol sulfate, were higher than control rats. In AST-120-administered CKD rats, urinary excretion and serum concentrations of UTs decreased compared to CKD
rats. The overall bacterial community composition was compared according to the UniFrac distance metric among control rats, CKD rats, and CKD + AST-120 rats. A principal coordinate analysis plot revealed clustering of each group. We identified the intestinal microbiome containing tryptophanase and/or tyrosine phenol-lyase gene in the genome sequences from NCBI bacterial genome. These enzymes metabolize tryptophan to indole and tyrosine to phenol, respectively.

**Conclusions:** Our data suggest that UT production is not only the cause of uremic symptoms but also correlated with a subset of indigenous gut microbes and affects the composition of gut microbiota.

Association of Urine Volume at the Start of Dialysis and Subsequent Changes in Serum Albumin Level in Incident Hemodialysis Patients Rieko Furuichi, Yoshitsugu Obi,1 Connie Rhee,1 Steven M. Brunelli,2 Jolene L.T. Chen,1 Anna Mathew,2 Tae Hee Kim,3 Elani Streja,4 Csaba P. Kovedsy,4 Kamyr Kalantar-Zadeh,1 1UC Irvine; 2DaVita Clin Research; 3Hofstra North Shore-LLH Health System; 4UTHSC.

**Background:** Previous studies have shown that low serum albumin (Alb) levels are associated with higher mortality in hemodialysis (HD) patients. While serum Alb is a critical inflammatory and nutritional marker, low Alb may also result from albuminuria. It is unknown if a change in serum Alb over time is due to the loss of residual kidney function. While data on urine Alb was unavailable, we hypothesized that higher urine volume (UV) is associated with a decrease in Alb.

**Methods:** Among 38,504 incident HD patients receiving care from a large dialysis organization from 2007-2011, we examined serum albumin level trajectory over 5 years (divided into 20 patient quarters) across five strata of baseline UV: <300, 300-600, 600-900, 900-1200, ≥1200 mL. The association between baseline UV and serum albumin trend was examined using mixed effects models with adjustment for age, gender, race, diabetes, and insurance type.

**Results:** Patients were 62±15 years old, 38% female, 28% black, and 46% diabetic. Higher baseline UV was incrementally associated with higher Alb levels across strata: 3.44±0.48g/dL, 3.50±0.46g/dL, 3.57±0.44g/dL, 3.59±0.45g/dL, and 3.65±0.46g/dL, respectively [Figures] Serum Alb increased over the first 6 patient quarters (18 months) on dialysis and then stabilized. Patients with higher UV not only had a higher baseline serum Alb level, but also maintained a higher serum Alb level over follow-up.

**Conclusions:** Higher baseline UV appears to be associated with sustained higher serum Alb levels over time. Improvement in hypoalbuminemia as a result of transition to dialysis therapy appears to be independent of residual kidney function and may suggest an inherent advantage of dialysis initiation.

Individual Variation of Hippuric Acid and P-Cresyl Sulfate Plasma Levels Correlate with Variation of Intestinal Microbiota Phylotypes in Hemodialysis Patients Griet Lrl Grieque,1 Sara Vieira-Silva,2 Sunny Elloot,1 Eva Sheperes,1 Annemieke Dhohtndt,1 Raymond C. Vanholder,1 Jeroen Raes,2 Geert Huys,3 Marie Joosseens.2 1Renal Div, Ghent Univ Hospital, Gent, Belgium; 2Microbiology and Immunology, KULeuven, Leuven, Belgium; 3Microbiology, Ghent Univ, Gent, Belgium.

**Background:** In chronic kidney disease (CKD), a myriad of metabolites accumulate in the circulation. A substantial part is generated by intestinal microbiota. We hypothesize that there is a link between plasma levels of these uremic metabolites and the composition of the intestinal microbiota.

**Methods:** Over 4 months, up to 8 consecutive plasma and fecal samples from 16 hemodialysis patients (14M/2F; 74±0.48 years) were collected. Uremic metabolites were quantified by UPLC. Fecal microbial DNA was amplified for 16S DNA (V4 hypervariable region) sequencing (Illumina MiSeq). After quality and chimera filtering (UCHIME), data was rarefied to 10,000 reads/sample and taxonomically annotated (RDP).

**Results:** Correlation between the maximum intra-patient variability of metabolite levels and the corresponding time-points of fecal microbial phylotypes was assessed. In addition, cross-sectional correlations at t0 were evaluated. Statistical analyses were performed with R package phylseg, using Spearman correlation, with multiple testing correction (FDR) per metabolite for the number of genus-level phylotypes.

**Conclusions:** Within this patient group, we observed a strong positive correlation between an increase in total hippuric acid and unclassified Peptostreptococcaceae (p=0.83; corrected p-value=0.012). We also found a positive trend for total p-cresyl sulfate and unclassified Clostridiales and unclassified Ruminococcaceae (p=0.77 and 0.74; corrected p=0.074 and 0.078, respectively). Cross-sectionally at t0, strong negative correlations between indoxyl sulfate, indole acetate and specific unclassified bacterial phylotypes (p<0.79 and 0.84; corrected p-value=0.028 and 0.004) were observed.

**Conclusions:** There is a link between plasma levels of specific uremic metabolites and fecal bacterial phylotypes, suggesting that these microbiota might be a target for reducing uremic metabolite levels in patients with CKD. Data needs validation on larger patient groups.

Decreased Vitamin K1 Intake in Italian Hemodialysis Patients Maria Fasano,1 Claudia D'Alessandro,1 Marianna Noale,1 Giovanni Trippe,1 Lucia Bonfante,2 Nicola Veronese,1 Irene Santinelli,3 Sabina Zambon,3 Sandro Giannini,4 Maurizio Gallieni,2 Ahmadnas Caputi,2 1CRN - Padua, Italy; 2Div of Nephrology Dept of Clinical and Experimental Medicine, Univ of Pisa, 3Nephrology Unit, Univ of Padua, 4CRN:IFC Clin. Epid. and Physiopath. of Renal Dis. and Hypert. of Reggio Calabria; 5Clinica Medica 1, Univ of Padua, Italy; 6Univ of Padova; Dialysis Unit St Carlo, Milan, Italy.

**Background:** Vitamin K is involved in the production of Bone and Matrix Gla Proteins (BGP and MGP, respectively), regulating bone and vascular health. We carried out a pilot study to evaluate vitamin K intake in hemodialysis (HD) patients.

**Methods:** We measured vitamin K1 intake (7-day food record) in 78 Italian hemodialysis patients (48 M, 30 F) compared to intake in 39 healthy adults (28 M, 11 F).

**Results:** HD patients had a mean ± SD age of 62.8±15.0 years, median dialytic age of 97 months, mean BMI of 25.4±4.5 Kg/m2. Mean serum levels of interest for CKD-MBD were Ca×P, 4.3±mg/dL, PTH 231.5±pg/mL, ALP 81.5±U/L. Control group mean age was 64±13.9 years. HD patients had a significantly lower intake of vitamin K1 compared to controls (see Table). We also evaluated and compared between HD patients and controls the intake of other fat soluble vitamins and of nutrients closely associated with bone and mineral disorders in CKD patients (see table). All were decreased in HD patients.

**Conclusions:** This Vitamin K intake study is the first carried out on Italian diet. We found a decreased intake of Vitamin K1 in HD patients. This finding supports the hypothesis of supplementing vitamin K for the prevention of vascular calcifications and bone disorders in HD patients. Benefits of vitamin K supplementation should be proved by a randomized trial.

Association of Geriatric Nutrition Risk Index with Body Fluid Composition, Renal Adverse Outcomes and Mortality in Patients with Chronic Kidney Disease Rebin Tai, Yasushi Ohashi, Toshiyuki Aoki, Shizuka Kobayashi, Osamu Aikawa, Ken Sakaik, Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan.

**Background:** Decreased body stores of protein and energy fuels may express by the geriatric nutritional risk index (GNRI) consisting of body mass index (BMI) and serum albumin levels. We studied the association of the GNRI with body fluid composition, renal adverse outcomes and all-cause mortality in patients with chronic kidney disease (CKD).

**Methods:** Body fluid composition was measured in 306 patients with CKD from 2005 to 2014 and was separated into three components: (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Patients were categorized according to tertiles of GNRI levels. Of these, 275 patients were followed until March 2015. The adverse renal outcomes were defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy.

**Results:** Patients with the lower tertiles of the GNRI levels were more likely to be higher age, have a lower BMI, diastolic blood pressure, serum albumin, hemoglobin, glomerular filtration rate, and proteinuria (P < 0.05). In the body fluid composition, those tended to have lower free water mass (r = 0.73, P < 0.001) and the ratio of extracellular water to

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
intracellular water (r = 0.37, P < 0.001). Compared with patients with the middle tertile of the GNRI levels during a median 2.5-year follow-up, the lowest tertile of the GNRI levels had higher mortality (6.8 vs. 1.7 per 100 patient-years, P < 0.001), but had no worse adverse renal outcomes (16.5 vs. 9.0 per 100 patient-years, P = 0.08). In multivariate analysis, the lower GNRI levels independently remained as a risk factor for all-cause mortality (hazard ratio 3.16, 95% CI, 1.30–8.84, P < 0.001).

Conclusions: The GNRI may be a simple and useful tool for predicting the risk of mortality even in CKD population including patients with massive proteinuria. These findings emphasize the importance of adequate body stores of protein and energy fuels in patients with CKD.

FR-PO869
A Novel Index for Estimation of Sarcopenia Mass Using Biomarkers of Kidney Function: Sarcopenia Index
Kiannoush Banaci-Kashani,1 Luce Lucukralova,4 Erin N. Frazee,2 Rahul Kashyap,2 1Div of Nephrology and Hypertension, Dept of Internal Medicine, Mayo Clinic, Rochester, MN; 2Div of Pulmonary and Critical Care, Dept of Internal Medicine, Mayo Clinic, Rochester, MN; 4Faculty of Medicine in Hradec Kralove, Charles Univ, Prague, Czech Republic; 3Dept of Pharmacy, Mayo Clinic, Rochester, MN.

Background: Sarcopenia is associated with poor patients’ outcomes in Intensive Care Unit (ICU). Tools to evaluate sarcopenia are DXA scan, CT and MRI, which may not be feasible for critically ill patients. We hypothesize a novel index which can be used as a surrogate for sarcopenia among ICU patients.

Methods: This is a secondary analysis of prospectively enrolled critically ill patients. Adult ICU patients (>18 years) with shock, sepsis, use of IV antibiotics and contrast media exposure, in 24 hours of enrollment, intra-abdominal hypertension or severe Trauma were excluded. We included patients with pre-existing acute kidney injury, pregnancy, and kidney transplant, or those who were on dialysis or were moribund. We measures parasartial muscle surface area at L3 level, using Slice-O-Matic software (TomoVision®; Maggon, Canada). Sarcopenia Index (SI) was calculated as [Serum Creatinine (Scr) ± Muscle surface area at L3] / 100.

Results: A total of 226 patients met the inclusion criteria. Among these enrollees, 110 patients who had abdominal CT within ± 4 weeks of their index ICU admission were included in the final analysis. The median age (IQR) was 67 (57.77) years and 59 (54%) were male. SI and Parasartial Muscle Surface Area were found to be statistically correlated (R² = 0.26, P < 0.0001).

Conclusions: SI has a fair correlation with gold standard in critically ill patients. This index would be a surrogate for sarcopenia for patients who cannot tolerate transfer to imaging testing.

FR-PO870
Association with Activities of Daily Living and Geriatric Nutritional Risk Index Improves the Prediction of Mortality in Patients on Hemodialysis
Kaori Yasuda,1 Shoichi Maruyama,2 Kunio Morozumi,1 1Nephrology, Masuko Memorial Hospital, Nagoya, Aichi, Japan; 2Nephrology, Nagoya Univ, Nagoya, Aichi, Japan.

Background: Protein energy wasting (PEW) in a typical status of Malnutrition seems to be a prevalent complication in end-stage renal disease (ESRD), and is associated with poor prognosis. We previously reported that Geriatric Nutritional Risk Index (GNRI) is useful marker for the assessment of malnutrition status in hemodialysis (HD) patients. However the interaction between actual activities of daily living(ADL) and GNRI is uncertain. We investigated the prognostic value of the ADL and GNRI, and hypothesized that the combination of both indicators could improve predictive values for mortality in HD patients.

Methods: A total of 304 stable HD patients were enrolled. They were divided into tertiles according to the ADL defined by the Renal Data Registry of Japanese Society for Dialysis Therapy, tertile A: < independence, B: care-needed (mild) and C: care-needed (moderate or severe). They were also divided into tertiles of GNRI levels: L: < 91.7, M: 91.7-97.8 and H: >97.8, and GNRI were 95.9±6.94, 94.5±8.87, 11-11.0 in A, B and C of ADL, respectively (P = 0.0001 in both).

Results: During the follow-up period (40 month), 59 patients were died (19.4%). Kaplan-Meier survival rates for 4 years were 88.9%, 82.1% and 53.1% in A, B and C of ADL, and were 63.5%, 82.8% and 91.9% in L, M and H of GNRI, respectively (P = 0.0001 in both). The adjusted HR for mortality was 3.21 (95% CI, 1.57-6.95, P = 0.0006). C vs A) and 3.24 (95% CI, 1.62-7.06, P = 0.0019, L vs H). In the combined setting of ADL and GNRI (with 9 groups (3x3), the risk of mortality was 8.02-fold (95%CI 2.56-35.4, P = 0.0001, C vs A-H).

Conclusions: The ADL and GNRI can strongly predict the mortality, and combination of both settings also improved the prediction of mortality with ESRD patient on HD.

FR-PO871
Delta Neutrophil Index Is a Predictive Marker of Disease Severity in Patients With Acute Pyelonephritis
Sul A Lee,1 Jong Hyun Jhee,2 Jae Eun Um,2 Meiyan Wu,1 Hyung Jung Oh,1 Jung Tak Park,2 Seung Hyeok Han,1 Shin-Wook Kang,1,3 Taehyun Yoo.1 1Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; 2Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Delta neutrophil index (DNI) is the fraction of immature granulocytes provided by a complete blood count count. Previous studies demonstrated that DNI was a novel marker to predict clinical outcomes in sepsis patients. Therefore, this study was aimed to evaluate DNI as a predictive marker of disease severity in patients with acute pyelonephritis (APN).

Methods: Patients who were diagnosed with APN at Severance Hospital from December 2009 to July 2012 were retrospectively investigated. DNI levels were measured at the time of admission. Patients were classified into two groups according to the median value of DNI. Severe APN was defined as one or more of following conditions: bacteriaemia, acute kidney injury, hypotension requiring use of vasopressors, and admission of intensive care unit. Independent risk factors for severe APN were determined by multivariate logistic regression analysis. Area under the receiver operating characteristic curves (AUC) was compared among DNI, white blood cell (WBC) count, and C-reactive protein (CRP).

Results: A total of 258 patients were included in this study. The median age was 61.0 (19.0 – 87.0) years, and 237 patients (91.9%) were female. The median DNI levels were 2.5% Severe APN were significantly more prevalent in the high DNI group. Multivariate analysis showed that DNI independently predicted severe APN (P< 0.0001, odds ratio=1.287, 95% confidence interval=1.135-1.458, P< 0.0001). Furthermore, DNI was a better predictive marker of severe APN than WBC count [AUC (95% confidence interval); 0.697 (0.637-0.753) vs. 0.562 (0.499-0.624), P< 0.0001] and not inferior to CRP levels [0.697 (0.637-0.753) vs. 0.633 (0.571-0.692), P= 0.118].

Conclusions: DNI at admission could be a valuable predictor of disease severity in patients with APN.

FR-PO872
An Improved Magnesium Formulation for Mitigating Cisplatin-Induced Renal Epithelial Cell Injury
Malvika H. Solanki,1,2,3 Rachel Lauren Mintz,2 Xiaying Xue,2 Prodoy K. Chatterjee,2 Christine N. Metz.1,2,3 1Elmezzi Graduate School of Molecular Medicine, NY; 2Feinstein Inst for Medical Research, NY; 3Hofstra-North Shore-LIJ School of Medicine, NY.

Background: Cisplatin is a potent chemotherapy for treating cancer. It causes nephrotoxicity in ~25% and hypomagnesemia in ~90% patients. This hypomagnesemia is treated with oral magnesium (Mg) chloride (MgCl2) and/or i.v. Mg sulfate (MgSO4). Poor Mg intake and Mg deficiency are not uncommon in the US. Our previous studies revealed the beneficial effects of MgSO4 in reducing cisplatin-induced acute kidney injury (AKI) (Solanki et al, AJP Renal 2014). This study compared the efficacy of various Mg formulations in reducing cisplatin-induced renal epithelial cell injury.

Methods: LLC-PK1, renal epithelial cells were maintained in media containing 100% Mg (i.e. the amount of Mg found in growth media) or 10% Mg (Mg-deficient) for 3 days. To mimic Mg replacement, the 10%Mg cells were restored to 100%Mg using: MgSO4 (i.e. the amount of Mg found in growth media) or 10%Mg (Mg-deficient) for 3 days. The efficacy of MgT over other Mg-formulations in reducing cisplatin-induced renal epithelial injury were measured by DCF-DA assay, MTT assay and TNFα production, respectively. ERK activation was measured by in-cell-western.

Results: Cisplatin-induced oxidative stress, cytotoxicity, and inflammation were exacerbated by Mg deficiency, while Mg supplementation with all formulations consistently protected against cisplatin-induced oxidative stress, cytotoxicity, and inflammation provided by a complete blood count counter. Previous studies demonstrated that DNI was a better predictive marker of severe APN than WBC count [AUC (95% confidence interval); 0.697 (0.637-0.753) vs. 0.562 (0.499-0.624), P< 0.0001] and not inferior to CRP levels [0.697 (0.637-0.753) vs. 0.633 (0.571-0.692), P= 0.118].

Conclusions: DNI at admission could be a valuable predictor of disease severity in patients with APN.

FR-PO873
Nutrition, Inflammation, and Metabolism
epithelial cytotoxicity. Note: MgT has significantly lower GI-effects (bloating and diarrhea) than other Mg formulations. These results warrant further in vivo and clinical studies to investigate the beneficial role of MgT in protecting against cisplatin-AKI.

FR-PO873

Impact of Uremic Serum on the Barrier Function and Inflammation in Human Colonocytes  
Laila Santos Andrade,1 Maria Dalboni,2 Jose Tarcisio Giffoni,2 Caren Cristina Grabulosa,2 Lilian Cuppari,2,3  
1 Nutrition, Diet, and Metabolism; 2 Nutrition, Inflammation, and Metabolism; 3 Nutrition, Medical Education.

**Background:** In chronic kidney disease (CKD) it has been suggested that alterations of the gut are associated with inflammatory state and uremic toxicity. Studies suggest that uremia may impair the intestinal barrier function, by promoting increased intestinal permeability. In this study we aimed to evaluate the in vitro effect of uremic serum on the transepithelial electrical resistance (TER), inflammation and apoptosis in the intestinal epithelial cells.

**Methods:** Pools of serum were prepared from blood samples from patients maintained on hemodialysis (Pre-HD and Post-HD), and of patients with CKD stage 4 (NND-CKD). A pool of serum form healthy individuals served as control (CTL). When the TER exceeding 1,000 Ω cm² was reached, the T84 cells were incubated for 24 h in medium containing 10% pool of serum from each group. At the conclusion of the incubation period, the TER was measured again and the following parameters were determined by flow cytometry: expression of toll-like receptor (TLR), production of reactive oxygen species (ROS) and apoptosis. TNF-α and IL-6 in the culture supernatant was determined by ELISA. A total of nine experiments were performed.

**Results:** No differences among groups were found regarding TER (p=0.443), apoptosis (p=0.751), ROS (p=0.999), expression of TLR-2 (p=0.493), TLR-4 (p=0.418) and TLR-9 (p=0.937) and secretion of TNF-α (p=0.438). IL-6 secretion was higher (p=0.001) by cells incubated with post-HD pool (2.07±0.93 pg/ml) when compared with cells incubated with CTL pool (0.67±0.35), NND-CKD (0.61±0.53) and pre-HD (0.11±0.45).

**Conclusions:** The results obtained from this model suggest that uremic serum per se does not seem to impair the integrity of intestinal epithelial cells. The increased IL-6 secretion in post-HD condition may be a consequence of pro-inflammatory stimuli of the dialysis process.

Prediction of One-Year Mortality and Hospitalization Risk Using Nutritional Indicators and Their Trajectories in a Large Prevalent Hemodialysis Cohort  
Michelle M.Y. Wong,1 Stephan Thijssen,2 Yuedong Wang,2 Len A. Usuyat,1 Qingqing Xiao,1 Peter Kotanko,1 Franklin W. Maddux,3 1 Renal Research Inst; 2 Univ of California - Santa Barbara; 3 Fresenius Medical Care North America.

**Background:** Existing nutritional scores developed in the hemodialysis (HD) population do not consider temporal trajectories of nutritional parameters. We aimed to develop predictive models for mortality and hospitalization using readily available nutritional indicators and their rates of change.

**Methods:** Using retrospective data from a large US HD provider, a cohort with HD vintage ≤1 year (N=21,082 and N=23,384 in mortality and hospitalization analyses, respectively) was randomly split 2:1:1 for model development, testing and validation. Parameters included demographics, nutritional/inflammation parameters, and slopes of all continuous variables over 6 months. Follow-up period was January-December 2012. Performance of generalized linear models and generalized additive models (GAM) was evaluated with area-under-the-curve (AUC), sensitivity and specificity.

**Results:** For both mortality and hospitalization prediction, GAM performed best. The best mortality model included neutrophil:lymphocyte ratio (NLR) slope, serum bicarbonate slope, albumin, creatinine, age, sex and vintage (AUC 0.85, 95% CI 0.83-0.86; sensitivity 0.70; specificity 0.83). The best hospitalization model included NLR slope, albumin, congestive heart failure, serum bicarbonate slope, creatinine, serum phosphate slope, vintage, diabetes, serum phosphate, volume of urea distribution, age and enPCR (AUC 0.70, 95% CI 0.62-0.79; sensitivity 0.41; specificity 0.88).

**Conclusions:** We developed novel and accurate predictive models for mortality and hospitalization using nutritional indicators and their slopes over time. Future studies are needed to assess if its application can improve nutritional intervention allocation and outcomes in HD patients.

**Funding:** Government Support - Non-U.S.

FR-PO875

Extracellular Fluid/Intracellular Fluid (ECF/ICF) Volume Ratio Is A Novel Risk Indicator of Death and Highly Related to Malnutrition-Inflammation-Artherosclerosis (MIA) Complex in Hemodialysis (HD) Patients  
Fumiyuki Kim, Soyon Rhee, Jiwon Ryu, Hee Jung Jeon, Jun-woo Noh, Ja-Ryong Koo.  
Nephrology, Hallym Univ Hospital, Dongtan-Seoul, Korea.

**Background:** Fluid overload and malnutrition are well recognized risk factors contributing to the high mortality in HD patients. Recent studies suggest pathophysiological link between fluid overload and malnutrition as a part of MIA complex. Because the ECF and ICF volume can represent fluid volume and nutritional status respectively, ECF/ICF ratio could be defined as a novel integrated marker reflecting both fluid overload and malnutrition. Accordingly we investigated the relationship of ECF/ICF ratio to survival in the context of MIA complex in chronic HD patients.

**Methods:** 77 HD patients (age 53±13 year, diabetes 38%) were prospectively enrolled. ECF/ICF volume was measured by multi-frequency bioimpedance analysis. Nutrition, inflammation, arteriosclerosis and volume status were measured by serum albumin, C-reactive protein (CRP), pulse wave velocity (PWV) and serum B-type natriuretic peptide (BNP) respectively.

**Results:** ECF/ICF ratio was 0.56±0.06 and cut-off value for maximum discrimination of survival was 0.57 by ROC curve. As compared with low ECF/ICF group (ratio<0.57, 58%), high ECF/ICF group (ratio³0.57, 42%) had higher all-cause mortality, CRP, PWV, BNP and lower serum albumin level. During the 5-year follow-up, 24 all-cause death occurred (18 in high ECF/ICF group versus 6 in low ECF/ICF group, log rank P<0.001). In Cox analysis adjusted for age, diabetes, BP and cardiac function, the ECF/ICF ratio was an independent predictors of all-cause death (HR=1.25, 95% CI=1.01-1.54, per 0.01 in ECF/ICF ratio) and nullify the effect of MIA component and volume marker on survival. The degree of malnutrition (albumin), inflammation (CRP), arteriosclerosis (PWV) and fluid overload (BNP) were correlated well with ECF/ICF ratio.

**Conclusions:** Chronic HD patient with high ECF/ICF ratio is not only fluid overloaded but malnourished and have stiff artery with more inflammation. As a novel integrated marker of fluid overload and malnutrition, ECF/ICF ratio is highly related to MIA complex and a major risk indicator of death in chronic HD patients.

FR-PO876

Weight Gain After Listing Independently Predicts Pre-Transplant Sensitization Status  
Pritika Shrivastava,1 Krista L. Lentine,2 Ankit Sakhuja,1 Fidel Barrantes,2 Diane M. Cibrik,1 Yihung Huang,1 Abhijit Naik.1 1 Univ of Michigan; 2 Saint Louis Univ; 3 Renal Medical Associates, NM.

**Background:** Non-alloimmune stimuli such as infections, vaccinations and pro-inflammatory events cause sensitization to HLA antibodies and increased panel reactive antibodies. Obesity is recognized as an inflammatory state. Given relationship between obesity and inflammation we speculated that weight gain on the waitlist may increase sensitization status at the time of transplantation.

**Methods:** Using national data from the Organ Procurement and Transplantation Network we identified first time kidney only transplant recipients, aged 18-70, transplanted between January 1,2009 and June 30,2013. Previous non-renal transplants were excluded. A calculated panel reactive antibody of 20% or more at the time of transplant was considered to be “sensitized”. Using a priori chosen variables we performed a logistic regression model with sensitized status at time of transplantation as the dependent variable and change in BMI from listing to transplantation, BMI at transplant, recipient age, prior transfusion status, prior pregnancy, dialysis time and race as independent variables.

**Results:** For both mortality and hospitalization prediction, GAM performed best. The best mortality model included neutrophil:lymphocyte ratio (NLR) slope, serum bicarbonate slope, albumin, creatinine, age, sex and vintage (AUC 0.85, 95% CI 0.83-0.86; sensitivity 0.70; specificity 0.83). The best hospitalization model included NLR slope, albumin, congestive heart failure, serum bicarbonate slope, creatinine, serum phosphate slope, vintage, diabetes, serum phosphate, volume of urea distribution, age and enPCR (AUC 0.70, 95% CI 0.62-0.79; sensitivity 0.41; specificity 0.88).
High Salt Diet Impairs the Immune Defense against Uropathogenic Escherichia coli in Murine Pyelonephritis
Kazutaka Hasegawa, Hirobumi Tokuyama, Hiroshi Itoh.
Univ of Bonn, Bonn, Germany.

Background: Recent studies demonstrated that NaCl stimulates immune responses, for example by promoting Th17 cells differentiation, macrophage recruitment into tissues and pro-inflammatory cytokine release from epithelial cell lines. Specially, high salt diet (HSD) exacerbated experimental autoimmune encephalomyelitis and improved immune defense against L. major infection. Little is known about the influence of HSD on anti-microbial responses in the kidney—an organ with extremely high sodium chloride concentration.

Methods: Wild type female mice were given normal salt diet (NSD) or HSD one week prior to infection with uropathogenic E. coli into the bladder resulting in pyelonephritis development. 20 after the infection, kidneys were harvested and analyzed for CFU and immune cell subsets by flow cytometry.

Results: HSD exacerbated pyelonephritis as measured by CFU. Additionally, in kidney medullas of mice fed HSD the number of PMNs, Ly6c+ macrophages and NK cells was significantly decreased in comparison with NSD fed mice. Although PMNs from mice given HSD produced more ROS than PMNs from mice on NSD, in vitro studies demonstrated that less mediatory PMNs from mice fed HSD than NSD were able to perform phagocytosis.

Conclusions: Contrary to the expectations, HSD worsened experimental pyelonephritis, possibly through affecting immune cell activation and/or migration into the kidney medulla. This finding may be of clinical significance and, if confirmed in human studies, decreasing salt intake during bladder infection or pyelonephritis could support antibiotic therapy. Further studies are needed to elucidate the immune mechanisms underlying the negative effect of HSD on pyelonephritis.

Gut Microbiota Lactobacillus Protects against the Progression of Renal Impairment Through the Modulation of TLR2-Mediated Gut Barrier Stability in Rats
Ayumi Yoshifuji, Shu Wakino, Junichiro Iric, Takaya Tajima, Kazuhiro Hasegawa, Hirobumi Tokuyama, Hiroshi Itoh.
Keio Univ, Japan.

Background: Gut microbiota has been shown to have some role in the pathogenesis of various diseases and previous study demonstrated that Lactobacillus (Lact) decreased in number in CKD. In this study, we elucidated the significance of Lact in the pathogenesis of CKD.

Methods: Six-week-old spontaneously hypertensive rats (SHR) were rendered CKD by 5/6th nephrectomy (Nx). The SHR were divided into three groups; sham-operated SHR (SHR), SHR with Nx (Nx) and Nx given Lact (Nx+Lact). After 12 weeks, biochemical parameters, urinary protein excretion, IL-6, histological changes in the kidney, and molecular changes of tight junctions and TLR2 expression were explored. Furthermore, concentrations of fecal uremic toxins were measured. To confirm the effect of Lact, rats are administered with broad antibiotics as pseudofeed-free condition and kept for 8 weeks with Lact. Human colon cell line, Caco-2 cells were treated with uremic toxin precursor, indole in the presence or absence of Lact or OxPAPC, an inhibitor of toll-like receptor, putative receptor recognizing Lact. The expressions of colon tight junction proteins were examined by immunoblotting.

Results: The gut flora analysis revealed that the decrease in Lact in Nx, which was restored in Nx+Lact. However, fecal uremic toxins did not show significant changes. Both serum indoxylsulfate and IL-6 increased in Nx. These increases were ameliorated in Nx+Lact. The decreases in the tight junction proteins Occludin and ZO-1 as well as in TLR2 in Nx were mitigated by Lact. In the pseudofeed-free condition, Lact decreased the urinary protein excretion. In Caco-2 cells, the downregulations of Occludin and ZO-1 by indole were ameliorated by Lact. OxPAPC inhibited the Lact-induced restoration of these tight junctions.

Conclusions: The supplementation of Lact improves the gut environment through the activation of TLR2 pathway. This improvement would contribute to the decrease in systemic uremic toxin levels, systemic inflammation and urine protein excretion. This probiotic therapy can provide novel therapeutic strategy against the progression of CKD.

Funding: Government Support - Non-U.S.
Conclusions: Leucine disposal rate reliably measures amino acid utilization in MHD patients. The lack of correlation between GDR versus LDR in MHD subjects requires further investigation for understanding the effects of insulin signaling on protein metabolism in MHD patients.

FR-PO881
Age and Dependence on Dialysis Are More Important Predictors of Immune Response to Influenza Vaccine Than Inflammation and Iron Status
Jaromír Eiselt,1 Lukas Kielberger,2 Daniel Rajdl,2 Jaroslav Racek,2 1Internal Dept I, Charles Univ, Plzen, Czech Republic; 2Dept of Biochemistry, Charles Univ, Plzen, Czech Republic.

Background: The immune response to influenza vaccine is not uniform and may be influenced by many factors, e.g. comorbidities, age, inflammation or iron metabolism. The aim of our study was to identify factors associated with low production of hemagglutination-inhibition antibodies (HIA) after vaccination in hemodialysis (HD) patients and controls.

Methods: We evaluated the immune response to the influenza vaccine in a total of 122 stable HD patients and in 37 subjects without renal dysfunction. To identify factors associated with immune response, a stepwise backward and forward algorithm for a linear regression model was used with postvaccination increase in HIA titre against H1N1 vaccine strain as dependent variable and following independent variables: age, dependence on dialysis, diabetes, iron, transferrin, transferrin saturation, ferritin, hepcidin, interleukin-6, C-reactive protein, albumin, prealbumin and pre-vaccination HIA protective titre.

Results: The rate of HIA production was lower in HD patients than in controls. Factor increases in geometric mean titer for the H1N1 strain were 2.9 in HD and 6.6 in controls (p<0.001), with the respective figures being 2.8 and 3.1 (p<ns) for the H3N2 strain, and 2.4 and 4.7 (p<0.05) for the B strain. Also, post-vaccination seroconversion rates were lower in the HD group than in controls (43% versus 73% against the H1N1 strain; p<0.05; 43% versus 53% against the H3N2 strain; p<ns; and 36% versus 62% against the strain B; p<0.05). According to the regression model (adjusted R² 0.298, p<0.00001), the predictors of low HIA production against H1N1 strain were high age (p<0.0001), dependence on dialysis (p<0.001) and high transferrin saturation (p<0.03).

Conclusions: The immune response to the influenza vaccine was lower in HD patients than in controls. Besides dependence on dialysis, the most significant predictors of low antibody production were high age of vaccinated subjects and high transferrin saturation. Immune response was independent of other markers of iron metabolism and inflammation.

FR-PO882
Intravenous Administration of L-Carnitine (LC) May Maintain the Muscle Volume in Hemodialysis (HD) Patients
Junichiro Hashiguchi,1 Takuiisa Uchino,1 Miki Yano,1 Satoshi Funakoshi,1 Osamu Sasaki,1 Hiroshi Ichinose,1 Kenji Sawase,1 Yoko Obata,2 Tomoya Nishino,2 Yutaka Mori,2 Kazunori Utsunomiya,2 Takashi Harada,1 1Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan; 3Jikei Univ, Tokyo, Japan.

Background: Patients on maintenance HD usually suffer from dialysis-related carnitine deficiency, causing various clinical symptoms. At Carnitine Consensus Conference in 2003 convened by The National Kidney Foundation, the level of evidence was strongest for the treatment of anemia, and weakest for the response of muscle weakness. We hereby investigated whether intravenous administration of LC can maintain the muscle volume in HD patients as assessed by % creatinine generation rate (CGR).

Methods: Thirty-eight HD patients were enrolled in this study after appropriate informed consent. Subjects were treated with intravenous administration of 1000mg / body of LC at the end of every HD session for 12 months, then assessed by %CGR. Normalized protein catabolic rate (nPCR), geriatric nutritional risk index (GNRI) as well as serum albumin, hemoglobin, nPCR and GNRI stayed the same level during observation period.

Results: As shown in Figure 1, average %CGR significantly declined during 1 year before the start of LC, and then stabilized 1 year after the treatment, suggesting LC administration might prevent the loss of muscle volume. Serum albumin, hemoglobin, nPCR and GNRI stayed the same level during observation period.

Conclusions: Intravenous LC administration may potentially maintain the muscle volume in patients undergoing HD.

Nutrition Application Mobile Application in Patients with Chronic Kidney Disease

Chavakrit Krittawong,1 Sakkarin Chirapsangthorn,2 Zhou Wang,4 Hua Ann Jenny Lu.1 Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; 2Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; 3Div of Gastroenterology, Dept of Medicine, Phramongkukhos Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; 4Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background: While mobile phone applications have become increasingly important in the last decade, few eating healthy mobile applications exist for patients. Yet in their daily lives, patients on a restricted diet often lack instant access to health information with regards to the foods that is in front of them. It is therefore an objective of this pilot project to introduce a device that patients can utilize to overcome such problems.

Methods: The nutrition analysis application is named GoFoody Project and primarily consists of two functions: a scanning system and a recommendation system.

Results: The first major component is the food scanning and recognition process, which is comprised of two sub-processes: a photo recognition and a barcode scanning. In the photo recognition, the user can take a picture of food and send it to the cloud database for further processing, regardless of their location. Second, the recommendation system compares the patient’s medical profile with their consumptions records in order to make health and dietary suggestions.

Conclusions: Over the next few weeks, we anticipated that this invention will be popular in grocery stores such as Walmart, Target, etc. We plan to demonstrate our invention to the healthcare industry by using the example of computer vision technology and cloud database.

FR-P0884
Lipoxin A4 Attenuates Obesity-Induced Adipose Inflammation and Associated Liver and Kidney Disease

Emma Borjesson,1,2 Kumar Sharma,1 Catherine Godson,2 1Center for Renal Translation Medicine, Inst for Metabolomic Medicine, UC San Diego, San Diego, CA; 2Diabetes Complications Research Centre, Convay Inst, Univ College Dublin, Dublin, Ireland.

Background: Visceral obesity and adipose inflammation is considered a driving force of systemic disease, e.g. chronic kidney disease (CKD). Inflammatory resolution is actively regulated by specialized pro-resolving mediators (SPMs), including the lipid LXA4. Impairment of SPMs may underlie development of obesity-related pathology. Here we explored the therapeutic potential of LXA4 in experimental obesity-induced systemic disease, e.g. liver cirrhosis and CKD.

Methods: C57BL/6 or Adiponectin-/- mice were fed a standard (10% fat) or high fat (60% fat) diet for 12 wks. LXA4 (5ng/g) and benzo-LXA4 analogue (1.7 ng/g) were given daily in the last decade, few eating healthy mobile applications exist for patients. Yet in their daily lives, patients on a restricted diet often lack instant access to health information with regards to the foods that is in front of them. It is therefore an objective of this pilot project to introduce a device that patients can utilize to overcome such problems.

Methods: The nutrition analysis application is named GoFoody Project and primarily consists of two functions: a scanning system and a recommendation system.

Results: The first major component is the food scanning and recognition process, which is comprised of two sub-processes: a photo recognition and a barcode scanning. In the photo recognition, the user can take a picture of food and send it to the cloud database for further processing, regardless of their location. Second, the recommendation system compares the patient’s medical profile with their consumptions records in order to make health and dietary suggestions.

Conclusions: Over the next few weeks, we anticipated that this invention will be popular in grocery stores such as Walmart, Target, etc. We plan to demonstrate our invention to the healthcare industry by using the example of computer vision technology and cloud database.

FR-P0885
Prevalence of Protein-Energy Wasting Syndrome and Its Association with Anemia, Erythropoietin Resistance, Overhydration and Body Composition in Hemodialysis Patients

Carlos Adrián Chávez-Mendoza, Jose Luis Ortega vargas, Jorge Osvaldo Montes rivera, Ricardo Correa-Rotter, Olynka Vega-Vega. Nephrology and Metabolism National Inst of Medical Science and Nutrition Salvador Zubiran, Mexico City, Mexico.

Background: The prevalence of protein-energy wasting syndrome (PEW) in Mexican hemodialysis (HD) patients is unknown. Accordingly, there is no information on which clinical, biochemical, quality of life (QL), and body composition (BC) variables are associated or predictive of PEW in this population.

Methods: Observational comparative study that included 191 prevalent HD patients. BC was determined by BIS employing (BCM,Fresenius®), QL was measured with KDOOL and presence of PEW according to ISRNM criteria.

Results: General characteristics are shown in Figure 1, prevalence of PEW was 22%(n=41). No differences between groups (with or without PEW) were present in age, Charlson index, number and type of drugs employed, time on dialysis, vascular access, history of PD or kidney transplant and hospitalization days in the last year. PEW patients had a higher prevalence of DM(p=0.04), lower Hb(0p=0.006) and higher EPO requirements(p=0.04) despite similar iron reserves. In terms of BC, PEW patients had more overhydration (OH) and higher extracellular water (ECW), and lower lean and fat tissue indexes (LTL,FTI). Surprisingly, QL indicators were not different between groups. In a Cox multivariate logistic regression model analysis, predictors of PEW were degree OH(OR 3.2,95% CI 1.2-8.3,p=0.001), and ECW(OR 0.51,95% CI 0.22-0.89,p=0.01).

Conclusions: Prevalence of PEW in the studied population was lower compared to other series. PEW patients exhibit a state of overhydration which is given by increased ECW, and accompanied by loss of LTL and FTI. No PEW impact on QL was observed. PEW patients have increased anemia and higher requirements of EPO possibly associated to chronic inflammation.
Efficacy of Nutrition Counseling on Protein Intake Restriction in Chronic Kidney Disease Patients – Niigata Part of SOFT-J (Study on Regional Variation of FROM-J Intervention by JSN) Ryohei Kasada,1 Michihiro Hosojima,1 Toshiko Murayama,1 Akihiko Saito,1 Yoshiki Suzuki,1 Kunihito Yamagata,2 Ichiei Narita.1 1Niigata Univ; 2Japan; 3Tsukuba Univ, Japan.

Background: Low adherence is frequently observed in patients with chronic kidney disease (CKD) who are following a diet therapy. This study was evaluated the efficacy of nutrition counseling focused on protein restriction for CKD patients in clinics by national registered dietician using iPad and textbook used in FROM-J (Frontier of Renal Outcome Modification in Japan) study, aiming at promoting relationship between home doctor and nephrologist.

Methods: 47 patients with CKD stage 3 (eGFR 30-59 ml/min/1.73m²), age 40-85 were recruited. Nutrition counseling was conducted once for 30 min by national registered dieticians using iPad and textbooks in clinics without any dieticians in the staff. Optimal protein and energy intake were prescribed as 0.9 g/kg/day and 25-30 kcal/kg/day, respectively. The amount of protein intake was estimated from dietary records and by 24 hours urine collection before and 2 months after counseling (pre/post, respectively).

Results: All patients recorded their daily diets, 26/47 provided 24 hours urine collections. Counseling significantly decreased protein intake (record pre 1.10±0.23 g/kg day post 1.00±0.01, urine pre 1.02±0.29 post 0.91±0.22 p=0.04). Although energy intake slightly decreased (record pre 31.9±6.4 kcal/kg/day post 30.1±5.2 p=0.03), this was not below the prescribed optimal calories. Salt intake decreased in recorded data but not in urine data (record pre 8.4±2.8 g/day post 7.6±1.2 p=0.03, urine pre 9.0±4.2 post 9.1±4.4 p=0.86, respectively). There was no significant difference in body mass index, eGFR, HbA1c (diabetic patients), LDL, cholesterol, uric acid and blood pressure.

Conclusions: iPad and textbook counseling by dieticians is effective in reducing protein intake without compromising necessary caloric requirements, even in clinics without regular nephrologist or dietary staff. Informational technology may be an effective method of delivering on-demand nutritional counseling that can directly benefit patient care.

Activin B Has a Functional Role in Hepcidin Induction by Inflammation

Methods: 8 male Wistar rats per group were used. LPS (10mg/kg BW i.p.) or saline were administered. Hepcidin was measured in plasma 4 hours after injection.

Results: LPS injection significantly increased plasma hepcidin levels (p<0.05), while saline injection had no effect. Activin was also able to induce hepcidin expression, but not to the same extent as LPS.

Conclusions: These results suggest that Activin may play a role in hepcidin induction by inflammation, but also that other factors may be involved in the full induction of hepcidin.

Risk of Anemia and Blood Transfusion following Reduction of Maximum ESA Doses

Methods: 162 stable patients on chronic hemodialysis (HD) were enrolled. The primary endpoint was the occurrence of a HGB decline below 90 g/L following a reduction in ESA dose. The secondary endpoint was the need for blood transfusion during a 4-week follow-up period following the dose reduction.

Results: 28 patients (17.3%) had a HGB decline below 90 g/L, and 22 patients (13.6%) required blood transfusion. The risk of transfusion was significantly higher in patients with a lower baseline HGB (p=0.02) and in those receiving a higher baseline ESA dose (p=0.006).

Conclusions: Reducing ESA doses in patients with chronic kidney disease can lead to a significant risk of anemia and blood transfusion, especially in those with lower baseline HGB levels and higher ESA doses.

Association of Moderate Ascorbic Acid Supplementation with Plasma Oxalate Levels in Prevalent Hemodialysis Patients

Methods: 48 prevalent HD patients receiving HD 3 times a week were enrolled. Ascorbic acid (AA) supplements were administered for 4 weeks, followed by 4 weeks of placebo treatment. Plasma oxalate levels were measured at baseline, after 4 weeks of AA supplementation, and after 4 weeks of placebo treatment.

Results: Plasma oxalate levels decreased significantly after 4 weeks of AA supplementation (p=0.007) and returned to baseline levels after placebo treatment (p=0.02). The decrease in plasma oxalate levels was associated with a reduction in urinary oxalate excretion.

Conclusions: Moderate ascorbic acid supplementation can decrease plasma oxalate levels in HD patients and may be a potential strategy to reduce oxalate load and prevent oxalate stone formation.
Conclusions: These findings support the notion that moderate AA supplementation may be able to safely and effectively raise plasma AA levels.

FR-PO891
Chronic Kidney Disease Is Associated with Altered Muscle Mitochondrial Energies by Functional MR Spectroscopy and Optical Spectroscopy

Background: Exercise intolerance and muscle weakness are frequent clinical complications of CKD associated with adverse health outcomes, yet the pathophysiology underlying these conditions is poorly understood.

Methods: Cross-sectional study of in vivo muscle mitochondrial energetics using 31P Magnetic Resonance Spectroscopy and optical spectroscopy (MRS/OS) in 12 subjects with non-diabetic CKD (eGFR<60) and 26 controls. 31P MRS and OS were performed on the hand muscle under controlled ischemia. ATP flux (ATPase rate) was measured from phosphocreatinine breakdown. Hemoglobin and myoglobin desaturation rates were assessed by OS to measure muscle oxygen uptake (O2 uptake). The primary outcome was the coupling efficiency of mitochondrial oxidative phosphorylation ATP production (ATP flux) per unit of oxygen consumed (O2 uptake) or P/O ratio. Grip strength and walked up and go were assessed. Pearson’s correlation coefficient was calculated for univariable associations. We used multivariable linear regression adjusting for age.

Results: Mean age of CKD patients was 53±13yrs. Physical performance of the CKD group was no different from predicted normal values. Mean P/O values were 1.46±0.7 in the CKD group vs. 2.22±0.6 in the control group (age-adjusted P=0.002). The strongest correlates of P/O ratio age (P=0.42), followed by eGFR (P=0.32). In contrast to controls, patients with CKD had higher O2 uptake (P=0.03) without concomitant change in ATPase rate.

Conclusions: Application of non-invasive tools reveals that CKD is associated with greater muscle O2 uptake reflecting uncoupling of oxidative phosphorylation. These results suggest altered mitochondrial respiration in skeletal muscle of patients with CKD prior to dialysis.

FR-PO892
Improving Outcomes with Nutrition in Older People with Advanced Chronic Kidney Disease – Baseline Data from a Pilot Randomised Controlled Trial

Background: It is difficult to determine when to start dialysis in older people as creatinine and eGFR can be misleading. Dialysis start is often determined by weight loss, symptoms, potassium and fluid overload, all of which are potentially modifiable with nutrition. This pilot RCT aims to determine whether dietary interventions can result in improved patient outcomes, including time to dialysis, in older people with advanced chronic kidney disease (CKD).

Methods: Patients ≥65 years, with eGFR 10-20mls/min were randomised to an observational or intervention group (greater dietetic input). Data will be collected every 6 months for up to 2 years: nutritional status (Subjective Global Assessment), symptoms (Palliative Outcome Scale – Symptoms Renal), function (4 metre walk gait speed test and Jamar handgrip dynamometer) and fluid overload using Body Composition Monitor (Fresenius).

Results: 80 patients were recruited, baseline data presented. The 2 groups have statistically similar baseline demographic and clinical characteristics. Overall, 30% have malnutrition of which 58% are overweight/obese. 28% have nutritionally relevant potentially uraemic symptoms (nausea, vomiting and/or poor appetite). Fluid overload (+2L) was observed in 22% of those that were assessed (n=58).

FR-PO893
Retention of Acetyl carnitine in Chronic Kidney Disease Causes Insulin Resistance in Skeletal Muscle

Background: Insulin resistance occurs frequently in patients with chronic kidney disease (CKD) and ameliorates after introduction of hemodialysis (HD). However, the mechanisms of insulin resistance associated with CKD are unclear. An increased mitochondrial acetyl-CoA/CoA ratio causes insulin resistance in skeletal muscle, and this ratio is regulated by carnitine acetyltransferase (CAT), which transfers excess acetyl moieties to carnitine (CT). Because the resulting acetylcarnitine (AcCT) is excreted in urine, increased AcCT levels indicate increased CAT activity and can be measured as an indicator of insulin resistance.

Methods: Serum samples were collected from 64 patients with CKD (including 14 HD patients) and 31 control subjects who underwent a medical examination. CT and AcCT concentrations in sera were measured by HPLC-ESI-MS/MS. The effects of exogenous AcCT (0-300 µM) on insulin-dependent 2-deoxyglucose (2DG) uptake, mitochondrial CT and AcCT levels, and the mitochondrial acetyl-CoA ratio were examined in a cultured skeletal muscle cell line (C2C12 myotubes).

Results: The serum concentration of ACT, but not that of CT, significantly increased with reduction of renal function, as classified by eGFR (stage I: 3.7 ± 0.6 µM, stage III: 6.1 ± 1.1 µM, stage III: 3.0 ± 1.9 µM, stage IV: 4.6 ± 2.1 µM, stage V: 5.2 ± 5.9 µM, mean ± SEM). After introduction of HD, the increased AcCT levels were significantly reduced (p<0.001). The results of experiments in skeletal muscle cell lines showed that uptake of 2DG was significantly and dose-dependently inhibited by addition of AcCT.

Conclusions: Acetyl carnitine is retained in skeletal muscle cells of patients with CKD, and this may contribute to insulin resistance in these cells.

Funding: Fresenius.
Conclusions: The results suggest that increased AcCT in patients with CKD causes insulin resistance in skeletal muscle by stimulating the reverse reaction of CAT, which leads to accumulation of acetyl-CoA in mitochondria.

High-Fat Diet Induces the Production of IKKє by Macrophages to Promote Nephroptoph bicyxia. Xin Wan, Binbin Pan, Changchun Cao. 1 Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital).

Background: The NF-kB activation may participate in lipid nephrotoxicity which may be regulated by inhibitor kappa B kinase epsilon (IKKє). To investigate the role of IKKє in this process, mouse experiments were performed.

Methods: Mice were grouped by wild-type and hyperlipidemic mouse model with normal diet (WN), (2) wild-type with high fat diet (WH), (3) IKKє knockout with normal fat diet (KN), (4) IKKє knockout with high fat diet (KH). Renal function, lipid, histological changes and tubular proliferation were analysed. IL-1β, TNF-β, p50 and p65 were determined by western blot. NF-кB level was tested by EMSA. Expression of IKKє was evaluated via immunohistochemistry and immunofluorescence.

Results: Cystatin C levels were significantly higher in WH group than others. Staining with hematoxylin-eosin revealed that tubular lesions in WH group (3.53 ± 0.21) were more severe than in WN group (0.32 ± 0.11). By Immunohistochemistry, WH group exhibited marked macrophages infiltration than WN, KN and KH groups. Western blot showed significant increase of IL-1β, TNF-β and marked increase in the expression of NF-кB pathway components consists of p50 and p65 in WH group, while these increases were blocked in KN and KH groups. Furthermore, NF-кB level in WH group was higher than other groups. WH group exhibited remarkable macrophages infiltration than other groups by Immunofluorescence. Immunohistochemistry showed remarkable increases in the expression of IKKє in the WH group compared with other groups. Immunofluorescence analysis demonstrated that the expression of IKKє was located around macrophages.

FR-PO895

Background: The intestinal microbial flora consists of diverse bacterial species that inhabit the gastrointestinal tract. These bacteria are integral to the etiology and regulation of the immune system, and maintenance of intestinal homeostasis. In the chronic kidney diseases, changes of the intestinal bacterial flora have been reported, which contribute to nutritional disorder, systemic or local inflammation, and the uremic toxin production. Phosphate promotes a bacterial growth. So, by phosphate adsorption, intestinal bacterial flora may be changed. We examined whether phosphate adsorption with lanthanum carbonate can change intestinal bacterial flora in renal failure mice.

Methods: We used 5 weeks old male ICR-derived glomerulonephritis (ICGN) mice (n=10) for renal failure group and ICR mice (n=10) for control group. Each group mice were fed with standard diet or diet supplemented with 3% lanthanum carbonate for 10 weeks. Gene expression patterns of whole bacterial flora in the intestine were analyzed by terminal restriction fragment length polymorphism analysis method. Fecal bacteria products (peptide, para-cresol, indole and skatole) were examined by quantitative chemical analysis.

Results: The ratio of "bad" bacteria clostridia was increased, and the ratio of opportunistic pathogen bacteria was decreased in intestinal bacterial flora of ICGN mice. By the lanthanum carbonate administration, the ratio of clostridium was decreased, and the ratio of beneficial bacterium lactobacilli was increased. Fecal bacteria products (peptide, para-cresol, indole and skatole) were examined by quantitative chemical analysis.

Conclusions: The intestinal bacterial flora in chronic renal failure mice was changed by lanthanum carbonate administration. The change of the bacterial flora affected the fecal bacteria products, which may contribute the production of uremic toxin.

FR-PO897
Clinical Determinants of Toll Like Receptor 4-Mediated Inflammatory Response in Skeletal Muscle of Patients with Chronic Kidney Disease Daniela Verziano, 1 Alice Bonanni, 2 Antonella Sofia, 1 Francesca Ansoldo, 1 Elisa Vezzani, 1 Valeria Cademartori, 1 Emanuele L. Parodi, 2 Giuliano Brunori, 1 Chiarla Venturelli, 1 Giacomo Garibotto. 1 DIML, Nephrology Div., Univ of Genoa, Genoa, Italy; 2 Nephrology Div., Santa Chiara Hospital, Trento, Italy.

Background: Inflammation in skeletal muscle is implicated in the pathogenesis of insulin resistance and cachexia. We previously observed that the Toll-like receptor-4 (TLR4) dependent muscle signaling is upregulated in muscle of CKD subjects.

Methods: We studied the associations between muscle (rectus abdominis) TLR4 protein (western blot and immunohistochemistry) and gene (rt-PCR) expression and clinical parameters in 38 CKD stage 5 patients (23M/15F, eGFR 8±1 ml/min).

Results: CKD subjects had significantly elevated TLR4 gene expression and protein content in muscle (~4-fold increase vs. controls p<0.05). LogTLR4 protein content in
FR-PO998

Randomized, Double-Blind, Crossover Clinical Trial on Oral Rice Endosperm Protein Supplementation to Patients on Maintenance Hemodialysis

Mochihiro Hosojiima,1 Hisaki Shimada,2 Shigeru Miyazaki,2 Yoshitsugu Obi,3 Hakuzi Kondo,3 Mikio Fujii,3 Reiko Watanabe,4 Shoji Kuwahara,5 Ryohsei Kaseda,1 Ichiti Harita,1 Yoshiki Suzuki,1 Motoni Kadowaki,2 Akihiko Saijo.6 1Dept of Clin Nutr Sci, Niigata Univ, Japan; 2Shirakiku-en Hospital, Japan; 3Univ of California; 4Kameda Seika Co., Ltd., Japan; 5Univ of Niigata Prefecture, Japan; 6Div of Clin Nephrol & Rheumatol, Niigata Univ, Japan; 7Health Adminstr Center Div, Niigata Univ, Japan; 8Faculty of Agriculture, Niigata Univ, Japan.

Background: Protein-energy wasting, a state of metabolic and nutritional derangements, is an important risk factor that affects outcomes of patients with CKD, particularly in ones with ESRD and on maintenance dialysis (MHD). Purified rice endosperm protein (REP) contains less phosphorus (150 mg/100g) compared with soybean (787 mg/100g) and casein (737 mg/100g) proteins, and may improve nutritional status without imposing further metabolic derangements.

Methods: We carried out a randomized, double-blind, placebo-controlled, cross-over study to evaluate the effect of REP supplementation (5 g per day x 4 weeks) on nutritional and metabolic status in 50 MHD patients (UMIN000010876). The primary outcome was the change in urea kinetic-based normalized protein nitrogen appearance (nPNA), an indicator of protein intake in MHD patients. The inclusion criteria were: (1) nPNA < 1.2 g/kg/day, (2) serum albumin concentration ≤ 3.5 g/dl, (3) body mass index ≥ 23 kg/m², and metabolic status in 50 MHD patients (UMIN000010876). The primary outcome was the change in urea kinetic-based normalized protein nitrogen appearance (nPNA), an indicator of protein intake in MHD patients. The inclusion criteria were: (1) nPNA < 1.2 g/kg/day, (2) serum albumin concentration ≤ 3.5 g/dl, (3) body mass index ≥ 23 kg/m².

Results: By intention-to-treat analyses, REP increased nPNA by 0.07 (95% CI: 0.03-0.11) g/kg/day compared with placebo, whereas serum phosphorus concentration was not significantly different between the groups (0.18 (95% CI: -0.23-0.58) mg/dL). REP did not show significant effects on other nutritional parameters. Per-protocol analyses yielded similar results. There were no specific complications associated with the REP supplementation.

Conclusions: Purified REP may be useful for dietary supplementation in MHD patients. Further studies are warranted to evaluate its long-term or high-dose efficacy.

Association of Serum Phosphate Levels and Mortality Risk in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis

Anawin Sanguankeo,1,2 Sítkarin Upala,1,2 1Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; 2Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

Background: Abnormalities of serum phosphate are associated with increased risk for mortality in end stage renal disease (ESRD) or dialysis patients. Use of phosphate binders has shown to reduce risk of mortality in these population and is recommended in several guidelines. However, there is still controversy on the management of serum phosphate in patients with chronic kidney disease (CKD). This meta-analysis evaluated the impact of serum phosphate on mortality in patients with CKD not requiring dialysis.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT and prospective cohort studies assessing effects of high serum phosphate (compared to normal range) and a 1 mg/dL increase in serum phosphate level in patients with CKD (eGFR < 60 mL/min/1.73 m²). We excluded ESRD, dialysis, or renal transplant patients. The primary outcome was risk of all-cause mortality. We used hazard ratio (HR) or risk ratio (RR) in the multivariate model as an effect estimate.

Results: From 15 full-text articles, five studies involving 6,536 patients were included in the meta-analysis. All were prospective cohort studies of CKD stage 3 or 4 patients. There was an increase all-cause mortality risk in higher phosphorous levels (HR = 1.36, 95% CI: 1.24 to 1.0, p<0.01, I²=0%) compared with normal phosphorous levels. A 1 mg/dL decrease in serum phosphate also increases mortality risk with HR=1.23 (95% CI: 1.14-1.34, p<0.01, I²=0%).

Conclusions: Elevated serum phosphate levels were independently associated with increased mortality risk among patients with CKD. Randomized controlled trials are needed to assess the benefits of using phosphate lowering therapy in patients with CKD before developing ESRD or dialysis.

Serum Phosphate Levels prior to Transition to Dialysis and Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study

Amanda R. Tortorici,1 Yoshitsugu Obi,3 Melissa Soohoo,1 Connie Rhee,1 Elani Streja,2 Jennie Jing,1 Rajiv Saran,3 Bruce M. Robinson,4 Yi Li,5 Danh V. Nguyen,1 Keith C. Norris,2 Csaba P. Kovsedyl,7 Kamyar Kalantar-Zadeh,1,2 UC Irvine; 3UM-KECC; 4UCHLA; 5UTHSC.

Background: Previous studies have shown that higher phosphorous (Phos) levels were monotonically associated with higher risk of death in patients with chronic kidney disease and end-stage renal disease (ESRD). The impact of the pre-ESRD Phos levels on early post-ESRD mortality is not known.

Methods: In US veterans who transitioned to dialysis between 10/2007 and 9/2011, we identified 10,724 patients with available Phos measurements within the last 6 months prior to transition. We examined the association of Phos (averaged over 6 months) as a continuous predictor of all-cause mortality within the first 3 months post transition, using restricted cubic spline analysis and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region of residence.

Results: The mean±SD age of the cohort was 66±11 years, among whom 34% were African-American, 8% were Hispanic, and 52% had diabetes listed as their primary cause of ESRD. We observed a reverse J-shaped association between pre-ESRD Phos and 3-month post-ESRD mortality risk. Patients with Phos levels <4.7 mg/dL had a higher risk of mortality, and patients with Phos levels >9.0 mg/dL trended towards a higher risk of mortality as well. However, patients with Phos levels between 4.7 and 7.2 mg/dL demonstrated lower mortality risk.

Conclusions: Among veterans transitioning to dialysis, both lower and higher Phos levels were associated with higher risk of early post-ESRD mortality, while patients with Phos levels between 4.7 to 7.2 mg/dL had the lowest risk of mortality. Further studies are needed to determine if using dietary and medication interventions to attain this Phos range confers higher survival in this population.

FR-PO091
The Comparison of Serum Calcium, Phosphorus and Intact Parathyroid Hormone Between Peritoneal Dialysis Patients and Hemodialysis Patients
Guisen Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: In this study, we compared the serum calcium, phosphorus and intact parathyroid hormone between peritoneal dialysis patients and hemodialysis patients to study the difference in MBD biochemical variables between PD and HD.

Methods: 597 patients were enrolled from July 1, 2014 to December 31, 2014, including 148 patients received peritoneal dialysis and 359 patients received hemodialysis patients (HD) more than 3 months. Basic clinical information, data of dialysis, serum calcium, phosphorus and iPTH levels were collected in all patients, and comparative analysis was carried out based on those information.

Results: The age and the dialysis vintage was significantly higher in HD group than in the PD group (P <0.001). Serum phosphorus was lower, percentage of phosphorus in target was higher and percentage of calcium in target was lower (P =0.271) in PD group than in HD group(P=0.001). The serum phosphorus levels of PD patients with peritoneal high transport characteristics or high average transport were much lower than those with low transport or low average transport (P = 0.0167). The levels of serum phosphorus (P <0.001), iPTH(=0.0167)and alkaline phosphatase(=0.001) were much lower in patients with RRF<2ml/min than those with RRF>2ml/min. The levels of serum calcium (P <0.01), corrected calcium(<0.001), phosphorus (P = 0.025), iPTH(=0.001)and alkaline phosphatase(=0.001) were much lower in patients with urine volume >100ml/d than those <100ml/d. There was a negative correlation between RRF and serum phosphorus(=0.291, P <0.001)and iPTH(=0.271, <0.001) in PD group. The weekly total Kt/V(=0.201, P = 0.019) and weekly total creatinine clearance(Ccr)(=0.407, P<0.001) negatively related to serum phosphorus. The Ccr(=0.241, P<0.001) negatively correlated with serum iPTH.

Conclusions: The serum levels of phosphorus is lower and the percentage of achieving target of phosphorus is higher in PD patients than HD patients. The peritoneal high transport characteristics, RRF<2ml/min, urine volume >100ml/d and the nutrition status have obvious influence on the serum phosphorus and iPTH levels in PD patients.

FR-PO092
Increased Risk of Cerebral Hemorrhage in Hemodialysis Patients with Hyperphosphatemia: The Q-Cohort Study
Shunsuke Yamada,1 Masanori Tokumoto,1 Masatomo Taniguchi,1 Takanari Kitazono,1 Kazuhiko Tsuruya.2 1Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; 2Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan; 1Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.

Background: Mounting evidences have shown that hyperphosphatemia, an established component of CKD-MBD, accelerates cardiovascular disorders in dialysis patients. However, previous studies did not separately determine the effects of hyperphosphatemia on the onset of cerebrovascular disorders and cardiovascular disorders in dialysis patients.

Methods: The present study is an observational study consisting of 3431 outpatients undergoing hemodialysis. The associations between the baseline serum phosphate (Pi) level and the onset of cerebral bleeding and infarction were examined. Independent variable was serum Pi level. Dependent variable was the onset of cerebral hemorrhage and infarction. Age, sex, diabetes mellitus, history of cardiovascular events, dialysis vintage, Kt/V for operating characteristic (ROC) curves for hypercalcemia determined by iCa (r<0.25 mg/dL).

Results: Albumin was associated with iCa, but its coefficient was -0.15, not -0.8 as shown in the conventional correction equation. Furthermore, albumin-corrected iCa showed lower correlation than uncorrected iCa with iCa (r=0.69 and 0.76, respectively). Two equations were developed from the derivation set as follows; [EQ1] 1.1*tCa – 0.08*(anion gap – 2). In the validation set, EQ1 and EQ2, compared to the conventional correction by albumin, showed better correlation with iCa (r=0.78 and 0.80, respectively), lower BIC (96% and 92%, respectively), and higher area under the ROC curve for Ca-defined hypercalcemia (P <0.01 for both).

Conclusions: Novel correction equations for iCa show better association with iCa and hypercalcemia evaluated by iCa. Its clinical usefulness needs to be evaluated in further studies.

Relationship Between Dietary Phosphorus Intake and Protein and Energy Intakes in Hemodialysis Patients
David E. St-Jules,1 David S. Goldfarb,2,3 Mary Lou Pompeii,1 Kathleen Woolf,4 Kamyar Kalantar-Zadeh,5 Mary A. Sevick.1 1NYU School of Medicine; 2NY Harbor VA Medical Center; 3NYU Langone Medical Center; 4NYU Steinhardt; 5UCLA School of Public Health.

Background: Excess dietary phosphorus may contribute to mineral and bone disorders in hemodialysis (HD) patients. However, many high phosphorus foods are also important sources of dietary protein, which raises concerns that phosphorus restriction may compromise protein status.

Methods: We conducted a cross-sectional study of 190 African American and white men and women on intermittent HD for >3 months. Dietary data were collected by three 24-hour recalls, which were analyzed using NDDS®. Only participants who completed all three recalls and reported intakes >500 kcal/d were included (n=137).

Results: Dietary phosphorus and protein were highly correlated (R=0.73). Based on linear regression, a 1,000 g/d phosphorus restriction would provide about 78 g protein/d (or 1.1 g protein/kg/d for a 70-kg person). When adjusting for energy intake, the association of dietary phosphorus and protein was far less apparent (R=0.42). Further, the highest phosphorus intake was about two times greater than the lowest phosphorus intake for each energy and protein intake level (500 kcal and 5% of kcal increments), reaching 600 mg/d for some groups.

Figure 1. Ranges in reported dietary phosphorus intake of hemodialysis patients in relation to daily energy and protein intake in the Balance/Wise study (n=137)

FR-PO093
Development and Evaluation of Novel Correction Equations for Serum Calcium Concentrations in Hemodialysis Patients
Yoshitsugu Yamada,1 Wei Ling Lau,1 Elanl Streja,1 Connie Rhee,1 Steven M. Brunelli,2 Csbasha P. Kovesdy,1 Kamyar Kalantar-Zadeh,5 1UC Irvine; 2DaVita Clinical Research; 3UTHSC.

Background: Ionized calcium (iCa),but not total calcium (tCa), is the physiologically relevant component of blood calcium. However, these measurements correlate poorly in hemodialysis patients even after correction for serum albumin, which may be partly explained by electrolyte and acid-base derangements in this population.

Methods: In 1,366 patients who initiated conventional HD over four years (1/2007-12/2010), we identified 6,830 iCa measurements where serum albumin, tCa, sodium, chloride, phosphorus, and bicarbonate were measured simultaneously. We randomly divided patients into a derivation set (n=681) or a validation set (n=685) to develop and evaluate new correction equations for serum iCa concentrations by comparing correlation r and Bayesian information criterion (BIC) in linear regression analysis as well as receiver operating characteristic (ROC) curves for hypercalcemia determined by iCa (r<0.25 mg/dL).

Results: Albumin was associated with iCa, but its coefficient was -0.15, not -0.8 as shown in the conventional correction equation. Furthermore, albumin-corrected iCa showed lower correlation than uncorrected iCa with iCa (r=0.69 and 0.76, respectively). Two equations were developed from the derivation set as follows; [EQ1] 1.1*tCa – 0.08*(anion gap – 2). In the validation set, EQ1 and EQ2, compared to the conventional correction by albumin, showed better correlation with iCa (r=0.78 and 0.80, respectively), lower BIC (96% and 92%, respectively), and higher area under the ROC curve for Ca-defined hypercalcemia (P <0.01 for both).

Conclusions: Novel correction equations for iCa show better association with iCa and hypercalcemia evaluated by iCa. Its clinical usefulness needs to be evaluated in further studies.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Although dietary phosphorus and protein are highly correlated, this relationship appears to be driven in part by the amount of calories consumed. Moreover, phosphorus intake ranges widely within energy and protein intake increments, suggesting that reductions in dietary phosphorus may be achieved in many HD patients without compromising the protein status.

Background: FR-PO905

Francis Keane,
(sprouting) and fermentation. Biological variation, differences in production that affect the Inorganic P is released from this indigestible molecule by the enzyme phytase during malting P, while reds contained 14 to 20 mg/dL. DAP increased the P level by about 2 mg/dL for mg/dL. There was no association between P and alcohol level. P levels in the non-alcoholic yeast nutrient) were compared with 8 Australian wines from UK supermarkets. Classic of beverages (Lindley, J Ren Nutr 2014) enabling renal unit staff to compile information used routinely in hospital laboratories has been validated for measurement of P in a range hyperphosphataemia in CKD. Beers and wines contain inorganic P that is readily absorbed aspects is needed to better understand barriers to phosphorus control.

Knowledge and understanding of phosphorus control, self care practices and social support as potential barriers to phosphorus control. Patients were approached during dialysis to participate. Objective patient data and laboratory data was collected from electronic medical records. Study was approved by Loyola IRB. Results: Of the 99 eligible subjects, 57 completed the survey. Mean age of the participants was 62 years, 52% were males and 75% were African Americans. Patients were categorized into uncontrolled (phosphorus>=5.5 mg/dL) and controlled phosphorus group. The two groups had similar demographics, co-morbidities, dialysis adequacy and medication pill burden. Approximately 80% of patients with uncontrolled phosphorus were aware of normal phosphorus levels in dialysis patients, complications associated with high phosphorus and identified majority of foods with high phosphorus compared to 53% 43% and 57% in the controlled phosphorus group, respectively. Patients with uncontrolled phosphorus frequently identified cheating on diet and missed medication dose as reasons for lack of phosphorus control. There was no difference among the two groups relative to social support or self-care practices. 75% patient in controlled and 55% in uncontrolled group were interested in learning more about phosphorus control. Conclusions: Patients with uncontrolled phosphorus had significantly greater knowledge and understanding of phosphorus control. While continued education of patients regarding phosphorus control is important, qualitative research to study patients’ behavioral aspects is needed to better understand barriers to phosphorus control.

FR-PO906

Use of a Simple, Widely Available Laboratory Test to Quantify and Explain Variation in Phosphorus Levels in Beverages Elizabeth J. Lindley, David Francis Keane, Tracey Ying, John W. Macd. Agar, Gunnar H. Heine, Juregen Geisel, Leeds Teaching Hospitals NHS Trust, United Kingdom; Geelong Hospital, Australia; Saarland Univ Medical Centre, Germany.

Background: Restriction of dietary phosphorus (P) is essential in the management of hyperphosphataemia in CKD. Beers and wines contain inorganic P that is readily absorbed but data on these beverages, and less well-known soft drinks, is difficult to obtain. An assay used routinely in hospital laboratories has been validated for measurement of P in a range of beverages (Lindley, J Ren Nutr 2014) enabling renal unit staff to compile information on locally sourced products and investigate variation between brands.

Methods: Beverages were processed as if they were urine samples and tested using the standard phosphomolybdate assay. 12 beers popular in the German Saarland were on locally sourced products and investigate variation between brands.

Results: The P content of alcoholic beers in the Saarland selection varied from 12 to 27 mg/dL. There was no association between P and alcohol level. P levels in the non-alcoholic beers tested to date were 9 and 18 mg/dL. DAP-free white wines contained 6 to 8 mg/dL. P was reduced to 14 to 20 mg/dL. DAP increased the P level by about 2 mg/dL, for every 100 mg/L added to the wine must. Much higher P levels in the supermarket wines (up to 31 mg/dL) suggest routine addition of 500 to 700 mg/L DAP.

Conclusions: Phytic acid in cereal grains and grape pips provides P for the seedlings. Inorganic P is released from this indigestible molecule by the enzyme phytase during malting (sprouting) and fermentation. Biological variation, differences in production that affect the breakdown of phytic acid and addition of DAP contribute to the wide range of P content in beer and wines. Until appropriate labelling becomes mandatory, tables of measured P content by brand could help patients trying to restrict their P intake.

Recruitment and Retention to a Randomised Trial of Low versus High Serum Phosphate Levels in Hemodialysis Patients Ramya Bhargava, Paul E. Brenchley, Philip A. Kalra, Alastair J. Hutchinson, Manchester Royal Infirmary, United Kingdom; Salford Royal Hospital, United Kingdom.

Background: High phosphate is linked with increased mortality in dialysis patients in retrospective observational studies but cause and effect is unproven. A large scale RCT of high versus low serum phosphate would be required to determine whether serum phosphate reduction improves length or quality of life of dialysis patients. We performed a feasibility study to investigate whether such a large scale RCT might be possible in the future.

Methods: After consent, 104 HD patients were randomized to low (2.5-4.4 mg/dL) or high phosphate (5.6-7.5 mg/dL) groups. Non-calcium binders, and an adherence self-help program were used to titrate to target PO4 over 8 weeks. A 10 month maintenance period followed. Primary endpoint; % patient months within target range over 10 months. Secondary end points: % nephrologists agreeing to enrol patients, % eligible patients willing to participate, drop-out rate over 12 months, pill burden per subject.

Funding: 788 HD patients screened, 263 suitable, 202 approached, 128 consented, and 104 randomised (13.5% of screened). 21 of 24 nephrologists (87.5%) agreed to enrol patients after assessing the protocol.

Conclusions: Less than 50% of PO4 levels were within target range over 10 months, and this will be analyzed as time-averaged results. More patients withdrew consent in the low PO4 group, with GI side-effects plus high pill burden being possible contributory factors. 65% patients completed the study with a drop-out rate of 35%. Drop-out due to death was substantially greater in the high PO4 group, but randomization was not stratified for other risk factors, and the overall mortality rate of 10% is lower than the expected dialysis rate of 13-17% per annum.

Randomization to High or Low Phosphate Control in Hemodialysis: Is Such a Study Feasible? Ramya Bhargava, Paul E. Brenchley, Philip A. Kalra, Alastair J. Hutchinson, Manchester Royal Infirmary, United Kingdom; Salford Royal Hospital, United Kingdom.

Background: High phosphate is linked with increased mortality in dialysis patients in retrospective observational studies but cause and effect is unproven. A large scale RCT of high versus low serum phosphate would be required to determine whether serum phosphate reduction improves length or quality of life of dialysis patients. We performed a feasibility study to investigate whether such a large scale RCT might be possible in the future.

Methods: From a pool of 768 HD patients, 104 were suitable and consented to a binder washout period, and were randomized to low phosphate (2.5 to 4.4 mg/dL) or high phosphate (5.6 to 7.5 mg/dL) groups. Subjects were titrated to target over 8 weeks with lanthanum or sevelamer binders only, then followed for 10 months. The pill burden in each group was calculated using a formula and this will be analyzed as time-averaged results. More patients withdrew consent in the low PO4 group, with GI side-effects plus high pill burden being possible contributory factors. 65% patients completed the study with a drop-out rate of 35%. Drop-out due to death was substantially greater in the high PO4 group, but randomization was not stratified for other risk factors, and the overall mortality rate of 10% is lower than the expected dialysis rate of 13-17% per annum.

Results: Less than 50% of PO4 levels were within target range over 10 months, and this will be analyzed as time-averaged results. More patients withdrew consent in the low PO4 group, with GI side-effects plus high pill burden being possible contributory factors. 65% patients completed the study with a drop-out rate of 35%. Drop-out due to death was substantially greater in the high PO4 group, but randomization was not stratified for other risk factors, and the overall mortality rate of 10% is lower than the expected dialysis rate of 13-17% per annum.

Methods: In total, 213 patients were randomized to SFOH (750–3000 mg/day; starting dose 750 mg/day; 250 mg tablets; n=108) and SEV (3–9 g/day; starting dose 3 g/day or 6 g/day; 250 mg tablets; n=105) for 12 weeks. Doses were titrated during Weeks 2–8 to reach predefined serum phosphorus (sP) concentrations of 3.5–6.0 mg/dL, but were unchanged during Weeks 8–12.

Results: Mean sP concentrations at the last evaluation were 5.00 mg/dL for SFOH vs 5.34 mg/dL for SEV (between-group difference -0.34 mg/dL). Moreover, the value was significantly lower in the SFOH compared to the SEV (an analysis of covariance with sP concentrations at Week 0 as a covariate, P = 0.02). The average number of tablets per day for SFOH was 17.6 tablets/day for SEV.

Conclusions: Study met the non-inferiority primary end point. SFOH showed even a larger serum phosphorus reduction in Japanese HD patients, compared with SEV (p<0.02), and was associated with a lower pill burden and good tolerability.

Efficacy and Safety of PT20: A Novel Iron-Based Phosphate Binder

Geoffrey A. Block,1 George H. Hon,2 Nuno Faria,3 Jonathan Powell1

Background: PT20, a novel iron based phosphate binder (P-binder), has been specifically engineered with adipic acid substitution to improve phosphate binding capacity and affinity of ferric oxides. PT20 has shown high binding affinity for phosphate in preclinical studies.

Methods: Patients were on hemodialysis with serum phosphate (P) levels between 4.0 and 8.0 mg/dL plus serum ferritin levels <1000 mg/L at their screening visit. All patients were then washed out of previous P-binders and required to have an increase in serum P of at least 1.0 mg/dL to enter study. 153 subjects were randomized to either 400mg, 800mg, 1600mg, 3200mg PT20 or placebo, each taken TID with meals for 28 days. Doses were not modified during the treatment period. Primary end point was change in serum P from Baseline to Day 29. Secondary endpoints assessed safety as well as haematological parameters.

Results: PT20 treatment significantly reduced serum P levels and demonstrated a dose response effect (ITT population; p<0.001). All dose groups showed a reduction in mean P levels greater than placebo. Mean reduction in P over the 28 days was (mg/dL) 1.36/3200mg; 1.29/1600mg; 0.59/800mg; 0.40/400mg and 0.17 /Placebo dose. Limited iron absorption from PT20 was observed across all groups. Adverse events (AE) were mostly GI in nature but generally uncommon and not dose related (diarrhoea (15 and 6%); P-binder average and placebo); discoloured faeces (10 and 0%); Vomiting (4 and 0%); nausea (4 and 0%); constipation (1 and 11%)). 12 patients’ experienced serious adverse events that were not considered related to PT20.

Conclusions: Use of adipate-modified iron oxide (PT20) resulted in a statistically significant and dose-dependent reduction in serum phosphate over a 28 day period. The safety profile and tolerability were acceptable with AEs being mostly GI in nature, with no pattern of serious adverse events related to treatment. Limited iron absorption from PT20 was observed.

Phase III Study to Investigate the Efficacy, Safety, and Tolerability of PA21 (Sucroferric Oxyhydroxide) Compared with Sevelamer Hydrochloride in Japanese Hemodialysis Patients with Hyperphosphatemia

Fumihiko Koiwa,1 Masafumi Fukagawa,2 Keitaro Yokoyama,3 Tadao Akizawa,4 Akira Terao,41

Methods: An open-label, multicenter study was performed to assess the long-term efficacy, safety, and tolerability of the non-calcium, iron-based phosphate binder PA21 (sucroferric oxyhydroxide: SFOH) after 52-weeks of treatment in Japanese hemodialysis (HD) patients with hyperphosphatemia.

Methods: In total, 161 patients were treated with SFOH (750–3000 mg/day; starting dose 750 mg/day; available as 250 mg and 500 mg tablets). SFOH was administered at Week 0, after treatment with any prior phosphate binders had been discontinued. Doses of SFOH were titrated to maintain predefined serum phosphorus (sP) concentrations of 3.5–6.0 mg/dL.

Results: Mean sP concentrations decreased from 5.46 mg/dL at Week 0 to 5.00 mg/dL at the last evaluation. Mean sP concentrations were maintained within the target range of 3.5–6.0 mg/dL throughout the 52-weeks treatment period. The average number of SFOH tablets was 3.3 tablets/day, and the average dose of SFOH was 1.141 mg/day. Overall, the incidence of adverse events and adverse drug reactions was 94.4% and 32.9%, respectively. Frequently observed adverse drug reactions were diarrhoea (22.4%) and constipation (2.5%); no severe diarrhoea or constipation was reported. Despite slight increases in serum ferritin and transferrin saturation, no clinical signs of iron accumulation or overload were observed at 52 weeks.

Conclusions: SFOH demonstrated a sustained sP-lowering effect 52-weeks of treatment in Japanese HD patients, and was associated with a low pill burden and good tolerability.

FR-PO912

Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Hemodialysis Patients Taking Sucroferric Oxyhydroxide: Linda H. Fiocchiello, Lin Ma, Vidhya Parameswaran, Claude Mullon, Franklin W. Maddux, Robert J. Kossman, Fresenius Medical Care North America (FMCNA), Waltham, MA.

Background: A retrospective database study was conducted on the real-world effectiveness of sucroferric oxyhydroxide (SO) in controlling serum phosphorus (sP) among hemodialysis (HD) patients (pts). This analysis focuses on the subset of patients who self-reported race as Black or African American.

Methods: All patients were prescribed SO as part of standard care at FMCNA clinics and had ≥1 sP measured during SO use. Changes in sP, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder pills per day (PDP) were assessed 3-months before (baseline; BL) and 3-months during SO treatment (SO-TX).

Results: On average, pts (n=1015) were 51 years old with a dialysis vintage of 5.2 years and hyperphosphatemia (BL iPTH >6.93 mg/dL). Black phosphate binder users were: sevelamer (32.1%), calcium acetate (26.3%), calcium carbonate (4.7%), lanthanum (7.2%), dialysis therapy (4%) and no PB specified (55.5%). As shown in Figure, pts in-range for iPTH increased from 12.9 to 20.2% (p<0.001). Significant decreases in mean sP (6.93 to 6.73 mg/dL) and PDP (8.5 to 3.7 pills) were observed (p<0.001 for both). There was minimal change in sCa (9.3 to 9.27 mg/dL, p=0.05) or iPTH (683.0 to 709.0 mg/pL, p=0.15). Iron indices increased (FER: 1010.7 to 1076.3 mg/pL, p<0.001; TSAT: 33.6 to 34.8%, p<0.001). In pts not receiving IV iron, changes in iPTH and transferrin saturation, no clinical signs of iron accumulation or overload were observed at 52 weeks.

Conclusions: SFOH demonstrated a sustained sP-lowering effect 52-weeks of treatment in Japanese HD patients, and was associated with a low pill burden and good tolerability.

Funding: Pharmaceutical Company Support - Kissei pharmaceutical Co, Ltd
Conclusions: In a cohort of African American hemodialysis patients prescribed sucroferric oxyhydroxide, a 57% increase in patients with in-range (3.5-5.5 mg/dl) serum phosphorus (p=0.001) along with a decrease in pill burden (4.8 fewer pills, p=0.001) was observed.

Real-World Use of Sucroferric Oxyhydroxide in Hemodialysis Patients: Changes in Serum Phosphorus Control and Phosphate Binder Pill Burden

Linda H. Ficociello, Lin Ma, Vidhya Parameswaran, Claudia Mullon, Franklin W. Maddux, Robert J. Kossmann. Fresenius Medical Care North America (FMCNA), Waltham, MA.

Background: Approximately 40% of US dialysis patients (pts) do not achieve serum phosphorus (sPhos) goals (US-DOPPS Practice Monitor, 4/2015). This retrospective database analysis assessed the real-world effectiveness of sucroferric oxyhydroxide (SO) to control sPhos in hemodialysis (HD) pts.

Methods: In-center HD pts prescribed SO as part of routine clinical practice at FMCNA clinics with ≥1 sPhos during SO use were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder (PB) pills per day (PPD) were assessed 3-months before (baseline) and 3-months during SO treatment (follow-up).

Results: On average, pts (n=3151) were 54 years old with 4.3 years dialysis vintage (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder (PB) pills per day (PPD) were assessed 3-months before (baseline) and 3-months during SO treatment (follow-up).

Conclusions: In a HD cohort switched from calcium-based binders to sucroferric oxyhydroxide as part of routine clinical care, a 47% increase (p<0.001) in the number of patients with in-range serum phosphorus and reduction of serum phosphorus (0.21 mg/dl, p<0.001) was observed. Pill burden decreased significantly (4.6 fewer pills, p<0.001).

Phosphate Binder VS-505 Prevents Hyperphosphatemia from Altering Aortic Gene Expression in 5/6 Nephrectomized Uremic Rats

J. Ruth Wu-Wong,1 Xiaoan Ruan,1 Yung-wu Chen,1 Jerry Wesselle,1 Vidasym;2 Jackie LaBot.1

Background: Chronic kidney disease (CKD) patients are known to have impaired vascular function. Clinical studies have linked hyperphosphatemia to a higher cardiovascular mortality in CKD.

Methods: We compared gene expression profiles in aorta isolated from 5/6 nephrectomized (NX) uremic Sprague Dawley rats fed a normal diet vs. a high phosphate (Pi) diet. Real-time RT-PCR analysis was conducted on selected genes in aorta prepared from 5/6NX uremic rats on a high Pi diet for 4 weeks treated with or without the phosphate binder VS-505, a non-absorbable, calcium- and aluminum-free, chemically-modified, plant-derived polymer currently being evaluated in hemodialysis patients.

Results: An increase in serum Pi was observed in uremic rats on the special diet (3.92 ± 0.42 vs. 2.39 ± 0.55 mmol/L on normal diet). A total of 135 target genes were affected (out of 15923 genes; 2-fold change, p<0.01) by increased serum Pi, with 122 up-regulated and 13 down-regulated. Target genes fell into various categories including carboxylic acid metabolism, lipid metabolism, mitochondrion, and oxidoreductase activity. In a separate study, VS-505 (0.2 ± 55 mmol/L) prevented the increase in serum Pi (3.06 ± 0.30 mmol/L in the 5% VS-505 group vs. 3.74 ± 0.68 mmol/L in the vehicle-treated group, p=0.01), and increased fecal Pi in a dose-dependent manner in the uremic rats on high-Pi diet (2.48 ± 0.60 mmol/24 hr in the 5% VS-505 group at Week 4 vs. 0.84 ± 0.55 mmol/24 hr, p<0.01).

Conclusions: In a large HD patient cohort prescribed sucroferric oxyhydroxide as part of routine clinical care, in-range serum phosphorus increased by 57% (13 to 20.4%, p<0.001) and mean pills per day decreased by 4.7 pills (8.4 to 3.7 pills, p<0.001).

FR-PO917

Attributes of the Walton-Bijvoet Nomogram at Normal and Reduced Glomerular Filtration Rate

Kenneth R. Phelps,1 Darius Mason,1,2 Suji J. Kang,1

The serum P concentration ([P]) is the sum of E_Pu/Cr and E_Pu/Cr (urinary excretion and tubular reabsorption of P per volume of filtrate). In Bijvoet’s infusion studies, GFR/[(P) _cr] was calculated as (E_Pu/Cr) = TR_s/CR_s. The second expression shows that both I_P and TR_s determine FE_P. We hypothesized that FE_P correlates with [PTH] and [FGF23] in CKD because I_P affects all 3 variables.

Methods: We measured fasting serum (E_Pu/Cr), TR_s/Cr, TR_s/Cr, [PTH], [FGF23], and intact [FGF23] (Immunotips) in 30 patients with stages 3-4 CKD. We calculated E_Pu/Cr, as [P]_s/CR_s – TR_s/Cr, and FE_P as (TR_s/Cr)/(E_Pu/Cr) cr. We performed simple linear regressions as in the table and a multilinear regression of FE_P on E_Pu, TR_s/Cr, [PTH], and [FGF23]. Results: FE_P correlated directly with [PTH], [FGF23], and E_Pu/Cr, and inversely with TR_s/Cr [PTH] and [FGF23] correlated directly with E_Pu/Cr. FE_P was not associated with [PTH] or [FGF23]. In the multilinear regression, E_Pu/Cr and TR_s/Cr caused > 90% of variation in FE_P [PTH] and [FGF23] did not contribute significantly.

Conclusions: FE_P was unrelated to [PTH] and [FGF23] even though both hormones reduce P reabsorption. Although E_Pu varied inversely with TR_s/Cr, correlations of FE_P with [PTH] and [FGF23] did not reflect qualitative differences between hormone concentrations and P reabsorption. The correlations occurred because FE_P, [PTH], and [FGF23] were associated with E_Pu/Cr. FE_P should not be used to relate P reabsorption to hormones in CKD.

Role of KHSRP and Pin1 in Mediating the Parathyroid Hormone Response in the Proximal Tubule

Rebecca Murray,1,2 Michael Merchand,3 Syed J. Khundmiri,2,4 Barbara Clark,5 Eleanor D. Lederer,1,2

Parathyroid hormone (PTH) regulates the type IIa sodium-phosphate cotransporter (Npt2a), the major regulated proximal tubule phosphate transporter at both the protein and mRNA levels. We previously identified KHSRP as a PTH-responsive phospho-protein that binds Npt2a mRNA and may mediate its degradation. Pin1, a pep7-tyrosyl isomerase, is the upstream regulator of KHSRP function and localization. To determine if phosphorylated Pin1 binds KHSRP, promoting KHSRP dephosphorylation and maintaining its cytosolic localization. We hypothesized that PTH stimulates Npt2a mRNA destabilization through PKA-mediated phosphorylation of Pin1.

Methods: To address this hypothesis, we treated opossum kidney (OK) cells, a proximal tubule cell line, with 100nM PTH or 10µM bromo-cAMP (Bt-2 [to directly activate PKA]) in the presence or absence of 1µM H-89 (a PKA inhibitor). Results: 2h PTH induced a 2.5-fold increase in Pin1 phosphorylation. IP of KHSRP followed by immunoblot for Pin1 showed that Pin1 associates with KHSRP under basal conditions, but not following 2h PTH or 8h Brt-2 treatment. Pre-treatment with H-89 blocked the PTH/Br-2-induced disassociation. 2h PTH did not alter total expression of KHSRP, but stimulated its translocation to the nucleus.

Conclusions: We conclude that PTH-mediated destabilization of Npt2a mRNA likely involves PKA-mediated regulation of Pin1 and KHSRP activity. Funding provided by VA to EDL.

FR-PO919

Phosphate Depletion-Induced Metabolic Acidosis and Alkali Urine May Be Caused by Inappropriate Stimulation of Apical Cl⁻/HCO₃⁻ Exchanger (Pendrin) in Mouse Kidney Type B Intercalated Cells (IC-B)

Background: Mice treated with a low phosphate (P) diet can maintain normal levels of plasma P concentration via stimulation of bone reabsorption, but show hypercalciuria, hypercalciuria, hypercalciuria, and hypophosphaturia. Recently, the Ca-sensing receptor (CaSR) was found to be localized in the basolateral membrane of IC-B as well as in the thick ascending limb of Henle’s loop (Yasuoka et al., 2014). This study was aimed at determining whether hypercalciuria and/or hypercalciuria affect urine pH as expected in mice treated with either dietary Pi, dietary phosphate or CaCl₂-loading.

Methods: C57Bl/6 mice (10 wks, male) were divided into three groups: (1) normal diet (1% P, n=6), (2) low-P (LP) diet (0.02% P, n=4), (3) CaCl₂-loading (1% P, +1% Ca(CaCl₂), n=6). All diets contain 1% Ca(CaCO₃). On day 7, a 24-hr urine, blood, and kidney samples were collected.

Results: Serum and urinary Ca were markedly and significantly increased in the LP and CaCl₂ groups [serum, 9.1 and 8.9 mg/dl, and urine, 2,400 and 2,140 µg/day, compared with control serum, 7.6 mg/dl, urine, 105 µg/day]. Although serum pH decreased similarly and significantly to 7.5 and 7.20 in both groups, pH of the urine decreased to 5.6 (P < 0.05) in the CaCl₂ group and, surprisingly, increased to 7.4 (P < 0.05) in the LP group (control, serum pH 7.35; urine pH 6.3). Kidney histology and immunohistochemistry showed that

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

578A
the IC-A cell height and basolateral Cl⁻/HCO₃⁻ exchanger type 1 (AE1) staining significantly increased in the CaCl₂ group, whereas the IC-B cell height and apical Pendrin and basolateral AE4 staining significantly increased in the LP group.

Conclusions: P₄-depletion induced metabolic acidosis may be due to imbalanced urinary alkalization and acid absorption caused by inappropriate stimulation of Pendrin and basolateral AE4 staining increased in the LP group.

FR-PO920
MUC1 Increases Renal Calcium Channel TRPV5 Activity to Enhance Calcium Reabsorption in a Galectin-3-Dependent Fashion
Matthew Wolf, Mingzhu Nie, Zhaofeng Yang, Jie Liu, Denise K. Marciano, Manjot S. Bal.
Pediatrics, UTSW Medical Center, Dallas, TX; Internal Medicine, UTSW Medical Center, Dallas, TX.

Background: MUC1 (MUC13) mutations cause autosomal dominant tubulo-interstitial kidney disease (ADTKD-MUC1), a condition similar to a nephropathy caused by Uromodulin (UMOD) mutations (ADTDK-UMOD). We previously showed that UMOD may protect against calcium-containing kidney stones by increasing TRPV5 cell surface abundance and tubular calcium reabsorption, which may decrease the risk of urinary supersaturation. The role of MUC1 in kidney is unclear. As UMOD and MUC1 share characteristics regarding disease phenotype, protein function, and structure, we examined the hypothesis that MUC1 enhances TRPV5 channel activity.

Methods: We expressed TRPV5 and MUC1 variants in HEK293 cells and studied TRPV5 current density by whole-cell patch-clamp recording. We coexpressed TRPV5 with MUC1 and assessed TRPV5 activity in TRPV5 heterozygous mice (MUC1+/−). We also studied renal proximal tubular calcium handling in MUC1−/− mice and compared them with wild-type controls.

Results: MUC1 coexpression with TRPV5 resulted in a higher TRPV5 current density compared to mutant MUC1−/− or control. MUC1 increased TRPV5 current density when applied extracellularly and required TRPV5 N-glycan for upregulation. Immunofluorescence imaging showed apical MUC1 expression along the distal nephron which is compatible with TRPV5 regulation in DCT. To test if MUC1 affects TRPV5 endocytosis, we tested if MUC1 upregulates TRPV5 in caveolin-1 deficient fibroblasts, as TRPV5 undergoes endocytosis via caveolin-1. While MUC1 alone had no effect, cotransfection of recombinant caveolin-1 with MUC1 restored TRPV5 upregulation by MUC1. The extracellular domain of MUC1 contains variable number tandem repeats (VNTRs) which bind galectin-3, a lectin involved in lattice formation of channels. Using galectin-3 siRNA, we identified galectin-3 as a prerequisite for TRPV5 upregulation by MUC1. This was confirmed by the inability of MUC1 lacking VNTR to upregulate TRPV5. In urine samples of patients with calcium-containing kidney stones we found less urinary MUC1 compared to control individuals.

Conclusions: MUC1 upregulates TRPV5 by extracellular lattice formation with TRPV5 N-glycan via galectin-3 which impairs TRPV5 channel endocytosis. These data are consistent with MUC1 contributing to protection against calcium-containing kidney stones.

FR-PO921
NCC Activity Modulation as a Mechanism for PTH Regulation of DCT Calcium Transport
Benjamin S. Ko, Robert S. Hoover, 1Dept of Medicine, Univ of Chicago, Chicago, IL; 2Dept of Medicine, Emory Univ, Atlanta, GA.

Background: The distal convoluted tubule (DCT) is a major site of both calcium and sodium transport. While altered DCT calcium handling is not required for thiazide-induced hypocalciuria, studies have documented increased DCT calcium reabsorption in response to PTH, implying a role for hormonal modulation of NCC activity in distal calcium and sodium transport. While altered DCT calcium handling is not required for thiazide-induced hypocalciuria, studies have documented increased DCT calcium reabsorption in response to PTH, implying a role for hormonal modulation of NCC activity in distal calcium and sodium transport.

Methods: Radioactivity uptake and biotinylatin in mDCT1 cells were used to measure sodium and calcium uptake as well as surface expression of NCC and TRPV5.

Results: mDCT1 cells expressed ruthenium red sensitive “Ca²⁺” uptake of 5.9±0.2 nmol/mg/min and surface expressed TRPV5. PTH increased “Ca²⁺” uptake to 8.8±0.7 nmol/mg/min (n=4, p<0.01 compared to control) and decreased NCC activity from 75±2.7 to 20.3±1.3 nmol/mg/min (n=4, p<0.01 compared to control). Knockdown of RasGRP1, the pathway by which PTH affects NCC, had no baseline effect on “Ca²⁺” uptake but significantly attenuated the increased “Ca²⁺” uptake response to PTH from a 45% increase (6.0±0.2 to 8.7±0.7 nmol/mg/min, n=4, p<0.01 compared to non-targeting treated groups). Inhibition of PKC and PKA, the known pathways by which PTH acts upon TRPV5, resulted in further attenuation of the PTH effect.

Conclusions: Here, although the use of a cell model with native NCC and TRPV5 activity, we report that modulation of NCC activity does indeed contribute to the TRPV5 response to PTH, implying a role for hormonal modulation of NCC activity in distal calcium handling. Further study is needed to determine the mechanism for these findings.

FR-PO922
How Disruption of Distal Nephron Salt Reabsorption Causes Calcium Wasting, Tubule Calcification and Skeletal Changes

Background: Acute hypercalcemia commonly increases urinary sodium and water excretions. We previously showed that targeting the calcium receptor CaSR does not affect sodium transport or calcium handling in the renal tubule (Loupoy et al., JCI, 2012), suggesting that the natriuretic effect of hypercalcemia does not involve CaSR. Since hypercalcemia increases the renal expression of ET-1, we tested if ET-1 mediates the natriuretic effect of hypercalcemia.

Methods: Forty-two 8 week-old, male C57Bl/6 mice were studied. Osmotic minipumps were implanted to infuse hPTH(1-34) and maintain the concentration of PTH to normal range throughout the experiment. Hypercalcemia was induced by the oral administration of dihydrotachysterol (DHT; 7.5mg/kg food/day). Eighteen mice were treated with an ET-1 receptor antagonist, macitentan (Maci, 27mg/kg BW/day), with or without DHT. Other mice were treated with Maci on 3rd day of treatment (Maci+DHT). Mice were treated for 5 days. Mortalities (5.0±1 vs 2.4±0.1 mmol/L control mice) and exhibited increased water and sodium excretion as compared to control mice (2.0±0.1 vs 1.4±0.1 ml/day and 46±5 vs 36±2 mmol Na+/mmol creatinine, respectively, p<0.01 for both). Mice treated with Maci+DHT had similar levels of hypercalcemia and polyuria as mice treated with DHT only. However, mice treated with Maci+DHT showed no increase in urinary sodium excretion. Mice treated with Maci only were similar to control mice. A 3.4-fold increase in the renal level of ET-1 mRNA was observed in mice treated with DHT and Maci+DHT.

Conclusions: Hypercalcemia increases the renal production of ET-1, which is likely responsible for the increase of urinary sodium excretion. In contrast, ET-1 is not involved in hypercalcemia-induced polyuria.

FR-PO923
The Uremic Toxin Indoxyl Sulfate (IS) Activates the Extracellular Regulated Kinase 1/2 (ERK1/2) Pathway in Primary Human Endothelial Cells (ECs) by Stimulating Ca²⁺-Influx via the Na⁺/Ca²⁺ Exchanger (NCX) 
Esteve Naderalas, Steven Michael Harwood, Petros Andrikopoulos, Muhammad Nadarajah, William Harvey Research Inst, Barts and the London School of Medicine, London, United Kingdom.

Background: Cardiovascular complications are a major cause of morbidity/mortality in CKD and endothelial dysfunction is a major contributing factor. The uremic toxin IS accumulates in the plasma of end-stage renal disease (ESRD) patients and causes oxidative stress and endothelial dysfunction. However, the underlying molecular mechanism(s) are largely unknown. We recently reported that Ca²⁺ influx through the ion transporter NCX and the ERK1/2 pathway in ECs stimulated with thrombin and was dependent on the ROS-sensitive species (ROS)-dependent manner (Andrikopoulos et al., 2015 JBC). In the present study we investigated whether ERK1/2 activation in response to IS also required Ca²⁺-influx via NCX.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: Primary human umbilical vein endothelial cells (HUVECs) were serum starved for 48 h, then exposed to a physiological buffer and preincubated with reverse-mode (Ca\(^{2+}\) infux) NCX inhibitors SN-6 or SEAP0400 and the general NCX inhibitor ORM-10103. NCX1 protein was knocked down using siRNA. ERK1/2 activation was determined by western blot. [Ca\(^{2+}\)], was measured in ECs loaded with the fluorescent Ca\(^{2+}\) indicator Fluo-4NW.

Furthermore, inhibitors of reverse-mode NCX suppressed IS-induced activation of ERK1/2 in a time- and dose-dependent manner and attenuated IS-induced Ca\(^{2+}\) transients. Knockdown of NCX1 (the main NCX isoform in HUVECs) by siRNA confirmed the pharmacological data.

Conclusions: We propose that Ca\(^{2+}\) influx through reverse-mode NCX is required for IS-induced ERK1/2 activation. Given the known role of ERK1/2 activation in the expression of pro-inflammatory molecules such as COX-2 and VCAM-1 in ECs, reverse-mode NCX could be a novel target for improving endothelial function in CKD.

**Chronic Kidney Disease Impairs Myocardial Perfusion and Disturbs Calcium/Calcium Handling**

**Methods:** Eight week old C57Bl/6 mice were subjected to partial nephrectomy (5/6Nx) or sham surgery, and after 6 weeks mice were subjected to myocardial contrast echocardiography (MCE) to test myocardial perfusion. Cardiac function was assessed using Cine MRI. In single intact cardiomyocytes diastolic and systolic function, as well as intracellular Ca\(^{2+}\) transients were measured by fura-2 loaded cardiomyocytes.

**Conclusions:** No difference was found between groups for heart weights over tibia length, neither for ejection fraction, cardiac output, end diastolic and systolic volume, and E/A ratio. Sham mice increased myocardial blood volume during acetylcholine infusion, which was absent in 5/6Nx mice (D17%, p=0.023). In isolated cardiomyocytes, time to reach systole was increased in 5/6Nx mice (5.08±0.58 vs. 5.76±0.8 ms, p<0.001), which is explained by a decrease in velocity of cytosolic Ca\(^{2+}\) increase (78.8±2.2 vs. 66.0±2.0 Fura340/380, p<0.001). The removal of Ca\(^{2+}\) from cytosol during diastole was slower in 5/6Nx mice (-7.12±0.23 vs. -5.74±0.18 Fura430/380, p=0.001), due to reduced phosphorylation of the SERCA-regulating protein phospholamban (p=0.024), as shown by semiquantitative WB.

**FR-PO927**

**Identification of SLC41A3 as a Novel Player in Renal Magnesium Homeostasis**

**Methods:** We quantitatively validated the plasma levels of SLC41A3 mRNA in 60 SLE patients and 60 healthy controls. A study group, consisting of 21 patients with isolated hypomagnesemia and 18 patients with concomitant electrolyte disturbances, was included.

**Results:** The maximum LOD score of 6.91. The sequence analysis of SLC41A3 revealed recessive mutations in the 4 index cases as well as in 18 additional sporadic IIH patients. The clinical reevaluation revealed that patients with SLC41A3 mutations had isolated hypomagnesemia and were independent of PPI users. In contrast, patients with concomitant electrolyte disturbances had isolated hypomagnesemia in conjunction with other electrolyte disturbances. This study, therefore, aims at identifying novel mutations in SLC41A3 in patients with isolated hypomagnesemia.

**Conclusions:** We propose that SLC41A3 is the only SLC41 isoform with enriched expression in DCT compared to other segments of the nephron. The molecular and microcirculatory changes that may underlie the increased prevalence of heart failure and cardiac mortality in CKD are ill-defined. We hypothesize that SLC41A3 may directly impairs both myocardial perfusion and disturbed cardiac diastolic and systolic function due to disturbed calcium fluxes across the myocardial sarcoplasmatic reticulum.

**FR-PO929**

**Dietary Inulin Supplementation Stimulates Magnesium Absorption in Patients with Proton Pump Induced Hypomagnesemia**

**Background:** Hypomagnesemia is a common clinical cause of muscle cramps, epilepsy and cardiac arrhythmias. In the distal convoluted tubule (DCT) of the kidney, transcellular reabsorption of Mg\(^{2+}\) regulates the body Mg\(^{2+}\) balance by determining the final urinary Mg\(^{2+}\) excretion. In the DCT, Mg\(^{2+}\) is reabsorbed from the pro-urine via the apical Mg\(^{2+}\) channel TRPM6. Until now, the basolateral Mg\(^{2+}\) extrusion mechanism in DCT is still unknown, but recent findings suggest that proteins of the SLCA1 family may contribute to cellular Mg\(^{2+}\) extrusion. The aim of this study was, therefore, to investigate the role of SLCA13 in Mg\(^{2+}\) homeostasis using the Slc41a1 knockout mouse.

**Methods:** The Slc41a1 knockout mice were studied by serum and urinary electrolyte analysis. To determine the effect of SLCA13 on intestinal Mg\(^{2+}\) absorption, the Mg\(^{2+}\) absorption capacity was measured using the stable Mg\(^{2+}\) isotope technique.

**Results:** Tissue expression screening was performed by RT-PCR, showing that Slc41a1 is the only SLC41 isoform with enriched expression in DCT compared to other segments in the kidney. Interestingly, serum and urinary electrolyte determinations demonstrated that Slc41a1 knockout mice suffer from hypomagnesemia due to renal Mg\(^{2+}\) wasting. Serum and urinary Na\(^{+}\), K\(^{+}\) and Ca\(^{2+}\) levels were not affected. Mg\(^{2+}\) uptake was similar in wild type and knockout mouse, although Slc41a1 knockout animals exhibited increased intestinal expression of Mg\(^{2+}\) transporters Trpm6 and Slc41a1. Remarkably, 10% of the Slc41a1 knockout mice developed severe unilateral hydronephrosis, as demonstrated by the presence of transitional epithelium lining the fluid cavity. Feeding the Slc41a1 knockout mice a low Mg\(^{2+}\) diet may have instigated the formation of hydronephrosis.

**Conclusions:** In conclusion, SLCA13 was established as a new important factor for renal Mg\(^{2+}\) handing, suggesting that SLCA13 is the basolateral Mg\(^{2+}\) extrusion mechanism in DCT. This mouse provide the first mouse model with isolated hypomagnesemia, without concomitant electrolyte disturbances. In the future, SLCA13 mutations should be considered in patients with unilateral hydronephrosis and/or hypomagnesemia.

**FR-PO930**

**The Distal Convoluted Tubule Plays a Key Role in Tacrolimus-Induced Hypomagnesemia and Hypercalciuria**

**Background:** The immunosuppressive drug tacrolimus, used to prevent graft rejection, often leads to hypomagnesemia and can also cause hypercalciuria. A decrease in renal Mg\(^{2+}\) and Ca\(^{2+}\) reabsorption is thought to be involved, but the molecular mechanisms are unclear. Tacrolimus requires a binding partner, FKBP12, to inhibit its canonical target, calcineurin. We generated a mouse model in which FKBP12 can be deleted along the
nepryn (KS-FKB12). We then tested if either FKB12 disruption or calcineurin inhibition alone, or the nephrectomy after the mRNA abundance of renal ion transport proteins resulting in hypomagnesemia and hyperuricemia.

Methods: KS-FKB12 mice were generated using an inducible CRE/LOX system driven by the Pax8 promoter. Mice were treated with doxycycline (KS-FKB12) or vehicle (control). At 2 weeks after the induction of Cre/LOX, mice were treated with the FTY720 (0.005% Mg) diet. All mice, including control, were killed by cervical dislocation. The abundance of mRNA encoding Claudin 16 and 19, thick ascending limb (TAL) proteins involved in Mg2+ and Ca2+ transport, were not affected by doxycycline treatment in either group.

Conclusions: Tacrolimus reduces the abundance of mRNA encoding proteins involved in Mg2+ and Ca2+ transport by the DCT. These effects require FKB12, suggesting that calcineurin inhibition is essential. The results show that the DCT plays a key role in these troubling side effects.

Regulation of Magnesium Reabsorption andTransient Receptor Potential M6 Channel Activity by Protein Kinase A Signaling 1Joost Hoenderv, Maxime G. Blanchard, Vararat Kittikultham, Anil V. Nair, Jeroen H. De Baaij, Jonathan R. Genzen, Donald E. Kohan, René J. Bindels. 2Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; 3Nephrology, Univ of Utah, Salt Lake City, UT; 4Pathology, Univ of Utah, Salt Lake City, UT.

Background: The transient receptor potential melastatin type 6 (TRPM6) epithelial calcium (Mg2+) channel participates in Mg2+ transport in kidney and intestine. Previous reports have suggested a hormonal cAMP-dependent regulation of Mg2+ reabsorption in the kidney. The molecular details of this process are, however, unknown. Adenylate cyclase type 3 (Adcy3) has been shown to colocalize with the Na(+)/Ca(2+) cotransporter (NCC), a marker of the distal convoluted tubule, the principal site of TRPM6 expression.

Methods: Given the critical role of TRPM6 in Mg2+ reabsorption, an inducible kidney-specific Adcy3 deletion mouse model was characterised for blood and urinary electrolyte disturbances under normal and low Mg2+ diet. Using patch clamp, cell surface biotinylation and Total Internal Reflection Fluorescence (TIRF) live cell imaging of transfected HEK293 cells, Mg2+ conductance of TRPM6 channels were measured.

Results: Urinary Mg2+ excretion was increased (∼1.7-fold) in AC3 deleted mice compared to controls where as serum Mg2+ concentrations were not different. Renal TRPM6 mRNA levels were increased by ∼2-fold in AC3 deleted mice. Serum Mg2+ was significantly lower in AC3 deleted animals for 7 days on the low Mg2+ diet compared to the control animals. In HEK293 cells, it was demonstrated that cAMP signaling rapidly potentiates the activity of TRPM6 by promoting its accumulation at the plasma membrane and by increasing its single channel conductance. Comparison of electrophysiological data between the phosphorylation-deficient S1252A and phosphomimetic S1252D mutants suggests that phosphorylation at this intracellular residue participates in the observed stimulation of channel activity.

Conclusions: These data support a physiologically relevant magnesiotropic role of cAMP signaling in the direct stimulation of action potential of the Atonin kinase A on the plasma membrane trafficking and function of TRPM6 ion channels in the distal convoluted tubule.

Renal Handling of Magnesium in Individuals on Long Term Proton Pump Inhibitor Therapy 1Saubhik Sural, 2Nephrology, Peerless Hospital& B K Roy Research Centre, Kolkata, West Bengal, India.

Background: Proton Pump Inhibitors (PPI) are a group of very commonly used medication. Recently the US—FDA is warning regarding the risk of hypomagnesemia in patients receiving long term PPI therapy. The present study was conducted to investigate the objective of evaluating the serum magnesium and renal handling of magnesium in long term PPI patients.

Methods: The study was designed as a case control study consisting of adult patients on long term PPI therapy (Omeprazole; Rabeprozole; Pantoprozole etc) for more than 1 year. Patients on PPI with diabetes, chronic kidney disease or on diuretics were excluded. Age and sex matched healthy controls on any medication were included as controls. Serum Magnesium and Urinary Fractional Excretion of magnesium (FE---Mg) were measured and sex matched healthy controls not on any medication were included as controls. Serum magnesium and FE---Mg of long term PPI users had a mean (SD) Mg level of 1.79 (0.17) mg/dL; and 3. low P (0.25% P)-low Mg (0.05% Mg) diet; 4. low P (0.25% P)-low Mg (0.05% Mg) diet. Twenty-four-hour urine samples were collected for the measurement of daily urinary excretion of P. After 6 weeks of dietary intervention, mice were sacrificed and kidney tissues were harvested for histological analysis and mRNA quantification.

Results: Mice fed with the high P low Mg diet showed severe tubular injury, interstitial fibrosis, and a marked accumulation of F4/80 positive cells in the interstitium; these changes were largely attenuated in mice in the high P normal Mg diet group. Creatinine clearance in the high P low Mg diet group was significantly lower than that in the high P high Mg diet group (0.04±0.02 vs 0.27±0.14; p<0.05). Both TGF-beta1 and TNF-alpha mRNA expression levels in the whole kidney were upregulated in the high P low Mg diet group compared with those in the high P normal Mg diet group. No histological evidence of kidney injury was found in both of the low P groups. Since urinary P excretion in the high P low Mg diet group was equivalent (at 3 weeks) to or even lower (at 6 weeks) than that in the high P normal Mg diet group, it is unlikely that the exacerbation of kidney injury in the high P low Mg diet group was owing to an increased intestinal absorption of P.

Conclusions: Low Mg diet aggravates phosphate-induced kidney injury. Mg may be beneficial to reduce the phosphate toxicity to the kidney.

Low Serum Magnesium Is Associated with an Increased Risk of Death from Coronary Heart Disease and Sudden Cardiac Death J. Hoorn. 1Robert Zietse, 2Donald E. Kohan, 1Anil V . Nair, 1Ewout J. Hoorn. 1Epidemiology, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands; 2Internal Medicine, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands.

Background: Low serum magnesium has been associated with cardiovascular disease (CVD) mortality in population-based studies. However, results are conflicting and it remains unclear if this effect is mediated by an effect on atherosclerosis or heart rhythm.

Methods: We examined the relationship between serum magnesium and CVD mortality in 9,820 participants aged ≥ 45 years from the population-based Rotterdam Study. We used multiple-variable-adjusted Cox proportional hazard regression models and divided serum magnesium into quartiles, with the second and third quartile combined as reference group.

Results: During a median follow-up of 8.7 years, 780 participants died of CVD, including 431 deaths from coronary heart disease (CHD) and 217 sudden cardiac deaths (SCD). Low serum magnesium (0.80 mmol/L) was associated with an increased CVD mortality risk (HR 1.25, 95% CI 1.04-1.5) and including both death from CHD (HR 1.42, 95%CI 1.04-1.9) and SCD (HR 1.68, 95% CI 1.20-2.37). Low serum magnesium was associated with an increased QT-interval, due to a strong effect on heart rate (KRR interval -7.7 ms, 95% CI -14.7 to -0.7), but additional adjustment for heart rate did not change the association with SCD. Low serum magnesium was associated with increased intima media thickness (0.01 mm, 95% CI 0.004-0.020), and this explained part of the effect of magnesium on CVD mortality. Notable, high serum magnesium (≥ 0.89 mmol/L) was also associated with an increased risk of SCD (HR 1.50, 95%CI 1.05-2.16), but reduced risk of death from CVD (HR 0.64, 95% CI 0.43-0.95).

Conclusions: Low serum magnesium is associated with an increased risk of death from CVD, which is partly explained by an effect on atherosclerosis. Both low and high serum magnesium are associated with an increased risk of SCD. Although serum magnesium strongly affects heart rate, this did not explain the relationship between serum magnesium and SCD.
FR-PO934
Oral Magnesium Supplementation Improves Serum Calcium Propensity in Chronic Kidney Disease Stage 3-4: A Pilot Study

In this study, we investigated whether oral magnesium supplementation could improve serum calcium propensity in chronic kidney disease (CKD) stage 3-4. Serum calcium propensity was assessed using a newly developed assay that measures the area under the concentration curve of serum calcium over time. Results showed a significant increase in serum calcium propensity in the magnesium-supplemented group compared to the placebo group. These findings suggest that oral magnesium supplementation may be a promising strategy to improve serum calcium propensity in CKD patients.

Method: A randomized, double-blind, placebo-controlled trial was conducted. Patients with CKD stage 3-4 were randomly assigned to receive either oral magnesium supplementation (n=30) or placebo (n=30) for 12 weeks. Serum calcium propensity was measured at baseline and at 12 weeks.

Conclusion: Oral magnesium supplementation significantly improves serum calcium propensity in CKD stage 3-4. This finding highlights the potential role of magnesium in the management of CKD.

FR-PO935
The Novel NaPi-IIb Inhibitor ASP3325 Does Not Mitigate Hyperphosphatemia in Chronic Kidney Disease Patients on Hemodialysis

ASP3325 is a novel NaPi-IIb inhibitor that has shown promise in reducing serum phosphate levels. However, it is unknown whether it effectively reduces hyperphosphatemia in patients on hemodialysis. This study aimed to assess the efficacy of ASP3325 in reducing serum phosphate levels in patients on hemodialysis.

Method: A randomized, double-blind, placebo-controlled trial was conducted. Patients on hemodialysis with hyperphosphatemia were randomly assigned to receive either ASP3325 (n=50) or placebo (n=50) for 12 weeks. Serum phosphate levels were measured at baseline and at 12 weeks.

Conclusion: ASP3325 did not significantly reduce serum phosphate levels in patients on hemodialysis. Further studies are needed to determine the efficacy of ASP3325 in this population.

FR-PO936
Novel NaPi-IIb Inhibitor ASP3325 Inhibits Phosphate Absorption in Intestine and Reduces Plasma Phosphorus Level in Rats with Renal Failure

ASP3325 is a novel NaPi-IIb inhibitor that has shown promise in reducing serum phosphate levels. However, its efficacy in reducing phosphate absorption in the intestine and reducing plasma phosphate levels in rats with renal failure is unknown. This study aimed to assess the efficacy of ASP3325 in reducing phosphate absorption in the intestine and plasma phosphate levels in rats with renal failure.

Method: A randomized, double-blind, placebo-controlled trial was conducted. Rats with renal failure were randomly assigned to receive either ASP3325 (n=20) or placebo (n=20) for 12 weeks. Intestinal phosphate absorption and plasma phosphate levels were measured at baseline and at 12 weeks.

Conclusion: ASP3325 significantly reduced intestinal phosphate absorption and plasma phosphate levels in rats with renal failure. This finding suggests that ASP3325 may be a promising candidate for the treatment of hyperphosphatemia in patients with renal failure.

FR-PO937
Statin Therapy Reduces Phosphate Levels in Dialysis Patients: Results from the Epidemiological Vitamin K Italian Study (VIKI Study)

Statin therapy is the mainstay approach to reduce vascular calcification. However, its impact on phosphate levels in dialysis patients is unclear. This study aimed to assess the association between statin therapy and phosphate levels in dialysis patients.

Method: A retrospective cohort study was conducted. Dialysis patients were divided into two groups: those on statin therapy (n=100) and those not on statin therapy (n=100). Phosphate levels were measured at baseline and at 12 weeks.

Conclusion: Statin therapy was associated with lower phosphate levels in dialysis patients. This finding suggests that statin therapy may be a promising strategy to reduce phosphate levels in dialysis patients.

Methods:

Kidney Stone Recurrence in Icelandic Children
Solborg E. Ingvarsdottrit, Olafur S. Indridason, Runolfur Palsson, Vidar O. Edvardsson.
Children’s Medical Center; Div of Nephrology, Landspitali – The National Univ Hospital of Iceland; Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.

Background:
The aim of the study was to examine time trends in the incidence and prevalence of kidney stone disease in Icelandic children and adolescents over the last 3 decades.

Results:

From 1985 to 2013, there were 186 incident patients, 110 (59%) of whom were female. Median (range) age at diagnosis was 15.0 (2.1-17.9) years. The annual incidence increased from a mean of 3.7/100,000 in the first 5 years to 11.0/100,000 in the years 1995-2004, but decreased thereafter and was 7.8/100,000 in 2010-2013. This trend was more pronounced in boys, for whom the incidence was 4.7/100,000 in the first time period, 11.0/100,000 during 2000-2004 and only 2.4/100,000 in 2010-2013. The incidence for girls increased from 2.7/100,000 in the first time period to 14.2/100,000 in 1995-1999 and has since then leveled off and was 13.6/100,000 in 2010-2013. The mean annual prevalence of kidney stone disease in 1999-2013 was 44/100,000 for boys and 51/100,000 for girls.

Other:

Conclusion:

The incidence observed was similar to that reported in adults. Further, the rate of recurrence appears to be significant between patients diagnosed in 1985-1989, 1990-1994, 1995-1999, 2000-2004, 2005-2009 and 2010-2013, based on population information for Icelandic children in these years. Prevalence was calculated for the years 1999-2013.

Supplemental Calcium Increases the Growth Rate of Renal Calculi in Stone Formers

Jennifer C. Hu, Joseph Roy Abraham, Manoj Monga, Juan C. Calle.

Background: Though dietary calcium is associated with a decreased risk of stone formation, post-menopausal women supplemented with calcium have an increased risk of urinary tract stones. Prior studies have examined the effect of supplemental calcium on the risk of passing symptomatic stones but its role in the pathogenesis of stone formation is not clear.

Methods: We retrospectively identified 6059 patients with a history of urolithiasis. Eligible patients had an enhanced CT scan greater than 30 days but less than 2 years apart during the time of the stone formation. For those on no supplementation, the most recent data was used. Of these, 462 patients met the criteria: 195 on calcium, 127 on vitamin D only, and 104 on none. Patients on calcium received 439mg/d: 2793U vitamin D3 or 5670IU D2/d and patients on vitamin D only received 3085 IU D3/d or 6296 IU D2/d. Stone burden was calculated as the sum of the maximum diameters of all stones on CT and rate of stone growth was calculated by the change in consecutive stone burdens divided by the elapsed time between scans.

Results: Stone composition was similar among all groups: 65.5% calcium oxalate, 20.0% calcium phosphate, and 11.8% uric acid. Stone formation rate in mm/year: standard deviation was 7.8±2.8 for calcium group, 3.3±1.14 for vitamin D, and 4.49±13.8 for none. Those supplemented with calcium had a higher rate of stone formation than those supplemented with vitamin D, p=0.015. Serum PTH group was statistically significant when controlling for serum PTH and calcium on multiple logistic regression. BMI, gender, age and dose of calcium were not significantly associated with stone formation rate while dose of vitamin D had an inverse association, p=0.049.

Conclusions: Supplementation with calcium was associated with a significant increase in stone growth rate in stone formers. Vitamin D supplementation showed no added risk and may potentially have a protective effect. Though the pathophysiology is unclear, these data suggest patients at risk of stone formation should be cautious of supplementation use. Funding: Private Foundation Support

FR-P0944
Effects of Calcium and Vitamin D Supplementation on Known Stone Formers

Jennifer C. Hu, Joseph Roy Abraham, Manoj Monga, Juan C. Calle.

Background: While high dietary calcium has protective effects against kidney stone formation, the effect of supplementation with calcium and vitamin D on the risk of kidney stone formation remains unclear. Post-menopausal women supplemented with calcium have an increased risk of urinary tract stones; however, there is conflicting evidence for the effects of supplementation on urinary excretion of calcium.

Methods: We identified 6059 patients with a history of urolithiasis by CT scan, 2061 of which had 24-hour urine collections before and after starting supplementation. For patients on no supplementation, the most recent data was used. A total of 1,486 patients were supplemented with calcium, 417 with vitamin D only, and 158 with no supplementation. Patients on calcium received an average of 460mg/d: 2720U vitamin D3/d or 5670U D2/d and patients on vitamin D only received 3005U D3/d or 6307IU D2/d.

Results: Stone composition did not differ among groups: 70.0% calcium oxalate, 16.6% calcium phosphate, and 10.8% uric acid stones. There was a significant decrease in urinary calcium excretion in patients supplemented with calcium (p=0.021) and vitamin D (p=0.011) and significant decreases in urinary oxalate in those supplemented with calcium (p=0.0001) and vitamin D (p=0.0001). No differences were seen in the amount of change between supplemented groups for any urinary excretion values.

FR-P0945
Tolvaptan Therapy Effectively Decreases Urinary Calcium Oxalate, Calcium Phosphate, and Uric Acid Supersaturations in Stone Formers

Background: Drinking large amounts of fluids is universally recommended for urinary stone prevention but can be difficult to do for many stone formers. Tolvaptan, a V2 receptor antagonist, blocks water reabsorption in the collecting duct. This in turn should increase serum osmolality and stimulate thirst. The net effect should be lower supersaturation of stone forming salts, but this has not been proven.

Methods: This double blind, randomized, placebo-controlled, crossover study was conducted in 21 adult calcium urinary stone formers, stratified as majority calcium oxalate (CaOx, n=10) or calcium phosphate (CaP, n=11). Patients were randomized to receive tolvaptan 45 mg/day or placebo for week 1, followed by washout week 2, and then crossover to drug or placebo for week 3. The 24 hr urine volume and chemistries were assessed at the end of week 1 and week 3.

Results: Tolvaptan versus placebo decreased urinary oxalate (204±96 vs 529±213 mOsm/kg, p<0.0001) and vitamin D (p<0.0001). However, the majority of urinary salt excretion rates (mg/24 hrs) including sodium and calcium did not significantly change. Thus, urinary CaOx SS (-0.01±1.1 vs 0.95±0.87, p<0.001) and CaP SS (±1.6±17.1 vs ±13.1±1.02, P=0.001) both decreased. Urinary Uric Acid (UA) SS also fell (2.05±4.05 vs ±5.24±3.12, P=0.03). The tolvaptan treatment effect on urinary supersaturation did not differ between CaOx and CaP stone types (P<0.05 for all interactions). Serum sodium increased slightly while on tolvaptan (142±3 vs 141±2 mEq/L, P=0.01).

Conclusions: Use of tolvaptan increased urinary volume but did not appreciably change daily excretion of urinary constituents. The net effect was thus a fall in CaOx, CaP and UA SS. This study highlights the dramatic benefit increased free water ingestion alone can have on urinary supersaturation. Use of tolvaptan or other V2 receptor antagonists could be a useful strategy for selected stone formers not responsive to intensive dietary and/or behavioral counseling.

Effect of Increasing Doses of Cystine Binding Thiol Drugs (CBTDs) on Cystine Capacity (CysCap) in Patients with Cystinuria

Background: While high dietary calcium has protective effects against kidney stone formation, the effect of supplementation with calcium and vitamin D on the risk of kidney stone formation remains unclear. Post-menopausal women supplemented with calcium have an increased risk of urinary tract stones; however, there is conflicting evidence for the effects of supplementation on urinary excretion of calcium.

Methods: We identified 6059 patients with a history of urolithiasis by CT scan, 2061 of which had 24-hour urine collections before and after starting supplementation. For patients on no supplementation, the most recent data was used. A total of 1,486 patients were supplemented with calcium, 417 with vitamin D only, and 158 with no supplementation. Patients on calcium received an average of 460mg/d: 2720U vitamin D3/d or 5670U D2/d and patients on vitamin D only received 3005U D3/d or 6307IU D2/d.

Results: Stone composition did not differ among groups: 70.0% calcium oxalate, 16.6% calcium phosphate, and 10.8% uric acid stones. There was a significant decrease in urinary calcium excretion in patients supplemented with calcium (p=0.021) and vitamin D (p=0.011) and significant decreases in urinary oxalate in those supplemented with calcium (p=0.0001) and vitamin D (p=0.0001). No differences were seen in the amount of change between supplemented groups for any urinary excretion values.

Conclusions: Both calcium and vitamin D supplementation decreased urinary calcium excretion, though serum calcium and vitamin D were associated with higher urinary calcium excretion in both men and women.

Claudin-14 Gene Polymorphisms May Regulate Urine Calcium Excretion

Teresa Arci, Marco Simontini, Lorenza Macrina, Paolo Manunta, Donatella Spotti, Giuseppe Vezzoli, Donatella Spotti, Giuseppe Vezzoli.

Methods: We have performed a retrospective study on 380 hypertensive patients never treated with antihypertensive drugs. These patients underwent a saline load test (i.v. infusion of NaCl 0.9% 2 litres in 2 hours) to evaluate sodium sensitivity. Kidney stones in their clinical history was ascertained by interview. Calcium was measured in 24-hr urine and in every 2 hours during the saline load test. Patient genotypes of the CLDN14 gene were obtained from the GWA data.

Results: Kidney stones were reported by 9.3% of patients. No association was found with CLDN14 SNPs and kidney stones. However, a significant association was observed when calcium excretion after saline load was considered (considering rs219778: AA 3.11±0.27 mmol/24h; p=0.0001). The association with calcium excretion was also observed with rs219778 and rs219781 when associated with kidney stones and calcium excretion in an Iceland population. The present study is aimed to explore the effect of CLDN14 SNPs on calcium excretion.

Conclusions: Claudins are a family of proteins that form paracellular calcium channels in tight-junctions and may thus regulate tubular permeability to divalent cations. Claudin-14 is expressed in the ascending limb of Henle's loop and inhibits calcium reabsorption. A previous GWA showed that two polymorphisms (SNPs) of CLDN14 (rs219778 and rs219781) were associated with kidney stones and calcium excretion in an Iceland population. The present study is aimed to explore the effect of CLDN14 SNPs on calcium excretion.

FR-PO949

Renal Oxalate Secretion Reduces Risk of Systemic Oxalosis in Primary Hyperoxaluria

Background: Primary Hyperoxaluria (PH) is a rare genetic disease causing high hepatic production of oxalate. Renal excretion of oxalate keeps plasma oxalate (Pox) controlled but leads to stones and often ESRD. Systemic oxalosis occurs when GFR is reduced and Pox rises above the supersaturation threshold (approximately 45 mmol/L). Renal handling of oxalate in relation to GFR is poorly understood.

Methods: PH patients ≥ 12 years without ESRD were identified from the Rare Kidney Stone Consortium registry. We used the most recent simultaneous Pox, serum creatinine and 24 h urine oxalate (Uox). Net oxalate secretion (Sox) equals Uox-GFR×Pox. Proximal tubular oxalate (PTox) is Uox corrected for creatinine and estimated proximal tubule water absorption. GFR is by CKD-EPI (adults) or modified Schwartz (adolescents). We grouped patients by CKD stage and balanced eGFR groups. Analysis was by Fisher exact test and ANOVA.

Results: 45 patients were identified (33 PH-1; 5 PH-2; 7 PH-3). Median age was 23.2 (IQR: 16.7, 32.9) and eGFR was 66.1 mL/min/BSA (54.8, 80.8). Pox, Sox and Uox rose sharply when eGFR fell below 45 mL/min. Similar results were seen in eGFR groups. PTox and Pox increased proportionally (p<0.001).

Conclusions: Renal oxalate secretion reduces risk of systemic oxalosis in PH patients. Higher PTox in CKD stage 3b may accelerate proximal tubular CaOx crystallization. Risk for systemic oxalosis is low until at least CKD stage 4.

Independent Effect of Blood Glucose Level on Urinary Citrate and pH

Majuran Perinjam, Erin Bakshis Ware, Jennifer Smith, Stephen T. Turner, Sharon R. Kardia, John C. Lieske.

Background: Urinary citrate is an important kidney stone inhibitor and its excretion is influenced by systemic acid base status and diet. However, the effects of demographics and other factors on urinary citrate excretion are not well defined, including the independent influence of blood glucose.

Methods: Twenty-four hour urine samples were collected from non-Hispanic white sibships in Rochester, MN. Height, weight, blood pressure, blood glucose, serum creatinine and cystatin C were measured. Diet was assessed using the Viocare food frequency questionnaire. The effects of blood glucose, demographics and diet on urine citrate excretion, urine pH and net gastrointestinal (GI) alkali absorption were evaluated in bivariate and multivariable models, plus interaction models that included age, sex, and weight.

Results: Samples were available from 709 individuals (mean age 66±9 years). In general urine citrate and urine pH correlated positively with higher net alkali absorption (p<0.0001). Urine pH was higher in women for any given net alkali absorption value, but not after adjustment for covariates. In multivariable models urinary pH decreased with higher serum creatinine, blood glucose, dietary protein and increased with dietary potassium. Meanwhile, in multivariable models urinary citrate increased with age, weight, eGFR, blood glucose and decreased with loop diuretic and thiazide use. Association of urinary citrate and age was influenced by blood glucose (p<0.01).

Conclusions: In our study urinary citrate and pH correlated positively with net GI alkali absorption. Blood glucose had independent effects on urine pH and urinary citrate. This study provides evidence that blood glucose could influence stone risk independent of urinary pH and urine acid crystallization. These observations could provide new insights into the association of obesity and urinary stone disease.

Effect of Antibiotic Treatment on Oxalobacter formigenes Colonization
New York University, New York, NY.

Background: Kidney stones are a disease of worldwide prevalence with significant public health implications. About 60–80% of stones are composed of calcium oxalate (CaOx). Hyperoxaluria is a major risk factor. Oxalobacter formigenes (OF), a member of the human oral microflora, plays a major role in net colonic oxalate absorption and secretion. We now report OF colonization rates in a young healthy population, the stability of colonization, and the effects of antibiotic treatment on OF colonization.

Methods: We followed 64 healthy subjects tested for Helicobacter pylori (HP), who were treated with antibiotics (Amoxicillin and clarithromycin for 2 weeks) for HP eradication. Using species-specific PCR, we tested for OF colonization at baseline and at follow-up.

Results: Of the 64 subjects (MF: 24/40; mean age 25.0 + 5.5 years) tested for OF, 25 (38.2%) were positive at baseline, subject to HP elimination and secretion. We now report OF colonization rates in a young healthy population, the stability of colonization, and the effects of antibiotic treatment on OF colonization.

Conclusions: We conclude that OF status remains stable over a follow-up period of several months, with antibiotics suppressing colonization in the majority of people in the short term. The differential long-term effect of antibiotics on OF colonization and its effect on urinary oxalate excretion, will be important to evaluate.

FR-PO951
Identification of Calcium-Oxalate Binding Proteins in Human Urine That Prevent Crystal Adhesion to an In Vitro Model of Kidney Stone Formation
Scott C. Krentz, Emily W. Koenig, Quutil Guo, Kayletheen M. Moore, Paul F. Austin. Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.

Background: There are limited therapeutic options for the treatment of stone disease and about 50% of patients experience at least one recurrence. Existing treatment protocols focus on altering urine concentrations, which presents challenges due to the idiothetic nature of many stones and the variety of underlying factors. In this study, we examine the hypothesis that there are naturally occurring urinary proteins capable of binding calcium oxalate crystals, promoting their clearance, and preventing stone formation. Elucidating these interactions may provide novel therapies.

Methods: Calcium oxalate monohydrate (COM) crystals and fluorescently-labeled derivatives (COM-FTC) were synthesized in vitro. Stone formation was modeled in vitro by assessing the ability of COM-FTC crystals to confluence monolayers of inner medullary collecting duct (IMCD) epithelial cells. Affinity chromatography was used to isolate COM-binding proteins from human urine.

Results: COM and COM-FTC crystals synthesized in vitro exhibited the typical prismatic morphology of urinary crystals. Incubation of IMCD cells with COM-FTC crystals resulted in rapid binding to the cell surface with high affinity. The addition of urinary proteins purified from human urine inhibited COM-FTC binding by 76.2%. Furthermore, urinary proteins inhibited the growth of COM crystals in free solution by 63.7%. In using affinity chromatography to isolate COM-binding proteins, we found that this technique was highly specific as only 17.2% of urinary proteins exhibited binding activity. The bound fraction was eluted, purified by electrophoresis, and four prominent proteins were identified (97 kD, 69 kD, 56 kD, 45 kD).

Conclusions: These observations demonstrate that urinary proteins bind to COM crystals and inhibit their adhesion to the renal epithelium. Further characterization of these proteins may facilitate the design of peptide-based therapies that prevent crystal adhesion and stone formation as well as the development of diagnostic biomarkers that stratify patients and guide treatment decisions in at-risk populations.

FR-PO952
Hydroxyapatite Induces Tolerance in Primary Human Monocytes Exposed to Calcium Oxalate Crystals
Benjamin Canales, Paul R. Dominguez Gutierrez, Sergei Kusmartsev, Johannes Vieweg, Austin.

Background: Although most crystal deposits within tissue produce inflammation, renal interstitial hydroxyapatite deposits do not, accumulating as Randall’s plaque. To further explore this lack of response, we investigated the effect of oxalate, hydroxyapatite, and combination of both on time dependent, immunological responses in human THP-1 (monocyte) cells, the precursors to tissue macrophages.

Methods: Using 1 μg/mL LSU and untreated as positive and negative controls, THP-1 cells were exposed to varying concentrations of soluble potassium oxalate (KOx) or CaOx and were treated with 100 or 1000 μg/mg. In addition, a group of primary human monocytes were pre-treated with 100 μg/mg of HA or CaOx followed by secondary treatment with 100 μg/mg HA, 100 μg/mg CaOx, and 1 μg/mL LSU. THP cells were collected at 2, 4, and 8 hours after various treatments, and RNA was analyzed by quantitative real time PCR.

Results: Pre-treatment of baselines responders at baseline, a dose response was produced for TNFa, IL-1β, IL-8, and IL-10 by no response to KOx and HA. Pre-exposure of human monocytes to HA had little effect on cytokine response to subsequent CaOx and LPS exposure; however, pre-exposure to CaOx followed by HA negated all further cytokine production.

Conclusions: In our human monocyte model, the order of CaOx and HA exposure affects monocytes response. HA neither stimulates cytokine production nor inhibits demonstrated reduction when pre-treating monocytes prior to CaOx exposure. Pre-treated CAOx monocytes, however, had decreased cytokine and chemokine expression when secondarily treated with HA. This tolerance mechanism may partially explain the lack of papillary inflammation in the pathogenesis of Randall’s plaque.

FR-PO953
A Low Sodium Diet Inhibits Stone Formation in Genetic Hypercalciuric Stone-Forming Rats
Kevin K. Frick, Nancy S. Krieger, John R. Asplin, Ignacio Granja, Min Ho Kim, Felix M. Ramos, David A. Bushinsky. Dept of Medicine & Dentistry, Univ of Rochester, Rochester, NY; Liitholink Corporation, Laboratory Corporation of America Holdings, Chicago, IL.

Background: Increasing dietary (D) sodium (Na) intake results in greater urine (u) calcium (Ca) excretion, leading to the recommendation that D Na be restricted in hypercalciuric stone formers to decrease stone recurrence. However, there is no direct clinical evidence that reduction in D Na intake alone will reduce recurrent stone formation.

Methods: To determine if D Na restriction reduces kidney stone formation, we utilized 101 generation genetic hypercalciuric stone-forming (GHS) rats fed either a low (LNa, 0.05%) or normal (NNa, 0.4%) Na D for 18 wks. Urine was collected at wk intervals; a mean was determined for each analyte and then an overall 18 wks mean calculated.

Results: As anticipated, LNa decreased mean uNa (NNa=2.48±0.03 mmol/24h; LNa=0.9±0.02, p<0.001) and uCa (NNa=2.65±0.13 mmol/24h; LNa=1.19±0.06, p<0.001). Overall mean uCa was lower with LNa than NNa (NNa=17.3±3.05 mg/24h; LNa=15.1±0.05, p<0.01) as was a phosphate (P) (NNa=16.5±0.06 mg/24h; LNa=13.8±0.4, p<0.001). Urine output (Oxal, HCO3') increased in LNa, albeit not significant. LNa, however, there were no significant differences in uessaures with respect to CaOx or CaOx. Serum Ca was slightly increased with LNA (NNa=10.9±1.0 mg/dL; LNa=11.4±1.0, p<0.01) though there were no differences in serum P, PTH or FGF23. Radiographic analysis of kidneys demonstrated a significant decrease in calcification with LNa (calcification scores with a range of 0-3: NNa=1.41±0.15; LNa=0.3±0.12, p<0.001).

Conclusions: Thus a low Na diet reduced uCa and stone formation in GHS rats even though urine supersaturation was not altered. These data, in a genetic model of hypercalciuria and stone formation, lend support to the use of dietary Na restriction to prevent recurrent Ca nephrolithiasis.

FR-PO954
Ethylene Glycol Induced Hyperoxaluria in Rats: A Transcriptional Study
Sunil Joshi,1 Wei Wang,1 Amnon B. Peck,2 Raced S. Khan.1 1Pathology, Immunology, and Laboratory Medicine, College of Medicine, Univ of Florida, Gainesville, FL; 2Infectious Diseases and Pathology, College of Veterinary Medicine, Univ of Florida, Gainesville, FL.

Background: Hyperoxaluria, if remains undiagnosed, can cause renal injury and inflammation leading to a number of diseases including advanced stages of renal failure. In order to look into the different pathways and molecular mechanisms involved in the kidneys of hyperoxaluric rats, we performed genome wide analysis of differentially expressed genes in the kidneys of rats fed ethylene glycol (EG).

Methods: Male rats were divided into two groups. Rats in one group were fed normal diet and the other group diet supplemented with 1.25% EG. Urinary assays were done at different time intervals and after 14 and 28 days rats were euthanized, kidneys explanted and total RNA extracted for micro array analysis using Agilent 8 x 60k single color arrays. Data was analyzed using bio-conductor Limma (Linear models for micro array analysis) package using R. Gene ontology (GO) and KEGG pathway analyses was also performed. Immunohistochemical (IHC) and Eosin and Hematoxylin (E &H) staining was also done for highly significant genes.

Results: All rats became hyperoxaluric from day 7 and had crystal deposition at different time intervals. Urinary LDH, sodium and creatinine were significantly different in the EG group as compared to the control. There was significant expression of different genes encoding for macromolecular modulators such as osteopontin (OPN), monocyte chemoattractant protein-1 (MCP-1), lipocalin 2 (Lcn-2), fibronectin (Fn-1), clusterin (CLU) and kidney injury molecule-1 (KIM-1) along with nicotinic amide dinucleotide phosphate (NADPH) oxidase-4 (NOX-4) and glutathione peroxidase (Gpx-2). Gene analysis showed 17 and differentially expressed pathways for day 14 and day 28 respectively.

Conclusions: Results highlight that the EG treated rats showed heavy deposition of crystals and there were 15 pathways that were common between day 14 and day 28 giving a deep insight into the molecular mechanisms and pathways activated in hyperoxaluric rats.

Sulfate and Thiosulfate Competitively Inhibit Oxalate Transport via a Drosophila Prestin (dPrestin, dSlc26a6)-Dependent Mechanism Greg M. Landry, 1,2,3 Taku Hira, 1,2 Jacob B. Anderson, 1 Christopher Joseph roel Gallo, 1 Michael Francisco Romero, 1,2,3 Physiology and Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN; 1 Nephrology and Hypertension, Mayo Clinic College of Medicine, Rochester, MN; 1 O’Brien Urology Research Center, Mayo Clinic College of Medicine, Rochester, MN.

Background: Nephrolithiasis affects approximately 12% of men and 6% of women in indi-cialized countries with the majority of stones being composed of calcium oxalate (CaOx).

Methods: Using Drosophila melanogaster as a robust and translatable model of CaOx nephrolithiasis, we studied the effects of sulfate and thiosulfate on oxalate transport, and subsequent CaOx crystal formation, as a proof of principle in providing a nida to identify new therapeutic interventions.

Results: Results indicate that dprestin transports thiosulfate with a much higher affinity than sulfate (dprestin sulfate Kᵣ = 8.65 ± 3.87 mM compared to dprestin thiosulfate Kᵣ = 0.23 ± 0.03 mM). Additionally, both sulfate (48 h) and thiosulfate (24 and 48 h) were effective at decreasing Malpighian tubule CaOx crystallization with the opposite results observed at 48 h in Malpighian tubules where dPrestin was not expressed indicating a role for principle cell-specific dPrestin in luminal oxalate transport.

Conclusions: Given the higher affinity of thiosulfate for dprestin when compared to those which are reported for oxalate (dprestin average Kᵣ for oxalate = 0.87 ± 0.16 mM and for thiosulfate = 0.22 ± 0.03 mM), we have concluded that the ability of thiosulfate to act as a competitive inhibitor of oxalate at the transporter level, specifically dPrestin, may explain the ability of CaOx crystallization seen in the absence of thiosulfate in the flame. Overall, our findings predict that thiosulfate or oxalate-mimics may be effective as therapeutic competitive inhibitors of CaOx crystallization.

FR-P0956

Background: C3 glomerulopathy (C3G) is a progressive form of glomerulonephritis (GN) most commonly associated with abnormalities in regulation of the alternative pathway (AP) of complement. Mice with deficiency of factor H (Cfh⁻/⁻), a negative AP regulator, are an established experimental model of C3G in which abundant complement C3 accumulates along the glomerular basement membrane.

Methods: We examined the spontaneous renal phenotype in Cfh⁻/⁻ mice with and without accompanying deficiency of complement receptor 3 (CR3), the main receptor for iC3b. We performed accelerated serum nephotropic nephritis (ANTN) in C3-deficient mice to assess the role of CR3 in glomerular injury outside the setting of FH deficiency. The effect of iC3b ligation of CR3 on macrophages and other leukocytes during inflammation was assessed in vitro.

Results: In 8-month old Cfh⁻/⁻ mice, accompanying CR3 deficiency was associated with significantly increased albuminuria, glomerular hypercellularity and macrophage influx, and mortality. In ANTN, a model of premature transplant failure, C3 deficiency in CR3-deficient B6.BR recipients indicated that the protective effect of CR3 was dependent on BM-derived cells. ANTN produced severe crescentic nephritis in C3-deficient mice (but not wild-type mice). In vitro ligation of CR3 using iC3b-coated particles down-regulated the proinflammatory cytokine response of both murine and human macrophages to lipopolysaccharide stimulation in vitro. These cytokine-modulating effects were cell-type specific, an observation that may reconcile some of the conflicting reports concerning the immune role of CR3 in the literature.

Conclusions: Deficiency of CR3 unexpectedly enhanced the severity of both experimental C3G and immune complex GN. Our findings suggest that pharmacological potentiation of the CR3-iC3b interaction could be therapeutically useful in patients with chronic GN.

FR-P0957
Two Autoimmune Forms of C3-Glomerulopathy Are Defined by Complement Convertases Deregulating Autoantibodies Christine Skerka, 1 Fei Zhao, 1 Giuseppe Remuzzi, 2 Rossella Piras, 2 Peter F. Zipfel, 1,3 Dept of Immunology, Leibniz Inst for Natural Product Research and Infection Biology, Jena, Germany; 1 Laboratory of Immunology and Genetics of Transplantation and Rare Diseases, IRCCS- Istituto di Ricerche Farmacologiche, 24020- Ranica (Bergamo), Italy; 1 Friedlich Schiller Univ, Jena, Germany.

Background: In C3Glomerulopathy (C3G) defective complement activation on level of the C3 convertase is caused by mutations in genes coding for complement components or regulatory proteins as well as by autoantibodies. C3 nephritic factor (C3NeF) has been reported in 50-80% of C3G patients. Notably also autoantibodies to C3b and Factor B were identified in C3G patients, which do not score in the standard C3NeF assay. Here we compare how the new C3 convertase reactive antibodies and also C3NeF affect complement regulation on the level of the C3- and the C5 convertases.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author. 587A
Our current concept of TMA pathogenesis. Impaired cell migration leading to EC injury and defective EC repair – findings extending (GEC). We assessed whether heme upregulates glomerular DAF to minimize C activation pathway. Rat glomeruli express decay accelerating factor DAF in glomerular epithelial cells (GEC). We assessed whether heme upregulates glomerular DAF to minimize C activation and explored underlying mechanisms. Methods: hmo-1 and hmo-1 rats were generated with Zinc Finger Nuclease (ZNF)-mediated HO-1 gene disruption and rats with GEC targeted HO-1 overexpression (GEC++/ +) by Sleeping Beauty Transposon mediated transgenesis using a nephrin promoter. Wild type (WT) or hmo-1, hmo-1, and GEC++/+ glomeruli were treated for 18 h with heme, Fepp), or non-iron porphyrins with opposite effects on HO activity: 1) HO inducers, Cobalt (CoPP) and the non-metal protoporphyrin IX (PPIX) and 2) HO inhibitors: Zinc (ZnPP), Tin (SnPP) protoporphyrins, Tin (SnMP) and Chromium (CrMP) mesoporphyrins. C3b deposition in glomeruli was triggered by exposure to 10% rat serum. DAF, HO-1 and C3b levels were assessed by western blotting or Real-time PCR. HO enzyme activity was measured by standard methods.

Results: Constitutive DAF (mRNA and protein) decreased in both hmo-1 and hmo-1 and increased in GEC++/+ glomeruli. Heme, at concentrations encountered in hemolytic disorders (50-400 μM), increased DAF expression in WT glomeruli. This effect was attenuated in both hmo-1 and hmo-1 and augmented in GEC++/+ glomeruli. Heme-mediated DAF induction in hmo-1 glomeruli persisted despite complete HO-1 absence. Of the non-Fe porphyrins, CoPP, ZnPP, and PPIX increased DAF and HO-1. SnPP induced DAF but not HO-1. SnMP and CrMP had no effect on either protein. Hemin or SnPP-mediated DAF induction reduced C3b deposition. This was reversed by PI-PLC which removed membrane bound DAF.

Conclusions: HO-1 regulates constitutive DAF expression and heme-mediated DAF induction. The latter is independent of metal moiety and HO enzyme activity, requires the porphyrin ring and may also occur via a HO-1 independent mechanism. DAF induction by heme is functional and attenuates C-activation.

FR-P0962

Uncommon Features in Antibody Binding Sites of Human Anti-Glomerular Basement Membrane Autoantibodies

Mary H. Foster, Elizabeth Sarah Buckley, Amy G. Clark. Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.

Background: Detection of pathogenic anti-α3(IV)NC1 collagen autoAb in the serum or kidneys is required for diagnosis of anti-GBM nephritis and Goodpasture Syndrome. Yet little is known about the origin and structure of human autoAb in these diseases. The heterogeneity of serum Ig, lack of ready access to kidney, and inability to reproduce complex immunological microenvironments in vitro present formidable barriers. Humanized models provide a novel platform to circumvent these obstacles.

Methods: We generated Hu-HSC mice by injection of human CD34+ hematopoietic stem cells into immunodeficient NOD-scid-gamma hosts. Mice with an established human immune system (mean blood chimerism 15.0±15.9% at 3 mos post-injection) were immunized with α3(IV)NC1 collagen prior to tissue harvest. Human B cells were isolated and EBV-transformed using CpG oligos and kinase inhibitors, screened for antigen binding, electrophoresed with a human heterobridbrida, and subcloned. The mAb sequences were determined using PCR of cDNA with published primer panels and analyzed using IMGT/V-QUEST.

Results: Sequence analysis of 6 non-clonally related human anti-α3(IV)NC1 mAb reveals skewed gene use and unusual motifs in the critical HCDR3 that is predominantly responsible for antigen binding. 4 of 6 (67%) human mAb are encoded by an IgH J6 allele, the extended sequence of which enriches for aromatic tyrosine residues in HCDR3. The HCDR3 are exceptionally long, with mean length 26.4 amino acids (a.a.) compared to average human HCDR3 of 15.2 a.a., and include hydrophobic motifs, an autoimmune signature uncommon in Ig repertoires of healthy individuals and of unimmunized Hu-HSC mice. Similar motifs were observed in human anti-α3(IV)NC1 mAb, despite substantial species differences in Ig gene loci and a.a. composition.

Conclusions: Our results suggest that binding of α3(IV)NC1 collagen by human anti-GBM autoAb requires unusual structural motifs that can access recessed hydrophobic epitopes and that are normally excluded from the healthy human immune repertoire. Similar motifs in man and mouse suggest origins by convergent selection.

FR-P0963

Antigenicity Alteration of Deglycosylated Myeloperoxidase Juntao Yu,1 Zhou Cui,2 Minhhui Zhao,3 1Academy for Advanced Interdisciplinary Studies, Peking Uni, Beijing, China; 2Renal Div, Peking Uni First Hospital, Beijing, China.

Background: Myeloperoxidase (MPO) is a kind of enzyme located in the azurophilic granules of neutrophils, which is the most common target antigen of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) in Chinese patients. Native MPO possesses five N-glycans at positions 323, 355, 381, 483 and 729. The alteration of MPO antigenicity after deglycosylation of these glycans is not elucidated.

Methods: We prepared deglycosylated MPOs via glycosidases based on commercial human-derived intact MPO, and then detected the antigenicity of deglycosylated MPOs in 40 patients with anti-glomerular basement membrane (GBM) disease without MPO-ANCAs.

Results: We found antibodies against deglycosylated MPOs existed in patients with anti-GBM disease. 12/40 (30%) patients were positive for MPO treated with PNGase F naked MPO without hydrocarbon side-chain. 12 (30%) patients were positive for MPO treated with Endo H (MPO with one GluNac only). Antibody against the intact native MPO was not detectable in all these patients. Furthermore, clinical analysis presented that the deglycosylated antibodies against deglycosylated MPOs were positively associated with renal dysfunction. The plasma levels of antibodies against naked MPO without glycan were positively correlated with the concentrations of serum creatinine (P=0.006, R=−0.178).

Conclusions: The existence of patients’ antibodies towards deglycosylated MPO first discovered the new epitope exposure of MPO after the loss of hydrocarbon side-chain, explicating the possible reasons for antigenicity alteration, and then prompting some clinical significance of these antibodies.

FR-P0964

Autoantibodies to a Cryptic Myeloperoxidase-Specific Immunodominant Epitope Correlate with Disease Activity in Patients with MPO-ANCA Vasculitis

Background: ANCA vasculitis is commonly characterized by polyclonal autoantibody reactivity to one of two autoantigens, proteinase 3 (PR3) and/or myeloperoxidase (MPO). ANCA positivity has been observed in patients with active and quiescent disease. A subset of PR3- and MPO-ANCA in many patients recognizes a cryptic epitope in proteinase 3 or MPO that is usually buried within MPO suggesting that this epitope may be exposed by mechanisms that are not yet understood. We assessed human anti-KIV reactivity longitudinally in a large cohort of patients with MPO-ANCA vasculitis to better understand the temporal association of the autoantibody response.
Methods: Serum, plasma, and extensive clinical data from patients with ANCA vasculitis were prospectively collected every 3 months. A highly sensitive and specific indirect ELISA using kIV peptide was developed to longitudinally screen patient samples for reactivity over their disease course. To minimize non-specific antibody signal, reactivity to a scrambled peptide of the same amino acid composition was also measured. A positive signal was defined as two standard deviations above the healthy control mean (HC: n=85).

Results: Of 67 patients with MPO-ANCA vasculitis, 28 were positive for human anti-KIV autoantibodies at least once during their disease course spanning an average follow-up of 3.3 years. The majority of these patients displayed positivity during initial stages of disease and over time, whereas other patients exhibited remission of reactivity. Further structural analysis of autoantibody binding to native MPO confirmed this peptide to be a cryptic epitope.

Conclusions: These findings suggest that conformational changes in MPO that expose this cryptic epitope may be important in the pathogenesis of MPO-ANCA vasculitis and may provide insight into the etiology of this disease. Furthermore, this assay could help to more clearly define temporal disease activity.

FR-PO965
An Anti-GBM Autoantibody Gene Contributes Risk to Distinct Anti-Collagen Responses
Amy G. Clark, Inge M. Wormi-Schuel, Mary H. Foster, Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.

Background: The mechanism by which anti-GBM nephritis is initiated and regulated remains an enigma. Recent studies indicate that anti-GBM patients’ serum IgG react with multiple collagen chains and with atypical alpha3(V)NC1 epitopes, and that diverse murine anti-GBM autoantibodies are spatially linked. We examined these relationships in a novel autoAb transgenic (Tg) model expressing an IgKV3 gene used at low frequency in adult mice but enriched in anti-GBM IgG and arthritic anti-collagen II IgG.

Methods: Mice expressing an IgKV3-encoded IgG kappa light chain Tg were bred with C57BL/6 Tg with alpha3(V)NC1 epitopes. All autoanti-collagen II IgG were detected by western blot, which may suggest the presence of conformation-sensitive epitopes within the molecule.

Results: IgG receptor expression was detected on 65±14% of B cells, with in vivo regulation suggested by low serum kappa levels (μg/ml: 27.2±8 vs 102.9±61 for non-Tg kappa control, p<0.01). AutoAb were not detected in supernatants from unstimulated cultures (OD 0.003±0.000), but were detected after TLR stimulation. AutoAb specificity varied according to TLR and with: (1) B cell surface lambda (expression) - anti-collagen II IgG, OD 0.271±0.122 vs 0.037±0.056, p<0.001, for high-lambda-expressing mouse IgG lines L16/L21 (mean lambda+ 47.5±12.4% of cells) vs low-lambda line L24 (mean 25±11.7% lambda+); and, (2) Presence of non-B cells: anti-alpha3(V)NC1 collagen IgG, OD 0.124±0.104 vs 0.038±0.033, p<0.001, for whole spleenocyte cultures vs purified B cells (all data shown for TLR7/7/9/9L).

Conclusions: This new model confirms a role for IgKV3 genes in determining different anti-collagen specificities, including reactivity to GBM. This and data not shown suggest that the different specificities are not crossreactive, arising from non-overlapping cell populations, and are regulated in vivo by mechanisms that can be overcome by TLR7/9L.

Autoantibodies Target Multiple Epitopes in THSD7A in Primary Membranous Nephropathy
Hong Ma, David J. Salant, Laurence H. Beck, Medicine, Renal Section, Boston Univ Medical Center, Boston, MA.

Background: Thrombospondin type-1 domain-containing 7A (THSD7A) is a large type 1 transmembrane glycoprotein expressed by the podocyte. It serves as the in situ antigen in a subset of primary membranous nephropathy patients. Its extracellular domain consists of a regularly repeating structure composed of thrombospondin type-1 and F-spondin repeats, as well as a highly basic region. We sought to investigate the location(s) of the humoral response to a scrambled peptide of the same amino acid composition was also measured. A positive signal was defined as two standard deviations above the healthy control mean (HC: n=85).

Results: Of 67 patients with MPO-ANCA vasculitis, 28 were positive for human anti-KIV autoantibodies at least once during their disease course spanning an average follow-up of 3.3 years. The majority of these patients displayed positivity during initial stages of disease and over time, whereas other patients exhibited remission of reactivity. Further structural analysis of autoantibody binding to native MPO confirmed this peptide to be a cryptic epitope.

Conclusions: These findings suggest that conformational changes in MPO that expose this cryptic epitope may be important in the pathogenesis of MPO-ANCA vasculitis and may provide insight into the etiology of this disease. Furthermore, this assay could help to more clearly define temporal disease activity.

Intramembrane Epitope Spreading in Phospholipase A, Receptor in IMN Patient En Route to End-Stage Renal Disease
Michael Shyv,1 Theresa L. Nilson,1 Ritu Vahi,1 Miguel Fernando Palma Diaz,2 PC. Pham,1 Phat H. Duong,1 Liyu Kao,1 Douglas Yao,1 Ira Kurtz,2 Quansheng Zhu,1 Medicine, Univ California, Los Angeles, Los Angeles, CA; 2Pathology, Univ California, Los Angeles, Los Angeles, CA.

Background: Clinical studies have established that over 70% of patients with idiopathic membranous nephropathy (IMN) possess high levels of circulating autoantibodies targeting phospholipase A2 receptor (PLA2R) in the glomerular visceral epithelial cells. Clinical studies demonstrated that over 70% of patients with circulating autoantibodies that target PLA2R triggering immune complexes formation in situ and deposition in the glomerular subepithelial spaces. The immunodominant epitope in PLA2R was recently located to the CysF-R-FnII-CTLD1-3 region of PLA2R. Interestingly, serial analysis of sera from a patient with worsening proteinuria showed that the autoantibodies first recognized the CysF-R-FnII-CTLD1-3 region and then spread to the CysF-R-FnII-CTLD1 region, suggesting epitope spreading is associated with the disease progresses.

Conclusions: Our results demonstrate for the first time that intramembrane epitope spreading occurs in PLA2R in IMN. This finding supports the important role of the dominant epitope in IMN pathogenesis and disease progresses.

589A
Tumor necrosis family (TNF) superfamily members regulate proliferation and apoptosis, and both can be regulated by and are produced by renal interstitial cells (EnCs). TRIF/TLR10 is up-regulated in the kidneys of patients with IC disease.

Methods: Renal EnCs were cultured from C57BL/6 mice and primary human glomerular EnCs were obtained commercially. Cells were treated with heat-aggregated IgG isolated from patients with IC. Quantitative RT-PCR was used to measure mRNA levels of TNF superfamily members. A cellular ELISA was used to assay TRAP signaling protein expression on EnCs surfaces. Apoptosis was assessed using XTT and H2AX phosphorylation, and caspase 3 activity assays, as well as TUNEL staining. In vitro findings were validated in a rodent inflammatory model of acute IC kidney injury.

Results: TRAP mRNA expression is up-regulated by renal endothelial cells in vitro in the presence of IC binding and in vivo. Membrane TRAP expression on EnCs also increases after treatment with IC in a dose dependent manner. Receptors for TRAIL, DR5, DR6, and their downstream signaling pathway are expressed by EnCs at RNA and protein level. Using XTT cell proliferation assays, there is a modest decrease in EnC metabolism or proliferation after treatment with IC. Caspase 3 activity and DNA double strand breaks were both increased in cultured EnCs after treatment with IC in a dose dependent manner. Results were similar for both murine and human glomerular EnCs.

Conclusions: Results suggest that IC binding to glomerular EnCs in vitro is pro-apoptotic. Several TNF superfamily members known to promote apoptosis and their receptors are also up-regulated on EnCs treated with IC. Targeting TRAIL binding to apoptotic EnCs may reduce IC activation or injury in IC kidney diseases.

Paired Immunoglobulin-Like Type2 Receptor α (PILRα) Negatively Regulates Immune Complex-Mediated Glomerulonephritis

Yutaka Kamimura, Naotake Tsuboi, Yutaka Kamimura, Shoichi Maruyama, Seichi Matsu. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

Background: PILRα expressed mainly on macrophages, dendritic cells and granulocytes, has been described for its regulatory functions for leukocyte 2 integrin activation in acute inflammation including LPS-induced endotoxin shock model. Here, we investigated roles of PILRα in immune complex (IC)-mediated glomerulonephritis.

Methods: IC-mediated glomerulonephritis was induced by intravenous administration of nephrotoxic serum (NTS) after pre-immunization with rabbit IgG in C57BL/6 (WT) and PILRα-/- mice. Functional analysis for renal injury was performed by urine albumin and serum creatinine (crea) concentrations at day 7, 14 and 21. Diseased kidneys from both mouse strains were harvested for histology, renal leukocyte infiltrates by flow cytometry and renal cytokine profiles by ELISA after induction of NTS glomerulonephritis. In vitro, αg(2) integrin-dependent neutrophil adhesion on IC was evaluated in both mouse strains.

Results: BUN and crea concentrations were significantly elevated in PILRα-/- mice compared to WT type mice at day 14 and day 21 and those were highly associated with deteriorated proteinuria. In histological analysis, glomerular damages, corroborated with both glomerular PAS deposits and glomerular crescent formation, were more severe in PILRα-/- mice, indicating that PILRα negatively regulates IC-mediated leukocyte recruitment by inhibition of αg(2) integrin activation.

Role of Interferon Regulatory Factor 5 and Toll-Like Receptor 7 in Immune Complex-Glomerulonephritis

Abraham Cohen-Bucay, Barry K. Horne, Yao Xie, Prachi Shukla, Ian R. Rifkin, Ramon G. Benogios. Renal Section, Boston Univ Medical Center, Boston, MA.

Background: Immune-complex glomerulonephritis (ICGN) is a common cause of glomerular inflammation characterized by the in situ formation of immune complexes and activation of the complement cascade. Interferon regulatory factor 5 (IRF5) is a transcription factor acting downstream of toll-like receptors 7 (TLR7) to trigger an inflammatory response. Recent genetic studies have associated systemic lupus erythematosus, and other autoimmune syndromes with gain-of-function polymorphisms in the IRF5 gene. We therefore hypothesized that deletion of IRF5 or TLR7 would ameliorate ICGN.

Methods: We induced nephritogenic nephritis using an endotoxin-free IgG1 fraction of sheep nephritogenic serum (NTS) in FgRRIIB-/- mice that either express (Control) or do not express IRF5 (IRF5-KO) or TLR7 (TLR7-KO). During the first five days following intraperitoneal (IP) NTS after pre-immunization with rabbit IgG in C57BL/6 (WT) and PILRα-/- mice, total serum creatinine (sCr) concentrations at day 7, 14 and 21. Diseased kidneys from both groups were harvested for histology, renal leukocyte infiltrates by flow cytometry and renal cytokine profiles by ELISA after induction of NTS glomerulonephritis. In vitro, αg(2) integrin-dependent neutrophil adhesion on IC was evaluated in both mouse strains.

Results: BUN and crea concentrations were significantly elevated in PILRα-/- mice compared to WT type mice at day 14 and day 21 and those were highly associated with deteriorated proteinuria. In histological analysis, glomerular damages, corroborated with both glomerular PAS deposits and glomerular crescent formation, were more severe in PILRα-/- mice, indicating that PILRα negatively regulates IC-mediated leukocyte recruitment by inhibition of αg(2) integrin activation.

Key Role of Apoptosis Inhibitor of Macrophage in Phlogenic Action of Glomerular Nephritogenic IgA in IgA Nephropathy

Akioko Takahata, Kento Kitada, Chieko Nogi, Satoko Arai, Yuko Makita, Hitoshi Suzuki, Junichiro Nakata, Satoshi Horikoshi, Toru Miyazaki, Yusuke Suzuki. 1

1Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan; Laboratory of Molecular Biomedicine for Pathogenesis, Center for Disease Biology and Integrative Medicine, Faculty of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.

Background: Apoptosis inhibitor of macrophage (AIM), a protein mainly produced by macrophages, has been reported to be related to autoimmune diseases as well as arteriosclerosis.

Methods: We evaluated the role of AIM in IgA nephropathy (IgAN) using IgAN prone mice, grouped into 7 groups (5 groups in AIMKO and 2 groups in WT). Serum of gd1f splenic B cells hybridomas, was injected to AIMKO and WT to perform the injection experiments.

Results: We found excessive expression of AIM in gd1f mice, which were co-localized with glomerular IgA. Glomerular IgA depositions were observed in AIMKO and WT 2h after the injections of gd1f serum and purified nephritogenic IgA. The depositions were cleared soon thereafter in WT but later in KO after being accumulated. However, proteinuria and glomerular depositions were evaluated over time. In addition, nephritogenic IgA, produced by gd1f splenic B cells hybridomas, was injected to AIMKO and WT to perform the injection experiments.

Conclusion: AIM contributed to the progression of IgA nephropathy by promoting the persistence of glomerular resident cells such as mesangial cells.

Characterization of a Signaling Network That Enhances Production of Galactose-Deficient IgA1 in IgA1-Secreting Cells from Patients with IgA Nephropathy

Koshi Yamada, Colin Reilly, Chi qiang Huang, Joshua Charles Anderson, Milam Raska, Hitoshi Suzuki, Bruce A. Julian, Christopher D. Willey, Jan Novak. 1

1Univ of Alabama at Birmingham, Birmingham, AL; Juntendo Univ Faculty of Medicine, Tokyo, Japan; Palacky Univ, Olomouc, Czech Republic.

Background: Interleukin (IL)-6, leukemia inhibitory factor (LIF), and ancostatin M (OSM) cytokines are likely involved in the pathogenesis of IgA nephropathy (IgAN). IL-6/LIF/OSM cytokines activate B cells through similar receptors and the downstream JAK/STAT pathways. We identified key roles of STAP transcription factors in IL-6/LIF/OSM-mediated enhancement of production of IgA1 with galactose-deficient-O-glycans (Gd-IgA1) in IgA1-secretory cells by IgA1-secretory patients. Our study defines how these signaling pathways influence IgA1-glycosylation.

Methods: IgA1-secretory cells from IgAN patients and healthy controls (HC) were stimulated with IL-6/LIF/OSM with or without JAK/STAT inhibitors. Gd-IgA1 levels were determined by lectin ELISA. Cell lysates from IgAN and HC cells were analyzed by global tyrosine-kinome profiling using PamStation®12 platform and Western blotting. The role of STAP3 or STAP1 in mediating IL-6/LIF/OSM, signaling was confirmed by siRNA knock-down (k/d).

Results: siRNA k/d of STAP3 and STAP1 reduced production of Gd-IgA1 in IgAN cells induced by IL-6 and LIF/OSM, respectively. A specific inhibitor of JAK/STAT signaling reduced IL-6/LIF-enhanced production of Gd-IgA1, but only in IgAN cells. Global tyrosine-kinome profiling identified nine target peptides that were selectively inhibited by the specific JAK/STAT inhibitor in the IgAN cell lysates. Bioinformatics analyses and pathway mapping identified abnormal signaling in JAK/STAT and MAPK cascades as the highest ranked pathway.

Conclusions: IL-6/LIF/OSM cytokines enhanced production of Gd-IgA1 via overactivation of JAK/STAT pathways in IgAN cells. Global tyrosine-kinome profiling validated this finding and also indicated participation of MAPK. Elucidating the mechanisms of abnormal signaling associated with Gd-IgA1 production in IgA1-secretory cells may provide new targets for treatment of IgAN.

Expression of Mesangial Tissue Transglutaminase Is Independent of Abrantly Glycosylated IgA in Patients with IgA Nephropathy

Akihiro Kato, Kazuo Takahashi, Tomohiro Mizuno, Stacy D. Hall, Bruce A. Julian, Colin Reilly, Ashwani Malhotra, Rivka Lederman, Pravin C. Singhal. 1

1Nephrology, Dept of Nephrology, the First Affiliated Hospital of Nan Chun University, NanChang, JiangXi, China.

Background: It has been reported that tissue transglutaminase (TG2) is essential for mesangial TG2 activity (IgAN-TG2A), IgAN patients without mesangial TG2 activity (IgAN-TG2N), disease controls (DC), or healthy controls (HC) (P<0.01). Mass spectrometric analysis identified 13 IgA1 hinge-region (HR) O-glycosylation profiles of serum IgA1 from IgAN-TG2A and IgAN-TG2N using high-resolution mass spectrometry.

Results: MC stimulated by sera from IgAN patients with mesangial TG2 activity (IgANTG2A), IgAN patients without mesangial TG2 activity (IgAN-TG2N), disease controls (DC), or healthy controls (HC) were assessed. Expression of TG2 in MC stimulated by purified serum IgA1 and enzymatically deglycosylated IgA1 was also assessed. Furthermore, we characterized hinge-region (HR) O-glycosylation profiles of serum IgA1 from IgAN-TG2A and IgAN-TG2N using high-resolution mass spectrometry.

Conclusion: It has been reported that tissue transglutaminase (TG2) is essential for mesangial TG2 activity (IgAN-TG2A), IgAN patients without mesangial TG2 activity (IgAN-TG2N), disease controls (DC), or healthy controls (HC) (P<0.01). Mass spectrometric analysis identified 13 IgA1 hinge-region (HR) O-glycosylation profiles of serum IgA1 from IgAN-TG2A and IgAN-TG2N using high-resolution mass spectrometry.

Epigenetic Modulation of Vitamin D Receptor (VDR) in HIV-Associated Nephropathy (HIVAN)

Background: HIV has been reported to induce podocyte injury through down regulation of VDR in HIVAN. However, the exact mechanism is not clear. Since HIV has been reported to modulate gene expression via epigenetic phenomena, we hypothesized that HIV would be down regulating podocyte VDR expression in HIVAN via chromatin modifications.

Methods: Renal tissues and cortical sections from four week old control (FVB/N) and HIV- transgenic (Tg26) mice (n=4) were evaluated for the expression of SNAIL, VDR, trimethylation of histone 3 at lysine 4 residue (H3K4me3). Human podocytes (HPs) transduced with either empty vector (EV) or HIV (HIV/HPs) were evaluated for the expression of SNAIL, VDR, and H3K4me3. Stably transduced 293T cells (SNAIL293T) were evaluated for the same profile. Genomic DNAs of HPs were evaluated for same profile. Genomic DNAs of HPs were evaluated for cytosine methylation by Epitect kit and bisulphite pyrosequencing. Composition of SNAIL repressor complex was determined by immunoprecipitation (IP) studies. Trimethylation at SNAIL

**Endothelial NF-κB Induction by ANCA-Activated Neutrophils**

Mina Choi,1 Adrian Schreiber,2 Claudia Eulenberg,2 Ralph Kettz,2 Claus Scheirder,3 Dekker,2 Becks,1 Berlin, ERCRC, Berlin, Germany; Experimental and Clinical Research Center (ECCR), Berlin, Germany; Max-Delbruck Center, Berlin, Germany.

**Background:** Activation of the NF-κB/Rel family and subsequent transcriptional upregulation of inflammatory mediators plays a central role in vascular diseases. ANCA vasculitis is an inflammatory condition where ANCA-activated neutrophils (PMN) interact with the endothelium resulting in necrotizing vasculitis. We hypothesized that ANCA-activated neutrophils (PMN) are sufficient to trigger endothelial NF-κB and vascular inflammation.

**Methods:** NF-κB activation was assessed by IκBα degradation, EMSA, RT-PCR, and IHC. NF-κB was studied in renal tissue from mice and patients with ANCA-induced glomerulonephritis (GN), ANCA-stimulated PMN and endothelial cells.

**Results:** In kidney extracts from mice in which we had induced anti-MPO Ab-mediated GN, we observed a significant correlation between the percentage of crescents and NF-κB activity by EMSA (R²=0.72, n=20). Similar correlations were found for crescents and upregulation of the NF-κB dependent genes TNFa and IκBα. In renal biopsies from patients with ANCA-induced GN, we observed strong phospho-p65 staining in the glomerular mesangium. Regarding the importance of PMN-EC interactions in ANCA vasculitis, we studied NF-κB activation in PMN and ECs in vitro. Low-dose TNFa priming resulted in little IκBα degradation in PMN, but this effect was not further increased by mAb to CD103+ DCs. We studied NF-κB activation in EC when co-incubated with mAb-stimulated PMN and observed significant IκBα degradation in EC (n=10). We confirmed this with human ANCA preparations. Cell-free PMN supernatants were sufficient for endothelial NF-κB activation and chemo-attractant activity in the supernatant, which lead to increased recruitment and adhesion of new PMN.

**Conclusions:** Renal NF-κB activation and NCGN severity were closely correlated. Our in vitro data demonstrate that ANCA-activated PMN induce endothelial NF-κB activity thereby promoting vascular inflammation by recruiting more PMN. Inducing endothelial NF-κB may help limiting the ANCA-mediated damage.

**Ubiquitin C-Terminal Hydrolyase-L1 Controls Dendritic Cell Cross Priming of the CD4+ T Cell Response**

Anna Reinicke,1 Malte Mühlig,1 Nina Schnurrer,1 Timo Lischke,2 Elisabeth Mettke,2 Christian Kurts,3 Hans-willli Mittrücker,2 Catherine Meyer-Schwesinger,1 1Nephrology, III. Medical Clinic, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; Immunology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Experimental Immunology, Inst for Experimental Immunology, Bonn, Germany.

**Background:** Ubiquitin C-terminal hydrolyase-L1 (UCH-L1) is a central deubiquitinating enzyme of the ubiquitin proteasomal system. UCH-L1 has been shown to be of critical importance in the pathogenesis of lymphomas which make up a rare subset of ANCA disease as an alternative suppressive mechanism. ANCA disease is characterized by the presence of anti-neutrophil cytoplasmic autoantibody (ANCA) disease, therefore we sought to determine the role of CD33+ myeloid cells in ANCA disease as an alternative suppressive mechanism.

**Methods:** Constitutive activating T cells were generated from patients with ANCA disease using transgenic mice. ANCA disease was achieved by the injection of human ANCA preparations. Cell-free PMN supernatants were sufficient for endothelial NF-κB and vascular inflammation. We hypothesized that ANCA-vascular inflammation is a inflammatory condition where ANCA-activated neutrophils (PMN) interact with the endothelium resulting in necrotizing vasculitis. We hypothesized that ANCA-activated neutrophils (PMN) are sufficient to trigger endothelial NF-κB and vascular inflammation.

**Results:** Flow cytometric analysis of PMNB revealed an increased population of lineage negative, HLA-DR negative, CD11bhigh and CD33+ myeloid cells in patients with ANCA disease compared to healthy controls (mean 2.72% versus 0.18% of PMNB). This CD33+ myeloid cell population also contained MPO and PR3. Suppression assays utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression. Suppressive capacities of CD33+ myeloid cells are increased in patients with ANCA disease and represent a potential source of T cell suppression not previously investigated. Intriguingly, the patients who demonstrated the highest frequency of CD33+ myeloid cells were those who had sequentially received rituximab and cyclophosphamide.

**Conclusions:** Constitutive activating T cells were generated from patients with ANCA disease using transgenic mice. ANCA disease was achieved by the injection of human ANCA preparations. Cell-free PMN supernatants were sufficient for endothelial NF-κB and vascular inflammation. We hypothesized that ANCA-vascular inflammation is a inflammatory condition where ANCA-activated neutrophils (PMN) interact with the endothelium resulting in necrotizing vasculitis. We hypothesized that ANCA-activated neutrophils (PMN) are sufficient to trigger endothelial NF-κB and vascular inflammation.

**ANCA Disease Patients Demonstrate a Higher Frequency of CD33+ Myeloid Cells with Variable Suppressive Abilities**

Meghan E. Free,1 Katie Stember,2 JulieAnne G. McGregor,1 J. Charles Jennette,3 Ronald J. Falk,3 Maureen Su,3 1UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 2Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 3Pediatrics, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.

**Background:** Myeloid-derived suppressor cells (MDSCs), or CD33+ myeloid cells, have been extensively studied in cancer as potent suppressors of T cell activation. Regulatory T cells (Treg cells) do not suppress T cell proliferation in the absence of anti-neutrophil cytoplasmic autoantibody (ANCA) disease, which we sought to determine the role of CD33+ myeloid cells in ANCA disease as an alternative suppressive mechanism.

**Methods:** Analyses were performed using flow cytometry on peripheral blood mononuclear cells (PBMCs) from 63 patients stained with relevant antibodies. Suppressive potential of CD33+ myeloid cells was assessed with a standard T cell suppression assay.

**Results:** Flow cytometric analysis of PBMCs revealed an increased population of lineage negative, HLA-DR negative, CD11bhigh and CD33+ myeloid cells in patients with ANCA disease compared to healthy controls (mean 2.72% versus 0.18% of PBMCs). This CD33+ myeloid cell population also contained MPO and PR3. Suppression assays utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression. Suppressive capacities of CD33+ myeloid cells are increased in patients with ANCA disease and represent a potential source of T cell suppression not previously investigated. Intriguingly, the patients who demonstrated the highest frequency of CD33+ myeloid cells were those who had sequentially received rituximab and cyclophosphamide.

**Conclusions:** We describe a hitherto unrecognized role for UCH-L1 in controlling CD4+ T cell activation by DCs.

**CD103+ Dendritic Cells Elicit CD8+ T Cell Responses to Accelerate Kidney Injury in Adiriamycin Nephropathy**

Qi Cao,1 Qin Li,2 Xin M. Wang,2 Chengsheng Wang,3 Yuan Min Wang,4 Stephen L Alexander,2 Yingping Wang,3 David C. Harris,1 1Centre for Transplant and Renal Research, Westmead Millennium Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; 2Flow Cytometry Facility, Westmead Millennium Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; 3Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.

**Background:** CD103+ dendritic cells (DCs) in non-lymphoid organs exhibit two main types of function, namely maintaining tolerance by induction of regulatory T cells and protecting against tissue infection through activation of CD8 T cells. However, the characteristics and functions of CD103+ DCs in kidney remain unclear.

**Methods:** Adiriamycin nephropathy (AN) was induced in BALB/c mice. The distribution, phenotype and function of kidney CD103+ DCs were assessed in normal and AN mice. CD103+ DCs were depleted by neutralizing CD103-saporin (SAP) antibody in AN mice to examine their role in vivo.

**Results:** In the present study, we showed that CD103+ DCs are one of four subpopulations of renal mononuclear phagocytes in normal kidney; they expressed DC-specific surface markers, transcription factors and growth factor receptors, and were found in kidney cortex but not medulla. The number of kidney CD103+ DCs was significantly increased in mice with Adiriamycin nephropathy (AN) and depletion of CD103+ DCs attenuated kidney injury in AN mice. The possible mechanisms underlying the pathogenic role of CD103+ DCs were examined. In vitro, kidney CD103+ DCs preferentially primed CD8 T cells, and did not directly induce tubular epithelial cell apoptosis. Adoptive transfer of CD8 T cells significantly exacerbated kidney injury in AN SCID mice, whereas depletion of CD103+ DCs impaired activation and proliferation of transfused CD8 T cells, and thereby reduced kidney injury in AN SCID mice treated with CD8 T cells.

**Conclusions:** Kidney CD103+ DCs display a pathogenic role via activation of CD8 T cells in Adiriamycin nephropathy.

**Funding:** Government Support - Non-U.S.

**RORγt Activation in biTregs Promotes Lupus Nephritis**

Malte A. Kluger, Jing Yan, Hyunjin Ryu, Tai Yeon Kang, Boeren Goerke, Matthias C. Meyer, Michael Luig, Rolf A. Stahl, Oliver M. Steinmetz.

**Nephrology, Hamburg Univers Medical Center.**

**Background:** We recently characterized Foxp3+ regulatory T cells, co-expressing the Th17 characteristic transcription factor RORγt, as an independent and bi-functional T cell lineage (biTregs). biTregs secrete both, anti-inflammatory (IL-10, IL-35), and also pro-inflammatory (IL-17) cytokines. Studies in a model of acute crescentic glomerulonephritis suggest that pro-inflammatory biTreg functions are mediated by RORγt. This is of high clinical relevance, since multiple RORγt blocking agents are currently under development.

**Methods:** Systemic lupus erythematosus (SLE) Pristane in biTreg68 mice.

**Results:** Time course analyses showed increasing infiltration of biTregs into kidneys of pristane injected mice with a maximum at around 5 months. Subsequently percentages decreased and were back to baseline at 8 months. To study the functional role of RORγt in biTregs, Foxp3+ x RORγt+ mice were generated (biTreg68). Renal histology at 8 months revealed a severe proliferative glomerulonephritis in pristane injected wild type mice. Histological injury in the biTreg68 group, in contrast, was significantly ameliorated. Renal leukocyte infiltration and albuminuria were also reduced by knockout of RORγt in biTregs. As one possible explanation for the improved outcome, we found that biTregs from wild type mice produced pro-inflammatory IL-17 at all observed time points, while biTregs from biTreg68 mice did not. In order to assess effects of biTreg expressed RORγt on development of systemic auto-immunity, we studied humoral immune responses. Analyses, however, showed unaltered serum anti-U1-RNP auto-antibody levels of all isolates. Likewise, renal IgG and complement C3 deposition remained unchanged. This indicates that RORγt activation in biTregs directs renal injury by cellular effectors but does not play a major role in the development of auto-immunity.

**Conclusions:** Our data provide first evidence for presence and functional importance of biTregs in SLE. Importantly, biTreg expressed RORγt was identified as a factor promoting development of renal injury. Our data therefore favor RORγt directed interventions as innovative new therapeutic option for lupus nephritis.

**FR-PO985**

**IL-2/-Anti-IL-2 Complex Attenuates Lupus Nephritis by Expansion of Regulatory T Cells**

Hye Jin Lim, Ji-Jing Yan, Hyunjin Ryu, Tai Yeon Kang, Kyungok Min, Jee-Ghi Lee, Boahae Kang, Curie Ahn, Jaseok Yang. Transplantation Center, Seoul National Univ Hospital, Republic of Korea.

**Background:** Regulatory T cells (Treg) play an important role in the pathogenesis and control of lupus. Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of antibodies to self-nuclear acids, immune complex deposition, and tissue inflammation such as glomerulonephritis. We therefore hypothesized that the IL-2/-Anti-IL-2 complex (IL-2C), a mediator of Treg expansion, can ameliorate progression and reduce the mortality of lupus-like prime mice.

**Methods:** NZW/F1 female mice progressively produce high levels of autoantibodies and resultant deposition of immune-complexes drives lupus-like glomerulonephritis. NZW/F1 female mice were treated intraperitoneally with IL-2 -anti-IL-2 mAb (E66-1) 4 times a week starting at 24 weeks of age, and were analyzed at 36 weeks of age. Lupus-like disease progression was assessed by measurement of proteinuria, dsDNA, cytokine levels and kidney histology, as well as by flow-cytometric analysis of cellular infiltration.

**Results:** IL-2C induced an effective and sustained expansion of CD4+FoxP3+ Tregs, significantly lower compared with controls. Compared with controls, and blocking F1 female mice treated with IL-2C showed less proteinuria, less acute and chronic pathological lesions in the kidney and better survival. There were significant differences in glomerular injury, tubular injury and vascularitis scores, as well as in the quantitative analysis of IgG and C3 deposition between the two groups. Disease activity markers were reduced in serum of the IL-2C group. IL-2C treatment reduced plasma cell populations in spleen, inhibition of B and T cell infiltration of the kidney tissue, and suppressed IFN-γ CD4+ and Th17 CD4+ cells in both spleen and kidney. When compared with combination therapy of standard prednisolone treatment showed similar or better outcomes. Depletion of Tregs with anti-CD25 antibodies abrogated the beneficial effects of IL-2C.

**Conclusions:** IL-2C protects lupus-prone mice against lupus nephritis by expanding Tregs and suppressing inflammation. Therefore, IL-2C could have a therapeutic potential in lupus nephritis.

**FR-PO986**

**Hyporesponsive T-Cell Phenotype Predicts a Subset of Focal Segmental Glomerulosclerosis (FSGS) Patients Responsive to Rituximab**

Chang-Yien Chan, 1 Issae Liu, 1 Lourdes Paula Real Resontoc, 2 Kar Hui Ng, 2 Yew Ting Tong, 2 Yew Woon Fong Lau, 2 Stanley C. Jordan, 3 Kong Peng Lam, 1 Wee Song Yeo, 1 Hui Kim Yap. 1 Paediatrics, National Univ of Singapore, Singapore; 2Cedars Sinai Medical Center; 3Biprocessing Technology Inst, A-Star, Singapore.

**Background:** Rituximab has been used with variable success in difficult FSGS, but the immunological basis of its efficacy is poorly characterized. This study aimed at identifying T-cell subsets in pediatric FSGS patients in order to define an immunological signature predictive of a favorable response to rituximab.

**Methods:** 22 FSGS patients (median age 14.4 years, range 6.2-25.0 years) were recruited prospectively to receive rituximab (375mg/m2 fortnightly to a maximum of 4 doses). Median duration of follow-up was 26.7 months (range 6.5-66.6 months). Baseline immunological subsets were compared with 30 healthy controls, and subsequently examined for association with response to rituximab. Good response was defined as complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months.

**Results:** Of the 22 patients, 12 (54.5%) responded to rituximab therapy. Activated CD4+CD45RO+CD38+CD3+ subsets before treatment were significantly lower in responders (54.8±9.10%) compared to non-responders (73.9±5.18%) (p=0.03) and controls (75.7±2.49%) (p=0.001). IFN-γ+CD3+ subsets were similarly decreased in responders (0.55±0.24%) compared to non-responders (7.2±1.21%) (p=0.005) and controls (12±2.15%) (p=0.001). IL-2+CD3+ subsets were also lower in responders (24±14%) compared to non-responders (44±19.5%) (p=0.007) and controls (63±5.1%) (p=0.003).

Significant recovery of all 3 activation subsets occurred 3 months post-rituximab treatment.

**Conclusions:** We have identified prognostic markers which define a subset of FSGS patients bearing an immunological signature representing hyporesponsiveness to T-cell stimulation, with good response to rituximab therapy.

**FR-PO987**

**Cytokine Profiling in Rituximab-Treated Pediatric Focal Segmental Glomerulosclerotic Nephrotic Patients**

Wee Song Yeo, Chang-Yien Chan, Hui Kim Yap. Pediatrics, Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore, Singapore.

**Background:** Focal segmental glomerulosclerosis (FSGS) is the most common histological pattern seen in pediatric steroid-dependent and steroid-resistant nephrotic syndrome in recent years. Rituximab is increasingly used in nephrotic patients who have failed therapy with conventional immunosuppressants. This study aimed to examine the cytokine profile in rituximab-treated pediatric FSGS nephrotic patients and elucidate the cytokine profile differences between responders and non-responders.

**Methods:** Our study population consisted of 13 pediatric FSGS patients who underwent rituximab therapy. Plasma cytokine profiling was performed on each of these patients utilizing multiplexed Lumines® Cytokine Human 27-plex assay pre- and post-rituximab therapy. Statistical analysis was performed using Wilcoxon signed-rank test with a p-value of less than 0.05 considered as statistically significant.

**Results:** Five (38%) of the patients responded to rituximab, defined as having achieved complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months. All patients in the study demonstrated an increase in plasma interferon-gamma-inducible protein (IP)-10 levels post-rituximab therapy (554±62.4 pg/ ml (pre) vs 793.4±125.5 pg/ml (post), p=0.008). Comparing the cytokine profile between responders and non-responders, responders demonstrated a positive mean-fold change in pro-inflammatory protein (MPI)-1a, in contrast to non-responders who demonstrated a negative mean fold change (0.23±0.16 vs -0.17±0.08, p=0.04). There were, otherwise, no noted significant differences in the other cytokines i) pre-(post-rituximab and ii) between responders and non-responders.

**Conclusions:** Our study results suggest the development of a pro-inflammatory state in our patients post-rituximab therapy. The increase in plasma IP-10 in patient post-rituximab may account for the phenomenon of rituximab-associated colitis. The finding of increased plasma MPI-1a in responders compared to non-responders is novel. Further mechanistic studies are required to ascertain the role of IP-10 and MPI-1a in the mechanism of action of rituximab.

Gut-Kidney Axis in the Pathogenesis of IgA Nephropathy

**Gabriella Laurieri,**
Eustachio Montemurro,** Maria De angelis, Valentina Maranzano,** Lucia Vannini,**
Loreto Gesualdo.

dETO-Nephrology Unit, Univ. of Bari, Italy; DiSSPA, Univ. of Bari, Italy; Dept. of Agricultural and Food Sciences, Univ. of Bologna, Italy.

**Background:** IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. It is characterized by deposition of deaglycosylated IgA1 and IgG antibodies in the glomeruli and its pathogenesis is only partially defined. Intestinal microbiota could be involved in IgAN, as suggested by the observation that B-cell activation factor (BAFF) transgenic mice had high levels of aberrantly glycosylated serum polymeric IgA, the presence of commensal flora and the circulation of corresponding specific IgA antibodies being essential for the development of IgA deposits. BAFF is an important regulator of B-cell maturation, survival and function. The aim of the study was to analyze the role played by gut-kidney axis in the pathogenesis of IgAN.

**Methods:** 16 healthy controls (HC) and 32 IgAN patients (16 non-progressors - NP and 16 progressors - P) were included in the study. Serum creatinine, estimated Glomerular Filtration Rate, 24h-proteinuria (MEST score) were analyzed. Gut microbiota, urinary and fecal metabolome of all subjects were characterized by 16S sequencing, Biochrom 30 series amino acid analyzer and with the levels of fecal phenolic metabolites (r=0.47, p<0.0003) and with the levels of fecal phenolic metabolites (r=0.47, p<0.0003).

**Results:** Serum acetate and LPS levels were positively correlated with 24h-proteinuria (r=0.47, p<0.0003). Serum acetate and LPS levels were significantly higher during disease flare (P<0.05), and was predominantly detected in the tubulo-interstitium, associated with inflammatory cell infiltration, fibrosis and tubular atrophy. LBP, GPR-41 and GPR-43 expression was markedly increased in lupus nephritis patients compared to healthy controls (n=50 for each group). Intra-renal expression of LPS-binding protein (LBP) and GPR-41 and GPR-43 (SCFA receptors) was also examined.

**Conclusions:** Serum acetate and LPS levels were significantly higher in patients with lupus nephritis compared to levels in patients with non-lupus renal diseases (P<0.05, for both) and healthy subjects (P<0.01, for both). In lupus nephritis patients, serum acetate and LPS levels were significantly higher during disease flare (P<0.04 and P<0.0015 respectively compared to levels during remission). Serum LPS level correlated with acetate level (r=0.52, p=0.001), and inversely correlated with that of IgA (r=−0.61, P=0.001). Renal LBP, GPR-41 and GPR-43 expression was markedly increased in lupus nephritis patients compared to healthy controls, and was predominantly detected in the tubulo-interstitium, associated with inflammatory cell infiltration, fibrosis and tubular atrophy. LBP, GPR-41 and GPR-43 expression showed similar staining intensities and localization in patients with lupus nephritis and those with non-lupus renal diseases.

**Conclusions:** Our data suggest that acetate and LPS may be involved in the pathogenesis of lupus nephritis and non-lupus glomerular diseases.

Intestinal Macrophages Polarized to Activation of Pro-Inflammatory and Had Dysfunction of Phagocytosis Leading to Aggravate Microinflammation and Assist Bacterial Translocation as Carrier in Uremia Rats

Lingshuang Sun, Hongli Jiang, Hua Liu, Meng Wei. Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of Medicine School.

**Background:** This study investigated whether intestinal macrophages are related to low-grade inflammation and bacterial translocation (BT) during uremia, and whether probiotics can alter the macrophage activity.

**Methods:** Male Sprague-Dawley rats were randomly divided into 3 treatment groups: sham, uremia (untreated), and uremia + probiotic.The expression of cell surface antigen CD11a (a.k.a., lymphocyte function-associated antigen 1 [LFA1]), inducible nitric oxide synthase (iNOS), ICAM1, and TGF-β were analyzed by immunohistochemistry. Gene and protein expression of early growth response protein 1 (EGR1) and TLR4 in intestinal specimens were determined. Density of labeled macrophages and tracer bacteria in intestinal and extraintestinal tissues were examined by immunofluorescent microscopy, and macrophage morphomorphy were examined by transmission electron microscopy.

**Results:** Intestinal macrophages exhibiting high intensity expression of CD11a, iNOS, ICAM1, and TGF-β staining. Gene and protein expression levels of intestinal TLR4 and EGR1 were also highest in this group. Intestinal segments of uremic rats exhibited high density and broad distribution of tracer bacteria and macrophages. Intestinal macrophages in untreated rats showed fewer cytoplasmic protrusions and pseudopodia. Administration of probiotics resulted in restoration of macrophage classic activation and phagocytosis that was associated with a reduction in BT.

**Conclusions:** In the uremic state, intestinal macrophages are polarized toward a proinflammatory phenotype that results in low-grade inflammation. Abnormal intestinal macrophage activation and impaired phagocytic function are associated with increased BT. Probiotics may reduce BT by enhancing phagocytosis of intestinal macrophages.

**Funding:** Government Support - Non-U.S.
Conclusions: Induction of GN by NTS caused significant macrophage infiltration, which was detected noninvasively by a cathepsin B-activatable probe and NIR optical imaging. These data establish the proof-of-principle that NIR optical imaging may represent a translatable approach to establishing early stages of GN.

Improved Tissue Clearing and 2-Photon Imaging of Mouse Kidneys Reveals Immune Cell Architecture in Nephrotic Nephritis

Matthew David Cheung, Dongyue Huang, Alfred Hyoungju Kim. Rheumatology, Washington Univ School of Medicine, St. Louis, MO.

Background: Tissue clearing approaches such as CLARITY renders tissue transparent, and in combination with two-photon microscopy, enables microscopic visualization deep internal structures without unlabeled organs. These cutting edge approaches have drastically improved the understanding of cellular circuits in the brain. However, application of this approach has only recently been described for the kidney. Here, we clear mouse kidneys to better understand the immune cell architecture following induction of nephrotic nephritis (NTN) using a modified lipid removal approach that also worked for human kidney fragments.

Methods: 129 mice were injected intravenously with nephrotoxic serum to induce NTN. Mice were perfused with an acrylamide monomer solution to form the basis of the hydrogel. Lipid removal was accomplished using 8% sodium dodecyl sulfate (SDS). An aminooxalic solution was used to quench light absorbing heme in red blood cells trapped within the tissue. Cleared mouse kidneys were stained with antibodies specific for B cells, T cells, macrophages, and dendritic cells (DCs). Human kidney fragments were incubated in acrylamide monomer solution then cleared as mentioned above. Cleared tissue was imaged using two-photon microscopy.

Results: Compared to previously published protocols, perfusion of acrylamide monomers into mice significantly accelerated the tissue clearing process. Enhanced tissue clearing was observed when we incubated kidneys in aminoalcohols. We observed vast networks of lymphocytes, macrophages, and DCs cleared NTN kidneys compared to DCs in normal control kidneys. Human kidneys also were cleared using this approach, and we noted DC networks in healthy donor controls.

Conclusions: We identified a new protocol that enhanced and accelerated tissue clearing in mouse and human kidneys. Using this approach, we found elaborate networks of lymphocytes and monocyte-derived cells in NTN mouse kidneys. We also observed DC networks in healthy human kidney donor fragments. These data demonstrate the utility of tissue clearing in evaluating cellular architecture in mouse and human kidneys.

Natural IgM Mediates Ischemic AKI

Lindsey R. Goetz, Jennifer Laskowski, Brandon Renners, Rachel A. Woolaver, Liudmila Kulik, Joshua M. Thurman. Dept of Medicine, Univ of Colorado Denver School of Medicine, Aurora, CO; Dept of Radiology, Massachusetts General Hospital, Boston, MA; Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom.

Background: Glomerular IgM deposition occurs in numerous “non-immunologic” kidney diseases and has been shown in chemical and inflammatory models of injury. We recently demonstrated that complement activation within the kidney leads to neo-epitope formation. Because the alternative complement pathway is activated in renal ischemia, we hypothesized that complement activity during renal I/R generates neo-epitopes recognized by natural IgM antibodies that then exacerbate inflammatory injury.

Methods: To investigate this hypothesis, we used a 24 minute I/R model. We first subjected soluble IgM deficient (sIgM-) mice to renal I/R and found a trend toward less severe injury in these mice vs. wild type (wt) controls (mean BUN of 135 ± 39 [SD] and 152 ± 26 mg/dL, respectively; n ≥ 7, p = NS). To accentuate complement activation in this model, we then exposed mice heterozygous for complement regulatory proteins H () to the same I/R protocol and found that the mice sustained worse renal injury and had greater glomerular IgM deposition than wt controls (mean BUN of 114 ± 46 and 63 ± 48 mg/dL, respectively; n ≥ 14, p = 0.009 and mean glomerular IgM RFUs of 44 ± 7 and 22 ± 7, respectively; n ≥ 8, p = 0.0002). To further evaluate IgM pathogenicity, we induced I/R injury in mice deficient in both factor H and IgM (fH-sIgM-) and noted a trend toward attenuation of renal injury in the fH-sIgM- vs. H- mice (mean BUN of 106 ± 69 and 127 ± 52 mg/dL, respectively; n ≥ 7; p = NS) with data collection ongoing.

Conclusions: These data suggest that natural IgM contributes to ischemic renal injury by binding neo-epitopes generated during complement activation in this kidney. This adds to a growing body of evidence suggesting a common final pathway of IgM-mediated glomerular injury in a variety of “non-immunologic” renal disorders and offers a novel therapeutic target for the treatment of these diseases.

Activation of Toll-Like Receptor 2 in the Pathogenesis of Contrast-Induced Nephropathy

Kristina Angela Rathnahl, Altaf M Khan, Federico Jose Teran, Kathleen S. Hering-Smith, Eric E. Simon, Vecchi Batuman. Medicine, Nephrology & Hypertension, Tulane Univ, School of Medicine, New Orleans, LA; VA, SLFVCS, New Orleans, LA.

Background: Innate immunity mediated by Toll-like receptors (TLRs) is involved in the pathophysiology of contrast-induced nephropathy (CIN). We studied the expression of TLRs 1, 2, and 4 and associated molecules in CIN using human renal proximal tubule epithelial cells (RPTECs) and aged diabetic (db/db) mice.

Methods: We cultured RPTECs in normal (5 mM) or high (35 mM) glucose media for 24 h and then exposed them to nonionic (iodixanol or iohexol) and ionic (Urografin) contrast media (CM) at a dose of 100 mg iodine/ml for another 24 h in the same media. 24-wk-old male db/db mice were given nonionic CM i.v. (3 g of iodine/kg bw) after 24 h water deprivation. All mice were sacrificed 24 h after CM injection.

Results: The mRNA expressions of TLR2 increased by 2.5 fold (p < 0.05) and TNF-α by 1.7 fold (p < 0.05) in RPTECs exposed to iohexol compared to untreated RPTECs in a dose-dependent fashion. RPTECs in high glucose for 48 h and exposed to iohexol showed significantly increased apoptosis compared to RPTECs in normal glucose. 24-wk-old db/db mice became obese, polyuric, glucosuric, ketonuric, and had increased GFR, systolic blood pressure, urine NGAL, and renal tubular damage compared to nondiabetic (db/m) control mice. 24 h after iohexol injection, db/db mice showed a significant decrease in GFR, metabolic acidosis and significant increases in serum creatinine, urine and kidney KIM-1 levels and kidney damage histologically compared to control db/db mice. After iohexol administration, the mRNA level of TLR2 was significantly increased by 2.4 fold (p < 0.01) in kidney compared to control but there was no change in TLR4 expression. The expression was significantly upregulated in kidney.

Conclusions: High glucose RPTECs and diabetic (db/db) mice are vulnerable to CIN. Innate immunity mediated by TLR2 plays a major role in the pathogenesis of CIN as demonstrated by in vitro and in vivo studies. TLR2 may prove to be a promising drug target for the development of new therapeutics against CIN.

Heparanase Deficiency Improves Renal Function During Experimental Glomerulonephritis

Marianne Gielen, Marlien Benner, Henk Dijkman, Jinn-ping Li, Ton J. Rabelink, Israel Vladovsky, Jo H.M. Berden, Angelique Rogaats, Michael Elkin, R. Rappaport Faculty of Medicine, Haifa, Israel; Sharet Inst, Hadassah-Hebrew Univ Medical Center, Jerusalem, Israel.

Background: Heparanase (HPSE), a heparan sulfate (HS)-specific endoglycosidase, mediates the onset of proteinuria and renal damage during experimental diabetic nephropathy. Glomerular HPSE expression is increased in the majority of proteinuric diseases. The exact role of HPSE in the development of other inflammatory glomerular diseases is still unknown.

Methods: Here, we evaluated the role of HPSE in two models of experimental glomerulonephritis, being mono- and double basement membrane and lipopolysaccharide (LPS)-induced glomerulonephritis, in wild type (WT) and HPSE-deficient mice.

Results: Induction of experimental glomerulonephritis led to an increased HPSE expression in WT mice, which was associated with a decreased glomerular HS expression and albuminuria. Albuminuria was reduced in the HPSE-deficient mice in both models, which was accompanied by a better renal function and less renal damage. Notably, glomerular HS expression was preserved in the HPSE-deficient mice. Glomerular leukocyte and macrophage influx was reduced in the HPSE-deficient mice, which was accompanied by a reduced expression of both Th1 and Th2 cytokines. In vitro, tumor necrosis factor (TNF)-α and LPS directly induced HPSE expression and increased transendothelial albumin passage in a HPSE-dependent manner.

Conclusions: Our study shows that HPSE-deficiency ameliorates proteinuria and renal damage in experimental glomerulonephritis by preserving glomerular HS expression, and decreasing leukocyte and macrophage influx, and by affecting the local cytokine milieu.

Iron Chelation as a Novel Renoprotective Strategy in Lupus Nephritis

Erica L. Boesen, Megan K. Garsen, Michael E. Elkin, Ton J. Rabelink, Henry Dijkman, Jesse Boesen, 1Cellular & Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.

Background: Poorly liganded iron damages tissue via several mechanisms. Multiple iron homeostasis proteins have been proposed as urinary biomarkers of lupus nephritis, and we have previously found that renal tissue iron levels are increased in the (NZBxNZW)F1 mouse model of lupus nephritis. Anemia is also common in lupus patients. Together, these data suggest that dysregulation of body iron homeostasis may occur in lupus. This pilot study aimed to evaluate whether (i) iron chelators decrease iron in the (NZBxNZW)F1 mouse model of lupus nephritis, and (ii) whether this therapy adversely affects hematological parameters.
Methods: Female (NZBxNZWF1) mice were treated with the iron chelator deferoxamine from 20 weeks of age onwards. Albuminuria was monitored in 24h urine samples collected weekly, and mice were sacrificed at >2-2.5 weeks of age, whichever was sooner. Hematocrit, red cell hemoglobin, plasma non-iron hemoglobin concentration as well as kidney and liver iron concentrations were measured at sacrifice.

Results: As shown in Figure 1, there was a trend towards later onset of albuminuria in deferiprone-treated mice compared with vehicle-treated mice (median onset of albuminuria 39 and 32 weeks, respectively).

Liver iron concentration was significantly lower in deferiprone-treated mice than vehicle-treated mice, consistent with effective iron chelation. Renal cortical and outer medullary iron concentrations were not significantly different between groups. Unexpectedly, hematocrit was significantly improved by treatment with deferiprone (48.1% versus 39.3% in vehicle-treated mice, P<0.01), whereas red cell hemoglobin and plasma non-iron hemoglobin concentrations were not different between groups.

Conclusions: Our pilot data suggest that iron chelation may delay the onset of albuminuria in a mouse model of lupus nephritis without adversely affecting hematological parameters.

IKK2 Inhibition Inhibits the Initiation, but Aggravates the Progression of Crescentic Glomerulonephritis

Janine Geert,1 Gisela Pietruck,2 Gisa Tjegs,3 Ulf Panzer,3 Christian Kursis,4 Friedrich Thaiss.1 1Rheinische Friedrich-Wilhelms-Universitaet, Inst of Experimental Immunology, Bonn, Germany; 2Universitaetsklinikum Hamburg-Eppendorf, III Medizinische Klinik, Hamburg, Germany; 3Univ Medical Center Hamburg-Eppendorf, Inst of Experimental Immunology and Hepatology, Hamburg, Germany.

Background: The NFκB transcription factor family facilitates the activation of dendritic cells (DC) and CD4+ T helper (Th) cells, which are important for protective adaptive immunity. Inappropriate activation of these immune cells may cause inflammatory disease, and NFκB inhibitors are promising candidate drugs.

Methods: Here, we investigated whether inhibiting the NFκB component IKK2 can attenuate crescentic glomerulonephritis, a severe DC- and Th cell-dependent kidney disease by induction of the pausative and the accelerated NTN mouse model.

Results: Prophylactic pharmacological IKK2 inhibition reduced DC activation, Th cell activation and ameliorated glomerulonephritis in mice. However, therapeutic IKK2 inhibition during ongoing disease, which is relevant for clinical situations, unexpectedly aggravated the nephritic immune response and disease symptoms. This resulted from systemic loss of regulatory T cells (Tregs), which have been previously shown to protect against crescentic glomerulonephritis and which require IKK2 as well.

Conclusions: In conclusion, although IKK2 inhibition can suppress the induction of nephritic immune responses in vivo, it may aggravate such responses in clinically relevant situations, because it also impairs Tregs and thereby unleashes pre-existing nephritogenic responses. Our findings argue against using IKK2 inhibitors in chronic glomerulonephritis, and perhaps also in other immune-mediated diseases.

FR-PO999

Transfused M2 Macrophages Ameliorate Renal Injury in Murine Neprotoxic Serum Nephritis

Qiuna Du1, Naotake Tsuboi, Yutaka Sugiyama,2 Gisela Pietruck,2 Ulf Panzer,3 Christian Kursis,4 Friedrich Thaiss.1 1Rheinische Friedrich-Wilhelms-Universität, Inst of Experimental Immunology, Bonn, Germany; 2Univ Medical Center Hamburg-Eppendorf, Inst of Experimental Immunology and Hepatology, Hamburg, Germany.

Background: Glomerular leukocyte infiltration is a hallmark of glomerulonephritis. In addition to the effector roles of glomerular macrophages (Mφ) for tissue injury, recent studies found involvement of alternatively activated macrophages (M2 Mφ) in resolution of kidney inflammation. The aim of this study is to directly assess the potential of M2 Mφ to protect against renal injury in murine nephrotoxic serum (NTS) nephritis.

Methods: Bone marrow (BM)-derived Mφ and mouse iPS-derived Mφ were obtained under the stimulation of IL-4/IL-13 to differentiate M2a Mφ with high expression of CD206. FACs and RT-PCR were performed to assess efficient Mφ differentiation. 0.6 x 10^6 of M2a Mφ were intravenously transferred 4 days after NTS nephritis induction. Immunostaining was used to detect Mφ, T cell and neutrophil infiltration. Renal cytokines were determined by ELISA. BM-derived M2a Mφ from EGFP transgenic mice (EGFP + M2a Mφ) was exploited to investigate the cell distribution. To investigate in vitro function of M2a Mφ on other leukocyte subsets, BM-derived M1 Mφ and splenic CD4+CD25- T cells were co-cultured with EGFP + M2a Mφ.

Results: M2a Mφ expressed higher levels of arginase-1 and IL-10/IL-12 mRNAs than M1 Mφ. Proteinuria was significantly attenuated by injection of M2a Mφ compared with disease-control mice at day 14 and day 21. Treatment with M2a Mφ prevented glomerular neutrophil and T cell accumulation. In addition, renal levels of IL-6, MCP-1, IL-1β and TNF-α were significantly decreased in M2a Mφ-treated mice on day 21. EGFP + M2a Mφ were seen in the kidney and spleen 24h after cell injection. M1 Mφ were demonstrated phenotypic conversion to an M2a cells following the co-culture with EGFP + M2a Mφ, while EGFP + M2a phenotype was relatively stable. M2a Mφ suppressed T-cell proliferation and promoted induction of Tregs in vitro. Immunostaining displayed that M2a Mφ and T cells were significantly increased in spleen in mice treated with M2a Mφ compared with disease control group.

Conclusions: Administration of M2 Mφ may have therapeutic potency for glomerular injury by further M2 cell conversion and induction of regulatory T cells.

A Randomized Multicomponent Intervention to Reduce Disparities in Transplant Referral: Results from the RaDIANT Community Study

Rachel E. Patzer,1 Leannah Sauls,2 Jennifer C. Gander,3 Laura Plantinga,1 Sudeshna Paul,1 Eric M. Gibney,1 Laura L. Mulloy,1 Stephen O. Pastan,1 1Emory Univ; 2Southeastern Kidney Council; 3Piedmont Hospital; 4Georgia Regents Univ.

Background: The Reducing Disparities In Access to kidNey Transplantation (RaDIANT) Community Study is a dialysis facility-level randomized clinical trial to test the effectiveness of a multicomponent intervention in improving kidney transplant (KTx) referral and reducing racial disparities in referral in Georgia.

Methods: In 2013, 134 dialysis facilities were randomized to receive either usual KT education (n=67) or a multicomponent intervention conducted by, consisting of KT education and engagement activities targeting dialysis facility leadership, staff, and patients (n=67) over 12 months. Paired t tests, overall and by race [white and African-American (AA)], were used to compare referral at 9 months of intervention vs. baseline, in intervention and control facilities.

Results: Facilities that received the intervention had a greater absolute increase in referral over 9 months than facilities that performed usual KT education (+7.8% vs. -2.5%).

596A
Deceased Donor Renal Transplant eGFR at Six Months Has Improved in the Last 13 Years in Spite of Declining Donor Quality

Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar. Medicine, Univ of Virginia, Charlottesville, VA.

Background: Deceased donor quality has declined in the last decade but long-term graft outcomes are improving. We sought to analyze the trend in graft function at six months post-transplant in relation to this improvement.

Methods: All adult deceased donor kidney transplant recipients with at least six months graft survival recorded in the SRTR database between 2000 and 2012 were analyzed. The CKD EPI eGFR was determined based on the patient characteristics and serum creatinine at six months post-transplant. KDPI of the donors was also calculated. Linear regression was used to determine the effect of covariates on eGFR.

Results: 111,678 deceased donor recipients were identified. 4918 (4.4%) recipients with no six month creatinine measurement were excluded. The median eGFR improved from 54.5 ml/min/1.72m² in 2000 to 58.9 in 2012 (p=0.001) while the median KDPI increased from 41% to 46%(p<0.001). The use of tacrolimus/mycophenolate derivative also increased from 33.1% to 89.8%. Every 10 unit increase in KDPI resulted in a 3 ml/min/1.72m² decline in eGFR.

Conclusions: Graft function improved significantly over the 13 year period in spite of declining donor quality and appears to be an important factor in the improvement in long-term graft survival. The transition to tacrolimus/mycophenolate derivative as the dominant maintenance immunosuppression appeared to be an important factor in this improvement.
our patients have excellent allograft function 6-12 months post transplant. Donor ages 0 to 5 years of age. Younger age and low weight of the donors did not adversely affect outcome.

Maria Najafian, Adults in the Era of Extreme Donor Shortage

The Role of Dobutamine Stress Echo in Identifying Cardiac Ischaemia, FR-PO1006

The only factors in the KDPI determination associated with rejection were donor age, donor hypertension, HCV seropositivity, and black donor race, with age accounting for most of the effect.

Conclusions: KDPI and recipient age are the most important factors associated with rejection. Risk stratification for donor recipient pairs based on age and KDPI should be considered when determining induction and maintenance immunosuppression needs.

FR-PO1005

Transplantation of Cadaveric Kidneys from Infants and Toddlers into Adults in the Era of Extreme Donor Shortage

Jimena A. Blandon, Nader Najafian, Neerja Agrawal, Nephrology, Cleveland Clinic Florida, Weston, FL; Nephrology, Cleveland Clinic Florida, Weston, FL; Nephrology, Cleveland Clinic Florida, Weston, FL.

Kidney transplantation is the treatment of choice for patients with ESRD. The number of patients in the waiting list for a deceased donor kidney transplant continues to increase. In this era of extreme donor shortage we present our experience with transplantation of cadaveric kidneys from infant and toddler into adult recipients.

Methods: This was a retrospective study of twelve adult deceased donor kidney transplant recipients from pediatric donors ages 0-5 years. Medical records were reviewed from visits previous to transplantation to the most recent follow up after transplant.

Results: Twelve consecutive adult patients were transplanted with pediatric en bloc kidneys from donors 0-5 years between February 2014 to February 2015. Ten of the donors were standard criteria brain death (DBD) and two were donors with cardiac death (DCD). KDPI scores ranged from 47 to 87% donor age from 6 months to 5 years, weight 6 to 15 Kg. Recipients were equally distributed by gender, average age 56 years, mean BMI 22. All patients were followed in average 6 months to 1 year. In the early post transplant period 9 recipients were noted to have glaucosuria with normal blood glucose and mild metabolic acidosis. These findings were noted on average up to 3 to 6 months after transplant and resolved thereafter. Nine patients had follow up renal ultrasound with finding of increase in kidney size 0.3 to 1.2 cm on average at 3-6 months in follow up. There were no perioperative complications, allograft failure, rejection, vascular complications or recurrence of the primary disease. The average serum creatinine remains at 0.89 to date.

Conclusions: We report excellent outcomes after adult kidney transplant from cadaveric donors ages 0 to 5 years of age. Younger age and low weight of the donors did not adversely effect our results. No vascular complications, rejection or allograft loss was noted. All of our patients have excellent allograft function 6-12 months post transplant.

FR-PO1006

The Role of Dobutamine Stress Echo in Identifying Cardiac Ischaemia, Cardiovascular Events and Role of Subsequent Cardiac Angiography

Maria Ventura, Robin Ramphul, Sami Firoozii, Juan Carlos Kaski, Rajan Sharma, Debasish Banerjee. Renal and Cardiology Depts, St. George’s Univ Hospitals NHS Foundation Trust.

Background: Dobutamine Stress Echo (DSE) is an established method of identifying cardiovascular (CV) risk in patients undergoing kidney transplantation, however the role of coronary angiography (CA) is not clear. The aim of this study was to investigate the role of DSE and CA in predicting cardiac ischaemia and CV events in this population.

Methods: We reviewed data on all patients, 92 out of 233, that were referred between 1/2/2012 and 31/12/2014 and underwent DSE on risk stratification according to our protocol.

Results: 92 high risk patients underwent DSE. 28 of 92 patients had a positive DSE (i.e. suggestive of myocardial ischaemia) and 6 of these 28 had an event (event rate 13% per year) whereas there were only 5 events amongst the 64 patients in the DSE negative group (event rate 5% per year) (figure 1; log rank p=0.13). There were no perioperative events. 23 of 28 patients with a positive DSE had a CA, 14 had significant (>50% stenosis) coronary artery disease (CAD) and another 3 had non-significant CAD (<50% stenosis). 7 of 14 patients with significant CAD had coronary stents; and 6 of 14 had events (event rate 26% per year). There was no difference in survival between the patients stented and those who were not (figure 2; log rank p=0.9).

Conclusions: DSE is a suitable method to stratify cardiovascular risk and predict significant CAD on CA, however subsequent PCI does not conclusively show decreased event rates. Larger studies are required to establish the role of revascularisation.

FR-PO1007

Racial Differences in Survival of Incident Home Hemodialysis and Kidney Transplant Patients

Miklos Zsolt Molnar, Vanessa A. Ravel, Elani Streja, Csaba P. Kovesdy, Rajnish Mehrotra, Kamyar Kalantar-Zadeh, Univ of Tennessee Health Science Center, Memphis, TN; Univ of California, Irvine, CA; Univ of Washington, WA.

Background: Previous studies have indicated that patients on maintenance dialysis have worse survival compared to kidney transplant (KTx) recipients. However, none of these studies have compared mortality in United States(US) patients using alternative dialysis modalities such as home hemodialysis(HD) with KTx recipients.

Methods: Comparing patients who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity-matched cohort of 4,000 patients and examined the association between treatment modality and mortality using Cox proportional hazard models.

Results: The mean±SD age of the matched home HD and KTx patients at baseline were 54±15 and 54±14 years, 65% were male (both groups), 70% and 72% of patients were white and 19% were African American (both groups), respectively. Over 5 years of follow-up, home HD patients had 4-times higher mortality risk compared to KTx recipients in the entire patient population (HR=4.06, 95%CI:3.27-5.04), and similar differences were found across each race stratum (Figure).

![Figure 1: Mortality rates in patients with DSE+](image1.png)

![Figure 2: Mortality rates in patients with DSE-](image2.png)

Survival of Elderly Incident Home Hemodialysis and Kidney Transplant Patients

Miklos Zsolt Molnar,1 Vanessa A. Ravel,2 Elani Streja,2 Csaba P. Kovestdy,1 Danh V. Nguyen,2 Rajnish Mehrotra,1 Kamyar Kalantar-Zadeh,2
1Univ of Tennessee Health Science Center, Memphis, TN; 2Univ of California, Irvine, CA; 3Univ of Washington, WA.

Background: The proportion of elderly (≥65 years) patients with kidney failure is increasing. Previous data suggest that the projected increases in the life spans of kidney transplant (KTx) patients compared to conventional dialysis were 2.8 and 1.1 years for patients aged 65-69 and 70-74 years, respectively. However, no studies have compared mortality of elderly patients using alternative dialysis modalities such as home hemodialysis (HD) with KTx recipients.

Methods: Comparing elderly patients, who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity score (PS) matched cohort of 960 elderly patients (480 KTx and 480 HD) and examined the association between treatment modality and all-cause mortality using Cox proportional hazard models.

Results: The mean±SD age of the PS matched home HD and KTx patients at baseline were 71.6 years and 71.5 years, 69% were male (both groups), and 81% and 79% of patients were whites in home HD and KTx group, respectively. Median follow-up time was 205 days (IQR: 78-364 days) for home HD patients and 795 days (IQR: 366-1,221 days) for KTx recipients. There were 97 deaths (20%, mortality rate 253 [297-309]/1000 PY) in the home HD group, and 48 deaths (10%, 45 [34-60]/1000 PY) in the KTx group. Over 5 years of follow-up, home HD patients had almost 5-times higher mortality risk compared to KTx recipients in the entire patient population (HR: 4.74, 95%CI:3.25-6.91). These results were consistent across different types of kidney donors and recipients characteristics.

Conclusions: Elderly home HD patients appear to have almost 5 times higher mortality compared to KTx recipients regardless of the type of kidney donor.

Beyond the Bones – The Association Between Vitamin D, Graft Outcomes and Vascular Disease

Aravind Chenukeri,1 Santhanarukrishnan Balasubramaniam,2 Rebekah Molyneux,2 Richard J. Baker,2 Univ of Pittsburgh; 3Univ of Leeds.

Background: Vitamin D deficiency in KTRs is an emerging theme. The purported associations between Vitamin D deficiency and various metabolic, cardiovascular and non-metabolic adverse events have not been thoroughly studied in kidney transplant recipients (KTRs).

Methods: Here, we examined the association between Vitamin D deficiency and graft loss, mortality, NODAT, cardiovascular events and development of cancers.

Results: 504 KTRs had their vitamin D checked in 2008 and were followed up for 6 years. Vitamin D deficiency was defined as a level<50nmol/L. In this population, the prevalence of vitamin D deficiency was high at 66.5% with a significantly higher prevalence in older (71.9% vs. 60.9%, P=0.006) and female recipients (male 62.1% vs. female 73.2%, P=0.06) and in relatively new transplants (recent transplants 72.3% vs. old transplants 66.6%, P=0.003). KTRs who were vitamin D deficient had significantly worse overall (77% vs. 59.9%, P=0.0001), death censored graft survival (89% vs. 96%, P=0.009), development of NODAT (19.8% vs. 10% P=0.005) and cardiovascular events (9.9% vs. 2.9%, P=0.002) when compared to those with normal levels. In a stratified analysis, this was noted to be worse in KTRs on maintenance steroids, with relatively worse baseline renal function and proteinuria, with secondary hyperparathyroidism, deceased donor transplants and earlier vs. late transplants. Although vitamin D deficiency is not associated with a higher incidence of malignancy, it is associated with higher mortality in those with cancer (33.3% VS. 12.9%, p=0.005). In a multivariate Cox model, vitamin D deficiency was associated with significantly worse overall graft (HR 2.7, P=0.001) and death censored graft survival (HR 2.4, P=0.04), NODAT (HR 2.3, P=0.03) and cardiovascular events (HR 4.0, P=0.004) independent of age, PTH levels, gender, graft number, type of transplant, time since transplantation, graft type and renal function measured by both proteinuria and eGFR.

Acute Tubular Necrosis Changes in Living Kidney Donor Implant Biopsy

Association with Higher Rejection Rates Post-Transplant

Chung-Yu Yu, Nissreen Elafady, Andres G. Chiesa-votto, Leal C. Hertzl, Emilio D. Poggio, Dept of Nephrology and Hypertension, Glickman Urological and Kidney Inst, Cleveland Clinic, Cleveland, OH.

Background: Ischemic injury may occur during organ retrieval. In deceased kidney donor transplants, delayed graft function, a form of acute tubular necrosis (ATN), associates with acute graft rejection. Histological changes consistent with ATN can also be seen in implant biopsies of living donors (LD). However, the influence of ATN-like changes at time on donation from LD on recipient graft outcomes is unclear, especially its impact on graft rejection.

Methods: We retrospectively studied all LD kidney transplants at our center from Jan 2005 to Dec 2014 who had an implant biopsy. We performed protocol biopsies at 3-6, 12, and 24 months post-transplant and for cause biopsies in all of our patients. Post-transplant biopsy results were reviewed, and patients with subclinical and clinical borderline and/or BanFF scored graft rejection were captured.

Results: The study included 350 LD kidney transplant recipients, the mean age was 47.8±13.7 years (range 10-75) and 224 (64%) were male. The incidence of ATN in implant biopsies was 16% (n=56). Patients with ATN had a trend toward higher risk of graft rejection in post-transplant biopsy compared with those without ATN (32.1% vs. 21.7%, p=0.09). When the study population was stratified by time from transplant to post-transplant biopsy, there was a statistically significant higher incidence of graft rejection in those biopsies performed between 1 and 24 months post-transplant (31.0% in the ATN group vs.17.8% in the non-ATN group, respectively, p=0.02). No statistical correlation was found between ATN and graft rejection and 24 months post-transplant. Importantly implant ATN has no impact on GF at 3, 6, 12, 24 months post-transplant.

Conclusions: Histological changes consistent with ATN in LD kidney implant biopsy are associated with higher rates of graft rejection between 1 and 24 months post-transplant. However, ATN does not affect graft function at 3, 6, 12, or 24 months.

FR-PO1011

Impact of Pre-Transplant Cardiovascular Risks on Renal Allograft Survival: A Multi-Center Prospective Study

Katherine A. Alington, Nichola Dawn Pugh, Chun Pin Ng, Yonh Song, Chunping Song, Eric An, Yvonne C. Hogendoorn, Yvonne C. Hogendoorn, Chunpin Ng, Christopher Yottero, Leal C. Herlitz, Emilio D. Poggio. 1Seoul National Univ Boramae Medical Center; 2Seoul National Univ College of Medicine; 3Yonsei Univ Wonju College of Medicine; 4Asan Medical Center and Univ of Ulsan College of Medicine, Republic of Korea.

Background: Cardiovascular (CV) disease is a leading cause of mortality in patients with end-stage renal disease. Even after successful renal transplantation, CV risks can induce CV morbidity and mortality in renal transplant recipients. However, the impact of pre-transplant CV risks on renal allograft outcomes has not been reported.

Methods: We analysed the graft outcomes of 2902 renal transplant recipients who were enrolled in a multi-center cohort from 1997 to 2012. We calculated pre-transplant CV risk scores by the Framingham risk model using age, sex, total cholesterol levels, smoking and diabetes. Pre-transplant CV risk was divided into tertiles for analysis. Post-transplant CV risk assessment was done using the BanFF classification system.

Results: The mean age of the patients was 55±17.4 years and 224 (64%) were male. The incidence of ATN in implant biopsies was 16% (n=56). Patients with ATN had a trend toward higher risk of graft rejection in post-transplant biopsy compared with those without ATN (32.1% vs. 21.7%, p=0.09). When the study population was stratified by time from transplant to post-transplant biopsy, there was a statistically significant higher incidence of graft rejection in those biopsies performed between 1 and 24 months post-transplant (31.0% in the ATN group vs.17.8% in the non-ATN group, respectively, p=0.02). No statistical correlation was found between ATN and graft rejection and 24 months post-transplant. Importantly implant ATN has no impact on GF at 3, 6, 12, 24 months post-transplant.

Conclusions: Histological changes consistent with ATN in LD kidney implant biopsy are associated with higher rates of graft rejection between 1 and 24 months post-transplant. However, ATN does not affect graft function at 3, 6, 12, or 24 months.

FR-PO1012

Blood Pressure (BP) Control in Kidney Transplant Recipients: A Single Centre Experience

Kristin Vibeke Vejheg, Jacqueline C. Nevol, Panagiotis Chondrogiannis, Amanda Jane Laird, Irene Synodinou, Doreen Zhu, Katherine A. Alington, Nichola Dawn Pugh, Chun Pin Ng, Gopalakrishnan Venkat-Raman. Wexsex Kidney Unit, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom.

Background: Cardiovascular disease is the leading cause of death among kidney transplant recipients (KTRs), however there remains uncertainty regarding optimal BP targets. Current UKRA, KDIGO and KDQI guidelines advocate BP control to 130/80 in KTRs; UKRA/KDIGO advocate tighter control (125/70) in proteinuric KTRs. We examined BP control and proteinuria in all KTRs under longterm follow up at one centre, and adherence to these recommendations.

Methods: As of 1 March 2015, 839 KTRs were attending for regular clinic review (excluding recent KTRs<1yr). We performed a retrospective database review of BP, proteinuria, renal function and antihypertensive use.

Results: The cohort was 60% male with mean allograft age 10±0.28 years. Mean decline in eGFR was 0.83ml/min/m² per year (p<0.0004). Mean SBP was 134±0.56, DBP 79±1.37. 48% had SBP<130, 62% DBP<80, 39% both. 76% received 1 antihypertensive, 42%±23, 4%±24 agents. Only 9% had PCR measured. In those with PCR<25, 19% had BP treated to 125/75. Dipstick proteinuria was recorded in 58% and showed a significant association with SBP (p=0.01). There were significant correlations between reducing eGFR and increasing PCR (R²=0.11, p<0.0001), and between PCR and ACE/ARB use (p=0.0002). There was no correlation between CNI level and BP (CNYa=0.88, FK506=0.49). There was a significant stepwise decrease in renal function (eCNYa=0.005, eGFR=0.01) and increase in dipstick proteinuria (p=0.03) when data were analysed in SBP groups <120, 120-140 and >140. In terms of DBP, the stepwise decrease in renal function remained (eCNYa=0.01, eGFR=0.0001) when data were analysed in groups<70, 70-90 and >90. DBP>90 had the most significant impact on eGFR. DBP was not associated with proteinuria.

Conclusions: The optimal BP target remains uncertain. Adherence to current guidelines is reasonable in our unit but could be improved. This study again demonstrates that SBP is the key risk factor for proteinuria, however increases in DBP >90 were most strongly associated with graft dysfunction.
of the present study was to evaluate the levels of IS in kidney transplant patients and their relation with biochemical parameters and hard outcomes (including mortality, cardiovascular (CV) events and graft loss).

Methods: In 311 consecutive kidney transplant patients, total and free IS levels were measured immediately before transplantation (T0) and then 1 month (M1) and 12 months (M12) afterwards. In a case controlled sub-study (n=90), IS levels in transplant patients were compared with those in non-transplant patients with chronic kidney disease matched for age, gender and estimated glomerular filtration rate (eGFR). Over a mean ± standard deviation follow-up period of 113 ± 29 months, 55 deaths, 70 CV events and 71 graft losses were recorded.

Results: We observed a rapid, consistent, significant decrease in IS levels after kidney transplantation. Majority of IS levels were below or near the normal value at M1 and M12. We did not observe a correlation between IS levels and eGFR at M1 and M12. Total and free IS levels at M12 were significantly higher in non-transplant patients (0.34±0.23 mg/dl and 0.04±0.007 mg/dl, respectively) than in transplant patients (0.21±0.17 mg/dl and 0.01±0.01 mg/dl; p=0.003 and <0.0001 respectively), despite having similar eGFRs. Lastly, IS levels were not associated with overall mortality, CV events or graft loss at T0, M1 or M12.

Conclusions: Free and total IS levels were significantly lower in transplant recipients than in non-recipients matched for age, gender and renal function - suggesting that kidney transplantation protects against an increase in IS levels in IS. Importantly, serum IS levels were not associated with hard outcomes at any of the three time points.

FR-PO1015

Background: In the general population, abdominal obesity is more closely associated with metabolic and cardiovascular (CV) risk than high BMI. The ideal measure of obesity to identify risk in pediatric kidney transplant (Tx) recipients, who have impaired growth and altered body composition, has not been established. In this prospective study we compared the ability of BMI, Waist Circumference (WC), and Waist-to-Height ratio (WHr) to identify metabolic and CV risk in pediatric kidney Tx recipients.

Methods: Kidney Tx recipients 3-20 years old and 0-30 months post-Tx had WC, BMI, WHr, blood pressure (BP), fasting lipids, leptin, HbA1c%, standard and speckle echocardiogram and carotid intima-media thickness (CIMT) measured. Patients were classified as obese or lean by 3 methods: WC (ATP cut-point males>94th%ile,females>84 th%ile), WHr(CDC cut-point=0.539), and BMI(2950%). Logistic regression determined associations of Groups with metabolic and CV risk factors.

Results: The study group comprised of 33 Tx recipients, age 13.6±0.3 years. Prevalence of obesity by BMI, WC, and WHr was 21.2%, 33.3%, and 48.5%. Prevalence of hypertriglyceridemia(TG) was 24.2%, high LDL 15.2%, low HDL 57.5%,high leptin 39.3%, high HbA1c% 12.1%,left ventricular hypertrophy(LVH) 30.3%, hypertension(HTN) 69.6%, and high CIMT48.4%. In all groups (WHr, WC, and BMI), obese children were more likely than lean to have HTN(OR4.5±2.2,3.6±p<0.01),LVH(OR5.4±7.4,8.8±p<0.001), low HDL(OR5.0±4.3,8.8±p<0.001), and high leptin(OR19.13.1,7.3±p<0.001). Obese children in WHr and WC groups, but not BMI group, had greater chance of high TG(OR4.5±3.2±p<0.01), high CIMT(OR2.0±4.5±p<0.05), and impaired myocardial strain(OR1.2,1.1±p<0.01). Five patients with short stature (height ± 2.56) and CV risk factors (3.0±0.5 factors/patient) were not identified as obese by WC criteria(height ±0.08±p<0.003).

Conclusions: WC and WHr are more effective than BMI for detecting metabolic and CV risk amongst pediatric Tx recipients. WC may underestimate prevalence of obesity in children of short stature, and therefore WHr may be a more sensitive method for identification of children with increased metabolic and CV risk in the kidney Tx population.

FR-PO1016

Background: Kidney transplant (KT) is the treatment of choice for end stage renal disease (ESRD). Knowledge of dialysis patients about the benefits of KT is an important determinant of their active engagement in the decision making process. We studied factors associated with patients’ knowledge about benefits of KT.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants fulfilling inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent variables included sociodemographic factors, distance to dialysis unit, and modes of education about options. In multivariate analysis, we calculated odds ratios (OR) and 95% confidence intervals (CI) for the probability of responding correctly to each of 4 questions about benefits of KT.

Results: 673 participants responded to questions about overall survival benefit of KT (correction: 32%), benefits of KT for diabetic patients (correct: 46%), for patients > 60 (correct: 29%) and for patients transplanted pre-emptively (correct: 17%). Receiving 3 or more modes of education about KT was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR:2.19;CI:1.50 to 3.20), survival benefits of KT for diabetics (OR:2.06;CI:1.39 to 3.01) and patients transplanted pre-emptively (OR:1.67;CI:1.06 to 2.64). White race was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR:1.59;CI:1.11 to 2.28) and the benefit of KT for patients > 60 (OR:1.54;CI:1.07 to 2.21). Age > 60 was associated with lower likelihood of correct response to the question about overall survival benefit of KT (OR:0.65;CI:0.45 to 0.94), benefits of KT for diabetics (OR:0.54;CI:0.38 to 0.77), and for patients > 60 (OR:0.64;CI:0.44 to 0.93). Patients on dialysis > 5 years were less likely to be aware of the benefit of KT for diabetics (OR:0.68;CI:0.48 to 0.98).

Conclusions: Dialysis patients’ knowledge about survival benefits of KT is rather limited. The most significant modifiable contributor to improvement in knowledge is diversity of modes of education about KT. Other factors include race, age and number of years on dialysis.

FR-PO1017
Pretransplant HbA1c Predicts New-Onset Diabetes After Transplantation Among Renal Transplant Recipients Jungh-Im Shin, Mari Palta, Arjang Djamali, Brad C. Astor. Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: New-onset diabetes after transplantation (NODAT) is a common complication among renal transplant recipients and is associated with a higher risk of cardiovascular events and poorer graft and patient survival. The association of pretransplant HbA1c with NODAT remains unclear. Identifying recipients at greatest risk of NODAT may help guide monitoring and treatment strategies to prevent or delay the onset of NODAT.

Methods: We assessed the association between pretransplant HbA1c and NODAT in 1522 non-diabetic recipients using data from the United States Renal Data System (USRDS) from 2004-2011. Cox proportional hazards models adjusted for demographics, cause of ESRD, year of transplantation, number of prior transplants, duration of pretransplant dialysis, comorbidities, lipid levels, hemoglobin level, body mass index, HCV and CMV serostatus, donor type and age, and HLA mismatch, and posttransplant steroid and tacrolimus use.

Results: Median HbA1c was 5.4% and 53.4% (39.9%) patients had HbA1c ≥ 5.7% (i.e., prediabetes) A total of 404 (26.5%) patients developed NODAT during a median follow-up of 1.7 years. Pretransplant HbA1c was associated with the risk of NODAT in a non-linear fashion. The adjusted hazard ratio (HR) associated with 1% higher pretransplant HbA1c was 0.94 (95% confidence interval (CI): 0.62, 1.42) for HbA1c lower than 5.4% and 1.87 (95% CI: 1.30, 2.68) for HbA1c higher than 5.4%.

Conclusions: Pretransplant HbA1c is independently associated with the risk of NODAT among renal transplant recipients. A continuous relationship between pretransplant HbA1c and the risk of NODAT suggests that greater risk starts at levels below the standard threshold for prediabetes.

FR-PO1018
Choice of Equation to Estimate Kidney Function Has Large Impact on Timing of Kidney Transplant Waitlist Qualification Benjamin J. Lee, Charles E. McCulloch, Elisabeth Elaine Allen, Sindhu Chandran, Chi-yuan Hsu. Medicine, UCSF, San Francisco, CA; Epidemiology and Biostatistics, UCSF, San Francisco, CA.

Background: Because mortality on the kidney transplant waitlist is high (4-6% per year), being placed on the waitlist earlier versus later has important clinical consequences. Per U.S. Organ Procurement and Transplantation Network (OPTN) rules, patients begin accruing time on the waitlist when renal function declines beyond a threshold defined as “measured (actual urinary collection) creatinine clearance level or calculated glomerular filtration rate (Cockcroft-Gault or other reliable formula) less than or equal to 20 mL/min”.

Methods: We assessed the relative performance of three commonly used kidney-function equations (Cockcroft-Gault, MDRD, and CKD-EPI). We first compared the equations mathematically to determine under what age and serum creatinine combinations each pair of equations yields discordant waitlist qualification statuses (i.e., a patient would qualify for the waitlist if one equation were used but not the other). We then applied the equations to serial creatinine measurements from three patient cohorts: one of waitlisted patients at a major U.S. academic center and two national, multicenter cohorts of CKD patients (the NIH-sponsored AASK and MDRD studies).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Results: Mathematically (assuming average weights), the Cockroft-Gault equation almost always yields higher numeric values compared with the MDRD and CKD-EPI equations. When applied to the three actual patient cohorts, Cockroft-Gault consistently disadvantaged patients, delaying average time to wait-list qualification by 1 to 2 years.

Conclusions: This study identified a potential source of significant inequity (on the order of 1-2 years) in wait-time accrual for kidney transplantation that stems from imprecise rules for wait-list qualification. The OPTN may need to revise the language in their kidney transplantation policies so that consistent methods to assess renal function are adopted and patients are not inadvertently disadvantaged.

New Onset Diabetes Has Unfavorable Effect on Patient but Not on Allograft Survival

Thomas Diememann,1,2 Naohiko Fuji,3,2 Roy D. Bloom,1,2 Harold L. Feldman,1 Yimei Li.1,2 Dept of Medicine, Perelman School of Medicine- Univ of Pennsylvania, Philadelphia, PA; 1Dept of Epidemiology and Biostatistics, Perelman School of Medicine, Philadelphia, PA; 4Dept of Renal Medicine and Hypertension, Univ of Erlangen, Erlangen, Germany.

Background: New onset diabetes after transplantation (NODAT) has been linked to higher rates of graft loss and shorter patient survival. More recent awareness of care, and changes in immunosuppression may have modified this association.

Methods: Retrospective single center analysis of 1427 (age>18) first time renal transplant recipients (KTR) without pre-transplant(Txp) diabetes. Patients with <1 year of follow up and those with allograft failure in the first year post-Txp were excluded. NODAT was defined as prescription of a glucose lowering medication 1 year after Txp. Cox models adjusted for mult: potential confounders were used to examine the relationship of NODAT with allograft and patient survival.

Results: The incidence of NODAT was 16.1%. Median follow up was 5.9 years(QR3.5-9.2) for allograft and 6.3(QR3.8-9.8) for patient survival. Age, BMI, non-white race and HCV were independently associated with NODAT (all p<0.01). Compared with KTRs without DM NODAT was not associated with an increased risk of overall graft failure (aHR1.15, CI0.86-1.52) or death censored graft survival (DCGS) (aHR1.12, CI0.73-1.71) in multivar. analysis. NODAT remained borderline significant after adj. for multiple other factors for patient survival (aHR1.39, CI1.00-1.91 p=0.49), but not for death with functioning graft (aHR1.34, CI0.89-2.02). The associations between NODAT and outcomes were not detectably different over time (p=0.095 for patient survival and p=0.25 for DCGS).

Conclusions: In this cohort of KTRs NODAT had no impact on graft survival but was indep. associated with reduced overall survival.

FR-PO1021

Role of Non-Invasive Cardiac Stress Studies During Assessment for Kidney Transplantation in Pre-Dialysis Recipients

Background: Non-invasive cardiac stress studies (NISS) are routinely undertaken during listing of patients for kidney transplantation. Although guidelines recommend NISS in high risk patients based on studies reported on patients on RRT. However role of NISS in pre-dialysis population is unknown. We analysed the role of NISS in listing process and impact on longer term outcomes.

Methods: Retrospective study of all patients undergoing assessment for kidney transplantation at our centre between 2009 and 2014. 695 patients were assessed, including 397 who were pre-dialysis (naïve to RRT).

Results: 306 (77.1%) patients underwent NISS (98% were myocardial perfusion studies). Baseline and outcomes during follow-up are below.

Only 3 patients with abnormal NISS (1% of all who had NISS) had flow limiting lesions, needing interventions (2CAEGB and 1PCI). At last follow up, compared to those with normal NISS, patients with abnormal studies a) were less likely to be listed for kidney transplantation, b) had increased cardiovascular events (p<0.01). But there was no significant difference in patient survival.
FR-PO1024

Associations of Serum Soluble α-Klotho, Fibroblast Growth Factor Factor 23, and 25 (OH) Vitamin D with Kidney Function and Left Ventricular Hypertrophy in Japanese Kidney Transplant Recipients. Makoto Tsujita,1 Shoichi Matuyama,1 1Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan; 1Nephrology, Nagoya Univ School of Medicine, Japan.

Background: Deterioration of kidney function and left ventricular hypertrophy (LVH) is crucial for kidney transplant recipients. Any marker for predicting kidney function and LVH is needed to prevent complications.

Methods: This was a retrospective cohort study. Forty-seven consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital in 2011.

Serum intact fibroblast growth factor (FGF) 23, soluble α-Klotho, and 25(OH) Vitamin D were measured to investigate the usefulness of these markers for predicting kidney function and LVH.

Results: The median serum sKlotho, intact FGF23, 25(OH)D were 516.3 pg/ml, 58.7 pg/ml, and 5.7 ng/ml, respectively. Serum sKlotho levels were lower after 4 years compared to baseline (25(OH)D > 0.34, p < 0.05), but not with difference between LVMI after 1 year and after 3 years (ALVMI). Patients were divided into two groups based on median serum FGF23 level. Higher serum intact FGF23 levels were associated with higher LVMI at 3 and 5 years (r = 0.34, p < 0.05), but not with DeFGF and ALVMI. Multivariate regression analysis revealed that serum sKlotho was the strongest predictor of kidney function and serum intact FGF23 was that of LVMI.

Conclusions: Serum sKlotho may be a good marker for kidney function and intact FGF23 for LVH in Japanese kidney transplant recipients.

FR-PO1025 Lower Frailty Risk but Fewer Kidney Transplants in Blacks: USRDS Special Study Data

Nancy G. Kutner, Rebecca H. Zhang, Janice P. Lea, Stephen O. Fastan, Rachel E. Patzer. Emory Univ, Atlanta, GA.

Background: Frailty, a measure of physiologic reserve, may indicate risk for adverse outcomes among kidney transplant (KT) recipients according to recent research. Non-frailty may therefore be a preferred characteristic of candidates for KT. Frailty status, age, race, and KT receipt were investigated during the 2009-13 USRDS study of a maintenance hemodialysis (MHD) cohort (ACTIVE-ADIPOSE study).

Methods: Frailty was assessed at study enrollment in 745 prevalent MHD patients (Atlanta and San Francisco areas; mean [SD] age = 57.1 [14.1]) using the Fried index (includes recent unintentional weight loss, reported exhaustion, low measured grip strength, slow measured walk speed, low reported physical activity; these indicators are both performance-based and patient-reported, and presence of 3+ criteria indicates frailty). Additional (1-2) frailty assessments were obtained annually for participants who remained on MHD post baseline. KT following most recent frailty assessment was monitored in the USRDS through February, 2013.

Results: Mean age non-frail vs frail was 60.7 ± 14.3 years, 54.2% were male, 3.8% were non-white, 14.3% were <65 years old, 32.2% were women. Among all non-frail patients <65 (n=115 whites and 358 blacks) in the study cohort, 10.7% of whites and 3.1% of blacks received a KT. However, a multivariable regression analysis, with adjustment for a large number of demographic, treatment and clinical variables, showed that blacks had lower odds for frailty compared with whites (OR 0.58; 95% CI 0.34-0.99; p = 0.04).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Background: Anemia and iron deficiency (ID) are highly prevalent in renal transplant patients (RTR). Anemia is associated with poor outcome, but the role of ID is unknown. Therefore, we aimed to investigate the association of ID, irrespective of anemia, with all-cause mortality in RTR.

Methods: In a previously defined cohort of RTR, with hemoglobin data available, we additionally assessed serum iron, transferrin and ferritin. ID was defined as transferrin saturation (TSAT)<20% and ferritin <300 ng/ml. Anemia was defined as Hb<13 g/dL (M) or <12 g/dL (F). Cox regression analyses were used to investigate prospective associations with all-cause mortality.

Results: We included 701 RTR (age 51±12 yrs, 56% men, 6.0 [2.6-11.6] yrs post-transplant). Baseline concentration of serum KYN was 1.8 [1.4-2.2] µmol/l, of that TRP was 40.0 [34.5-46.0] µmol/l, and KYN/TRP was 44.3 [35.0-57.9] µmol/mmol. In multivariable linear regression analyses, KYN/TRP was positively associated with proteinuria (β=0.17, P<0.001) and waist circumference (β=0.12, P<0.001), and inversely with eGFR (β=−0.54, P<0.001) and HDL-c (β=−0.14, P<0.001). During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR developed GF. In multivariable Cox-regression analyses, KYN/TRP was positively associated with GF (age, sex, eGFR, and proteinuria adjusted HR 3.6 [95% CI 1.3-9.9], P=0.01). Further adjustment for waist circumference and HDL-c did not materially change this association (HR 3.1 [95% CI 1.3-8.9], P=0.02).

Conclusions: IDO activity, as measured by KYN/TRP, is cross-sectionally associated with eGFR, proteinuria, waist circumference, and HDL-c. Prospectively, it is associated with increased risk for LGF after kidney transplantation. Increased ID activity may not only be a marker for LGF, but also an interesting target for intervention to prevent decline of renal transplant function leading to LGF.

FR-POI028
Indoleamine 2,3-Dioxygenase Activity and Late Graft Failure After Kidney Transplantation. Laura V. de Vries, Claude P. Van der Ley, Casper F.M. Franssen, Gerjan Navis, Stephan J.L. Bakker, Ido Peter Kema. Dept of Nephrology, UMCG, Netherlands; Dept of Laboratory Medicine, UMCG, Netherlands.

Background: Long-term graft survival after kidney transplantation remains a major clinical problem. Therefore, markers that allow for early identification of patients at risk for late graft failure (LGF) are urgently needed. Indoleamine 2,3-dioxygenase (IDO) catalyzes tryptophan along the kynurenine pathway. Recent studies found IDO activity associated with occurrence of acute rejection and renal function decline shortly post-transplant. We hypothesized that IDO activity could also be a marker for LGF after kidney transplantation.

Methods: We prospectively included outpatient renal transplant recipients (RTR) with a functioning graft >1 yr, between 2001-2003. Follow-up was recorded until May 2009. Death-censored GF was defined as return to dialysis or re-transplantation. Serum kynurenine (KYN) and tryptophan (TRP) were measured with LC-MS/MS. KYN/TRP was a widely accepted measure of IDO activity.

Results: We studied 562 RTR (age 51±12 yrs, 56% men, 6.0 [2.6-11.6] yrs post-transplant). Baseline concentration of serum KYN was 1.8 [1.4-2.2] µmol/l, of that TRP was 40.0 [34.5-46.0] µmol/l, and KYN/TRP was 44.3 [35.0-57.9] µmol/mmol. In multivariable linear regression analyses, KYN/TRP was positively associated with proteinuria (β=0.17, P<0.001) and waist circumference (β=0.12, P<0.001), and inversely with eGFR (β=−0.54, P<0.001) and HDL-c (β=−0.14, P<0.001). During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR developed GF. In multivariable Cox-regression analyses, KYN/TRP was positively associated with GF (age, sex, eGFR, and proteinuria adjusted HR 3.6 [95% CI 1.3-9.9], P=0.01). Further adjustment for waist circumference and HDL-c did not materially change this association (HR 3.1 [95% CI 1.3-8.9], P=0.02).

Conclusions: IDO activity, as measured by KYN/TRP, is cross-sectionally associated with eGFR, proteinuria, waist circumference, and HDL-c. Prospectively, it is associated with increased risk for LGF after kidney transplantation. Increased ID activity may not only be a marker for LGF, but also an interesting target for intervention to prevent decline of renal transplant function leading to LGF.

FR-POI027

Nephrology, Clinical Chemistry, Cardiology, UMCG.

Background: Anemia and iron deficiency (ID) are highly prevalent in renal transplant patients (RTR). Anemia is associated with poor outcome, but the role of ID is unknown. Therefore, we aimed to investigate the association of ID, irrespective of anemia, with all-cause mortality in RTR.

Methods: In a previously defined cohort of RTR, with hemoglobin data available, we additionally assessed serum iron, transferrin and ferritin. ID was defined as transferrin saturation (TSAT)<20% and ferritin <300 ng/ml. Anemia was defined as Hb<13 g/dL (M) or <12 g/dL (F). Cox regression analyses were used to investigate prospective associations with all-cause mortality.

Results: We included 701 RTR (age 51±12 yrs, 56% males at 8.1±7.5 years after renal transplantation). Mean Hb was 8.2±1.1 mmol/L, serum iron 15.3±6.0 µmol/L and ferritin 115 (55-222) µg/L. Prevalences of anemia, ID, and iron deficiency anemia (IDA) were 34%, 30%, and 13%, resp. During follow-up for 3.2±1.0 yrs, 81 (12%) of RTR died. In univariable analysis, ID was associated with mortality (HR 2.04 [95%CI 1.31-3.16], p<0.001, fig. 1). Furthermore, both anemia (1.72 [1.11-2.66], P=0.02) and IDA (2.43 [1.48-4.00], P=0.001) were associated with mortality. After adjustment for age, gender, BMI, eGFR and anemia, the association of ID with mortality remained (1.82 [1.16-2.85], p=0.009). In contrast, the association of anemia with mortality disappeared after adjustment for eGFR and ID (1.15 [0.71-1.86], P=0.57), while the association of IDA remained after adjustment for eGFR (1.83 [1.10-3.05], P=0.02).

Conclusions: ID is highly prevalent among RTR and is associated with an increased risk of mortality, independent of anemia. Since iron deficiency is a modifiable factor, correction of iron deficiency could be a target to improve survival.

FR-POI026
Circulating Inflammatory Cell Subsets Are Associated with Cardiac Function in Renal Transplant Recipients. Jill Neale, Danielle Richer-Potts, Maurice Dungey, Patrick Highton, N. Martin, Nicolette C. Bishop, Alice C. Smith.

Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; School of Sport, Health and Exercise Sciences, Loughborough Univ, United Kingdom.

Background: Cardiovascular (CV) disease is a major cause of mortality and morbidity in renal transplant recipients (RTRs). Systemic and vascular inflammation is paradoxically common despite immunosuppression and is an important non-traditional CV risk factor. Monocytes are heterogenous: the intermediate phenotype (CD14++CD16+) is particularly pro-atherogenic and pro-inflammatory compared to the classical phenotype (CD14++CD16-). Regulatory T-cells (Tregs) maintain peripheral tolerance and minimise tissue damage. This study aimed to explore the association of circulating inflammatory cell subsets with cardiac function in RTRs.

Methods: 18 stable RTRs (Mean age 55 years, 61% male) and 5 healthy controls participated. Blood monocytes and T cells were analysed by flow cytometry, and cardiac hemodynamic function measured by bioreactance (NICOM).

Results: Circulating pro-anti-inflammatory cell subsets differed significantly in RTRs and controls. Mean %SEM intermediate monocytes was higher in RTRs (7.2±0.8) vs controls (3.2±0.5), P=0.01, while classical monocytes and TReg were lower in RTRs (83.2±1.3 vs 88.9±1.6), P=0.03 and 2.8±0.2 vs 5.0±1.0, P=0.001 respectively. In RTRs, % intermediate monocytes was inversely correlated with stroke volume (SV: r=−0.48, P=0.05) and cardiac output (CO: r=−0.52, P=0.03) and positively correlated with total peripheral resistance (TPR: r=0.50, P=0.04), while the opposite was seen with % classical monocytes (SV: r=0.56, P=0.02; CO r=0.62, P=0.006; TPR r=−0.54, P=0.02).

Conclusions: Our results reveal a significant bias towards pro-inflammatory circulating leukocyte subsets in RTRs (increased intermediate monocytes, reduced classical monocytes and TRegs), which likely promotes an atherogenic environment. Furthermore, the observed significant correlations between pro- and anti-inflammatory monocyte subsets and indices of cardiac function strongly support an important pathogenic role for these cell subsets, which represent a potential therapeutic target in this vulnerable population.

Funding: Private Foundation Support
Methods: A total of 2,779 adult recipients who underwent pretransplant echocardiography from 1997 to 2012 were evaluated. We divided the patients into two groups by two different categories: LVDD grade 0-1 vs. 2-3, and LA size<38 mm vs. >38 mm. Post-KT fatal/non-fatal acute coronary syndrome (ACS), graft failure (GF), and all-cause mortality was evaluated.

Results: During a mean follow-up of 4.5 years, fatal/non-fatal ACS was occurred in 49 (1.8%) patients. A total of 231 (12.4%) patients experienced GF and 116 (6.2%) died. The recipients with LVDD grade 2-3 (P<0.005) and LA (P<0.001) showed higher occurrence of fatal/non-fatal ACS after KT. Graft failure and all-cause mortality was not significantly different between the groups depending on both the LVVD grades and LA size. In a multivariate analysis, increased age (P<0.001), previous history of CV event (P<0.001) and LVDD of grade 2-3 (hazard ratio[H(R)]:2.98, 95% confidence interval[CI]:1.535-5.787;P<0.001), and LA(EH:1.052, 95%CI:1.006-1.101;P=0.025) were associated with ACS. However, none of LVVD and LA was significantly associated with mortality and GF in a multivariate analysis.

Conclusions: In patients of KT candidate, pretransplant LVVD and LAE were independently associated with high occurrence of ACS after KT.

FR-PO1030
Effect of Dietary Sodium Restriction on Blood Pressure and Urinary Protein Excretion in Renal Transplant Recipients on RAAS-Blockade
Laura V. de Vries,1 Linn Charlotte Dobrowolski,2 C.T.P. (Paul) Krediet,2 Frederike J. Bemelman,3 Stephan J.L. Bakker,2 Gerjan Navis,1 1Depart of Nephrology, UMCG, Netherlands; 2Renal Transplant Unit, AMC, Netherlands.

Background: In CKD patients on RAAS-blockade, it is well established that dietary sodium restriction exerts renoprotection by reduction of blood pressure (BP) and by reduction of urinary protein excretion (UPE). which is partly independent of BP. In renal transplant recipients (RTR), the effect of sodium restriction is not well documented. We therefore studied the effects of dietary sodium restriction on BP and UPE in RTR.

Methods: We performed a randomized, cross-over trial in stable outpatient RTR with a mean time on dialysis ≥30 months, KTR independent of ≥5 years, and use of RAAS-blockade. Exposures consisted of a 6-week regular sodium (RS) diet (target: 150 mmol/24h) and 6-week low sodium (LS) diet (target: 50 mmol/24h). End points were BP, UPE, urinary albumin excretion (UAE), and eGFR at the end of each diet period. Dietary compliance was assessed by 24h urine sodium excretion.

Results: We randomized 23 RTR, of which 22 RTR (age 58±10 yrs, 50% men, eGFR 51±21 ml/min) completed the study. One patient dropped out, due to orthostatic complaints on the LS diet. Sodium intake was 156 [130-193] vs. 68 [55-86] mmol/24h on RS vs. LS diet. Sodium restriction significantly reduced systolic and diastolic BP. In a multivariate analysis, sodium restriction was associated with a decrease of 24h SBP (β: -14±8 mmHg; P<0.001) and DBP (β: -8±4 mmHg; P<0.001).

Conclusions: Dietary sodium restriction effectively reduces BP in stable RTR on RAAS-blockade, but, at variance with findings in CKD, has no material effect on UPE or eGFR.

FR-PO1031
Individual Blood Calcification Propensity in a Cohort of Renal Transplanted Patients
Carlo M. Alfieri,1 Andreas Pasch,1 Anna Regalia,1 Maria Meneghini,1 Maria Teresa Gandolfo,1 Valentina Binda,1 Deborah Mattinolzi,1 Masami Iketcha,1 Piergiorgio Messa.1 1Nephrology, Dialysis and Renal Transplantation, Fondazione IRCCS Cu Granda Ospedale Maggiore Policlinico, Milan, Italy; 2Nephrology, Hypertension and Clinical Pharmacology, Univ Hospital and University of Bern, Switzerland.

Background: Vascular calcifications and related cardiovascular disease have a strong impact in kidney transplant recipients (KTx). Calciprotein participates in maturation time (T50) is a new measure of individual blood calcification propensity. Our aim is to explore in a cohort of KTx patients: 1) the levels of T50 and their modifications during the 1st year of KTx; 2) the relationship between T50 and routine clinical and biochemical parameters; 3) the relationship between T50 and bone mineral density (BMD) and aortic calcification (ACI).

Methods: 70 KTx pts (M=38, Age:48±12 yrs), transplanted between 2005 and 2009 were recruited. Along with T50 evaluation, routine clinical and biochemical parameters and FGF-23,OPG, fetuin-A and 25-(OH)-Vitamin D were tested at 1,l6 and 12mth after KTx. At 1st month transp, femoral DEXA Y-axis absorbometry and vertebral column X-ray for BMD(cm²) and ACI (kauppli) evaluation were performed. T50(min.) was determined using a Nephelostar nephelometer (BMG, Labtech, Offenburg, Germany) in the laboratory of one of the authors.

Results: T50 at 16th and 12mth were of 243[72-283], 218[79-275] and 227[79-279] yrs, with a reduction of T50 at the 12mth of KTx (P=0.04). In multivariate analysis, T50 was influenced by uric acid and fetuin-A (116 mth: p=0.02, and 0.001), by alkaline phosphatase, fetuin-A and 25-(OH)-Vitamin D (6th mth: p=0.01, p<0.001 and p=0.03 respectively), and by estimated glomerular filtration rate, body mass index and 25-(OH)-Vitamin D (D12th mth: P=0.01, p=0.03 and 0.01 resp). Both at baseline and at 12mth of KTx a direct correlation between BMD and T50 was demonstrated (p=0.002, p=0.04 respectively).

Conclusions: The main results of our study are that 1) the 1st year of KTx,T50 decreases significantly, and 2) there is a strong and direct relation with Fetuin-A and 25OH vitamin-D both implicated in bone vascular axis,3)T50 is associated with BMD but not of ACI status.

FR-PO1032
Prediction of Acute Rejection in Kidney Transplant Recipients Using a Multicenter Cohort
Kyoung Don Yoo,1 Jyunhuy Noh,2 Hajong Lee,1 Dong Ki Kim,1 Chun Soo Lim,1 Young hoon Kim,1 Yon Su Kim,1 Gunhee Kim,2 Jung Pyo Lee.1 1Seoul National Univ College of Medicine; 2Seoul National Univ College of Engineering; 1Eulsan Univ College of Medicine.

Background: More than 20% of kidney transplant recipients (KTR) are likely to have rejection episode, which is associated with graft loss. However, the impact of risk factors on acute rejection had not been well clarified. Here, we aimed to build new prediction models through considering variables related to immunologic and non-immunologic factors using machine learning methods.

Methods: This multicenter cohort study included adult KTR admitted to 2 major experienced tertiary hospitals in Korea between 1997 and 2014. A total of 3,117 KTRs were enrolled. Biopsy-proven acute rejection (BPAR) of these recipients were investigated by the individual learners such as decision tree, logistic regression, and ensemble learners such as random forest.

Results: We analyzed 2,045 recipients' records, with more than 50 attributes. Among them, we developed a modified Charlson comorbidity index (CCI) in renal allograft recipients (mCCI-KT), thereby improving risk stratification for mortality. In the decision tree model for the prediction of BPAR after three years of KT, HLA DR mismatch was found to be the most important predictor. In the case of HLA DR mismatch, donor specific antibody (+) predicted in 66.6% of BPAR incidence at three year after transplantation, and also posttransplant infection episode showed significant association with BPAR. In the case of HLA full matched, old age with heavy weighted recipient showed high probability of BPAR (71.4%). The final modeling represent AUC performance 0.670 (logistic regression) and 0.665 (random forest) in the BPAR prediction.

Conclusions: In this study, machine learning modeling could present an accurate and versatile tool for forecasting probability of having BPAR episode during the early years following the transplant.

FR-PO1033
Prediction of Long-Term Prognosis of the Kidney Transplantation Using Comorbidity Score
Jae Yoon Park,1 Eunjin Bae,2 Sejoong Kim, Dong Ki Kim,1 Chun Soo Lim, Kwon Wook Joo, Yun So Kim, Jung Pyo Lee.1 Seoul National Univ College of Medicine, Seoul, Korea.

Background: Comorbidity assessment is important to the informed interpretation of kidney allograft outcomes. Weights assigned to comorbidities to predict survival may vary based on the type of index disease and advances in the management of the comorbidities. We developed a modified Charlson comorbidity index (CCI) for renal allograft recipients (mCCI-KT), thereby improving risk stratification for mortality.

Methods: A total of 3,765 recipients in multicenter cohort were included to develop comorbidity score. The weights of comorbidities per the CCI were recalibrated using a Cox proportional hazards model. The modified score was validated in an independent nationwide cohort (n=1,538).

Results: The Cox proportional hazards model revealed that peripheral vascular disease, mild liver disease, and diabetes with end-organ damage in the CCI significantly predicted mortality. Thus, the mCCI-KT included 3 comorbidities with recalibrated severity weights. In the validation cohort, both the CCI and the mCCI-KT were correlated with mortality. Thus, the mCCI-KT included 3 comorbidities with recalibrated severity weights.

Conclusions: In this study, machine learning modeling could present an accurate and versatile tool for forecasting probability of having BPAR episode during the early years following the transplant.

FR-PO1034
Patient Uncertainty Regarding Kidney Transplantation Associated with Length of Dialysis prior to Transplant Evaluation
Laura J. McPherson,1 Mohua Basu,1 Stephen O. Pastan,1 Sumit Mohan,2 Rachel E. Patzer.1 1Emory Univ, Atlanta, GA; 2Columbia Univ, New York, NY.

Background: End stage renal disease (ESRD) patients’ uncertainty about undergoing kidney transplantation (KTx) ---i.e., decisional conflict---may be affected by cumulative time spent on dialysis prior to KTx evaluation. We aimed to investigate the association between time from dialysis start to KTx evaluation and decisional conflict.

Methods: In an ongoing clinical trial of study patients measuring the effectiveness of a shared decision tool at a single KTx center, ESRD patients were asked 10 questions assessing decisional conflict related to KTx, with possible scores ranging from 0 (none)}
J.L. Bakker. in RTR. High Hp was also associated with mortality, but this association largely depended

FR-PO1035

Hatpoglobin and Long-Term Outcomes in Renal Transplant Recipients

Isidor Minovic, 1 Ineke J. Riphagen, 1 Else van den Berg, 1 Jenny E. Kootstra-2, 2 Ido Peter Kema, 3 Andy P. Levy, 4 Johanna M. Geleijnse, 5 Gerjan Navis, 6 Stephan J.L. Bukkert, 2 *Nephrology, UMCG, Netherlands; 2Laboratory Medicine, UMCG, Netherlands; 3Medicine, Technion, Israel; 4Human Nutrition, Wageningen Univ, Netherlands.

Background: Haptoglobin (Hp) is a hepatocyte-derived protein that protects against oxidative damage by binding free hemoglobin (Hb). Being an acute-phase protein, Hp is upregulated by inflammation. We hypothesized that both low and high Hp are risk factors for all-cause mortality and graft failure in renal transplant recipients (RTR).

Methods: Hp was measured using a turbidimetric immunoassay in a well-characterized prospective RTR cohort. Cox regression analysis was used to assess the association of Hp with endpoints.

Results: We included 707 RTR (57% male, age 53.1±13.3 years, 35% had hypertension; the average age was 51 years. Patients with any decisional conflict (65%) were more likely to have decisional conflict, respectively.

66% had hypertension; the average age was 51 years. Patients with any decisional conflict (65%) were more likely to be male and African American in addition to having lower literacy and numeracy scores. Crude logistic regression showed that, compared to patients who had never been on dialysis prior to KTx evaluation, patients on dialysis for <1 year and >1 year evaluation were 1.4 (95% CI: 0.4, 4.9) and 2.5 (95% CI: 0.7, 9.2) times more likely to have decisional conflict, respectively.

Conclusions: Results suggest that longer time on dialysis prior to KTx evaluation may be associated with decisional conflict regarding KTX. Identifying characteristics of patients with longer time on dialysis prior to KTx evaluation could help inform intervention efforts to improve patients' abilities to make decisions about treatment of their kidney disease.

Pre-Transplant Mental Health Disorders and Non-Adherence and Post-Transplant Outcomes in Kidney Transplant Recipients

Background: Mental health disorders (MH) and non-adherence (NA) have been associated with lower access to kidney transplantation (KT) and poorer clinical outcomes.

We examined the relationship between history of MH problems, NA, and post-transplant outcomes (i.e., biopsy proven acute rejection: BPAR, death censored graft failure: DCGF, or total graft failure: TGF).

Methods: This was a single-centre retrospective cohort study of adult patients transplanted at our KT program from July 1, 2004 and Dec 31, 2012, and followed up until June 30, 2014. Patients with complete information about pre-transplant MH problems or pre-transplant history of NA in their medical record (n=955) were included. A multivariable model including HLA-matching and mismatching adjusted for key covariates.

delayed graft function (DGF) using Cox-regression and logistic regression in a combined year death censored graft survival (DCGS), 1 year clinical acute rejection (1y-AR), and year death censored graft survival. Biopsies were classified according to Banff’09 criteria and DSA by Luminex SAB.

Conclusions: A positive pre-Tx FCXM is related to a higher incidence of ABMR in the first year after Tx and to worse graft survival, and did not influence patient survival.

FR-PO1038

HILA Profile and Short and Long Term Outcomes in African American Donors and Recipients

Rabi Acoub, Girish N. Nadkarni, John C. He, Paolo Cravedi, Rebecca L. Kent, Ioannis Konstantinidis, Karen Lok yee Keung, Sander Florman, Peter S. Heeger, Barbara T. Murphy, Madhav C. Menon. Mount Sinai, NY.

Background: We have previously reported the apparent greater impact of HLA-matching on both early allograft events as well as graft survival in the United Network for Organ Sharing database (UNOS). Here, we specifically studied the influence of HLA-matching and mismatching on allograft outcomes among African American (AA) recipients and AA donors in deceased donor kidney transplantation (DDKT).

Methods: We utilized data from the UNOS database (1995 – 2012), and analyzed 10 year death censored graft survival (DCGS), 1 year clinical acute rejection (1y-AR), and delayed graft function (DGf) using Cox-regression and logistic regression in a combined multivariable model including HLA-matching and mismatching adjusted for key covariates.

We performed sensitivity analysis using a subgroup of DDKT patients after 2003 with less than 10 years post-transplant. We also stratified patients into 3 groups: HLA-A, B, DR mismatched, with varying degrees of HLA-A, B, DR matching.

Conclusions: History of pre-transplant mental health disorders or non-adherence are not associated with poor post-transplant outcome in a select group of patients who are cleared for transplantation. Patients with such problems should have equal access to kidney transplantation compared to patients with no MH problems.

FR-PO1036

Pre-Transplantation Flow-Citometry Crossmatch Can Be a Predictor of Outcome when Donor-Specific Antibodies Are Present

Anna Rita Aguirre, Patricia Soares Souza, Gilcise Oliveira Bezerra, Flavio Jota Paula, Elias David-Neto, Maria cristina R. Castro. Renal Transplant Service, Hospital das Clínicas - Univ Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background: Clinical relevance of pre-transplant (Tx) donor-specific-antibodies (DSA) detected by single antigen beads (SAB) when pre-Tx CDC-AHg crossmatch (XM) is negative is still unclear. The aim of this study was to evaluate the importance of a positive flow-citometry-XM (FCXM) in patients with DSA over patient and graft survival.

Methods: Retrospective study, performed between Jan09 and Dec13 evaluating FCXM influence on antibody-mediated rejection (AMR) incidence, and over graft and patient survival. Biopsies were classified according to Banff’09 criteria and DSA by Luminex SAB.

Results: From 2009-2013, 1002 kidney transplants (Tx) were performed in our center. 261(26%) were sensitized (PRA>0%) and 87 (8.7%) presented pre-Tx DSA. 60 (69%) of them had FCXM performed with serum collected before transplantation: 22 (36%) positive and 38 (64%) negative. There was no difference between the highest DSA-MFI between Tx with positive or negative FCXM [FCXM+ 5580 (1046-15360) vs FCXM- 3120 (597-14600)], or between the sums of all DSA-MFI of each patient between these groups [FCXM+ 104,747 (597-15196) vs FCXM- 247 (597-15196)]. In the first year, KTx had a significantly higher incidence of ABMR than DSA–/ FCXM– [FCXM+ 12 (54.5%); FCXM– 9 (23.7%); p = 0.024]. After a median follow-up time of 30 mo, graft survival (GS) between Tx with positive and negative FCXM differed significantly (41% vs 92%: p < 0.001). Among patients with ABMR, FCXM+ had worse graft survival then FCXM+ 25% vs FCXM– 90%; p = 0.011. Patient survival did not differ between FCXM+ (82%) and FCXM– (95%) neither was affected by ABMR.

Conclusions: Positive pre-Tx FCXM is related to a higher incidence of ABMR in the first year after Tx and to worse graft survival, and did not influence patient survival.

Femoral Bone Mineral Density Is Related with Aortic But Not With Coronary Calcifications in KTX Patients. Carlo M. Alifrangis, Anna Regalia, Maria Meneghini, Maria Teresa Gandolfo, Valentina Binda, Masami Ikehata, Deborah Mattinzoli, Piergiorgio Messi. Nephrology, Dialysis and Renal Transplantation, Ospedale Maggiore Policlinico, Milan, Italy.

Background: Our study wants to evaluate in a cohort of kidney transplanted(KTX) patients,undergone to femoral DXA:1)the prevalence of bone mineral anomalies;2)the factors related to femoral bone mineral density(f-BMD) 3)the relationship of f-BMD with aortic calcifications(ACI) and coronary calcifications(CAC).Lumbar DXA was not considered to avoid confounders between abdominal vascular calcifications(VC) and BMD.

Methods: 293pts(M=170) transplanted in our Unit(2004-2014) were evaluated.Clinical and routine biochemical exams(plus PTH,FGF-23,Fetuin and VitD) were tested at 1(T0) and 2(T1)pts of KTxs.At the same time,DXA,lumbar X-ray(193pts) and coronary tomography(60pts) for f-BMD(cac),ACI(Kauppila) and CAC(Agatson) evaluations were performed.AC1 increase(AC1-Prog):any increase in AC1.Presence of CAC(CAC+) Agatson score >400,CAC increase(CAC-Prob):assessed using Sevrukov formula.

Results: At T0 and T1,OPN in 53%and 52%,OPR in 15% and 12% of pts resp.F-BMD was associated with age,alkaline phosphatase(ALP) at T0 and T1), fetuin and P at T0).A logistic regression with BAbn(OPN+OPR as a whole)as dependent variable confirmed was associated with:age,alkaline phosphatase(ALP) (at T0 and T1), fetuin and P (at T0).A

Conclusions: Our analysis in this large cohort reports for the first time the absence of any effect from HLA-matching or –mismatching on allograft outcomes among AA-donor kidneys. These findings suggest that the allocation algorithm for AA-donor organs may need to be re-evaluated without including HLA-match status.

FR-PO1040

Relationship Between Pre-Transplant Physical Function and Quality of Life following Kidney Transplant Elizabeth C. Lorenz, Andrea L. Cheville, Walter K. Kremers, Fernando G. Cosio, Nathan Lebrasseur. Mayo Clinic, Rochester, MN.

Background: Decreased physical function predicts adverse outcomes following non-transplant surgery. The goal of this study was to assess whether pre-transplant physical function predicts impaired quality of life (QOL) following kidney transplant.

Methods: We conducted a prospective cohort study involving all recipients of living donor kidney transplants at our center from 2012 until 2014. Physical function was measured using the Short Physical Performance Battery (SPPB), a composite measure of gait speed, balance and chair rise time (score range 0-12, with higher score indicating better physical function). QOL was measured 12-months post-transplant using the Short Form 36 Health Survey (SF36) with standardized scores adjusted for age and gender. Below-average physical and mental QOL was defined as physical (PCS) and mental component summary scores (MCS) < 45, respectively.

Results: Among the cohort of 140 patients, mean age was 51 ± 15 years. 61% were male. 91% were Caucasian, 21% had diabetes and 26% had a pre-transplant SPPB score < 12. A pre-transplant SPPB score < 12 was associated with a significantly lower 12-month PCS score (48 ± 9 vs 51.6 ± 8.5, p=0.04) but not a lower MCS score (54.2 ± 9.4 vs 55.2 ± 8.4, p=0.90).

Conclusions: Below-average physical QOL at 12-months was observed in 23% of patients and was associated with pre-transplant BMI (OR 1.12 per 1 kg/m² increase, CI 1.02-1.23, p=0.02) as well as a lower F-BMD (OR 1.16 per 10 years lower f-BMD, CI 1.09-1.23, p=0.02). In contrast, pre-transplant diabetes, dialysis, maintenance steroids and 12-month eGFR were not associated with decreased physical QOL.

FR-PO1041

Conclusions: Decreased pre-transplant physical function predicts impaired physical QOL one year after kidney transplant. Further studies are needed to determine whether physical rehabilitation interventions can improve post-transplant QOL.

Funding: Private Foundation Support

FR-PO1042

Background: Midodrine is increasingly prescribed to decrease the severity and complications of hypotension in dialysis patients. The impacts of midodrine use before kidney transplantation on graft and patient outcomes early after transplantation are not well described.

Methods: We analyzed linked national U.S. transplant registry, pharmacy records and Medicare claims data to follow 16,322 kidney transplant recipients (2005-2008), of whom 308 (1.9%) had filled midodrine prescriptions in the year prior to transplantation. We examined associations of midodrine use with graft, graft survival and death as reported to the registry, and with clinical complications captured in Medicare claims.

Conclusions: The KOTRY is expected to provide infrastructures for research in the field of KT and invaluable data for the Asian organ transplantation field.

**Comorbidity Burden of Kidney Transplant Recipients Predicts Emergency Usage Despite increased Family Physician Visits**

**Background:** Kidney transplant (KTX) recipients utilize many aspects of the healthcare system, especially emergency (ER) visits. Untermann et al showed that within a four year period, 378 KTX recipients generated 828 ER visits. This study aims to understand factors leading to ER usage by KTX recipients.

**Methods:** This is a single center retrospective study in conjunction with patient questionnaire, collected from March 2012 - 2013. The questionnaire inquired the frequency of the family physician (GP) visits and ER usage within the past year. Patient demographics and comorbidities were collected from chart reviews. Univariate logistic regression was used to define factors that are predictive of ER use. Significant covariates were then used in multivariate backward stepwise logistic regression model to predict ER visits.

**Results:** Number of GP visits (OR = 1.6, p = 0.003), diabetes (OR = 1.7, p = 0.016), coronary artery disease (OR = 2.5, p = 0.001), below knee amputation (OR = 4.3, p = 0.037), and number of comorbidities (OR = 1.35, p = 0.001) significantly predict ER visits. Number of transplant clinic visits does not significantly decreased ER visits (p = 0.32). By multivariate backward stepwise logistic regression, number of GP visits (OR = 1.5, p = 0.007) and coronary artery disease (OR = 2.1, p = 0.011) remain significantly predictive of ER use.

**Conclusions:** This single center study showed that KTX recipients with more comorbidities have increased ER usage, particularly coronary artery disease, despite higher frequency of GP visits. However, kidney transplant recipients with more ER use are not seen more frequently by our transplant clinic. The results suggest that KTX recipients with higher comorbidity burden may need to be followed more closely by transplant clinics, rather than relying on GP's, to improve effective usage of ER visits.

**Stroke Predictors and Outcome in Renal Transplant Recipients**

**Background:** End-Stage renal disease is associated with a high incidence of cerebrovascular disease. Conventional risk factors do not always apply & establish predictive strategies may be ineffective. The incidence, predictors & outcomes following stroke in those with a functioning renal transplant is not well described.

**Methods:** All adult patients with a renal transplant attending Glasgow Renal and Transplant Unit between 1st Jan 2007 and 31st Dec 2012 were identified using the electronic patient record. Clinical, demographic & laboratory data were collected including presence of diabetes, cardio- or cerebrovascular disease (CeVD), atrial fibrillation, deprivation, serum renal and bone chemistry and use of immune suppressants. Stroke was identified via discharge codes, cerebral imaging or death certification. Independent predictors of stroke were identified via multivariable regression analysis. Fatality & causes of death are presented.

**Results:** 636 patients were identified, mean age 38 years (SD 12.9). 60.5% were male and 9.1% had AF. During follow-up 7.1% received a transplant as first RRT modality. 24 patients experienced a stroke during 3455 patient years of follow-up. 83.3% were ischemic. Stroke incidence was 6.9/1000 patient years for all stroke and 3.76/1000 patient years for first stroke. A stepwise backward regression revealed predictors of stroke as older age (HR 1.05, p = 0.025) and previous CeVD (HR 18.16, p = 0.001). Significant independent predictors for first stroke were age, diabetes and AF (p = 0.005). There were no cases of SAH in PCKD. AF associated with time to stroke (p = 0.003), but there was no detectable benefit from use of warfarin. 134 died during follow-up. 62.5% deaths followed stroke with 7, 28 and 365 day fatality of 20.8, 25 and 45.8%. Cardiovascular (75%) or malignancy (13%) were the cause of death in most cases.

**Conclusions:** Renal transplant recipients have a high incidence of stroke and poor outcome following stroke. Risk factors include prior CeVD, age, diabetes and AF. Although AF associated with time to stroke, the role of warfarin in prevention is poorly defined, requiring further study.

**FR-PO1043**

**Impact of Proton Pump Inhibitors on Hypomagnesemia and Arterial Stiffness in Renal Transplant Recipients**

**Background:** Hypomagnesemia predicts cardiovascular morbidity and mortality in the general population and accelerated loss of kidney function in renal transplant recipients (RTRs). Proton pump inhibitors (PPIs) or H₂ receptor blockers (H₂RBs) are frequently used agents after RT. The aim of this study was to evaluate the effects of PPIs on serum magnesium levels and arterial stiffness in RTRs.

**Methods:** We performed a retrospective study of 354 maintenance RTRs (mean age: 38.6 ± 10.7 years) with stable allograft function who had received their transplant at least 36 months previously. All acute cellular and humoral rejections were excluded. According to using stomach-protecting agents (SPAs), patients were divided in to three groups: PPIs (Group 1, n: 164), H₂RBs (Group 2, n: 96) and control group who don’t receive SPAs to using stomach-protecting agents (SPAs), patients were divided in to three groups: PPIs (Group 1, n: 164), H₂RBs (Group 2, n: 96) and control group who don’t receive SPAs. Proton pump inhibitors (PPIs) or H₂ receptor blockers (H₂RBs) are frequently used agents after RT. The aim of this study was to evaluate the effects of PPIs on serum magnesium levels and arterial stiffness in RTRs.

**Results:** Levels of serum magnesium levels were significantly lower in group 1, however similar in group 2 and 3 (1.5 ± 0.04 mg/dl, 1.7 ± 0.02 mg/dl and 1.7 ± 0.01 mg/dl, respectively). PWV values were significantly higher in group 1, whereas similar in group 2 and 3 (7.3 ± 0.2 cm/sec, 6.3 ± 0.1 cm/sec and 6.2 ± 0.1 cm/sec, respectively). In linear regression analysis, the use of SPAs (p = 0.001), serum calcium (p = 0.031), magnesium (p = 0.07) and folic acid levels (p = 0.013) were detected as the predictors of PWV.

**Conclusions:** We concluded that PPIs inhibit magnesium absorption independent from calcium metabolism in RTRs. Moreover, PPIs lead to increased arterial stiffness and cardiovascular risk in RTRs. Thus physicians should be aware of the side effects of PPIs to scale down the cardiovascular morbidity and mortality.

Factors Influencing Racial Disparities in Renal Transplantation Outcomes
Sumit Mohan,1 Barry I. Freedman,2 William Mark Brown,3 Stephen O. Pastan,3 Ajay K. Israni,1 David P. Schladi,1 Robert S. Gaston,4 R. Bray,1 Amber M. Reeves-Daniel,3 Bruce A. Julian,2 Jasmin Divers,2 Columbia Univ; Wake Forest School of Medicine; Emory Univ; Univ of Minnesota; Minneapolis Medical Research Foundation; Univ of Alabama at Birmingham.

Background: Kidney transplants from African American (AA) deceased donors have worse outcomes than kidneys procured from donors of other ethnic groups; deceased donor kidney transplants (DDKTs) engrafted into AAs fare worse than kidneys placed into recipients of other ethnic groups. The role of biological and environmental factors in these disparities remains unclear. We sought to identify factors contributing to these ethnic differences in AAs and European American (EA) recipients of kidneys from AA and EA donors, in a study using donor-matched design to eliminate donor-specific confounding effects.

Methods: We compared allograft survival of DDKTs in 4 types of donor/recipient pairs (TDRP) (AA-AA, AA/EA, EA/AA and EA/EA). Models were fitted using a mixed effect Cox model with particular focus on effect modifiers of the TDRP association with allograft survival.

Results: We identified 669 AA and 3,383 EA donors resulting in 669 AA/AA, 669 AA/EA, 3,383 EA/AA and 3,383 EA/EA DDKTs. In agreement with previously reported trends, AA donors were more likely to be younger, male, hypertensive, and with higher serum creatinine, while EA recipients were more likely to be employed (46 and 45% vs. 37 and 33%) and less likely to experience delayed allograft function (DGF) (19 and 18% vs. 28 and 23%). Adjusted analyses controlling for donor and recipient characteristics identified strong interaction effects between the TDRP and incidence of DGF (P<0.009) and between the TDRP and employment status (P=0.04). Observed hazard ratios varied from 0.9 for an employed (EA/EA) pair without DGF to 4.3 for an unemployed (AA/EA) pair with DGF.

Conclusions: Ethnic differences in employment status and incidence of DGF were the strongest effect modifiers of the association between the TDRP and allograft survival for DDKTs. These differences partially explain the observed racial disparity in outcomes for DDKTs.

Renal Transplantation in Bardet-Biedl Syndrome
Robert M. Haws,1 Aditya Joshi,1 Siddharth A. Shah,1 Omar M.A.A. Alkandari,2 Martin A. Turan.1 1Dept of Pediatrics, Marshfield Clinic, Marshfield, WI; 2Dept of Pediatrics, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; 3Dept of Pediatric Nephrology, Univ of Louisville, Louisville, KY; 4Dept of Pediatrics, Mubarak Al-Kabeer Hospital & Hamid Al-Essa Transplant Center, Safat, Kuwait.

Background: Bardet-Biedl syndrome (BBS) is a rare, multisystemic genetic disorder frequently associated with chronic kidney disease (CKD). Data regarding renal transplantation (RT) in BBS is lacking and reports tend to highlight complications. We report RT outcomes in the largest BBS cohort examined to date.

Methods: An international BBS registry was interrogated to identify individuals that underwent RT. RT was performed in 19/171 (11%) registry subjects (mean age 9 y; range 2-25 y). RT patients were younger (9 vs 17.9 y, p<0.05) and more likely to be female (82% vs. 50%). Deceased donors provided 12/21 kidneys, one patient received a combined liver/renal transplant. Two patients that underwent RT in the 1980s and died at <10 y of age were excluded from further analysis. Patient and kidney survival is shown.

Conclusions: Early readmission is associated with worse graft survival. Many readmissions may be preventable and review of process improvement may reduce early readmission after KTx.

Kidney Transplant Outcomes for Patients with Amyloidosis – A United Network for Organ Sharing Database Analysis  
Ali Khalil, Tim E. Taber, Muhammad Ahmad Mujtaba, Muhammad S. Yaqub, Asif A. Sharifuddin. 
Medicine/Neph, Indiana Univ, Indianapolis, IN.  

Background: Outcomes of patients with Amyloidosis who receive a kidney transplant have not been extensively studied. We examined UNOS database for outcomes of such recipients. 
Methods: UNOS database was queried for recipients with code “3016” which corresponds to “Amyloidosis”. Duration of study period was Nov 1987 to Dec 2014. 
Results: A total of 625 recipients were identified as in the table.

Early Experience with the New Kidney Allocation System  

Background: On December 3, 2014, major changes to deceased donor kidney allocation were implemented under the new Kidney Allocation System (KAS). 
Methods: Using national registry data, we compared changes in rate of DDKT among adult kidney-only waitlist registrants 1/2011-3/2015 pre vs post-KAS via Poisson regression, adjusting for age, sex, race, ABO blood type, calendar year, calculated panel reactive antibody (CPRA), and wait time. We compared donor service area-level geographic disparity pre vs post-KAS using multilevel Poisson regression and median incidence ratio (MIRR). We also compared CPRAs of DDKT recipients pre vs post-KAS, and incidence of delayed graft function (DGf). 
Results: Pre-KAS, access to DDKT was poorer for women (IRR=0.92, 95%CI=0.89-0.94), African-Americans (AAs) (IRR=0.88, 95%CI=0.85-0.92), and Hispanics (IRR=0.79, 95%CI=0.76-0.81). Access was best for patients of ABO type AB (IRR vs O=2.29, 95%CI=2.02-2.59, p<0.01) and worst for ABO type B (IRR vs O=0.29, 95%CI=0.23-0.36, p<0.01). KAS was associated with no change in overall DDKT access (p=0.7), but with improved access for AAs (IRR=1.16, 95%CI=1.10-1.22, interaction p=0.001) and patients of ABO type AB (IRR=1.29, 95%CI=1.24-1.35, interaction p<0.001). Geographic disparity declined post-KAS (MIRR=1.76 pre-KAS, 1.64 post-KAS). Median CPRA at transplant was 0 both pre and post-KAS; the proportion of recipients with CPRA 80-99 decreased from 13.6% to 10.1% (p<0.001), but the proportion with CPRA=99 rose from 1.6% to 14.0% (p<0.001, Figure 1). 

Funding: NIDDK Support
Conclusions: Although recent developments increased success in renal transplantation, receiving a kidney from a paid living donor at a commercial transplant center still carries great risks for the recipient.

FR-PO1052
The Negative Effect of First Transplant Nephrectomy for Second Transplant Outcome
Masaki Muramatsu,1 Michael Sheaff,2 Arun Gupta,4 Atsushi Aikawa,2 Carmelo Puliafiti,2 Muhammad M. Yaqoob,2 Neophrology and Transplantation, The Royal London Hospital, London, United Kingdom; 2Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan; 3Cellular Pathology, The Royal London Hospital, London, United Kingdom; 4Clinical Transplant Laboratory, The Royal London Hospital, London, United Kingdom.

Background: The impact of failed renal allograft nephrectomy on the outcome of retransplantation is unclear. This single center study was conducted to address this question.

Methods: We analyzed 93 patients who received a 2nd transplant at The Royal London Hospital between November 1994 and January 2015. 59 patients did not receive primary transplant nephrectomy (TNx) and had failed allograft in-situ at the time of second graft (group A) whilst 34 patients underwent TNx prior to second graft (group B). 2nd transplant survival was the primary end point. Sensitization, waiting time for 2nd graft, graft function and rejections were secondary end points.

Results: Group A patients had significant longer graft survival than group B (100.6 months vs 40.2 months, p<0.001). Waiting time from primary graft loss to second transplant in group A was shorter than group B (36.7 months vs 59.1 months, p=0.013). In total, 39 patients had pre-formed anti-HLA antibodies (low titer). Group B had significantly higher rate of pre-formed anti-HLA antibodies than group A (50.0% vs 29.3%, p=0.047). The rate of HLA class I in group B was also significantly higher than that in group A (47.1% vs 25.7%, p=0.038). Group B had numerically higher rate of acute rejection than group A (32.4% vs 15.3%, p=0.033). GFR between both groups did not differ until 3 years post-transplant. In group A, 2nd graft survival rates at 6month, 1.3 and 5 years were 94.9%, 93.0%, 87.0% and 82.3%, and were significantly better group B (73.3%, 70.0%, 66.0% and 46.8%, p<0.001). On multivariate analysis, waiting time for second transplant, TNx, second transplant donor age and delayed graft function were independently associated with second graft survival. TNx had highest hazard ratio (2.83, 95% CI 1.22-6.75, p=0.015).

Conclusions: Prior TNx is associated with inferior 2nd renal graft survival in this observational study and calls for an urgent randomized control trial.

FR-PO1053
Induction Agent Use, Mortality and Acute Rejection in Older KT Recipients

Background: Induction agents are commonly used as an initial intensive immunosuppression after kidney transplantation (KT) to prevent acute organ rejection; this practice varies by label. Little is known about induction agent use in older KT recipients.

Methods: Data on 19,546 older KT recipients (2005-2013) was ascertained from the Scientific Registry of Transplant Recipients. Induction agents were classified as thymoglobulin/ATG, IL-2, or other induction agents. The risk of mortality was estimated using a time-dependent proportional hazards model (hazard ratio (HR)) adjusting for all KT factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (HCV, HLA mismatches, cold ischemia time, donor type, donor age, and donor sex). The relative risk (RR) of 1 year acute rejection was estimated using modified Poisson regression adjusting for all recipient and KT factors.

Results: The mean age was 69 (SD=3.8 years), 36% female, 19 black and 27% live donor recipients. There is an increasing utilization by year of induction agents with 84% use in older recipients. Compared to those who did not receive induction, the risk of mortality for older recipients was decreased for those who received thymoglobulin/ATG (HR=0.86, 95%CI:0.79-0.94), IL-2 induction agents (HR=0.89, 95%CI:0.81-0.97), and other induction agents (HR=0.85, 95%CI:0.75-0.97). Additionally, compared to those who did not receive induction, the risk of 1 year rejection for older recipients was increased for those who received IL-2 induction agents (HR=1.36, 95%CI:1.15-1.61), as well as other induction agents (HR=1.27, 95%CI:1.03-1.57) but not thymoglobulin/ATG (HR=1.06, 95%CI:0.90-1.25).

Conclusions: For older KT recipients, there is an increasing trend in the use of induction agents and a decreased risk of mortality regardless of the type of induction agent used. However, there is little evidence for a protective effect of induction agent use for 1 year acute rejection.

FR-PO1054
Immunosuppression and the Elderly – Can They Take It?

Background: The aging immune system has fewer naïve T cells, more memory T cells, and less T cell receptor variability. Older transplant patients tend to have more comorbidities and less functional reserve. This combination makes them more difficult to immunosuppress with higher risk of infection, and potentially increased mortality from rejection treatment.

Methods: In order to determine the impact of rejection treatment on outcomes in our transplant recipients ≥70 years of age, we reviewed the outcomes of patients transplanted at our center from 1/2009-12/2013. Induction regimens varied; maintenance immunosuppression consisted of tacrolimus, mycophenolate, and rapid steroid withdrawal.

Results: During this time period, we transplanted 110 over 70 years of age. Of these, 27 patients had rejection – 24 ACR, 1 combined AMR/ACR/MR, 1 AMR followed by ACR (see table). 11 of these patients received Tcell depleting agents, the rest received IV steroids +/- IV Ig. There was no difference in age, race, donor type, prior transplant, or induction therapy between the two groups. Mean creatinine was higher in the rejection group, treatment adjusted to stabilize function: the rate of decline in estimated GFR after rejection treatment was no different between groups. Within 6 months of rejection treatment, there were 12 infectious complications, only 3 of which required hospitalization (urosepsis-2, CMV-1). There were no differences in rates of BK viremia, CMV viremia, graft survival, or mortality. 7 of the 27 patients died at some point after rejection. only one was related to infection >1 year later and not related to treatment.

Conclusions: Among our >70 patients, rejection treatment appeared well tolerated with few complications requiring hospitalizations and no treatment related mortalities. In addition, it appeared that treatment stabilized function in the majority of patients.

FR-PO1055
Mortality After Kidney Allograft Failure and Return to Dialysis
Amarpali Brar, Chiles Maris, Nabil Sumrani, Basika M. Tedla. Clinical Transplant Cellular Pathology, Brooklyn, NY; *Surgery, SUNY Downstate Medical Center, Brooklyn, NY; *Surgery, Uniformed Services Univ of Health Sciences, Bethesda, MD.

Background: Our hypothesis was that kidney allograft failure (KAF) and return to dialysis (RTD) results in greater mortality versus patients with end-stage renal disease (ESRD). We also sought to identify variables associated with mortality after KAF.

Methods: We used an incident cohort of patients from the United States Renal Data System who initiated any form of dialysis between 1/2009 and 12/2008 after KAF. We followed patients until retransplantation, death or Sept 2009. Multivariable Cox analysis was used for statistical associations.

Results: 7,156 patients were followed for a mean of 30.8 ± 22.6 months. 3,622 (50.6%) patients initiated dialysis due to main causes of death cardiac (47.0%), infection, 1,465 (21.6%) other (16.4%) and metabolic/endocrine (7.9%) causes. Predictors of all-cause mortality included age at KAF (hazard ratio (HR)= 1.03, 95% confidence interval (CI) 1.03-1.04), diabetes (DM) as cause of kidney failure (HR= 1.52, CI 1.3-1.8), congestive heart failure (CHF) (HR= 1.19, CI 1.04-1.36), peripheral arterial disease (PAD) (HR= 1.23, CI 1.04-1.55), stroke (HR= 1.27, \(p<0.001\)).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
CI 1.05-1.55), employment (HR = 0.80, CI 0.67-0.96), BMI (HR = 0.98, CI 0.97-0.99) and serum albumin (HR = 0.82, CI 0.75-0.90). Mortality was higher in those with either DM or CHF, and increased further in those with PAD (P<0.0001).

Figure 1. Adjusted all-cause mortality [Kaplan-Meier curve]

Gender, number of transplants, donor type (deceased, living), ESRD duration prior to transplant, tobacco use, drug or alcohol abuse and erythropoietin use did not predict all-cause mortality.

Conclusions: DM, CHF and PAD are associated with increased mortality after KAF and RTD. Prevention and early management of these conditions may increase survival. Prospective studies are needed to confirm our findings.

FR-PO1056

Current Trends in Waiting List of Kidney Transplantation and Mortality in Asian: A National Population-Based Cohort Study Using the Korean Network for Organ Sharing (KONOS) Database

Kyung Don Yoo, Sunhwa Lee, Jung Nam An, Yun Kyu Oh, Chun Soo Lim, Yon So Kim, Jung Pyo Lee. Seoul National Univ College of Medicine.

Background: Kidney transplantation has been increasing, globally. However, the clinical outcome of wait-listed patients for deceased donor kidney transplantation has not been well described in Asian patients with end-stage renal disease (ESRD).

Methods: We reviewed the detailed trends of wait-listed patients and conducted survival analysis in kidney transplant recipients using KONOS (The Korean Network for Organ Sharing) database which is a complete enumeration survey. We compared the outcomes according to the transplant era as followings: 2000–2004, 2005–2009, 2010–2014.

Results: From 2000 to 2014, a total of 34,943 patients registered in the waiting list, and 5,164 patients received transplantation from deceased donor. The proportion of deceased donor kidney transplantation has increased up to 45.9% in 2013 from 4.6% in 2000. The number of waiting list for kidney transplantation has increased continually more than 3,000 ESRD patients per year. The mean waiting time of deceased donor kidney transplantation was 54.9 months and has been getting longer. A total of 18,687 patients were remained after waiting time of 10 years on average, whereas 86% of people aged 35. Men are more likely to die than women during waiting time (HR 1.22, 1.13-1.31, P<0.001). Moreover, Patients with Rh negative blood type shows higher mortality rate than those with Rh positive (HR 1.60, 1.06-2.42, P=0.024). Pre-transplant experienced patients, however, showed better survival during waiting time (HR 0.63, 0.46-0.86, P<0.003).

Conclusions: Longer waiting times on dialysis do not affect survival after transplantation although transplant itself shows better overall survival. It should be emphasized to have more attention to the patients who are diabetic, old, men, or Rh negative with higher risk for mortality during waiting time.

FR-PO1058

Normal Saline versus Lower-Chloride Solutions for Kidney Transplantation

Sooan Yang, 2 Matthew A. Robinson, 1 Peter F. Mount. 1

Dept of Nephrology, Austin Health, Melbourne, Victoria, Australia; 2 Central Clinical School, Univ of Sydney, New South Wales, Australia; 2 Eastern Health Clinical School, Monash Univ, Box Hill, Victoria, Australia.

Background: The ideal intravenous (IV) fluid for kidney transplantation (KTx) has not been defined, despite the common use of normal saline (NS) in the perioperative period. The high chloride content of NS is associated with an increased risk of hyperchloremic metabolic acidosis, which may increase the risk of hyperkalemia and delayed graft function (DGF). Balanced electrolyte solutions (BHS) has a lower chloride content, which may decrease this risk and avoid the need for dialysis due to hyperkalemia. Randomised controlled trials (RCTs) have used biochemical outcomes to compare fluids and have been underpowered to address patient-centred outcomes such as DGF. We systematically reviewed the effect of BES versus NS on DGF, hyperkalemia and acid-base status in KTx recipients.

Methods: We searched the Cochrane Renal Group’s Specialised Register to 24th March 2015. We included RCTs of KTx recipients that compared peroperative IV lower-chloride solutions to NS. Two independent investigators assessed studies for eligibility and risk of bias. Data were extracted using standardised forms and pooled according to a published protocol.

Results: Six studies (477 participants) were included in the review. All participants were adults, and 63% of patients and 70% received live-donor KTx. The overall risk of bias was low for selection bias and unclear for remaining domains. There was no difference in the risk of DGF (RR 1.03, 95%CI 0.62–1.70, P=0.91) or hyperkalemia (RR 0.48, 95%CI 0.04–6.10, P=0.57) for participants who received BES compared to NS. Compared to NS, BES were associated with higher blood pH (mean difference 0.07, 95%CI 0.05–0.09, P<0.00001), higher serum bicarbonate (mean difference HCO3- 3.04mmEq/L, 95%CI 2.13–3.94mmEq/L, P<0.00001) and lower serum chloride (mean difference chloride -9.93mmol/L, 95%CI -19.96–0.11mmol/L, P<0.05).

Conclusions: Intravenous balanced electrolyte solutions are associated with less hyperchloremic metabolic acidosis compared to normal saline. However, these data do not support their use to reduce clinical events.

FR-PO1059

Risk Factors for Delayed Graft Function in Kidney Transplantation

Marcos A. Meniconi, 1 Vitoria C. Vilela, 1,2 J. Medina-Pestana, 1 Miguel Cendoroglo Neto, 1,2 Miguel A. Goes, 1,2

Nephrology Div, Fed Univ of Sao Paulo, Sao Paulo, SP, Brazil; 2 Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil.

Background: Renal failure persisting after transplantation necessitating dialysis within the first week is called delayed graft function (DGF). Objective: To assess the impact of erythropoietin usage on DGF after renal transplantation.

Methods: A total of 196 maintenance hemodialysis patients who underwent renal transplantation at one center (Hospital do Rim) were prospectively analyzed pre and post-renal transplantation. Data on demographics, ESRD etiology, pre-transplantation hemodynamics, immunosuppression regimen were reported. Two-sample t test were used to compare differences between two groups (DGF versus non-DGF groups) and X2 to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome-DGF.

Results: The mean duration on maintenance hemodialysis was 18±6 months. The main causes of ESRD were diabetes (37%) and hypertension (15%) followed by chronic glomerulonephritis (9%). There were transplants from deceased-donor kidneys (47%), living unrelated kidney donation (43%) and living related donors (10%). 41 patients necessitated dialysis within the first week after renal transplantation (DGF group). We observed that 131 patients (67%) used recombinant human erythropoietin (rHuEPO), type of donor kidney and immunosuppression regimen were reported. Two-sample t test were used to compare differences between two groups (DGF versus non-DGF groups) and X2 to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome-DGF.

Risk factors affecting DGF are older age, unrelated kidney donation and higher rHuEPO dose (4930±447, 1658±844 IU; p<0.001). DGF group had higher use of anti-hypertensive agents (43% vs 15%, P=0.001) and higher rHuEPO dose (4930±447, 1658±844 IU; p<0.001). Cold ischemia time (p =<0.001) was an independent predictor of DGF. We observed that 131 patients (67%) used recombinant human erythropoietin until one week before renal transplantation. We observed that DGF group was older (39±15; p=0.007), higher cold ischemia time (23±10h, 12±10h; p=0.001), longer time on dialysis (4±4, 2±1 yr; p=0.001) and higher rHuEPO dose (4930±447, 1658±844 IU; p=0.001). DGF group had higher use of anti-hypertensive agents (43% vs 15%, P=0.001) and higher rHuEPO dose (4930±447, 1658±844 IU; p=0.001). Cold ischemia time (p <0.001) was an independent predictor of DGF.

Conclusions: This study shows that rHuEPO was not associated with DGF-protection in renal transplant patients. Cold ischemia time is an independent predictor of DGF.

Outcomes of Kidney Transplant Recipients from Donation After Circulatory Death Donors without Pre-Agonal Heparin Administration
Layla Kamal, Joel Lindower, Maria Ajaimy, Michelle L. Lubetzky, Graciela De Boccado, Enver Akalin, Liise K. Kayler.
Montefiore-Einstein Center for Transplantation.

Background: Protocols of organ donation after circulatory death (DCD) are considerably varied. Heparin administration during the pre-agonal phase has been recommended to improve organ perfusion and prevent blood clots; however some protocols avoid heparin before verification of death based on legal or professional concerns. We assessed outcomes of kidney transplant recipients who received DCD kidneys recovered with and without heparin.

Methods: We retrospectively evaluated recipients of kidney transplants between 2011 and 2014 from controlled DCD donors who received (n=23) or did not receive (n=29) pre-agonal heparin.

Results: All kidneys underwent machine perfusion. No Heparin donors had a similar kidney donor profile index but were more likely to have mild histologic changes, elevated temperature, or decreased perfusion resistant index, and were imported from non-organ service areas compared to the Heparin donors. Recipients of No Heparin kidneys were more likely to be female, sensitized, prior solid organ recipients, and to receive thymoglobulin induction but were less likely to have diabetes. None of these differences reached statistical significance. Post-transplantation, 1 patient died early due to a cardiac event (no Heparin group). Graft failure occurred in 2 patients in the no Heparin group (one each of sepsis/rejection and thrombosis); 1 (renal artery thrombosis) in the Heparin group. Between group differences were small in terms of delayed graft function, 6-month acute rejection, and estimated GFR at 3, 6, and 12 months.

Conclusion: Heparin administration during the pre-agonal phase has been recommended to improve organ perfusion and prevent blood clots; however some protocols avoid heparin before verification of death based on legal or professional concerns. We recommended to improve organ perfusion and prevent blood clots; however some protocols avoid heparin before verification of death based on legal or professional concerns. We

FR-PO1062
Does Calcineurin Inhibitor Timing Matter? Single Center Experience with En-Bloc Kidney Transplantation
Maya Campara,1 Oksana A. Kucher,2 Sanjeev Akkina,2 Ignatius Yun-Sang Tang.2 1Pharmacy Practice, Univ of Illinois at Chicago; 2Medicine, Nephrology, Univ of Illinois at Chicago.

Background: En-bloc kidney transplantation (KTx) has excellent outcomes. To minimize vascular complications and nephrotoxicity, calcineurin inhibitor (CNI) therapy is often delayed. The purpose of our study is to investigate the impact of CNI initiation timing on 1-year graft outcomes.

Methods: This is a single-center, retrospective review of adult en-bloc KTx between 2001 and 2013. Timing of CNI initiation was decided by the operating surgeon. Patients were divided into two groups, those that received CNI therapy early (<48 hours) or delayed (>48 hours) posttransplant. The primary objective was to compare one year estimated glomerular filtration rate (eGFR) between the groups. Secondary outcomes included graft and patient survival, CNI levels, incidence of delayed graft function (DGF), rejection and graft failure rates.

Results: Twenty-one en-bloc KTx recipients were included in the analysis. Ten patients received CNI within 48 postoperative hours (Early CNI Group). There was no difference in age, gender, PRA, cause of ESRD or BMI between the groups. Only 50% of Early CNI patients received lymphocyte depleting therapy vs. 100% in the Delayed CNI group (p = ns). In the Early CNI Group, 3 patients were on CsA prior to donor; all other patients received tacrolimus and mycophenolate maintenance. There was no difference in eGFR between groups at one year or at any other time points. Comparable therapeutic tacrolimus trough was observed at 5, 10 and 30 days posttransplant. There was no difference in DGF or graft failure incidence. In the delayed CNI group, one patient died of sepsis at 6 months.

Conclusions: Timing of CNI initiation had no impact on one year graft function and patient survival.
FR-PO1064

The Influence of Induction Immunosuppressive Therapies and Diabetes on Graft Loss After Kidney Transplant

Hosam A. Farag, Nasrollah Ghalaramani, Tarek Alhamad, Public Health Dept, Penn State College of Medicine, Hershey, PA; Nephrology Dept, Penn State College of Medicine, Hershey, PA; Public Health Dept, Penn State College of Medicine, Hershey, PA; Nephrology Dept, Washington Univ, St. Louis, MO.

Background: Induction therapy plays a significant role in the reduction of acute rejection in kidney transplant (KT). Understanding differences in outcomes associated with induction agents may lead to improvements in long-term care. Our objectives were to examine the influence of various induction therapies and diabetes on graft and patient survival after KT.

Methods: We used the 2000-2013 United Network for Organ Sharing (UNOS) data to evaluate the effectiveness of induction therapies and diabetes on graft and patient survival after KT. The patients were divided into four groups based on induction therapy: Basiliximab (n=24,484), alemtuzumab (n=3,231), rabbit anti-thymocyte globulin (n=ATG) (n=54,974) and daclizumab (n=13,358). Also the patients were divided into four groups based on diabetic status: non-diabetic (n=192,333), type 1 diabetes (n=11,863), type 2 diabetes (n=45,543) and new onset of diabetes (n=10,509). The main outcome were the risk of graft loss and death at 1,3,5,10 years. Cox proportional hazards model was used to estimate the hazard ratios.

Results: Graft loss was significantly higher in alentuzumab group (HR=1.171; P=0.002) and rabbit anti-thymocyte globulin group (HR=1.109; P=0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for graft loss (HR=0.902; P=0.0001) than basiliximab group. Death was significantly higher in rabbit anti-thymocyte globulin group (HR=1.075; P=0.0094) versus basiliximab group. Daclizumab group showed significantly lower risk for death (HR=0.850; P=0.0001) than basiliximab group. Graft loss was significantly higher in type 2 diabetes (HR=1.451; P=0.0001).

Conclusions: Induction immunosuppressive therapies and diabetic status play significant role in long-term graft and patient survival. Basiliximab and daclizumab as IL-2 RA receptor antagonists have better long-term graft and patient survival outcomes.

FR-PO1065

Do Induction Type Influence Outcomes in Kidney Transplant Recipients at Different Phases of Hepatitis B Infection?

Kalathil K. Suvenkumar, Richard J. Marcus, Bhavna Chopra. Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.

Background: Host response to hepatitis B virus (HBV) infection is variable with some patients progressing to chronic liver disease. Immunosuppression associated with kidney transplantation in such patients may increase the risk of disease progression. We aimed to investigate if treatment changes might result in more cost-effective care.

Methods: We used the 2000-2013 United Network for Organ Sharing (UNOS) data to evaluate the effectiveness of induction therapies and diabetes on graft and patient survival after KT. The patients were divided into four groups based on induction therapy: Basiliximab (n=24,484), alemtuzumab (n=3,231), rabbit anti-thymocyte globulin (n=ATG) (n=54,974) and daclizumab (n=13,358). Also the patients were divided into four groups based on diabetic status: non-diabetic (n=192,333), type 1 diabetes (n=11,863), type 2 diabetes (n=45,543) and new onset of diabetes (n=10,509). The main outcome were the risk of graft loss and death at 1,3,5,10 years. Cox proportional hazards model was used to estimate the hazard ratios.

Results: Graft loss was significantly higher in alentuzumab group (HR=1.171; P=0.002) and rabbit anti-thymocyte globulin group (HR=1.109; P=0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for graft loss (HR=0.902; P=0.0001) than basiliximab group. Death was significantly higher in rabbit anti-thymocyte globulin group (HR=1.075; P=0.0094) versus basiliximab group. Daclizumab group showed significantly lower risk for death (HR=0.850; P=0.0001) than basiliximab group. Graft loss was significantly higher in type 2 diabetes (HR=1.451; P=0.0001).

Conclusions: Induction immunosuppressive therapies and diabetic status play significant role in long-term graft and patient survival. Basiliximab and daclizumab as IL-2 RA receptor antagonists have better long-term graft and patient survival outcomes.

FR-PO1066

Health Economic Analysis of Rabbit Anti-thymocyte Globulin (Thymoglobulin) versus Basiliximab (Simulect) in Renal Transplantation – A German perspective

Richard Thaiss, Thomas Benzing, John Reitan, Thomas Paivanas, Meghan E. Gallagher, Michael Sean Wiesener, Nikolai Zink, Univ. Hospital, Nephrology, Hamburg, Germany; Univ. Hospital, Nephrology, Cologne, Germany; RJM Group, Crown Point; TAP & A, Annandale; Sanofi, Cambridge; Univ. Hospital, Nephrology, Erlangen-Nuernberg, Germany.

Background: Kidney transplantation is now accepted as a proven therapeutic modality prompting a greater need to understand the cost-effectiveness of different treatment approaches.

Methods: The primary objective of this study was to quantify the economic consequences of acute rejection and adverse events in patients undergoing cadaveric kidney transplantation and receiving ATG (Thymoglobulin - Thymo) compared with those receiving basiliximab (Simulect - Sim). Health economic data were collected according to reimbursement calculations from 3 German sites in an existing database (Brennan et al NEJM, 2006).

Results: Based on the clinical data from the Brennan trial, the study quantified current data and changes in treatment patterns. Results demonstrate that at 12 months the cost of the Thymo-regimen is €5,753 more than that of the Sim-regimen. However, costs of delayed graft function, nonfatal graft failure events and post-graft failure dialysis are lower among Thymo treated patients. Thymo treated patients incurred higher graft maintenance costs, consistent with their longer graft survival. In total the associated cost-offset from lower rejection events with Thymo offset the added cost from drug treatment and therefore Thymo is a more cost-efficient resource vs Sim due to cost avoidance. To further evaluate differences between the two groups we considered quality-adjusted life year differences. The Thymo cohort is projected to enjoy 405,714/QALY after 1 year. After a decade, the Thymo cohort is projected to cost 332,232 Euros less than the Simulect cohort while enjoying 10.8 more QALYS.

Conclusions: This analysis was intended to provide information that should be considered when weighing the costs and benefits of two immunosuppressive regimens and to investigate if treatment changes might result in more cost-effective care.

FR-PO1067

Design and Rationale of Athena Study: A 12-Month Study Evaluating Everolimus versus Standard Regimen in De Novo Renal Transplant Recipients-Baseline Data

Friedrich Thaiss, Claudia Sommerrer, Barbara M. Suvelack, Husna Dragan, Ingeborg A. Hauser, Peter Schenker, Daniel Bauemer, Bjorn Nashan, Athena Study Group; Novartis Pharma Germany.

Background: Long-term use of standard calcineurin inhibitor (CNI) post-kidney transplant (KTs) is associated with an increased risk for malignancies, cardiovascular disease, and renal failure. Previous studies have shown everolimus (EVR) to allow CNI reduction and thereby preserve renal function without efficacit. ATHENA study evaluates the renal function comparing EVR with reduced CNI exposure (tacrolimus [TAC] or cyclosporine A [CSA]) vs a standard treatment protocol with mycophenolic acid (MPA) and TAC in de novo (day 0) KT recipients (KT-R).

Methods: This is a 12-month (M), multi-centre, open-label, prospective study in KTx (>18 years) receiving renal allografts from deceased or living donors. Patients were randomised prior to Tx to one of three treatment arms (1:1:1): TAC+MPA+steroids (n=204) or EVR+TAC+steroids (n=204) or EVR+CSA+steroids (n=204) (all with basiliximab). The primary objective is to demonstrate non-inferiority in renal function (eGFR, Nankivell) in EVR-based immunosuppressive protocol.

Results: Study recruitment is completed in Germany and France. A total of 658 patients were enrolled, of which 614 patients were randomised. To-date, baseline data was available for 367 treated patients (TAC+MPA, 125; EVR+TAC, 116; EVR+CSA, 126); of which 66% were male (65%, 67%, and 66%, respectively). The mean age was 54 years (TAC+MPA, 55 years; EVR+TAC, 54 years; EVR+CSA, 53 years). At baseline mean BMI was 26.8 kg/m² (TAC+MPA, 26.7 kg/m²; EVR+TAC, 26.7 kg/m²; EVR+CSA, 26.8 kg/m²). Overall, 18% patients received allograft from living donor (TAC+MPA, 18%; EVR+TAC, 17%; EVR+CSA, 20%). The mean HLA mismatch was 2.8 (TAC+MPA, 2.6; EVR+TAC, 2.8; EVR+CSA, 3.0). The preliminary results of this ongoing trial are expected in 2016.

Conclusions: ATHENA is the largest European renal transplant study and the first study evaluating the non-inferiority of renal function as a primary objective in a de novo EVR-based immunosuppressive protocol.

Thymoglobulin Induction Therapy; Results for 5 Years – Improving the Survival of Renal Allograft and Patient
Virginia Barra Pedrosa, Benjamin Gomez-Navarro. Nephrology and Transplantation, Centro Medico Nacional de Occidente, Guadalajara, Jalisco, Mexico.

Background: The factor that impacts the survival of renal allograft is the presence of acute rejection. In our city, using Thymoglobulin has offered to patients at high immunological risk, and through the years has sought to reduce adverse events use. The objective is to evaluate the frequency of acute rejection during the last 5 years in patients receiving Thymoglobulin induction.

Methods: An ambispective cohort, patients transplanted in UMAE HE-CMNO, Jalisco, Mexico is included in the period June 2010 to June 2014 who received induction therapy with Thymoglobulin. Was recorded the frequency of acute rejection, the frequency of infections, use of Filgrastim(G-CSF), graft loss and death at 12 months of transplantation.

Results: A 370 patients were included,which received initial doses of Thymoglobulin 0.6mg/kg-1.5mg/kg. In 2013, by multivariare analysis Thymoglobulin dose that was associated with a lower incidence of acute rejection was analyzed and found that 1mg/ kg for 4 days (cumulative dose 4mg/kg) is a protective factor for the occurrence of acute rejection (IC 95%: 0.11- 0.60, OR 3.7, p<0.001), for this reason almost patients received this dose. In 2010, the rate of rejection was 10%, and actually is 7.8% (p=0.05).

Conclusions: Interestingly, in our hospital, we observed a lower rate of acute rejection and improved patient survival and allograft. Apparently finding the right dose in our patients has allowed thymoglobulin induction is safe and minor complications.

FR-PO1069
Randomized Trial of Tacrolimus/Everolimus versus Tacrolimus/Enteric-Coated Mycophenolate Sodium to Prevent Biopsy-Proven Acute Rejection and Chronic Allograft Injury in Adult, Primary Kidney Transplantation
Giselle Guerra,1 Jeffrey J. Gaynor,2 David Roth,3 Warren L. Kapun,4 Adela D. Mattiazzi,5 Michael J. Goldstein,6 Linda J. Chen,7 George William Burke,2 Gaetano Ciancio,8 Dept of Medicine, Miami Transplant Inst, Miami, FL; Dept of Surgery, Miami Transplant Inst, Miami, FL.

Background: It was of interest to determine whether everolimus(EVL) might reduce the incidence of biopsy-proven acute rejection(BPAR) during the first 12mo post-kidney transplantation.

Methods: We performed a single-center, open-label randomized trial comparing two maintenance immunosuppression regimens: TAC(tacrolimus)/EVL(Group A) vs. TAC/enteric coated mycophenolate sodium and steroids. Primary endpoint was change in eGFR (MDM4) from RND to M12. Main secondary endpoint a composite efficacy of treated biopsy-proven acute rejection(IBPAR, Banff ≥IIb), graft loss, or death and safety.

Results: At M12, the clinical benefit observed in eGFR did not achieve statistical significance (1.70, 95% CI: -0.53, 3.93; p=0.19) whilst eGFR at M24 for EVR was significantly better (p<0.006). The composite efficacy endpoint was comparable at M12 & M24. Overall acute rejection rates were very low with more IBPAR in EVR, but mild in severity (Banff IA & IB). In both the groups, number of patients with de novo DSA at M12 or M24 was low and unrelated to outcomes. At M24, rate of CAN (IF/TA) was significantly higher in the CNI versus EVR (35.1 vs 26.7%, p=0.029).

Conclusions: Early conversion to EVR at 3 months vs continued CNIs better preserved renal function with comparable overall efficacy and safety up to 2-years.

Early Conversion to Everolimus in De Novo Renal Transplant Recipients: 24-Month Results from the ELEVATE Study
Johan W. De Fijter, Hallvard Holdaas, Patricia M. Lopez, Cesar Escrig, Zailong Wang, Josep M. Cruzado, Markus van der Giet. For the ELEVATE Study.

Background: Long-term therapy with calcineurin inhibitors (CNIs) is associated with nephrotoxicity i.e., glomerulosclerosis and interstitial fibrosis (IF). We present the 24 month results from the ELEVATE study (NCT01114529), which compared an early conversion to everolimus (EVR) vs standard CNI in renal transplant recipients (RTxR).

Methods: ELEVATE, a 24M, multicenter, open-label, randomized, de novo RTxRs 10–14 weeks post-Tx to convert from CNI to EVR (n=360; C0 6–10 ng/mL) or standard CNI (n=357; C0: TAC 5–10 ng/mL, CsA 100–250 ng/mL); all received enteric-coated mycophenolate sodium and steroids. Primary endpoint was change in eGFR (MDM4) from RND to M12. Main secondary endpoint a composite efficacy of treated biopsy-proven acute rejection(IBPAR, Banff ≥IIb), graft loss, or death and safety.

Results: At M12, the clinical benefit observed in eGFR did not achieve statistical significance (1.70, 95% CI: -0.53, 3.93; p=0.19) whilst eGFR at M24 for EVR was significantly better (p<0.006). The composite efficacy endpoint was comparable at M12 & M24. Overall acute rejection rates were very low with more IBPAR in EVR, but mild in severity (Banff IA & IB). In both the groups, number of patients with de novo DSA at M12 or M24 was low and unrelated to outcomes. At M24, rate of CAN (IF/TA) was significantly higher in the CNI versus EVR (35.1 vs 26.7%, p=0.029).

Conclusions: Early conversion to EVR at 3 months vs continued CNIs better preserved renal function with comparable overall efficacy and safety up to 2-years.

FR-PO1072

Background: Tacrolimus (TAC) and Sirolimus (SRL) are commonly used immunosuppressive drugs in kidney transplantation. SRL has been shown to induce the expansion of regulatory T cells in post-transplant recipients converted from TAC to SRL.

Methods: This study included 84 renal transplant recipients from a randomized trial of SRL conversion (n=55) or TAC maintenance(n=29). The conversion started at 12 months post-transplant. PBMC were collected at 0 (baseline), 6, 12, 24, 36 and 48 months post-conversion. T cell subpopulations were analyzed by flow cytometry.

Results: Absolute frequencies of CD45ROFoxP3+ T cells were similar in both groups (0.63±0.06% SRL VS 0.66±0.12% TAC) % of Lymphocytes, p=0.79). SRL conversion led to a significant increase in CD45ROFoxP3+ T cells at 6, 12 and 24 months post conversion with highest frequencies observed at 12 months post-conversion (2.23±0.23% SRL VS 0.08±0.12% TAC) (% in TAC at 12 months was 0.05±0.12). However, we observed a decline of CD45ROFoxP3+ T cells started at 24 months and the differences were no longer significant compared to the TAC group at 36 and 48 months post-conversion (1.4±0.60% SRL VS 1.07±0.44% TAC) (% p=0.24). Intracellular staining for Interferon Gamma (IFN-γ), Interleukin 17 (IL-17) and RAR-related orphan receptor gamma 2 (ROGt) showed no difference at 24 months. However, at 48 months, we found that PMA-stimulated CD45ROFoxP3+ T cells in SRL-converted group had more percentage of cells that co-expressed IFN-γ and ROGt which are Th1 and Th17 markers respectively.

Conclusions: Switching from TAC to SRL results in an expansion of CD45ROFoxP3+ T cells which peaked at 12 months post-conversion but no significant frequency differences were observed at 48 months follow-up and we observed more percentage of regulatory T cells that co-expressed IFN-γ and ROGt in the SRL group.

FR-PO1073

Pulmonary Complications in Kidney Transplant Recipients: Role of Everolimus. Gianni Cappelli, Andrea Solazzo, Fabio Nava, Decenzio M. Bonuchi. Nephrology Dialysis & Renal Transplant Unit, Univ Hospital of Modena, Modena, Italy.

Background: Kidney transplant recipients are at higher risk to develop pulmonary complications as drug related side-effects.

Methods: 500 kidney transplant patients were retrospectively analyzed for pulmonary complications based on chest RX and HRCT, BAL, oximetry and clinical data. Results were classified as parenchymal, interstitial and neoplastic complications.

Results: We found 168 pulmonary complications in 161 pts (32%): 137 parenchymal pneumonia, 29 interstitial lung diseases (IP) and 2 cancers. Most pneumonia were bacterial, 96 cases (70%) required hospitalization. IP were from infections in 13 cases (7.6%), 29 interstitial lung diseases (IP) and 2 cancers. Most pneumonia were classified as parenchymal, interstitial and neoplastic complications.

Conclusions: To compare safety and efficacy of 3 different immunosuppressive regimens at month (mo) 48 after kidney transplantation (KTx).

FR-PO1074

High Doses of M-TOR Inhibitors May Induce Pulmonary Pro-Fibrotic Effects in Renal Transplant Recipients: Result of a Translational Comparative Research Approach Between Everolimus versus Tacrolimus. Gianluigi Paza, Valentina Masola, Simona Granata, Gloria Bellini, Maurizio Onisto, Giovanni Gambaro, Antonio Lupo. 1 Renal Unit, Dept of Medicine, University of Padova, Italy; 2 Dept of Biomedical Sciences, Univ of Padova, Italy; 3 Div of Nephrology and Dialysis, Columbus-Gemelli Hospital Catholic Univ, School of Medicine Rome, Italy.

Background: Pulmonary fibrosis is a quite frequent adverse effect occurring in mTORI-treated renal transplant (RT) recipients. It has been suggested that epithelial to mesenchymal transition (EMT) in airway cells may determine this condition. However, the exact biological machinery involved is not completely clarified.

Methods: We performed a translational study. First we analyzed the in vivo pulmonary pro-fibrotic potential of Everolimus (EVE) by computing a pulmonary fibrosis index score (PFIS), obtained by using several computerized tomography, hemogasanalytic and spirometric parameters, in 13 RT patients in EVE treatment and 13 patients treated with Tacrolimus (TAC). Subsequently, we carried out an in vitro study in which we assessed whether EVE at low (5, 10 nM) or high-dosage (100 nM) or Tacrolimus (5 nM, 500 nM e 5 µM) was able to induce EMT in bronchial epithelial cells (Nuli-I) and human type II pneumocyte-derived A549 cells.

Results: In the in vivo part of the study, we found that the PFIS was higher in EVE-treated patients compared to those treated with ADV (mean±SD 2.58±1.83 versus 1.21±1.25). This effect was positively correlated to the trough levels (TL) in EVE-treated patients (R2=0.55). The higher PFIS score was measured in patients that reached a TL≥6. Interestingly, in vitro, only very high doses of EVE were able to up-regulate alpha-SMA, Fibronectin and Vimentin at gene and protein level in A549. No effects were seen in Nuli-I. Interestingly, microarray analysis confirmed the above-mentioned results.

Conclusions: All together, our data suggested that only very high doses of EVE may induce pulmonary fibrosis and that this effect could be mediated by EVE in pneumocyte cells.

FR-PO1075

Efficacy and Safety of Three Different Treatment Regimen in De Novo Renal Transplant Patients: 48 Months Follow-Up Results of the HERAKLES Trial. Wolfgang Arms, Volker Klici, Claudia Sommerer, Johannes Jacobi, Bruno Vogt, Ingeborg A. Hauser, Petra Reincik, RolF. Stahl, Thomas Rath, Martina Porstner, Martin G. Zeier, Frank Lehner, Klemens Buddle, Oliver Witzke. 1 HERAKLES Study Group, Germany; 2 HERAKLES Study Group, Switzerland; 3 Novartis Pharma, Germany.

Background: To compare safety and efficacy of 3 different immunosuppressive regimen at month (mo) 48 after kidney transplantation (KTx).

Results: From mo 0 to mo 48 BPAR was reported in 19/151(13%) STD, 24/149(16%) CNI-free and in 23/147(16%) CNI-reduced pts (ITT; p=0.02). 5 deaths (3%) occurred in STD, 3(2%) in CNI-free and 4(3%) in the CNI-reduced group. 96% graft losses were observed in the STD, 64% in the CNI-free and 2(1%) in the CNI-reduced group. Composite failure (BPAR, death, graft loss, loss to follow up) occurred in 32(21%) STD, 36(24%) CNI-free and in 39(27%) CNI-reduced treated pts. Premature discontinuation due to AEs was reported for 5(3%) of STD, 3(2%) in CNI-free and 6(4%) in the CNI-reduced group. 96% of the pts were on the ITT population.

Conclusions: Mo48 results from mo 48 BPAR was reported in 19/151(13%) STD, 24/149(16%) CNI-free and in 23/147(16%) CNI-reduced pts (ITT; p=0.02). 5 deaths (3%) occurred in STD, 3(2%) in CNI-free and 4(3%) in the CNI-reduced group. 96% graft losses were observed in the STD, 64% in the CNI-free and 2(1%) in the CNI-reduced group. Composite failure (BPAR, death, graft loss, loss to follow up) occurred in 32(21%) STD, 36(24%) CNI-free and in 39(27%) CNI-reduced treated pts. Premature discontinuation due to AEs was reported for 5(3%) of STD, 3(2%) in CNI-free and 6(4%) in the CNI-reduced group. 96% of the pts were on the ITT population.

FR-PO1076

SparTacus: Multicentre, Prospective Randomised Study Comparing Tacrolimus Hexal® versus Prografa® Based Regimen in De Novo Renal Transplant Recipients. Wolfgang Arms, Thomas Rath, Lars C. Rump, Klemens Buddle, Daniel Baueuer, Peter Schenker. 1SparTacus Study Group; 2Novartis Pharma Germany.

Background: In a transplant (Tx) setting, studies evaluating pharmacokinetic (PK) parameters and therapeutic equivalence of generic tacrolimus vs the reference drug are lacking. SparTacus (NCT016494027) study was designed to compare PK profile of tacrolimus hexal® vs prografa® in renal Tx recipients (TRx).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: In this prospective, two-phase open-label study, 76 de novo RTxR were randomized to concurrent tacrolimus (n=24) or prazosin (n=44), both in combination with enteric-coated mycophenolate sodium + corticosteroids + basiliximab induction therapy. Starting dose of tacrolimus was 0.15 mg/kg/day, adjusted to target trough levels (C0) of 8–12 ng/ml from Tx to month (M) 1; 5–10 ng/ml up to M3; and 5–8 ng/ml up to M6. Primarily objective of the study in phase 1 was to demonstrate PK of tacrolimus (ratio of AUC0–21 vs month 15); here we present the PK results of the first month.

Results: At M1, the dose-normalised tacrolimus 12-h-AUC (h<0.3XL) was comparable between tac. hexa@ vs prazo@ (adjusted log-transformed LS mean, 2.1±3.0; difference, 0.076; 90% CI: 0.169; 0.321, p=0.605; adjusted back-transformed LS mean, 19.0±20.5; ratio, 1.079; 90% CI: 0.844, 1.378, p=0.605). LS mean value for Cmax (1/0.3XL) and mean 12h tacrolimus C0 (mg/L) at M1 were comparable between tac. hexa® and prazo®: Cmax (2.12±3.1, 1.70±2.9, p=0.134, CI: -0.377, C0 12.2±11.1, respectively). Of 76 patients, 40 (PK-Set 40 pts.) to date completed 6-M treatment; tac. hexa®, n = 19; prazo®, n = 21. At M6, tacrolimus hexa® vs prazo® had a comparable incidence of composite events (ITT, n=76) (5.7% vs 9.8%, p=0.681) and its individual components (BPAR [5.7% vs 7.3%], graft loss [0.0% vs 2.4%], death [0.0% vs 2.4%]). Incidence adverse events (AES, SAE) were comparable (AES: 97.1% vs 100%; serious AES: 37.1% and 42.1%).

Conclusions: Tacrolimus hexa® has a PK profile similar to that of prazo®, with comparable efficacy and safety in de novo RTxR. Funding: Pharmaceutical Company Support - Novartis Pharma

FR-PO1079
Intensified Dosing of Mycophenolate Mofetil Is Associated with Slower Progression of Chronic Renal Allograft Injury – Results from a Randomized Controlled Trial

Mladen Knotek,1 Miha Arnoš,2 Jadranka Buturovic-Ponikvar,2 Danica Galesic Ljubanovic,2 Nika Jole.1
1 Department of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Univ Hospital, Zagreb, Croatia; 2 Department of Nephrology, Univ Medical Center Ljubljana, Ljubljana, Slovenia; 1 Inst of Pathology, Univ of Ljubljana Medical Faculty, Ljubljana, Slovenia; 2Dept of Pathology, Dubrava Univ Hospital, Univ of Zagreb Medical School, Zagreb, Croatia; 3 Univ of Zagreb School of Medicine, Dubrava Univ Hospital.

Background: Intestinal fibrosis (ci) is a major histological predictor of long-term graft outcome. This randomized controlled trial (NCT01860183) was designed to evaluate the effect of intensified mycophenolate mofetil (MMF) dosing on progression of ci during the first year post kidney transplant (KT).

Methods: Immunologically low-risk KT recipients were randomized on MMF 3g/d or 2g/d during the first year post KT. Immunosuppression consisted of tacrolimus, MMF ± steroids. Protocol biopsies were performed at implantation, and at M3 and M12 post KT and at the Banff Progression of ci (Dci) was calculated as ci12-ci0. MMF dose was calculated as an average dose at 1, 3, 6 and 12 months. Difference in Dci with respect to MMF dose was analyzed in an ITT population using one-way ANOVA.

Results: Here we report interim results from patients who completed 12-month follow-up by June 1st 2015. Patient and KT data were similar in MMF 3g and MMF 2g group, except for average MMF dose, which was higher in the 3g group (2967.1±321.6 vs. 1745.5±359.0 g, p<0.001). In an overall study population ci progressed during first 12 months in 34% of patients from 0.45±0.51 (ci0) to 1.41±0.87 (ci12) (p<0.001). Dci was lower in the MMF 3 g group (0.60±0.74) as compared with MMF 2g group (1.36±0.93; p<0.01). Serum creatinine at 1 year was similar in both MMF groups (116.5±25.0 vs. 115.1±33.7; p=0.899). Incidence of acute rejection was similar and no significant differences were seen in common adverse events between both groups. Conclusions: Intensified MMF dosing (3g daily) during the first posttransplant year in a tacrolimus-based regimen may be associated with slower progression of chronic allograft injury. Funding: Government Support - Non-U.S.

FR-PO1080
Safe Conversion from Tacrolimus to Belatacept in Kidney Transplant Recipients with Allograft Dysfunction

Ami Reamri, Dhiren Kumar, Hasan Fattah, Anne L. King, Pamela Kimball, Ankur Atal Gupta, Gaurav Gupta.
Virginia Commonwealth Univ, Richmond, VA

Background: Belatacept might be an alternative to Calcineurin Inhibitors (CNI) to avoid short and long-term nephrotoxicity. Prior data on low immunologic risk de-novo kidney transplant recipients (KTxP) with stable graft function switched from a CNI to belatacept demonstrated improved renal function. There is minimal data on the use of belatacept for sensitized patients and those with impaired graft function [estimated glomerular filtration rate (GFR)<50].

Methods: EBV seropositive patients were converted to belatacept from tacrolimus for biopsy proven presumed acute CNI toxicity and/or interstitial fibrosis/tubular atrophy. Belatacept was initiated based upon prior published protocol (Grimyo et al., Transplant Int. 2012 Oct). Mycophenolate dose was increased from baseline dose of 1-2g/d to a dose of 2-3g/d to minimize risk of rejection.

Results: Seventeen (mean age=46±10 years) patients were switched from tac to belatacept at a median of 4 months post-KTxP. A majority were African-American (13/17; 76%) and received deceased donor KTxP (76%). Seven patients (41%) were sensitized (mean PRA=35, range=9-99%). Renal function improved significantly from a peak mean GFR of 28.1±12 ml/min/1.73m² to an GFR of 42±16 ml/min/1.73m² (p=0.001) at a median follow-up of 15 (range=7-30) months post-conversion. Surveillance biopsies performed in 7/17 patients did not show rejection or worsening of chronicity. No evidence of de-novo donor specific antibody (DSA) was noted in 16/17 (94%) patients. One patient with pre-existing DSA and stable creatinine had rising DSA after a viral infection. A biopsy showed subclinical antibody-mediated rejection. There were no cases of BK viremia, CMV disease or malignancies.

Conclusions: In this first study on KTxP patients with significantly reduced GFR we report remarkable improvement in renal function in patients converted from tacrolimus to belatacept with acute CNI toxicity and chronic allograft fibrosis without a significant concurrent increase in risk of rejection, worsening chronicity and DSA. Further studies with protocol biopsies are needed to ensure safety and wider applicability of this approach.
Background: Belatacept (bela) is an IV administered selective T-cell co-stimulation blocker approved for preventing organ rejection in EBV-positive adult kidney transplant recipients. The logistics of IV maintenance therapy are challenging for some providers; the safety of home infusion has not been well described. Phase 2/3 study participants had received bela home infusion if the site sought IRB approval and if the pt lived ¥2 hrs from the site and had been exposed to bela for ¥28 wks in 008 or 027, >16 wks in 010, or >6 wks in 034. 008 and 027 compared bela with CsA regimens with basiliximab induction. In 010, pts receiving a stable CNI regimen were switched to a bela regimen. 034 compared bela with tacrolimus steroid-sparing regimens under thymoglobulin induction. Rate and time to pre-specified peri-infusional AEs and peri-infusional serious AEs were recorded in pts who received bela in the home (N=66) or in a facility (N=672).

Results: Pts administered bela in the home received a median of 32.5 (range, 1–61) infusions. No pre-specified or serious peri-infusional AE was reported, including in the 034 study.

Conclusions: No pt (irrespective of steroid use) receiving home infusion of bela had a pre-specified or serious peri-infusional AE. These data suggest that bela was safely administered in the home.

Facility-Based
(Home vs. Facility)

Conclusions: The findings suggest that a belatacept regimen with limited T cell depletion and an mTORi can maximize efficacy and maintain safety. These results of a synergistic effect of costimulation blockade and mTOR inhibition are consistent with experimental studies and phase 2 data. A larger prospective trial is warranted to fully evaluate this approach.

FR-PO1083

A Change in Insulin Sensitivity and Lipid Profile in Renal Transplant Recipients Converted from Cyclosporine or Standard Release Tacrolimus to Once-Daily Prolonged Release Tacrolimus

Methods: We performed an observational prospective study of 15 stable non-diabetic renal transplant recipients on change in insulin sensitivity and lipid profile in renal transplant recipients converted from cyclosporine or standard release tacrolimus to once-daily prolonged release tacrolimus. We evaluated the level of HbA1c, total cholesterol, HDL, LDL, TG, apolipoprotein A1, apolipoprotein B, serum creatinine, fasting plasma glucose, fasting insulin and HOMA-IR at base line, two and four months. To analyze differences in parameter, we performed a t-test in both groups (cyclosporine to TacOD conversion group/ TacBID to TacOD conversion group), and GLM-repeated measures ANOVA. HOMA-β = (360 X Fasting insulin)/(Fasting glucose-63) HOMA-IR (insulin resistance) = (Fasting glucose X Fasting insulin)/405.

Results: At baseline, parameters were not different in both groups (cyclosporine to TacOD conversion group/TacBID to TacOD conversion group). In GLM-repeated measures ANOVA, the result did not showed and any change in insulin sensitivity and lipid profile and noversion at baseline, two and four months.

Conclusions: Conversion from standard TacBID or cyclosporine to TacOD is safe. In spite of a reduced Tac exposure, there was no change in insulin sensitivity and lipid profile in renal transplant recipients.

Funding: Pharmaceutical Company Support - BMS

FR-PO1084

Tacrolimus Dose Requirement Based on the CYP3A5 Genotype in Renal Transplant Patients

Background: CYP3A5 is a cytochrome P450 enzyme involved in the metabolism of many drugs, including some immunosuppressants used in renal transplantation. Patients with a CYP3A5*1B/*1B genotype have a reduced ability to metabolize tacrolimus, resulting in higher drug concentrations and increased risk of adverse reactions.

Methods: We conducted a double-blind, randomized, controlled trial to evaluate the efficacy and safety of a TacOD regimen compared to a TacBID regimen in renal transplant recipients. Patients were randomized to receive either TacOD or TacBID, and the dose was adjusted to maintain CYP3A5*1B/*1B patients in the TacOD group and CYP3A5*1B/*1B patients in the TacBID group. The primary endpoint was the percentage of patients achieving target blood concentration levels.

Results: The study included 200 patients, 100 in each group. The TacOD group achieved target blood concentration levels in 95% of patients, while the TacBID group achieved target levels in 82% of patients. The difference was statistically significant (p<0.05).

Conclusions: The TacOD regimen was more effective in achieving target blood concentration levels compared to the TacBID regimen. This study supports the use of a TacOD regimen in patients with a CYP3A5*1B/*1B genotype to reduce the risk of adverse reactions and optimize drug efficacy.

Intraprotential Tacrolimus Level Variability in Pediatric Kidney Recipients Predicts Allograft Loss After Transfer to Adult Care

*Background:* Allograft loss is especially common in 17-24 year olds and is associated with non-adherence around the time that transplant care is transferred from the pediatric to adult setting. We explored whether coefficient of variation of tacrolimus (CV TAC) levels prior to transfer, as a marker of non-adherence, predicted allograft loss in a cohort of pediatric kidney recipients transferring to adult transplant centers.

*Methods:* Retrospective cohort of transplant recipients at Children’s Hospital of Philadelphia transplanted 1999 to 2011 who transferred care to University of Pennsylvania or Hahnemann University Hospital, identified by chart review. CV TAC was calculated as SD divided by mean TAC over 12 mos. Date of transfer was defined as the last pediatric visit. We compared pre-transfer TAC CV in those that subsequently lost their graft (n=20) (49.4% vs 26.2%, p = 0.0275).

*Results:* 24 of 65 subjects had sufficient data for analysis. Median age at transplant was 15.9y (8.5-18.9). The cohort was primarily male (66%), White (77%), had CUKAT (8%), and 46% had LRTK. Median age at transfer was 20y (17.4-22.1). Four patients had allograft loss within 365 days post-transfer. Pre-transfer CV TAC for subjects with allograft loss post-transfer (n=4) was significantly higher as compared to subjects without allograft loss (n=20) (49.4% vs 26.2%, p = 0.0275).

*Conclusions:* CV TAC may aid in identifying patients at risk for allograft loss post-transfer. Future analysis will investigate the effect of race, age at transfer, rejection, de novo DNA pre-transfer that may also help predict adolescent kidney transplant recipients at risk for allograft loss following transfer to adult transplant centers.

High Tacrolimus Level Variability in the Early Post-Transplant Period Is Associated with Reduced Patients and Graft Survival After Kidney Transplantation
Benaya Rosen-zvi, Avry Changac, Ruth Rahaminov.

*Background:* To determine whether increased drug level variability is associated with reduced graft survival and evaluate the relative effect of exposure to high and low drug levels.

*Methods:* We screened the Rabin Medical Center registry database for adult patients from 2001 to 2013 that were treated with tacrolimus, mycophenolate mofetil and corticosteroids and had at least 6 values of drug level during the first six months after the transplantation. Variability was defined as the time average of the absolute value of the difference from the mean and this value was divided by the mean to get the variability index. Univariate and multivariate Cox proportional hazard model was used with the combination of death and graft failure as composite outcome.

*Results:* We identified 803 patients who met the inclusion criteria, ninety eight (12.2%) of them reached the end point during median follow up time of 3.7 years (range 0.5 to 12.9 years). Increased variability index was associated with increased hazard of death or graft failure by univariate (Hazard Ratio (HR) 1.029 per 1%, 95% Confidence Interval (CI) 1.006-1.052, p=0.013) and multivariate models (HR 1.036 per 1% , 95% CI 1.01- 1.062, p=0.006). Variability was still significantly associated with reduced graft survival after introducing acute rejection into the model (HR 1.038 per 1% , 95% CI 1.008-1.065, p=0.006), introducing exposure to levels above 15 mg/ml into the model didn’t change the association between variability index and the composite outcome while introducing exposure to levels below 5 mg/ml eliminated the association and made it non-significant (p=0.18).

*Conclusions:* High variability index in the first six month after kidney transplantation is associated with increased mortality and graft loss. This association is, probably, mediated by exposure to low drug levels.

FR-PO1087

Decision Tree Analysis of Renal Transplantation Recipients Outcomes: A Single Center Data Mining
Jingyi Zhou, Jianghua Chen. Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, China.

*Background:* From recent literature on factors influencing renal transplant outcomes are quite confusion and few include factors influencing outcomes of rejection cases. This study was intended to get the factors in order and provide predictive models for clinical practice with decision tree analysis, and attempted to discuss about decision tree proposed for renal transplant database, predict the model growth and to serve personal medical care in big data era.

*Methods:* Renal transplant recipients registering between May 1988 and April 2014 in Kidney Center of the First Affiliated Hospital of Zhejiang University were included. Living state, race, patient gender, date of birth, transplant rejection, cause of death, xenograft, cold ischemic time (CIT) were calculated by decision tree.

*Results:* Totally 3921 cases were included. The loss-to-follow rate is 9.7%. With survival rate as the object, we got the most important factor, steroids (P<0.01). Patients in the follow-up group combination showed the highest survival rate: steroids, mycophenolate mofetil (MMF), stenting, warm ischemic time (WIT) ≤6.5 min, cold ischemic time (CIT) £300min, and aspartate aminotransferase (AST) 6 months post operation £34UL (survival rate of 100%). Patients had the lowest acute rejection rate when in the factor combination: steroids, antihuman thymocyte globulin or basiliximab induction, no blood transfusion history and female (0%, 83). Patients with acute rejection were regarded as a new database. The patients who took steroids and received stents shows similar outcomes with patients who had no rejection. Important factors that could be intervened for long-term outcomes included stenting, staths, steroids, etc.

*Conclusions:* Decision tree analysis is an outstanding choice for risk stratification, prognosis prediction and dynamic follow-up. Immunosuppression therapy was regarded as the most important factor for renal transplant recipients’ survival, rejection and other outcomes. Factors should be considered in combination for each specific patient.
Conclusions: Lack of sensitisation with a history of leuco-depleted transfusion is associated with a lower risk of rejection post-transplantation. This suggest that previous mechanisms of transfusion tolerance or “non-sensitisers” are still relevant in the modern immunosuppression era.

FR-PO1092

Geriatric Renal Transplantation in Deceased Donor Showed Compatible Clinical Outcomes to Younger Recipients Hyungjin Cho, Eunhye Shin, Hyosang Kim, Su-KJ Park. Dept of Internal Medicine, Div of Nephrology, Asan Medical Center, Seoul, Republic of Korea.

Background: According to USRDS annual report, while 50.3% of patients who start hemodialysis were aged over 65 years, only 19.3% of patients who underwent renal transplantation was aged over 65 years. Elderly ESRD patients still are not underwent renal transplantation as much as younger recipients. There were many previous studies about geriatric renal transplantation outcome in white, however data in Asain were limited. The aim of this study is analysis of geriatric kidney transplantation outcome in Korea.

Methods: From May 1993 to December 2013, kidney transplantations performed in Asan medical center were retrospectively reviewed. Recipients younger than 20 years and who underwent other organ transplantation were excluded. Binary logistic regression was used for evaluating risk factors of graft failure before half-life. Half-life of kidney allograft was defined as 10 years according to previous study.

Results: Regardless of donor type, there is no statistically significant difference in death censored graft survival between geriatric population and younger recipients.

Conclusions: Renal transplantation in geriatric population can be encouraged in Asain ESRD patients.
FR-PO1093
Long-Term Survival and the Associated Risk Factors for Death in Patients (pts) with Kidney Transplantation (Tx) Tanja Abeling,1 Irlene Scheffner,1 Verena Broecker,2 Michael Mengel,1 Hermann G. Haller,1 Anke Schwarz,3 Wilfried Gwinner.1 1Hanover Medical School, Germany; 2Cambridge Univ, United Kingdom; 3Univ of Alberta, Canada.
Background: Deaths over a period of up to 10 years (yrs) and the related risk factors were studied in Tx pts with protocol biopsies (Bx) (total observation: 4805 patient-yrs). Methods: 892 pts with kidney Tx in 2000-2007 were included. Protocol Bx were taken at 6 weeks, 3, and 6 months post-Tx (n=2251). 862 Bx for cause were taken in the 1st year and 262 thereafter. Lost-to-follow up was negligible (n=15). All acute rejections and clinical borderline cases in protocol Bx were treated.
Results: Patient and graft survival was 80% at 5yrs and 68% at 10yrs. Patient survival was 92% at 5 yrs and 82% at 10 yrs. 99 deaths occurred, relating to infection (24%), cardiovascular disease (15%), malignancy (16%), other specified causes (8%). Deaths were less in living-donor or kidney pancreas Tx and more frequent for extended donor criteria-Tx. A three-level multivariate Cox regression model was created in stepwise fashion, using significantly different variables from the pre-Tx, peri-operative, and long-term post-Tx period between survivors and deceased pts. Pre-Tx variables in the final model included recipient age, HLA-DR mismatches, diabetes, coronary heart disease, heart failure, and peripheral arterial disease. A significant peri-operative variable was cold ischemia time. In the long-term course, variables for death included increased loss of graft function, urinary tract infection, and higher PTH levels. Compared to the survivors, deceased pts received more therapies for rejection seen in protocol Bx (0.30 vs 0.43 per patient) and in Bx for cause (0.29 vs 0.34 per patient), however, this was not a significant factor in the final model. Also, the proportion of anti-rejection treatments was not higher in pts who died from infections, compared to pts dying from other causes. Concordance of the final model was 0.79; 200-fold bootstrapping confirmed its applicability.
Conclusions: Based on these results a tool is presented allowing risk calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care. Funding: Government Support - Non-U.S.

FR-PO1094
Causes of Death-Censored Kidney Allograft Failure: A Matched Case-Control Study of 340 Kidney Allograft Recipients Mohamed M. Alkali,1 Jim Kim,1 Choli Hartono,1 Thangamani Muthukumar,1 Meredith J. Aull.1 1Medicine, Weill Cornell Medical College, New York, NY; Surgery, Weill Cornell Medical College, New York, NY.
Background: Causes of kidney allograft failure in the current era of immunosuppression have not been clearly defined.
Methods: We did a matched case-control study of death-censored allograft failures among the 1672 adult kidney transplants at our center between 11/2001 and 12/2011. The cases and controls were matched 1:1 for age, donor type and year of transplant. We reviewed the charts and used the last available biopsy diagnosis for each case to determine the cause of graft failure. We divided the causes of graft failure into 8 categories: (i) acute rejection, (ii) transplant glomerulopathy, (iii) IF/TA, (iv) glomerular diseases, (v) BK nephropathy, (vi) others/unclassified, (vii) surgical and (viii) medical causes. We used conditional logistic calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care.
Results: Based on these results a tool is presented allowing risk calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care.

FR-PO1095
Effect of Simultaneous Native Nephrectomy on the Outcome of Kidney Transplant Recipients with Autosomal Dominant Polycystic Kidney Disease Jeong Ho Kim,1 Bun soon Choi,1 Cheol Whee Park,1 Chul Woo Yang,1 Yong-Soo Kim,1 Byung ha Chung.1 1Internal Medicine, Seoul St. Mary’s Hospital, Seoul, Korea.
Background: End stage renal disease (ESRD) patients with autosomal dominant polycystic kidney disease (ADPKD) required native nephrectomy because of limited space for renal allograft. However, the appropriate timing for nephrectomy and also its effect on allograft patient survival has not been fully investigated.
Methods: We retrospectively analyzed 41 kidney transplant recipients with ADPKD in whom transplantation was done either simultaneously, after or without native nephrectomy at Seoul St. Mary’s hospital between January 1987 and February 2014. We divided patients into 2 groups; simultaneous nephrectomy group (group A, n=13), after or without nephrectomy group (group B, n=28) and compared the perioperative outcome, post-transplant complications, allograft survival rate.
Results: The mean operative time was significantly longer in group A than group B (6.48 ± 1.84 vs. 5.27±0.84 hours; P = 0.048). The mean intraoperative blood transfusions was also significantly more needed in group A than B (3.66±3.43 vs. 0.75±0.26 units; P = 0.018). However, there were no differences in the incidence of acute rejection and other complications such as post-operative bleeding, infectious complication between the two groups (P > 0.05). The graft survival rate also did not differ between the two groups (P > 0.05).
Conclusions: Our study suggests that the complication rates were acceptable and the patients were not suffering significant negative impact on graft survival rate when native nephrectomy was done during kidney transplantation in ADPKD patients with ESRD. Therefore, if native nephrectomy is needed in ADPKD for kidney transplantation it can be done safely during transplantation.

FR-PO1096
Predictors of Renal Function Change After Kidney Transplantation Yoshifumi Hamasaki,1 Kent Doi,1 Akihiko Matsumoto,1 Daigoro Hirohama,1 Nobuhiro Sato,1 Daisuke Katagiri,1 Rei Ishikshi,1 Wakako Kawarazaki,1 Eisei Noiri,1 Masaomi Nangaku,1 1Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; 3Urology, The Univ of Tokyo, Tokyo, Japan.
Background: Several perioperative factors including histological findings of allograft biopsy are known to be associated with graft function and allograft survival after kidney transplantation (KT). Urate L-type fatty acid binding protein (u-LFABP) was reported to be correlated with serum creatinine, serum cystatin C, and estimated glomerular filtration rate (eGFR) in a cross sectional study evaluating post-KT patients. It is unclear what factors in post-KT period predict the longitudinal change of renal function.
Methods: The data from post-KT patients followed at The University of Tokyo Hospital were collected retrospectively. Patients followed-up less than 6 months after KT were excluded. To identify predictors of the longitudinal change of renal function, we analyzed data including clinical parameters measured at each outpatient visit. The primary outcome was defined as the change of eGFR during 6 months period.
Results: 32 post-KT recipients were analyzed in this study. Age and eGFR at baseline of these patients were 51.3 ± 12.7 years old and 41.2 ± 16.1 ml/min/1.73m2 (mean ± SD), respectively. The duration from KT to collection of clinical parameters was 6.8 ± 7.3 years (mean ± SD). Changes of eGFR were evaluated 6 months after. When patients were divided into two groups with (N = 15) and without (N = 17) eGFR decline after 6 months, u-LFABP and urirnary protein were significantly higher in the eGFR decline group (u-LFABP, 11.6 ± 5.1 vs 4.5 ± 3.7 mg/ml, and urinary protein; 272.7 ± 97.2 vs 101.8 mg/gCr, respectively). On ROC analysis, u-LFABP and urinary protein predicted eGFR decline after 6 months (AUC [95%CI] = 0.78 [0.60-0.96] and 0.70 [0.51-0.89], respectively). On multiple regression analysis, u-LFABP and urinary protein were significantly correlated with the absolute and relative eGFR changes during 6 months observation period.
Conclusions: u-LFABP and urinary protein measured at outpatient clinic can predict the change of renal function of post-KT patients.

FR-PO1097
Plasma Proenkephalin and Poor Long-Term Outcome in Renal Transplant Recipients Lyanne M. Kienek,1 Joachim Struck,2 Ron T. Gansevoort,1 Michel M. Joosten,1 Rudolf A. de Boer,1 Oliver Hartmann,2 Stephan J.L. Bakker.1 1Nephrology, UMC Groningen, Netherlands; 2Sphingotec GmbH, Germany; 3Cardiology, UMC Groningen, Netherlands.
Background: Enkephalins are well-known endogenous opioid peptides. Recent evidence indicates that they are not only involved in regulation of pain, but also in homeostasis of the immune system and the circulation. Proenkephalin (pro-ENK) is stable in plasma and has been established as a reliable surrogate marker for unstable processes. Recent studies found associations of pro-ENK with acute kidney injury and prognosis after myocardial infarction. We aimed to investigate whether pro-ENK could be linked to chronic kidney injury and poor long-term outcome in renal transplant recipients (RTR).
Methods: We included 664 RTR who were 8.1±7.6 years after transplantation. Plasma levels of pro-ENK were measured with a double monoclonal sandwich immunoassay.
Results: Mean age was 53±13 years, 56% was male, estimated glomerular filtration rate (eGFR) 49 ml/min/1.73m2 (interquartile range [IQR]; 37-64 ml/min/1.73m2) and
urinary albumin excretion (UAE) 40 mg/24h (IQR: 10-196 mg/24h). Median pro-ENK was 110 pmol/L. (IQR: 85-148 pmol/L). Pro-ENK was correlated with both eGFR (r=0.73, P<0.001) and UAE (r=0.35, P<0.001). During a median follow-up of 3.1 years (IQR: 2.7-3.9 years), 45 RTR developed graft failure and 76 died. Pro-ENK was both associated with increased risk of graft failure (hazard ratio per standard deviation increment of the logarithm of pro-ENK, 2.52, 95% confidence interval, 1.69-4.53) and all-cause mortality (1.83; 1.24-2.69), independent of age, sex, eGFR, and UAE. These associations remained materially unchanged after additional adjustment for body mass index, alcohol consumption, smoking, systolic blood pressure, antihypertensive drug use, use of calciumin inhibitors, and high-density lipoprotein.

Conclusions: High concentrations of pro-ENK are linked to chronic kidney injury as reflected by correlations with eGFR and UAE. In addition, pro-ENK was independently associated with increased risk of graft failure and mortality in RTR. Pro-ENK is an interesting new biomarker which may aid in early identification of RTR at risk for later graft failure and premature mortality.

Pre-Kidney Transplant Left Ventricular Ejection Fraction, Long-Term Allograft Function, and Survival - Asjad Sadag, Mahal A. Mohamed, Arjang Djamali, Sandesh Parajuli, Didier A. Mandebro, Brad C. Astor. Div. of Nephrology, Univ of Wisconsin Hospitals and Clinics, Madison, WI.

Background: End stage kidney disease patients with low left ventricular ejection fraction (LVEF) are considered high risk for poor outcomes following kidney transplantation (KT). No consensus exists on the level of systolic dysfunction below which patients are at increased risk of unfavorable allograft outcomes.

Methods: We studied 387 KT patients transplanted from 1/02 to 12/09 who underwent pre-transplant invasive and non-invasive cardiac assessment of LVEF. Outcomes included Delayed graft function (DGF), allograft survival, patient survival and allograft function.

LVEF N DGF Patient Survival Graft Survival Mean Difference and (95% CI) in Cr
OR (95% CI) HR (95% CI) OR (95% CI) OR (95% CI) 1 Year 3 Years 5 Years

C: Confidence Interval, Ref: Reference

Data adjusted for age, sex, race, PRA, Duration of RRT, DM, CAD, LVH and Induction Therapy.

Associations between different LVEF values. Results: A total of 36 (13.5%) patients had LVEF > 60%, 215 (55.5%) had LVEF between 45-60% and 36 (9.3%) had LVEF <45% before KT. Patients with low EF were more likely to have DM, CAD, LVH and longer duration of dialysis. During median follow up of 4.4 years there were 122 graft losses including 71 deaths. 73 patients (18.9%) had DGF. There was no significant difference in rate of DGF, serum creatinine, allograft survival and patient survival.

Conclusions: Low LVEF does not appear to significantly effect patient and allograft survival and function, suggesting that patients with low LVEF should not be excluded from transplantation.

FR-PO1101

Progression of Coronary Artery Calcification in Renal Transplant Recipients – A Follow-Up Of 7 Years - Sibel Galicicnek, Nurhan Seehah. Dept of Internal Medicine, Div of Nephrology, Istanbul Univ, Cerrahpasa Medical Faculty, Istanbul, Turkey.

Background: In the general population coronary artery calcification (CAC) and its progression is associated with cardiovascular and all cause mortality. We conducted a study to determine the progression of CAC in renal transplant recipients; we also examined the factors associated with progression and the impact of the analytic methods used to determine CAC progression.

Methods: We used multi-detector computed tomography to examine CAC in 113 prevalent renal transplant recipients, who did not have a documented cardiovascular disease. More specifically, a baseline follow-up scan were performed and changes in CAC scores were evaluated in each patient individually, to calculate the incidence of CAC progression. Univariate and Multivariate logistic regression analysis was used to evaluate the determinants of CAC progression.

Results: A Baseline CAC prevalence was 34.5 % and the mean CAC score was 47.08 ± 135.25. At follow-up scan that was performed after an average of 6.9 ± 0.5 years, CAC prevalence increased to 47.6% and the mean CAC score to 140.18 ± 332.11. Progression of individual CAC score was found between 32.7 and 34.5%, depending on the method used to define progression (Hokanson and Sevrukov). In patients with baseline CAC, median maximized annual rate of CAC progression was 13.8. Based on univariate analysis, age, presence of baseline CAC, high baseline CAC score, high body mass index were significantly associated with CAC progression defined according to both the Hokanson and Sevrukov methods. Moreover, HDL cholesterol level were significantly associated with CAC progression when progression was defined according to Hokanson’s method and donor type, high triglyceride levels and systolic blood pressure were significantly associated with CAC progression according to Sevrukov’s method.

Conclusions: The factors associated with CAC progression were age, donor type, high triglyceride levels, high baseline CAC score, high body mass index, and low HDL cholesterol level.

FR-PO1099

Serum Albumin Level Has Association with Both Graft Failure and Mortality in Kidney Transplant Recipients – Hee Jung Jeon, Sooyeon Ryu, Eunjung Kim, Jung Pyo Lee, Ja-Ryong Koo. 1 Dept of Internal Medicine, Hallym Univ of College of Medicine, Seoul, Republic of Korea; 2Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea.

Background: The studies concerned the association between post-transplant serum albumin concentration and post-transplant outcomes in kidney transplant recipients (KTRs) were scarce.

Methods: To evaluate the impact of serum albumin level on graft and patient survival, we performed a retrospective multi-center cohort study in Seoul National University Hospital, Asan Medical Center, and Kangdong Sacred Heart Hospital. A total of 2815 KTRs who underwent renal transplantation from Jan 1997 to Jan 2012 were classified into two groups according to the level of serum albumin at 1 year after transplantation (higher albumin group, >4.0 g/dL, n=1978 vs. lower albumin group, <4.0 g/dL, n=837). The Cox proportional hazard model was adjusted with age and gender of recipient, donor type, age of donor, diabetes mellitus, and estimated glomerular filtration rate (eGFR) at 1 year after transplantation.

Results: The mean age of the recipients was 47.7±11.3 years, and 59.1% were male. The rate of graft failure was higher in lower albumin group compared to higher albumin group (Hazard ratio [HR] 1.840, 95% confidence interval [CI] 1.367-2.477, P<0.001). Moreover, albumin concentration and post-transplant outcomes in kidney transplant recipients (KTRs) were not significantly different between two groups in terms of baseline CAC, CAC progression defined according to both the Hokanson and Sevrukov methods.

Conclusions: Serum albumin level at 1 year after transplantation is a prognostic factor for graft failure and patients’ mortality in KTRs. Therefore, evaluation and management for hypoalbuminemia should be considered to improve outcomes in KTRs.
Transplantation: Clinical and Translational - II
Poster/Friday

FR-PO1102

Background: Although the risk for morbidity and mortality has been studied in subjects with renal transplantation (RTx), a few study has investigated the role of adiponectin (ADPN) for cardiovascular disease (CVD) in RTx recipients.

Methods: We studied 57 adult RTx subjects (39 males, 18 females; 10 cadaveric donors) with at least three years of allograft survival (median 251 months). We examined clinical backgrounds such as treated drugs, blood pressure (BP, mmHg), body mass index (BMI), and blood chemistry including cholesterol (total, LDL-C, HDL-C), glucose, glycated hemoglobin (HbA1c), and serum high- and low-molecular-weight (HMW-LMW) ADPN fractions with regard to the associations of the visceral and subcutaneous fat areas on CT scan. We also analyzed the associations of CVD and post-transplant diabetes mellitus (PTDM) with ADPN fractions and the fat areas.

Results: The visceral fat area was inversely correlated with serum HMW- and LMW-ADPN levels (r=−0.400, p=0.002 and r=−0.296, p=0.025, respectively). Furthermore, the visceral fat area was inversely correlated with the HMW ratio and positively with the LMW-ADPN ratio (r=−0.444, p<0.001 and r=0.467, p<0.001, respectively), but no signiﬁcant correlation was noted between the subcutaneous fat area and the ADPN ratio. On multiple regression analysis, eGFR and the visceral fat area were signiﬁcant reducing factors of HMW-ADPN levels, and the alteration of eGFR was identified as an increasing factor of HMW-ADPN levels. Patients with CVD had larger visceral fat area (p=0.004), lower HMW-ADPN ratio (p=0.022) and higher LMW-ADPN ratio (p=0.049), but not in the subcutaneous fat area. On multiple logistic analysis, the higher HMW-ADPN ratio and statin treatment were identiﬁed as reducing factors of the development of CVD, but the LDL-C level was an aggravating factor. Moreover, the higher LMW-ADPN ratio and the visceral fat area were aggravating factors of PTDM.

Conclusions: Even in Japanese renal transplant recipients, visceral fat area and ADPN fractions were signiﬁcant factors for the development of both CVD and PTDM.

FR-PO1103

Background: Post transplant outcomes, in obese chronic kidney disease (CKD) patients having bariatric surgery (BS) as a bridge to renal transplantation, have not been widely reported.

Methods: The database at our center of renal transplant recipients having BS prior to transplant from was reviewed. Control group: all obese renal transplant recipients not having BS with body mass index (BMI) greater than 37 at time of transplant. BMI, patient and graft survival, time on wait-list, acute rejections and infections requiring hospitalization, were compared between both groups. Immunosuppressant drug levels were assessed in patients having bariatric surgery (BS) as a bridge to renal transplantation, have not been compared between both groups. Immunosuppressant drug levels were assessed in patients having bariatric surgery (BS) as a bridge to renal transplantation, have not been.

Results: 11 patients had BS prior to transplant. There were 25 obese controls. Median follow up post transplant was 12 months (range 2 to 39 months) in BS group versus 63 months (range 48 to 75 months) in the controls. There were no deaths in the BS group but 5 deaths among controls, of which 4 had functioning grafts at time of death. No signiﬁcant difference in patient survival was found (P = 0.18). There were 2 graft losses in the BS group versus 6 in the controls (P = 0.77), 4 of which were due to death with functioning grafts. Death-censored graft survival was borderline worse in the BS group (P = 0.05). Rejections were more frequent in the BS group. 4/11 patients had acute rejections in the BS group versus 3/25 in the control group (P = 0.01). Tacrolimus levels were at target in cases seen in Biops. Bespect in 1 patient who was non-adherent. Tacrolimus levels were lower in cases of rejection seen in the controls. There were no signiﬁcant differences in time on waitlist, BMI prior to BS or mean eGFR at 6 months (60.6 in BS and 64.8 mL/ min/1.73 m² in controls). However, the rate of infections was signiﬁcantly higher in the BS group, 9/11 vs 4/25 in the control group (P = 0.02).

Conclusions: Despite possible increased transplant candidacy in obese CKD patients having BS, higher rejection rates and inferior death-censored graft survival compared to matched controls seen in this study suggest that vigilance is mandatory. Further investigation is required.

FR-PO1104

Background: New onset diabetes mellitus after transplantation (NODAT) is a serious complication following renal transplantation. Association between serum magnesium level and new-onset diabetes after renal transplantation is controversial. The aim of this study was to identify the association between serum magnesium level and the development of NODAT in Korea.

Methods: The recipients who underwent living donor kidney transplantation between January 2009 and April 2012 were reviewed. Diagnosis of NODAT is defined by American diabetes association criteria. Serum magnesium level were measured at pretransplant, 3 days, 7 days and 3 months posttransplant. Univaried and logistic regression analysis were performed to examine the association between serum magnesium level and NODAT at 1 year posttransplant.

Results: Total 419 patients were enrolled. NODAT was diagnosed in 85(20%) patients. Mean magnesium level at 3 and 7 days after transplantation was signiﬁcantly lower in patients who diagnosed with NODAT. On logistic regression analysis, Age >40, Obesity, pretransplant glucone were associated with NODAT. However, there is no a association between serum magnesium and NODAT.

FR-PO1105
Is NODAT Really Associated with Acute Rejection in Kidney Only Transplantation? Rosa M. Montero, Florence R. Delaney, Manohursingh Rungtil, Paula Mobillo, Syed K. Hasan, Parami Chowdhury, Maria P. Hernandez-Fuentes. 11 Nephrology & Transplantation, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 12NHR Comprehensive Biomedical Research Centre at Guy’s and St Thomas’ NHS Foundation Trust in partnership with King’s College London and King’s College Hospital, London, United Kingdom; 13MRC Centre for Transplantation,DTMB, King’s College, London, United Kingdom; 14King’s Clinical Trials Unit, Biostatistics Dept, King’s College, London, United Kingdom; 15Nephrology & Transplantation, King’s College Hospital NHS Foundation Trust, London, United Kingdom; 16Nephrology & Transplantation, East Kent Hospitals Univ NHS Foundation Trust, London, United Kingdom.

Background: Previous reports suggest an association with New Onset Diabetes After Transplantation (NODAT) and rejection however it is unclear whether this effect is secondary to hyperglycaemia or a result of previous episodes of treated rejection. This observational study aims to determine the association between acute rejection(AR) and NODAT

Methods: 381 renal transplant recipients(RTR) from the KALIBRE study were analysed. Clinical details and laboratory results were collected in this cohort from 2010-2014. Episodes of AR were identiﬁed by renal transplant biopsies;Banft 2009 Categories 2&4 and 3 that were treatment responsive. NODAT was deﬁned as HbA1C=6.5% 3months post renal transplant. Cox’s regression proportional hazards was used for survival analysis. diabetes asse: 381 RTRs (313female, 68%white, 39%non-white, Age at transplant range: 17-75). 47 patients were diagnosed with NODAT (13.1%) and 93 (24.4%) with AR. 17/47 (36.2%) patients with NODAT had AR. Rejection free survival in NODAT group was signiﬁcantly lower than patients without NODAT (p=0.036 HR 1.75). Mean tacrolimus

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
623A
levels between rejectors and non-rejectors were not significantly different (10.1 and 10.3 ng/mL, respectively). TIDM and T2DM combined did not increase the rates of rejection in the cohort.

**Conclusions:** An association between NODAT and AR has been observed that was independent of tacrolimus levels. RTRs with diabetes mellitus did not have the same effect on AR rates suggesting a different underlying mechanism specific to NODAT rather than just hyperglycaemia.

Insulin Resistance: Is It a Risk Factor for Left Ventricular Hypertrophy in Pediatric Renal Transplant Recipients? Jale Sezer, Nur Canpolat, Gulseren Pehlivan, Salim Caliskan. Pediatric Nephrology, Istanbul Univ Cerrahpasa Faculty of Medicine, Istanbul, Turkey.

**Background:** Renal transplantation reverses uremia-related risk factors for cardiovascular disease; however, immunosuppressive therapy causes metabolic abnormalities such as insulin resistance, hyperglycemia and dyslipidemia. The aim of the present study was to evaluate the effects of these metabolic abnormalities as a risk factor for left ventricular hypertrophy in pediatric renal transplant recipients.

**Methods:** This is a retrospective study involving 31 renal transplanted children and adolescents (19 male; age 4-20 years) and 19 healthy controls. Anthropometric indices, office blood pressure (BP) and laboratory measurements and also left ventricular mass index (LVMI) at the same time were recorded from the patients’ file. The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated. Insulin resistance was defined as a HOMA-IR ≥ 2.5. Dyslipidemia was defined as HDL-C < 40 mg/dl, and/or LDL-C > 130 mg/dl, and/or TG > 150 mg/dl.

**Results:** Age at transplantation was 12.4±4.4 years with a median follow-up of 27 months. One patient received pre-emptive transplantation, 25 were on PD and 5 on HD before transplantation; 25 patients received a kidney from a living donor. Triple immunosuppressive therapy was used in all patients, except two who were not using steroids at time of the enrolment. Patients had significantly higher BMI-SDS, fasting glucose, fasting insulin, HOMA-IR and TG as well as lower HDL-C levels than controls (p<0.05 for all). Nine patients (29%) had insulin resistance; 11 (42%) were dyslipidemic; and 15 (50%) were hypertensive. LVMI was significantly higher in the patients than the controls (40.0±9.1 vs. 25.8±5.7; p<0.001); left ventricular hypertrophy was noted in 11 patients (48%), LVMI was correlated only with indexed diastolic BP (r=0.433, p=0.039), however, not with any of the lipid parameters or HOMA-IR. HOMA-IR was correlated with only BMI (r=0.381, p=0.035). There was no association between HOMA-IR and steroid doses.

**Conclusions:** Although insulin resistance and dyslipidemia are prevalent in pediatric renal transplant recipients, hypertension appears to be the main risk factor for left ventricular hypertrophy.

**FR-PO1108**

Parathyroidectomy for Tertiary Hyperparathyroidism in Kidney Transplant Recipients Brian M. Zwecker, Zahra Deen, Sreedhar A. Mandayam, Luan D. Truong, A. Osama Gaber, Edam H. Asham, Dana M. Hong, Venkat Ramanathan. 1Nephrology, Baylor College of Medicine; 2Transplant, Houston Methodist Hospital.

**Background:** Secondary hyperparathyroidism associated with ESRD improves after kidney transplantation (KT) in most patients. However, in some patients, high PTH persists post-KT to cause a tertiary hyperparathyroidism (ThPT) state, leading to hypercalcemia and worsening post-transplant bone disease. New calcimimetic drugs are often denied by insurance post-KT leaving few options for physicians.

**Methods:** In this retrospective study, we identified kidney transplant recipients between 2008 and 2013 who underwent parathyroidectomy (PTx) for ThPT.

**Results:** We identified 26 (2.5%) patients who underwent PTxs, out of 1001 patients who underwent KT at our center. Pre-surgery mean calcium and iPTH levels were 10.4±1.3 mg/dl and 508±404 pg/mL respectively. Post-KT, median time to PTxs was 482 days (Q1,Q3; 275-999); 65% underwent PTxs greater than one-year post-KT. PTxs indications included persistent hypercalcemia despite medical therapy (62%) and worsening osteoporosis (42%). Sestamibi scan showed hyperplasia and adenoma in 50% and 34% respectively. However, surgical pathology showed hypersecretory parathyroid tissue in 25/26 (96%) patients. Predictive value of the Sestamibi scan was poor (Cohen’s kappa index 0.1). PTxs complications included hypercalcemia (19%), transient renal failure (12%), and temporary nerve paresis (4%). There was no deleterious effect on long-term allograft function after PTxs compared with baseline values, serum creatinine was identical at 1 month (1.3±0.5 vs. 1.3±0.6; p=NS) and 2 years (1.3±0.6 vs. 1.3±0.6 p=NS). Seven patients had follow up post-surgical DEXA scans revealing an improvement in femur bone mass by 7.5%.

**Conclusions:** In one of the largest case series, we have shown that (a) Parathyroidectomy is required for tertiary hyperparathyroidism to treat hypercalcemia refractory to medical therapy and worsening osteoporosis (b) Sestamibi scan is inaccurate in differentiating between hyperplasia and adenoma and (c) Parathyroidectomy is well tolerated with no long-term deleterious effect on allograft function.

**Intra-Abdominal Hypertension and Renal Dysfunction in Pregnancy**

Nwogwarn Kittanamongkolchai, 1 Elliot G. Richards, 2 Mari Charisse B. Trinidad, 2 Wendy White, 3 Vesna D. Garovic. 1

**Nephrology, Mayo Clinic, Rochester, MN; 2Maternal Fetal Medicine, Mayo Clinic, Rochester, MN.**

**Introduction:** The effects of high intra-abdominal pressure (IAP) on renal function have been known for over a century. However, the diagnosis of peripartum intra-abdominal hypertension (IAH)/abdominal compartment syndrome (ACS) is challenging due to the lack of standardised definitions of IAP in pregnancy.

**Case Description:** A 32 year old obese primigravid with a twin pregnancy at 33 weeks gestation was admitted for intractable nausea and vomiting. She was oliguric and unresponsive to IV fluid. Her blood pressure was normal. Cr increased from a baseline of 0.9 mg/dL to 1.2 mg/dL within 4 weeks. A FeNa obtained after fluid resuscitation was 0.02%. Renal ultrasound showed patent renal vessels and no hydronephrosis. A diuretic was given with slight improvement in urine output. IAP measured by an intravesical catheter was 35 mmHg, and abdominal perfusion pressure (APP) (difference between mean arterial pressure and IAP) was 46 mmHg (normal = 50-60 mmHg). She was suspected to have IAH/ACS and was closely monitored. 2 days later, she developed hypertension, an increase in liver transaminases, and proteinuria. The decision was made to deliver with care due to severe preeclampsia. IAP measured immediately after C-section decreased to 18 mmHg, and it was 7 mmHg prior to dismissal. Urine output increased to 2.5 L per day and Cr declined to 0.7 mg/dL after delivery.

**Discussion:** Animal and human studies indicate that oliguria and acute kidney injury are frequent consequences of IAH/ACS, and can be present at relatively low levels of IAP. In our case, the IAP of 33 mmHg was quite extreme compared to IAP of 4-28 mmHg observed in cohort studies of peripartum patients. We suspected that obesity and twin pregnancy contributed to the extreme IAH. Her APP was significantly low and restoration of renal function was readily observed after reduction of IAP. Our case may support the theory that IAH/ACS is not always that severe. IAH/ACS is developing after obtained. Retrospective diagnosis from IAH is probably underrecognized as IAH is not routinely measured. Further study is needed to elucidate the impact of IAH in pregnancy.

**SA-PO002**

**Diabetes, Deafness and Renal Disease – A Case Report**

**Hospital Santa Maria, Lisboa, Portugal.**

**Introduction:** Deafness and kidney disease as well as diabetes and kidney disease are associations of which the Nephrologist is well aware. However, the concomitance of the three is not as usual, neither is a family history of these diseases.

**Case Description:** We present the case of a 49 year old woman with non-nephrotic proteinuria, no haematuria, normal renal function, slowly progressive bilateral sensorineural hearing loss and recently diagnosed diabetes and maculopathy and a maternal family history of deafness, diabetes and renal disease. The patient progressed with increasing proteinuria despite antiproteinuric measures and a renal biopsy was performed, revealing Focal and Segmental Glomerulosclerosis (FSGS). Autoimmune and Fabry disease investigation was negative. Facing the personal and maternal family history, the mitochondrial mutation m.3243A>G was pursued and identified in heteroplasmy and maternally inherited deafness and diabetes (MIDD) with renal involvement as FSGS. Renal biopsy ultrastructural study is ongoing. While waiting the etiologic investigation, a serum creatinine was 0.8 mg/dl.

**Discussion:** Mitochondrial diseases constitute a group of rare diseases in which renal involvement is uncommon, although possible. This is the case with MIDD, in which patients present with non-insulin dependent diabetes and sensori-neural hearing loss, which may be accompanied by other manifestations as cardiomyopathies or maculopathy. Renal involvement is possible, mostly as tubulointerstitial nephritis or less frequently presenting as glomerulopathy, namely FSGS. In this type of FSGS, the proteinuria is usually non-nephrotic, with scarce response to antiproteinuric measures, and slow progression to chronic kidney disease. The association of FSGS with mitochondrial diseases is not well known to the nephrologic community. Its timely diagnosis is particularly important to avoid exposure to ineffective and toxic immunosuppression.

**SA-PO003**

**Chronic Inflammatory Demyelinating Polynuropathy Associated with Advanced Focal Segmental Glomerular Sclerosis**

Albert Ndzemugo, 1 Radu Petrinjac-Nteadic, 2 Lekha K. George, 3 Elvira Gosmanova. 1 Nephrology, UTHSC, Memphis, TN; 2Neurology, Tri-State Neurology, PLLC, Memphis, TN.

**Introduction:** Chronic demyelinating polynuropathy (CDP) is rarely reported in patients with nephrotic syndrome (NS). CDP implies a tendency concomitantly with NS. We report a case of CDP developing at a time of focal segmental glomerular sclerosis (FSGS) progression to ESRD and mimicking uremic neuropathy.

**Case Description:** A 23 year male with NS dyspnoea on 1 try collapsing FSGS and serum creatinine (SCR) 1mg/dl was initiated on oral prednisone and lisinopril. He was lost to follow up and returned 1.5 years later complaining on burning pain and numbness in both feet for 4 weeks. Physical exam was normal except for unsteady gait, inability to perform tandem gait, decreased sensation from feet to upper legs, depressed Achilles and ankle flexor reflexes. Laboratory tests showed SCR 44mg/dL, hypekalemia, metabolic acidosis, normocytic anemia, and normal creatinine phosphokinase. A diagnosis of ESRD due to progression of untreated FSGS was made and dialysis was started. CT head and MRI spine were normal. Cerebrospinal fluid had protein of 74 mg/dL. Electrophoresis (EMG) showed absent compound muscle action potential (CMAP) and F-waves in both peroneal and tibial nerves, active denervation in tibialis anterior, gastrocnemius and extensor digitorum breves muscles, and prolonged distal latencies and reduced motor conduction velocity with normal amplitude of CMAP on both arms. Sensory nerves action potentials on sural and peroneal nerves were absent with prolongation of peak latencies on other nerves. The constellation of clinical, EMG and normal inflammatory, infectious and autoimmune laboratory markers was consistent with diagnosis of CDP. Plasmaapheresis was performed with partial improvement of neurological symptoms and was followed by intravenous immunoglobulin infusion as a maintenance therapy.

**Discussion:** CDP should be considered in patients presenting with peripheral neuropathy and history of FSGS. Correct diagnosis of CDP is critical as untreated CDP leads to inability to walk. Autoimmune mechanisms may be responsible for CDP and glomerular damage in FSGS but remain to be proven.

**SA-PO004**

**Silicone Implant Associated Acute Kidney Injury in a Male Transgender Patient**

Brian Y. Young, 1 Josephine Ambrus, 2 Eric E. Cohen. 1 Medicine, Medical College of Wisconsin, Milwaukee, WI; 2Pathology, Nephropath, Little Rock, AR.

**Introduction:** Obstructive kidney disease secondary to nephrolithiasis is a well-described cause of acute kidney injury. Stone formation is often due to dietary or metabolic factors, often no predisposing factors are found. We describe a rare case of obstructive acute kidney injury associated with hypercalcuria and hypercalciemia in a 32-year-old transgender patient. Patient was found to have granulomatous disease associated with silicone implants.

**Case Description:** 32-year-old male to female transgender patient presented to our institution with fatigue. Routine labs showed creatinine 11 mg/dL, BUN 140 mg/dL, K 7 mEq/L. She was emergently dialyzed, and imaging showed obstructing ureteric calculi, requiring bilateral stent insertion. Patient had a history of silicone implants in hips, buttocks and thighs 5 years previous. These were inserted by a non healthcare professional. There was no history of calculus patient ingestion or hormonal therapy use. Diagnostic work up for nephrolithiasis revealed, 24 hour urinary calcium 866 mg/24 hours, serum calcium 12.5 mg/dL, iPTH was normal. Other 24-hour urine values were normal. ACE level was 216 units/L. CXR was normal. PTH and malignancy work up was negative. CT abdomen revealed subcutaneous edema in lower back/gluteal area, around the sites of previous silicone implants, and inguinal lymphadenopathy. Subsequent gallium scan showed tracer uptake around Fabry disease but in ovaries. He had a serum creatinine was 0.8 mg/dl.

**Discussion:** His kidney biopsy stained positive for anti-agalsidase, but normal control kidney did not. He had anti-agalsidase antibodies in his serum that did not block agalsidase activity. Hypercalcemia due to silicone implant associated granulomatous disease was negative RPR, negative tests for hepatitis B and C, and an antinuclear antibody of 1:640 titer. A kidney biopsy showed Fabry disease and superimposed membranous nephropathy. Lisaonopril 2.5 mg/day was started. Rheumatological evaluation showed no evidence of lupus or vasculitis. The most recent serum creatinine was 0.71 mg/gram, with a serum creatinine was 0.8 mg/dl.

SA-PO006

Isolated Diplopia Caused by Calcineurin Inhibitor Therapy in a Patient with Idiopathic Membranous Nephropathy

Nader S. Bahit, Ashwani K. Gupta.
Nephrology and Hypertension, Univ of Florida, Jacksonville, FL.

Introduction: Neurotoxicity is a common side effect of treatment with calcineurin inhibitors. Tremors are frequently reported as the most common manifestation. Variable presentations can include headaches, seizures, visual hallucinations or blindness. Six nerve palsy has been reported in previous cases of bone marrow and cardiac transplant patients receiving calcineurin inhibitors. In many of these previously reported cases, the drug was administered intravenously and very high drug levels were found.

Case Description: 42 year-old Caucasian female with biopsy proven idiopathic membranous nephropathy (IMGN) who was being treated with tacrolimus and prednisone for nephrotic syndrome. Her tacrolimus levels were maintained between 6-8 ng/mL. Her urine protein/creatinine ratio of 8 g/gm was successfully reduced to less than 1 g/gm. She continued to be in complete remission but after 3 months of therapy she presented with diplopia. The diplopia was binocular and vertical. The patient was seen for an ophthalmologic evaluation. Her visual acuity was 20/20. Pupils were equal and reactive to light and accommodation. No nystagmus was observed. Visual fields and color vision was also normal in both eyes. Assay for Acetyl-choline receptor antibody was negative.

The patient remained compliant with her medications despite the side effects. At this time she was switched to low dose Cyclosporin (CyA) in anticipation that similar side effects may not be observed. Though CyA levels were 44 ng/mL and 59 ng/mL on two occasions but her symptoms did not resolve. A consultation with neuro-ophthalmology was sought and the patient was instructed to discontinue CyA. The symptoms completely resolved 4 days after stopping CyA.

Discussion: This is the first reported case of isolated diplopia secondary to calcineurin inhibitors in low doses for treatment of IMGN. Monitoring of serum concentrations of these drugs has not been correlated with toxicity. The mean duration to onset of symptoms was 3 weeks. The diplopia resolved after 3 days of discontinuing calcineurin inhibitors. This may be a rare case to report the association of RANKL inhibition due to CyA to neurotoxicity, as there are no reported cases of similar side effect in the calcineurin inhibitor class.

SA-PO007

Bilateral Renal Artery Stenosis in a Patient Treated with Nilotinib for Chronic Myeloid Leukemia

Omar M. Shahateet, Milos N. Budisavljevic. Medical Univ of South Carolina.

Introduction: The use of tyrosine kinase inhibitors (TKIs) targeting the BCR-ABL1 oncoprotein has been successful in chronic myeloid leukemia (CML). Nilotinib is a second generation TKI designed and used to overcome deficiencies of imatinib such as resistance or intolerance. Nilotinib also received approval in chronic phase (CP)-CML for resistance or intolerance. Nilotinib is a second generation TKI designed and used to overcome deficiencies of imatinib such as resistance or intolerance.

Case Description: A 45 year old Caucasian male diagnosed with BCR-ABL1 positive CML at age 31. He was treated with Hydroxy derivative followed by Gleevec and was in complete remission (CR) for 4 years when he developed ALL transformation necessitating chemotherapy and peripheral blood stem cell transplantation. He was in CR for 5 years being maintained on dasatinib which was switched to nilotinib due to intolerance from GI upset. He developed worsening creatinine and high blood pressure after being on nilotinib for 2 years. His blood pressure was 170/90, heart rate of 64/min. The remainder of his physical exam was unremarkable. U/S and CT revealed bilateral renal artery stenosis.

Discussion: Nilotinib treated patients should be monitored for hypertension and renal artery stenosis. Nilotinib blocks the receptor kinase KIT which regulates histamine and heparine release. This depresses vascular repair system and predisposes to arterostenotic events.

SA-PO008

A Case of Minimal Change Disease After the Administration of Anti-RANKL Monoclonal Antibody

Kesuke Horikoshi, Norihiko Sakai, Yasuyuki Shinozaki, Shiniji Kitajima, Akinori Hara, Yasunori Iwata, Mizo Shimizu, Kengo Furuchi, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.

Introduction: Receptor activator of nuclear factor kappab B (RANK)-RANK ligand (RANKL) has emerged as an important regulator of bone mineral density and micrornetabolism. In addition to bone, recent study has revealed that RANKL may contribute to the podocyte survival signal after its injury. Here we report a case that RANKL inhibition might contribute to the onset of nephrotic syndrome.

Case Description: A 59-year-old male without any episodes of proteinuria was given denosumab, a fully human monoclonal antibody to RANKL, to treat osteoporosis. Two weeks after its administration, he showed bilateral pretilial edema. Laboratory tests revealed that he had microscopic hematuria, severe proteinuria (15g/gCr), hypoprothrombinemia (4.0g/dL) and hypoalbuminemia (1.5g/dL). The proteinuria selectivity index was below 0.1, indicating that he had selective proteinuria. Based on the results, he was diagnosed to have nephrotic syndrome. Renal biopsy showed minor glomerular abnormality with less tubulointerstitial damage, indicating minimal change disease (MCD). Taken altogether, glucocorticoid therapy of prednisolone 50 mg/day had started. After four weeks of treatment, the level of urinary protein was still high (4.1g/gCr), but it decreased gradually to the range of partial remission (1.2g/gCr) with another 8 weeks treatment of prednisolone.

Discussion: This may be a rare case to report the association of RANKL inhibition with MCD. The responsiveness to glucocorticoid therapy was not good enough to promptly induce complete remission, suggesting that podocyte injury due to RANKL inhibition could be responsible at least in part in MCD in this case.

SA-PO009

Eculizumab in Management of Thrombotic Lesions in Kidney Allograft of Patient with Anti-Phospholipid Syndrome

Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero. Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.

Introduction: Thrombotic microangiopathy (TMA) is one of the hallmark vascular lesions of anti-phospholipid syndrome (APLS). These lesions are at high risk of recurrence after kidney transplantation. The complement pathway is thought to be active in this process by deposition and by presence of apoptotic and vascular cell markers on sequential transplant biopsies. Eculizumab is a humanized anti-C5 monoclonal antibody which has been used in atypical hemolytic uremic syndrome. Recently, there have been reports of use of Eculizumab in transplant patients with APLS/TMA.

Case Description: We present a case of a 58 year old Caucasian man with history of systemic lupus erythematosus, APLS on warfarin, hypertension, rheumatoid arthritis, transient ischemic attack, coronary artery disease with triple vessel bypass, chronic kidney disease stage 5 for which he received pre-emptive living unrelated kidney transplant. After an uneventful post-transplant course, he was discharged on warfarin. He presented to the hospital 4 days later, with acute renal failure, pain over the graft and sub-therapeutic INR. A perinephric collection was drained. Cytomegalovirus and BK polyoma viremia were ruled out. Transplant kidney biopsy, revealed TMA with segmental necrosis and small vessel fibrin thrombi and no acute rejection. High dose steroids along with aggressive anticoagulation were given. The patient received two sessions of Eculizumab. After meningooccal meningitis immunization, Eculizumab 900mg/week was started. After 4 doses, Eculizumab was changed to 1200mg/two weeks. Creatinine trended down from 7.3 to 3.0 mg/dl and dialysis was stopped after 7 sessions. He was positive for IgG anticoagulant, beta-2 glycoprotein, and lupus anticoagulant and was started on daily aspirin and warfarin with INR goal of 2.5-3.5.

Discussion: Treatment with Eculizumab and plasmapheresis resulted in a relatively rapid and dramatic improvement of graft function in our patient and should be considered in difficult to manage TMA/APLS in transplant patients. Its use permits a safer approach of controlling the complement final common pathway.

SA-PO010

Transient Gestational Diabetes Insipidus in a Patient with Pre-Eclampsia

Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero. Dept of Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.

Introduction: Diabetes insipidus (DI) is manifestation of post pituitary insufficiency characterized by polyuria and polydipsia. DI can be neurophyselial, nephrogenic, polydipsia related or gestational (GDI). L-Desamino-8-D-arginine vasopressin (DDAVP) is a vasopressin analogue which had higher and prolonged anti-diuretic activity with no effects on smooth muscle. An increase in urine osmolality by at least 50% following administration of DDAVP is diagnostic of disorder.

Case Description: We present a case of a 22-year-old African American primigravida woman with no past medical history, in 32nd week of pregnancy, admitted with pre-eclampsia with no liver injury. On admission, blood pressures were between 140-165/60-70 mmHg. After an uneventful delivery she had urine output ranging 6-9 liters along with polydipsia. Both of these were present all through out her third trimester. On exam there was no evidence of volume overload or dehydration. Labs were sodium 137mEq/L, Potassium 2.8mEq/L, AB 3.0mg/dl, TSH 4.16, urea nitrogen <0.3, creatinine 0.4, serum osmolality 284, urine osmolality 141, spot urine protein creatinine ratio of 0.8. With one dose of subcutaneous DDAVP patient’s urine output rose to 358 within 24hrs. Oral DDAVP
doses were titrated based on clinical response and labs. Hyponatremia was managed with oral repletion and resolved later. On discharge urine osmolality increased up to 523 with 2 liters urine output and no excessive thirst.

Discussion: GDI is attributed to decreased thirst threshold, secretion of vasopressinase from placental cells (cystine amino-peptidase) along with reduced vasopressin secretory capacity and increased breakdown of vasopressin by placenta-digested vasopressinase, decreased responsiveness to vasopressin by physiologically increased prostaglandin E2 activity in kidney and polyuria with hyponatremia renders collecting ducts resistant to vasopressin. Subclinical DI can manifest itself under the influence of physiological pregnancy changes. DDAVP is the only treatment, as it is not degraded by vasopressinase. Timely diagnosis with high index of suspicion can help with appropriate management and shorter length of stay.

SA-PO011

Introduction: The dangers of baclofen toxicity in patients with advanced kidney disease and in particular patients on dialysis remain underappreciated by many physicians.

Case Description: We present a case of a 64 year old male who developed an uncommon case of altered mental status during his hospitalization. His medical history included ERSD for which he was receiving in-center hemodialysis, diabetes and hypertension. He initially presented to the hospital with complaints of shortness of breath and hiccup. His shortness of breath was attributed to volume overload and resolved with two consecutive days of dialysis with fluid removal. For his intractable hiccup, he was started on baclofen. During his hospitalization, he became lethargic and was unable to move his lower extremities. Laboratory data including serum sodium, potassium, glucose, calcium, BUN, phosphorus, liver function tests, thyroid function tests, troponins, inr and prothrombin work up and ammonia levels were unrevealing. Neuroimaging, including CT head and brain MRI, were unchanged from previous studies and revealed moderate diffuse cerebral atrophy. An EEG was also performed and did not suggest signs of epileptic activity. Further investigation revealed that he had received a total of 20 mg of baclofen over 2 days. After other etiologies were ruled out, we determined that he may have suffered from baclofen induced encephalopathy. His baclofen was stopped and he was prescribed daily sessions of hemodialysis for three days with the intent of clearing baclofen. He was dialyzed for 4 hours during each dialysis session with a high flux dialyzer. After his first session of dialysis, the patient was more alert and would follow simple commands. At 3 days, the patient’s mental status returned to baseline and he was able to move his extremities.

Discussion: Although the kinetics of baclofen elimination during hemodialysis are not well understood, this case demonstrates the resolution of baclofen induced encephalopathy with frequent and consecutive dialysis. Furthermore, we hope this case raises awareness among physicians of the toxic effects that baclofen can cause in dialysis patients.

SA-PO012

Introduction: Urea cycle disorders (UCDs) are rare pediatric diseases but partial enzyme deficiency can persist throughout adulthood. Little has been published about the role of hemodialysis in addressing the acute complications of UCDs in adulthood. Catabolic states are well known trigger factors for the life-threatening acute hyperammonemia.

Case Description: We are reporting a 32-year old male patient with history of partial ornithine transcarbamylase deficiency diagnosed at age of 6 months. He presented with altered mental status due to acute hyperammonemia (108mcg/dl). He was treated with a pre-specified protocol (infusion of Na Phenylacetate/benzoate and Arginine HCl, fasting and high protein diet). An EEG was performed and did not suggest signs of epileptic activity. Further investigation revealed that he had received a total of 20 mg of baclofen over 2 days. After other etiologies were ruled out, we determined that he may have suffered from baclofen induced encephalopathy. His baclofen was stopped and he was prescribed daily sessions of hemodialysis for three days with the intent of clearing baclofen. He was dialyzed for 4 hours during each dialysis session with a high flux dialyzer. After his first session of dialysis, the patient was more alert and would follow simple commands. At 3 days, the patient’s mental status returned to baseline and he was able to move his extremities.

Discussion: Although the kinetics of baclofen elimination during hemodialysis are not well understood, this case demonstrates the resolution of baclofen induced encephalopathy with frequent and consecutive dialysis. Furthermore, we hope this case raises awareness among physicians of the toxic effects that baclofen can cause in dialysis patients.

Treatment of Atypical Hemolytic Uremic Syndrome Early in Pregnancy with Eculizumab Rahul N. Pawar, 1 Savneek S. Chugh, 1 Amy R. Patel, 1 Prachi Kale. 1 Nephrology, Westchester Medical Center, New York; 1Internal Medicine, Westchester Medical Center.

Introduction: Atypical Hemolytic Uremic syndrome (aHUS) is known to cause acute thrombotic microangiopathy (TMA) in pregnancy with adverse maternal and fetal outcomes. A French study showed that aHUS usually occurs postpartum when activity of placentally regulated alternative complement pathway increases. We present a case of a young lady early in pregnancy with severe thrombocytopenia and acute renal failure suspicious for TTP, but later diagnosed with aHUS, which improved with eculizumab.

A 30 year old G1P5A5L5 10 weeks pregnant with a past medical history of 5 first trimester miscarriages presented with vomiting, vomiting and watery diarrhea whose labs show a hemoglobin (Hgb) 7.8 g/dl, platelet (PLT) count 15k/µL, BUN 65 mg/dL and serum creatinine 2.44 mg/dL along with a LDL of 1.84 U/L, lactoglobulin <8 mg/dl, and albumin 3.2 g/dl. Liver function tests (LFTs) and coagulation studies were normal. She was suspected to have TTP and transferred to our tertiary medical center. Urinalysis revealed 3+ protein and 3+ blood. Blood smear showed schistocytes. A diagnosis of TMA was made and plasmapheresis was started. Serologies for lupus and anti-phospholipid antibody syndrome were negative and LFTs remained normal, ruling out HELLP. The ADAMTS-13 activity level was noted to be 129%. Renal function declined requiring the initiation of hemodialysis(HD). On the basis of ongoing hemolytic anemia with thrombocytopenia, renal failure and a negative ADAMTS-13, she was started on Eculizumab. After 2 doses, her renal function and urine output improved and HD was stopped. At discharge, her Hgb was 8.5 g/dl, PLT 150 K/µL, and BUN/creatinine 25/1.84 with the plan to receive monthly eculizumab infusions.

Discussion: aHUS is caused by activation of the complement system due to a genetic deficiency of its regulatory proteins, specifically complement factor H, factor I, and membrane cofactor protein. It can lead to TMA causing multi-organ failure and the potential for death if not managed in time. Pregnancy can cause aHUS in any trimester. One should maintain a low suspicion for aHUS in a pregnant patient with prompt initiation of eculizumab to prevent negative outcomes.

SA-PO014

Introduction: Relatively few renal manifestations have been detected in Familial Mediterranean Fever (FMF). We present a case of biopsy proven pauci-immune glomerulonephritis (GN) in a patient with clinically diagnosed FMF and review past treatments of pauci-immune GN in FMF patients.

Case Description: We present an interesting case of a 22 year old man who had suffered for nearly seven years a constellation of symptoms including fever, nausea, vomiting, abdominal pain, arthralgias, chest pain, and an erythematous rash consistent with a clinical diagnosis of Familial Mediterranean Fever. He had a normal serum creatinine of 1.0 mg/dl which peaked at 2.0 mg/dl. Repeated urinalysis indicated 6-10 RBCs per high powered field (hpf) and 6-21 WBCs per hpf. Laboratory testing revealed only an elevated creatine kinase (CK).

A kidney biopsy was performed which revealed 41% of glomeruli globally sclerosed and 54% of the viable glomeruli with active crescents and 25% interstitial fibrosis with tubular atrophy. Immunofluorescence revealed minimal C3 staining. This was consistent with Pauci-Imune Glomerulonephritis or ANCA negative vasculitis. It was treated with Colchicine and pulse steroids, and maintained with mycophenolate mofetil as detection for mutations in the MEFV gene in the diagnosis of FMF is ongoing. He has had no relapse of his FMF with initiation of colchicine and now has had resolution of his hematuria, proteinuria, and acute kidney injury.

Discussion: In the literature, there is minimal knowledge about the renal manifestations of Familial Mediterranean Fever and fewer documented reports on the treatment protocols for ANCA negative vasculitis in FMF. We were able to treat ANCA negative vasculitis in a patient with FMF with only pulse steroids and maintenance immunosuppression with mycophenolate mofetil with great response.

SA-PO015
Stress of Surgery – Is It Just Mental or Can It Be Renal as Well? Mitul Natu Patel, Maria M. Picken, Kavitha Vellanki. Nephrology, Loyola University Medical Center, Maywood, IL.

Introduction: Waldenstrom’s macroglobulinemia (WM) is a rare clinicopathological disorder with a reported annual incidence of 3 per 100,000 people. It is characterized by Ig M monoclonal gammoathy in the blood and lymphoplasmacytic lymphoma in the bone marrow. Clinical manifestations are non-specific and generally related to Ig M infiltration of hematopoietic tissues. While deposits of Ig M in the glomerular basement membrane and marrow. Clinical manifestations are non-specific and generally related to Ig M infiltration of hematopoietic tissues. While deposits of Ig M in the glomerular basement membrane and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis to be treated with mycophenolate mofetil with great response.

Case Description: We are reporting a 75 year old woman with WM, hypertension, obstructive sleep apnea and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis to be treated with mycophenolate mofetil with great response. She had a history of urinary retention following a post-operative catheterization in a patient with underlying WM with spontaneous recovery each time.

Case Description: Seventy five year old woman with WM, hypertension, obstructive sleep apnea and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis to be treated with mycophenolate mofetil with great response. She had a history of urinary retention following a post-operative catheterization in a patient with underlying WM with spontaneous recovery each time.

Case Description: Seventy five year old woman with WM, hypertension, obstructive sleep apnea and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis to be treated with mycophenolate mofetil with great response. She had a history of urinary retention following a post-operative catheterization in a patient with underlying WM with spontaneous recovery each time.
mg/dl, 5 days prior) and renal service was consulted for AKI. She had a prior episode of AKI with knee replacement in 2008, 11 years ago, but was otherwise well until 3 days prior to subsequent spontaneous recovery. Further work up revealed fairly active urine sediment with new onset 24 hour urine protein of 3.3 grams. C3 was normal, C4 < 5 mg/dl, cryoglobulin was positive, rheumatoid factor of < 20 ug/dl, serum IgM were elevated at 646 mg/dl (normal 46-304 mg/dl) and serum immunofluorescence showed an abnormal restricted band between the beta and gamma regions. Kidney biopsy showed strongly PAS positive hyaline-like precipitates in the glomerular capillaries with immunofluorescence strongly positive (3+) for IgM and lambda light chains. There were abundant, confluent electron dense deposits in the mesangium and subendothelial space. Her symptoms improved with diuresis and she refused any other major intervention. Renal function eventually improved with serum creatinine of 1.2 mg/dl at the time of discharge.

**Discussion:** In conclusion, we believe the stress of surgery precipitated intraglomerular deposition of IgM leading to AKI with spontaneous resolution thereafter.

**SA-PO016**

New Causes of Secondary Hyperparathyroidism: Unforeseen Effects of New Drugs on the PTH-Calcium Axis

**Introduction:** Calcium homeostasis is a function of the interplay between GI absorption, renal excretion and bone resorption. Although numerous effectors control these processes, PTH is primarily responsible. PTH affects the kidney and bone through PTH receptor 1. In the kidney PTH decreases phosphorus reabsorption, increases calcium reabsorption and stimulates 1-hydroxylation of vitamin D. In the bone PTH up-regulates expression of RANKL and decreases expression of osteoprotegrin. This process increases RANKL binding to RANK on osteoclast precursors stimulating them to become osteoclasts that increase bone resorption. New drugs that inhibit RANK are used to treat osteoporosis and bone metastases. We describe two patients who treated with recently developed chemotherapeutic agents who developed severe hypocalcemia, and secondary hyperparathyroidism with hypophosphatemia due to renal P404 wasting. We hypothesize that these drugs inhibit RANK.

**Case Description:** Case 1: A 72 y/o woman with metastatic leiomyosarcoma received Trabectedin, an experimental agent which interacts with DNA. She subsequently complained of weakness. Labs are shown. Case 2: A 73 y/o man with ALL positive for BCR-ABL was started on the tyrosine kinase inhibitor Dasatanib. He subsequently developed the laboratory abnormalities shown.

Creatinine was 0.7 mg/dl in patient 1 and 0.8 mg/dl in patient 2.

**Discussion:** Both patients developed secondary hyperparathyroidism. The renal effects of PTH appeared to be intact with increased calcium resorption, phosphorous excretion and hydroxylation of 25-Vitamin D. The effects of PTH on bone resorption, however, appeared blunted. Because PTH acts on both kidney and bone through the same receptor, we believe that this represents a post receptor phenomena involving the RANKL osteoprotegrin system. The tyrosine kinase inhibitor, Imatinib, has been shown to decrease bone resorption through a similar mechanism. As new drugs are developed it is important to recognize potential untoward effects.

**SA-PO017**

Connection or Coincidence: Behçet’s Disease and Focal Segmental Glomerulosclerosis with Nephrotic Syndrome

**Introduction:** Behçet’s Disease (BD) often presents with aphthous and genital ulcers, uveitis, and erythema nodosum. Rarely, renal amyloidosis, IgA nephropathy and crescentic glomerulonephritis result. Here we present a case of nephrotic syndrome from focal segmental glomerulosclerosis (FSGS) in a patient with BD evidence to suggest a direct association.

**Case Description:** A 28 year-old woman presented with a 4 month history of dysuria, hematuria, proteinuria and transient oliguric AKI. Initial work up revealed normal renal function. Renal biopsy showed 30% global sclerosis. Immunofluorescence showed a mesangial pattern of IgA, C3, C4, kappa, and lambda: negative. Electron microscopy: mesangial expansion with diffuse increase extracellular matrix, leading the patient to be classified as focal segmental glomerulosclerosis. Clinically, the patient had episodes of oral aphthous ulcers, uveitis, pathergy reaction and keratoconjunctivitis. A year later, a renal biopsy revealed 30% global sclerosis. The patient then developed proteinuria with diminished renal function and was admitted to our hospital. At admission, the patient’s creatinine was 5.7 mg/dl, proteinuria 15 g/gCr, and moderate hematuria. Free light chains and endocapillary proliferative GN with dominant C3 and trace IgG. Conservative therapy was started, given the repeated hemorrhagic ulcer, and decreased rate of renal function decline. Hemodialysis was initiated on hospital day 20 because of oliguria, but was ceased on day 60 with recovery of kidney function. SCr decreased to 1.2 mg/dl, and urinary protein decreased to <1 g/gCr. One year after discharge, the patient developed nephrotic-range proteinuria, and the second renal biopsy revealed the increased sclerotic glomeruli and fibrous crescents with isolated C3 deposits.

**Discussion:** To our knowledge, this is the first to describe reversal of dialysis-dependent renal failure after conservative therapy in a BD3GN patient. Similarly to the present case, the histological morphology and clinical presentation infrequently mimic the picture of postinfectious GN, although the transient recovery is usually partial. A novel classification of such cases among C3GN may be needed to avoid an unnecessary immunosuppression.

**SA-PO019**

Optical Coherence Tomography and In Vitro Retinal Findings in Membranoproliferative Glomerulonephritis Type 2

**Introduction:** Membranoproliferative glomerulonephritis type 2 (MPGN II) is a condition with electron dense deposits in the glomerular basal membrane that usually affects youngsters of 5-15 years old. Patients may have asymptomatic retinal drusen-like deposits but 10% of cases may have choroidal neovascularization that leads to visual loss. We evaluated patients with a high-speed spectral-domain optical coherence tomography (SD-OCT) device and in vivo OCT imaging of the retina.

**Case Description:** Four eyes of 2 patients with MPGN II were scanned using a high-speed 840-nm-wavelength SD-OCT (RTVue XR Avanti; Optovue, Inc, Fremont, USA). The split-spectrum amplitude-decorrelation angiography algorithm was used to detect blood flow. Fluorescein angiography (FA) (HRA System, Heidelberg Engineering) images were obtained in search for drusen-like deposits in the Bruch membrane or choroidal neovascularization.

Both patients (female, 34 years old and male, 25 years old) had best corrected visual acuity of 20/20 in both eyes, unremarkable anterior biomicroscopy, RPE mobilization and macular drusen-like deposits. There was no choroidal neovascularization at the FA. In vivo OCT showed hyperreflective dots with a hyperreflective ring at the RPE that corresponds to drusen-like deposits underneath the RPE and dilated choroidal image.

**Discussion:** At present, there is no proven correlation between BD and FSGS with nephrotic syndrome. Our patient presented with BD flare coinciding with the development of nephrotic syndrome both of which improved simultaneously with steroids suggesting a direct connection. Therefore, the clinician should be aware of this possible link and screen accordingly for proteinuria both qualitatively and quantitatively to detect early renal involvement in patients with BD.

**SA-PO018**

Reversal of Dialysis-Dependent Renal Failure and Nephrotic Syndrome after Conservative Therapy in an Adult with Proliferative Glomerulonephritis with C3-Dominant Deposition

**Case Description:** In December 2012, a 55 year-old man was admitted with rapidly progressive glomerulonephritis and nephrotic syndrome. In May 2011, his serum creatinine(Scr) was 0.63mg/dl. Seven weeks previously, he was admitted to another hospital with hemorrhagic gastric ulcer accompanied by renal failure (SCR 4.61 mg/dl, urinary protein 15 g/gCr, and moderate hematuria), in the absence of preceding infection. At admission to our hospital, SCR increased to 7.60 mg/dl. ANCA, anti-nuclear antibody, and decrease in complement factors were absent. A renal biopsy specimen showed crescentic and endocapillary proliferative GN with dominant C3 and trace IgG. Conservative therapy was started, given the repeated hemorrhagic ulcer, and decreased rate of renal function decline. Hemodialysis was initiated on hospital day 20 because of oliguria, but was ceased on day 60 with recovery of kidney function. SCR decreased to 1.2 mg/dl, and urinary protein decreased to <1 g/gCr. One year after discharge, he developed nephrotic-range proteinuria, and the second renal biopsy revealed the increased sclerotic glomeruli and fibrous crescents with isolated C3 deposits.

**Discussion:** To our knowledge, this is the first to describe reversal of dialysis-dependent renal failure after conservative therapy in a C3GN patient. Similarly to the present case, the histological morphology and clinical presentation infrequently mimic the picture of postinfectious GN, although the transient recovery is usually partial. A novel classification of such cases among C3GN may be needed to avoid an unnecessary immunosuppression.
Severe Hypoatremia following the Treatment of Pulmonary Strongyloides Stercoralis Infection

Introduction: Strongyloides stercoralis is a soil transmitted nematode which can cause serious infection in immunocompromised patients through skin penetration. The helminth can cause abdominal and pulmonary symptoms and can continue to autoinfect patients if untreated. It has been frequently reported to cause hypoaatremia which resolves with treatment of the infection.

Case Description: A 59-year-old Dominican man with a history of single lung transplant and chronic abdominal pain was admitted for treatment of pulmonary strongyloides infection found on routine outpatient bronchoscopy. On admission he was found to have an E. Coli bacteremia which was attributed to gastrointestinal translocation.

The patient was started on ivermectin (15 mg/day orally) and piperacillin tazobactam (4.5 grams every 8 hours intravenously in 5% dextrose solution). He developed a rapid decline in his serum sodium concentration from 135 mmol/L prior to admission to 109 mmol/L on his hospital day 5. Physical exam at this time was notable for euvoletic appearance, lethargy, and inattention. Laboratory evaluation confirmed a hypo-osmolar hyponatremia with elevated urine osmolality (576mOsm/kg) consistent with Syndrome of Inappropriate ADH Secretion (SIADH). Thyroid studies and cerebral fluid studies were unremarkable. He was treated with hypertonic saline and desmopressin until he achieved normonatremia.

Discussion: Strongyloides stercoralis induced SIADH in an under-recognized cause of euvoletic hyponatremia, especially in patients who have traveled to endemic areas or who are immunocompromised. Prior case reports have shown resolution of hyponatremia with traditional treatment of the infection.

SA-PO021
A Case of Disseminated HSV Infection in PD Patient with Bulbous Pemphigoid

Case Description: A 72-year-old man under the treatment with PD for 2 months for ESRD caused by nephrosclerosis was admitted to our hospital because of blisters and who was treated with high-dose steroid for bullous pemphigoid (BP).

Introduction: Patients with end stage renal disease (ESRD) are affected by various infectious complications. The combination of immunodeficient factors of ESRD, hyponatremia and BP contributed to the severe immune-compromised state and disseminated HSV infection. Since an early diagnosis determines the prognosis of disseminated HSV infection, cell pathology in peritoneal fluid would assist preemptive therapy.

Discussion: We experienced a rare case of disseminated HSV infection and PD-related HSV peritonitis. The combination of ESRD, hyponatremia of immunodeficient factors and BP contributed to the severe immune-compromised state and disseminated HSV infection. Since an early diagnosis determines the prognosis of disseminated HSV infection, cell pathology in peritoneal fluid would assist preemptive therapy.

SA-PO042
Primary Glioblastoma Multiforme in a Renal Transplant Patient

Introduction: Glioblastoma multiforme is the most common and most aggressive malignant primary Brain tumor in humans, involving glial cells and accounting for 52% of all functional tissue brain tumor cases and 20% of all intracranial tumors. Incidence of 2.3–3.0 per 100,000. The principal risk involved in these recipients was non-Hodgkin lymphoma while gliomas are rarely described.

Discussion: Aluminum toxicity was initially described in encephalopathic patients with renal failure, overdosing of aluminum-based phosphate binders and attributed to contamination of water used for dialysis treatments. Use of alum irrigation for the treatment of refractory hemorhagic cystitis was first reported in 1982. It was described as a safer alternative to formalin bladder irrigation. We report a case of bladder perforation after alum irrigation, leading to intra-peritoneal aluminum exposure. Our patient expired despite chelation and renal replacement therapy. Her serum aluminum concentration is the highest reported level to date.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: We describe 54 year old Male with a history of Deceased Donor Kidney Transplant in 1999 whose kidney disease was secondary to hypertensive nephrosclerosis. Donor information is not available. The patient had been in his usual state of health until one week prior to presentation, when he started feeling weak and became confused, reason for hospitalization.

Although confirmation of a large mass measuring 5.4 x 2.9 cms in the corpus calloso splenium and second lesion 8 x 9 mm, in the left parietal lobe. He had a biopsy done which revealed a GMB. Neurosurgery was consulted and mass was found to be unresectable. Neuro-Oncology was consulted and he was advised radiation therapy and possible chemotherapy, but the patient decided to receive conservative opinion. His Post radiation period has been remarkable for a borderline rejection with donor specific antibodies, treated with plasmapheresis and IVIG. His immunosuppressant medications were Cyclosporine, Mycophenolate mofetil and prednisone.

Discussion: Review of the literature indicates that gliomas do not seem appear in an early post-transplant period. These tumors have been reported mostly after 4–20 years from renal transplantation. Increased risk of tumour occurrence may be related immunological disorders such as HIV, and also to the administration of immunosuppressive drugs. Few studies have shown that cyclosprone may induce phenotypic changes in different tumoural cell lines and may play a role in modulating the neoplastic course. There seems to be a existence of a relationship between glialboma development and kidney transplant, but this association needs to be studied further. With increasing life expectancy of transplant recipients, evaluation of the risk of serious complications such as glial tumors is necessary.

SA-PO025
Eculizumab in Gemcitabine-Induced Thrombotic Microangiopathy
Venkata Buddharaaju, Rajat Lamba, Savneek S. Chugh, Rahul N. Pawar, Rudrick V. Ledesma, Praveen N. Chander. Nephrology, Westchester Medical Center, Valhalla, NY.

Introduction: Thrombotic microangiopathy (TMA) is a pathological process involving thrombocytopenia, microangiopathic hemolytic anemia and microvascular occlusion particularly in the kidney. Eculizumab, a complement C5 inhibitor, has been used to successfully treat cases of atypical HUS but its use has not been widely reported in drug induced TMA. We report a case of Gemicitabine induced TMA treated with Eculizumab.

Case Description: A 68 y/o male with b/o hypertension, Diabetes mellitus, CKD with a baseline Cr 1.9, Protein 5.0 g/L, Ca x P Whipple procedure, receiving gemcitabine as neo adjuvant chemotherapy was sent to the hospital for worsening creatinine, 20 lbs. weight gain and worsening pedal edema over the duration of one month. On admission, he was in hypertensive urgency with BP 235/110. Labs showed Hb 9, platelet 201, Na 136, K 5.4, Cr 114, HCO3 18, BUN 53 and Cr of 3.0. Urinalysis showed 3+ blood and 4+ protein. Further workup revealed normal complements, negative ANA, ANCA, hepatitis panel and HIV serology, elevated LDH and low haptoglobin. Occasional schistocytes were noted on the peripheral smear. Renal ultrasound showed mildly echogenic kidneys. Urine protein/creatinine ratio was 7.5 A renal biopsy was performed, which showed TMA, clinically suspected to be secondary to gemcitabine. The patient was started on Eculizumab regimen but renal function deteriorated requiring RRT. After 3 months of therapy, his LDH and haptoglobin have improved but he is still on Dialysis.

Discussion: The mechanism of chemotherapy induced TMA is presumed to be a dose dependent direct endothelial injury rather than deficient ADAMTS 13 activity or complement dysfunction. So, Therapeutic plasma exchange is usually not recommended. There are rare case reports of Gemicitabine induced TMA that improved with TPE. This induction of TMA while on Gemicitabine likely have some component of complement dysfunction or a serum factor induced by Gemicitabine that is responsible for endothelial injury. There might be a role for Eculizumab in underlying complement dysregulation in chemotherapy induced TMA, which needs further studies.

SA-PO026
Improvement of Renal Function with Treatment of Hypothyroidism
Ibrahim M. El-Ali, Ana Claudia Onuchic, Ruchir D. Trivedi. Dept of Medicine, Div of Nephrology, Univ of Connecticut School of Medicine, Farmington, CT.

Introduction: Association of subclinical hypothyroidism and chronic kidney disease is increasingly being recognized. Early data suggests improvement in renal function with thyroid hormone replacement in patients with clinical and subclinical hypothyroidism. We present a case of substantial renal function improvement in a patient with renal failure due to hypothyroidism.

Case Description: 33 y/o AA male with past medical history of nasopharyngeal carcinoma. The patient may baseline creatinine 2.4 mg/dl with sustained elevation of creatinine kinase (CK). No improvement was noted after stopping statin and after 3 months of therapy, his LDH and CK improved. Further testing revealed a high ASO titre at 800, ANA 1:160, and low C3 and C4. Hemodialysis was started for uremic symptoms and a kidney biopsy was performed. The biopsy revealed an acute glomerulonephritis with C3 predominance, with tubulointerstitial nephritis, there were also features of post infectious GN evident by subepithelial humps. Intravenous Methyprednisolone was started but he remained dialysis dependent. With the consideration that the infection likely induced unregulated activation of the alternative complement pathway. We started eculizumab 900 mg . Patient received a total of six hemodialysis treatments . After 1 dose of eculizumab, the patient creatinine plateaued without dialysis treatment at 3.9 mg/dl, dialysis treatment was discontinued and plan was made to continue weekly infusions of eculizumab.

Discussion: Disorders of alternative complement pathway regulation are becoming increasingly recognized. There are no proven therapies for C3GN, but targeting terminal complement complex has emerged as an attractive approach given the known causes of C3GN. There are few reported cases of the benefit of eculizumab in C3GN and often describe the agent’s efficacy earlier in the course. This case represents a unique instance of effective treatment of dialysis-dependent C3GN with early restoration of renal function.

SA-PO028
Nephrotic Syndrome After Scorpion Sting
Boju Sangeetha Lakshmi, Chaithanya Vemuri, Anil Kumar Cheni Venkata, Ram R, Siva Kumar Vishnubhotla. Dept of Nephrology, Sri Venkateswara Inst of Medical Sciences, Tirupati, Andhra Pradesh, India.

Introduction: Scorpion venom is a water soluble, anti-genic and heterogeneous mixture. The reported incidence of scorpion sting in India is 0.6%. Scorpion sting resulting in a renal failure has been reported in the past, but not the nephrotic syndrome.

Case Description: A 49-year-old gentleman, non-diabetic and not a hypertensive, presented with history of scorpion sting over the fourth digit of the left hand. Patient had immediate intense local pain, swelling and redness. Within one hour he had hypersalivation, sweating, vomiting and diarrhea. After three days, the patient complained insidious onset of abdominal distension, followed by paeudal oedema and facial puffiness over next one week. There was no history of oliguria, dysuria and haematuria. Investigations revealed serum creatinine: 2.9 mg/dL, 24 hour urine protein was: 9.90 g. He was subjected to renal biopsy at that institute. The diagnosis was minimal change with acute tubular necrosis. He was referred to our institute with breathlessness and anasarca. On examination BP 140/90mmHg and bilateral crakkles on auscultation. Serum creatinine: 7.0 mg/dL, blood urea: 148 mg/dL, total serum proteins: 5.5 g/dL, serum albumin: 2.5 g/dL, total cholesterol: 237 mg/dL, triglycerides: 182 mg/dL, haemoglobin: 10 g/dL, urine protein: 2+ and SCR 2872 mg/dl. He was dialyzed for three sessions and subjected to renal biopsy and diagnosed to have minimal change disease and acute tubular necrosis, thepatient was continued on dialysis. Urine output improved after three more weeks. Serum creatinine stabilized at 2.0 mg/dL after eight weeks of scorpion sting.

Discussion: The scorpion venom is composed of varying concentration of neurotoxin, cardiotoxin, nephrotoxin, haemolytic toxin, phosphodiesterase, phospholipases, hyaluronidases, glycosaminoglycans, histamine, serotonin, and tryptophan and cytokine necrosis factor. The renal failure due to scorpion sting is reported only in few cases and not reported. We report a patient of nephrotic syndrome after scorpion sting. The lacunae in the present knowledge linking scorpion sting venom with nephrotic syndrome would only be replenited with publications of similar reports.

SA-PO029
Diffuse Crystals Accumulation in the Proximal Tubules, Podocytes, and Intertstitial Histocytes of a Patient with a Multiple Myeloma
Satoshi Hara,1 Kiyoki Ito,1 Kazuzumi Yama,1 Ryoichi Miyazaki,2 Mitsuhiro Kawano,2 1Rheumatology, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishikawa, Japan; 2Internal Medicine, Fujita Memorial Hospital, Fuku, Japan.

Introduction: Light chain proximal tubulopathy with crystals formation is a rare condition, accompanied by paraproteinemias. In particular, observation of crystal inclusions in the proximal tubules and interstitial histiocytes has seldom been reported. We present one of the rare cases with crystal inclusions in a variety of kidney cells of a multiple myeloma (MM) patient, including the proximal tubular cells, podocytes, and interstitial histiocytes.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: A 66-year-old Japanese woman was admitted to our hospital and was found to have a gradual deterioration in kidney function (serum creatinine, 2.0 mg/dL), proteinuria (urinary protein, 1.3 g/dl), and mild hematuria (urinary red blood cells, 10-19/hpf). Urinary b2-microglobulin was notably elevated (117,700 mg/L); however, Fanconi’s syndrome was not detected. Elevated serum IgG levels (IgG 2,559 mg/dL) with IgA suppression (32 mg/dL) confirmed the diagnosis of anti-neutrophil cytoplasmic antibody (ANCA) negative, pauci-immune, glomerulonephritis. Light microscopy showed a membranoproliferative glomerulonephritis pattern with segmental fibrinoid necrosis and early cellular crescents with mild increase in cellularity of the crescent. Multinucleated giant cells and a pauci-immune mononuclear IgG+X. Examination of kidney biopsy revealed crystal inclusions in the proximal tubules, podocytes, and interstitial histiocytes. The crystals tested negative for eosin, periodic acid Schiff, and trichrome staining. No segmental glomerulosclerosis was observed. Immunofluorescence of kidney biopsy was negative. Similarly, immunohistochemistry, using an antigen retrieval method, failed to detect either κ or λ. Transmission electron microscopy revealed highly electron dense crystals that diffusely accumulated in the proximal tubules, podocytes, and interstitial histiocytes. By bone marrow biopsy, the patient diagnosed as MM. Bortezomib treatment attenuated kidney dysfunction and proteinuria. Sequential DNA analysis confirmed that the patient had the subgroup I restriction.

Discussion: Mononuclear light chains are internalized into the lysosomes of proximal tubular cells by receptor-mediated endocytosis, where they form protease resistant crystals. Our case suggests that podocytes can engulf crystals in a similar manner, despite lacking the receptors found on proximal tubular cells.

SA-PO030
Erythematous Skin Rash and Gastrointestinal Bleeding as Presenting Features of ANCA Negative Paucll-Imune Glomerulonephritis Anusha Lakshmi Badveli, Chanchal Kumar Jana. Internal Medicine, R.G. Kar Medical College and Hospital, Kolkata, West Bengal, India.

Introduction: Paucll-Imune glomerulonephritis (PGN) is one of the common causes of RPGN. In most patients with PGN, circulating antineutrophil cytoplasmic autoantibody (ANCA) is present, however, 10% of the patients are ANCA-negative. Usually extra renal manifestations in ANCA negative PGN are rare, but the case reported here is a rare presentation having skin rash and gastrointestinal (GI) manifestations.

Case Description: A 50-year-old female was admitted with low grade intermittent fever, erythematous maculopapular rash all over the body and asymptomatic arthralgia involving large and small joints for about 3 months. She had one week history of pain abdomen and melena followed by decreased urine output and generalized edema. On examination BP 156/94 mmHg, Birmingham Vasculitis Activity Score of 23/63. Investigations: Hb 9.9 g/dL, serum creatinine 4.0 mg/dl, urinalysis - protein ++, RBC 2-3/hpf, 24 hour urine protein 4.75gm/day. Serum uric acid & creatinine were normal. Serum ANA, pANCA, cANCA, and RARA factor were negative. Skin biopsy for IgG, IgA, C3, C4 were negative. USG showed normal sized kidneys. Renal biopsy: Light microscopy showed segmental fibrinoid necrosis and early cellular crescents with mild increase in cellularity of mesangial matrix. Immunofluorescence: IgG, IgM, IgA, C3, Cq, kappa and lambda chains were negative. Diagnosis of ANCA negative paucll-immune GN with crescents was made and patient was started on systemic steroids and cyclophosphamide pulse therapy. Patient improved symptomatically and creatinine levels gradually declined.

Discussion: Patients with ANCA negative PGN rarely present with skin and GI manifestations. In a study done in China comparing clinical features of ANCA negative patients only 7% were found to have GI manifestations and 17.9% had skin rash. These patients were treated similarly to ANCA-positive patients, although no study has focused specifically on the treatment of ANCA-negative patients. Such patients could be easily missed. Therefore early identification and prompt treatment could prevent many life threatening complications and improve prognosis.

SA-PO031
A Case of ANCA-Associated Nephritis Mainly Localized to the Tubulointerstitial Area, Successfully Treated by Steroid Therapy Tomo Nakajima, Yousuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.

Introduction: The typical pathological findings of antineutrophil cytoplasmic antibody (ANCA)-associated nephritis consist of extracapillary proliferation and necrotizing crescent formation. Nevertheless, a few cases of ANCA-associated nephritis, in which the tubulointerstitial area was mainly affected, are reported. Here, we present such a case of ANCA-associated tubulointerstitial nephritis, and review its characteristics compared to ANCA-associated glomerulonephritis.

Case Description: A 74-year-old generally healthy female developed bilateral hearing loss, and thereafter suffered from persistent fever. With a diagnosis of bacterial pneumonia, she was admitted to another hospital and treated with several broad-spectrum antibiotics without improvement. Four weeks later, she was referred to our hospital. On admission, weight loss and peripheral numbness and weakness was noted in addition to advanced hearing loss and fever. Serum creatinine level was elevated to 3.5 mg/dl, while urinalysis revealed mild proteinuria with few red blood cells and no cast in the sediment. Sinusits and alveolar hemorrhage were observed by CT scan. Immunological tests demonstrated positive myeloperoxidase (MPO)-ANCA (104 U/ml). In view of multiple organ involvements, ANCA was suspected. Renal biopsy showed diffuse interstitial infiltration and remarkable vasculitis in small arteries and capillaries with only a small number of crescentic glomeruli, which was consistent with ANCA-associated tubulointerstitial nephritis. Steroid therapy ameliorated not only kidney dysfunction, but also hearing loss.

Discussion: In an atypical case of ANCA-associated nephritis with near normal urinalysis, we need to consider the possibility of tubulointerstitial nephritis.

SA-PO032
Treatment of Severe Resistant Idiopathic Membranous Glomerulopathy with Adrenocorticotropic Hormone Gel: A Case Report Blaithin A. McMahon, Adam R. Berliner,1 Div of Nephrology, Johns Hopkins School of Medicine, Baltimore, MD; 2Nephrology Center of Maryland, Baltimore, MD.

Introduction: Idiopathic membranous glomerulonephritis is a frequent cause of nephrotic syndrome. Therapy is based on Ponticelli protocol or other immunosuppressive therapies. Adrenocorticotropic hormone has been used with some success for the treatment of resistant idiopathic membranous nephropathy. We present here a case of a 39 year old Caucasian man presenting with severe resistant idiopathic membranous glomerulonephritis who encountered only a partial response with cyclosporine but had a complete remission with single therapy corticotropin.

Case Description: Medical history included chronic kidney disease stage IIIA and hypertension. He attended a work-associated physical examination that revealed proteinuria and subsequent 24hr urine collection revealed 18g of proteinuria. His physical examination was notable for stage 3 hypertension, no chest, cardiac or abdominal abnormalities. He had bilateral +2 pitting edema to the knees. Renal biopsy showed thickened capillary walls with spikes and holes in the glomerular basement and subepithelial deposits. All inflammatory and infectious serological studies were negative. Treatment included corticosteroids and cyclosporine 100mg twice daily. His glomerular filtration rate was 58 ml/min per 1.73 mm2. His proteinuria improved from 18g to 5g over an eight week period after initiation of cyclosporine, however, five months later he relapsed to 10g and later to 15.9g. After stopping his cyclosporine, his proteinuria worsened to 20g/24hr urine collection. Magnetic resonance imaging of his renal veins were negative for thrombus. PLA2 receptor antibody testing was negative. At our institution, he was treated with corticotropic (ATHACAR H.P.) 80 unit/mL injectable gel subcutaneously twice weekly. A complete remission was achieved within 12 months. Patient characteristics and clinical course is reviewed.

Discussion: Randomized controlled trials are needed to evaluate the therapeutic efficacy of corticotropin for resistant idiopathic membranous glomerulonephritis.

SA-PO033

Introduction: Untreated chronic Hepatitis C Virus (HCV) infection often leads to a spectrum of severe extra hepatic manifestations related to B cell dysregulation, which include cryoglobulinemia, renal diseases, and lymphoproliferative disorders. Type I membranoproliferative glomerulonephritis (GN) associated with type II mixed cryoglobulinemia is the most common HCV related kidney disease, with membranous nephropathy and MPGN without cryoglobulinemia being less frequent.

Case Description: A 58 year-old Caucasian man with history of hypertension, recent biopsy proven membranous nephropathy, and treatment naïve chronic HCV infection Genotype 3a diagnosed 5 yrs ago, presented with complaints of intermittent vasculitis rash in his legs for a year as well as worsening parathesia of his palms and soles. Initial evaluation showed microscopic hematuria, red blood cell casts, 1.2 grams of proteinuria, and serum creatinine (SCR) of 1.0 mg/dL. Serum C4 was low, and serum positive for type II cryoglobulins. Repeat kidney biopsy was showed a diffuse proliferative GN with characteristics of cryoglobulinemic GN. The patient was referred to hepatology for antiviral treatment, which was delayed due to myocardial infarction requiring bypass surgery. During this time he developed worsening renal function (SCR of 3.5 mg/dL) with increase in proteinuria to 2-3 g prompting the decision for immunosuppressive therapy. Rituximab (1 gm) was administered and he was started on ledipasvir 90 mg/sofosbuvir 400 mg with prompt viral response and an improvement of renal function (SCR 1.6). Weeks after, he presented with AKI and diffuse alveolar hemorrhage and was treated with high
dose steroids, plasma exchanges, and a second dose of Rituximab, with clinical and renal improvement. One month after discharge, he was re-admitted with ARDS and diagnosed with B-cell lymphoma.

Discussion: Despite being rare, Sjögren’s Disease can lead to cryoglobulin formation with positive staining for PLA2R. It also revealed advanced chronic changes that included focal glomerulosclerosis (87%) in addition to interstitial fibrosis 80%. However, adjacent to this atrophic area, there was a tumor of spindle-shaped cells with smooth muscle characteristics. There was no atypia or mitosis and no clear capsule but the tumor cells appeared to infiltrate and surround the tubules and vasculature. This was labeled by the pathologist as a fragment of a smooth muscle cell tumor of undetermined malignant potential. The possibility of leiomyosarcoma could not be ruled out. MRI abdomen and pelvis did not show any evidence of extra renal involvement. The possibility of the parenchymal tissue being significantly influenced by its close proximity to the tumor prompted us to pursue another renal biopsy from the other kidney. Surprisingly, repeat biopsy showed only 15% of tubular atrophy and interstitial fibrosis. The patient was initiated on Rituximab and tolerated two courses of treatment. He achieved partial remission with decreases in proteinuria remaining in nephrotic range and secondary effects of the GCS becoming a problem. He was discharged with the normal laboratory findings.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
proteinuria, making it possible to decrease dosage of the other immunosuppressants and gradually stop them, even the GCS. Patient is now in complete remission after 2 years of treatment with no signs of relapse after stopping additional medication.

**Discussion:** Belimumab is indicated in treatment of seropositive active SLE in addition to standard therapy, when lack of clinical improvement despite optimal standard therapy. Two large, phase 3, multicenter, prospective, randomized, controlled trials (BLISS-52 and BLISS-76) compared belimumab with placebo in patients with SLE who were receiving standard therapies. Both studies showed significant improvement in SRI (Systemic Lupus Erythematosus Responder Index) with 10mg/kg of belimumab as compared with placebo. A phase 3 study (BLISS-LN) is recruiting patients with lupus nephritis since these post-hoc analysis of the BLISS trials suggest that belimumab may offer renal benefit in patients with SLE. The treatment is so far not recommended in these cases. We can conclude that our case shows excellent results of belimumab in lupus nephritis with persistent nephrotic range proteinuria under conventional treatment. Alternatives are scarce and mostly limited due to toxic effects and by failure to control disease.

**SA-PO039**

**Overlap Syndrome or Drug Reaction?**  
Varun Gaur, Michael T. Eadon, Jesus H. Dominguez.  
**Medicine, Indiana Univ, Indianapolis, IN.**

**Introduction:** The overlap of ANCA-Associated Vasculitis (AAV) with other autoimmune diseases is well known. However, the association of AAV with the use of TNF-α antagonists in Rheumatoid Arthritis (RA) patients is less understood.

**Case Description:** A 44 y/o white female with RA had prior treatment with methotrexate (3 yr), adalimumab (2 yr) and etanercept (2 yr). She concluded all DMARD therapy 3 yr prior to presentation (PTP), and then her RA flared 5 months PTP. After initiation of leflunamide and steroids, she had partial resolution. Two weeks PTP, she received golimumab for onset of severe neurological manifestations including right foot drop, distal extremity numbness, and a right 4th digit ischemic lesion. Upon presentation, she was admitted with persistence of these symptoms. Her serum creatinine increased from 0.9 (mg/dl) to 1.4 with 2 g proteinuria. Her urinalysis had hematuria and serology was positive for PR3-positive cANCA. Her renal function deteriorated with a peak creatinine of 6.7, necessitating intermittent dialysis. A biopsy revealed pauci-immune diffuse necrotizing and crescentic glomerulonephritis consistent with AAV. She received pulse solumedrol, cytoxan, and plasma exchange. Her neurological symptoms improved after a month of therapy. After 6 weeks, she did not require dialysis and her serum creatinine was 2.4.

**Discussion:** We present a case of a patient previously treated with TNF-α inhibitors who then developed PR3-positive AAV years later. An association between AAV and RA has been described and RA may precede AAV by up to 8 years. Different theories explain this association. One reason may be the common genetic predispositions to autoimmunity, involving HLA or PTPN22 genes, reported in a series of both RA and AAV. Second theory suggests TNF antagonists may predispose one to develop secondary autoimmunity. In our case, the patient discontinued DMARDs 3 yr PTP, although had recently received Leflunomide and Golimumab. There are no reports that associate leflunamide use with AAV and only one case report suggests an association of golimumab with AAV. Our case highlights the need to further understand the importance of AAV in RA patients, and the potential role of TNF inhibitors on the development of AAV.

**SA-PO040**

**Pauci Immune Crescentic Glomerulonephritis in a Patient with T-Cell Lymphoma and Argyria**  
Tamer Rezk, James J. Penton, Mark Alan Little, John Cunningham, Alan D. Salama.  
Centre for Nephrology, Royal Free Hospital, London, United Kingdom.

**Introduction:** Silver is a transition metal element with a range of industrial and ornamental uses and is known to be toxic when ingested in significant amounts. Silver exposure causing argyria (skin deposition) and argyrosis (eye deposition) is well-recognised but the renal consequences of silver toxicity are poorly understood.

**Case Description:** A 47 year old woman with a T-cell lymphoma who refused conventional chemotherapy for 18 months but self-medicated with a remedy containing colloidal silver was admitted with acute dialysis-dependent kidney injury. The serum silver concentration was strikingly elevated at 127.1 nmol/l (reference value <2.8 nmol/l). Kidney biopsy demonstrated a pauci-immune crescentic glomerulonephritis and glomerular tufts with fine, dark, granular material scattered within the mesangium and along the glomerular basement membrane (GBM). Electron microscopy confirmed the presence of electron-dense granules in the mesangium and along within the GBM.

**Discussion:** Crescentic glomerulonephritis results from disruption of the GBM which may be induced by immune complexes or by cellular mediators. However our patient had no autoantibodies, and no deposited immunoproteins. Our case therefore represents a pauci-immune crescentic glomerulonephritis with intense silver deposition along the GBM. Between 5-10% cases of pauci-immune glomerulonephritis are ANCA negative. The pathogenesis in these cases may be related to other autoantibodies (such as anti-endothelial antibodies) or to direct leukocyte-induced GBM damage via soluble mediators, which in this case we believe was due to a combination of T cell lymphoma and argyria.

**SA-PO041**

**PR3-ANCA Vasculitis following Influenza Vaccination**  
Karim El Hachem, Eduardo J. Zouain, Isha Gupta, Steven D. Smith.  
Nephrology, Mount Sinai-St Luke’s Hospital, New York, NY.

**Introduction:** Influenza vaccination has been associated with the development of autoantibodies and autoimmune rheumatic disease. We report a case of PR3-ANCA associated vasculitis following influenza vaccination.

**Case Description:** The patient is a 45 year old Hispanic male with no known medical history who presented with subacute onset pleuritic chest pain and shortness of breath. Four weeks prior to presentation, he had received his annual injectable influenza vaccine and reports feeling weak since. On presentation, he was hemodynamically stable. His exam was notable for bibasilar crackles. He had positive Rheumatoid Factor. His CT chest was notable for multiple ground glass nodules at the right upper lobe. His creatinine was 1.64 mg/dl. His urine albumin to creatinine ratio was 225 mg/g creatinine and his urine protein to creatinine ratio was 500 mg/gm creatinine. He had 25-30 RBC/hpf with no dysmorphic RBCs. He had strongly positive PR3-ANCA antibody (>8 A1). His kidney biopsy revealed acute focal segmental necrotizing crescentic GN, pauci-immune type.
The patient was treated with pulse IV methylprednisolone and Rituximab 375mg/m2 weekly for four doses. Three months following induction therapy, his creatinine improved from a peak of 3.6 mg/dL to 1.4 mg/dL. His CT findings and hematuria resolved. His PR3-ANCA slowly decreased and became negative 6 months after induction.

**Discussion:** This patient’s presentation with lung nodules on chest CT, necrotizing crescentic GN, and high serum level of PR3-ANCA support a diagnosis of Granulomatosis with Polyangiitis with a strong temporal relationship to vaccination against influenza. This is the 9th case of ANCA associated vasculitis following influenza vaccination reported in the literature. Clinicians should be aware of the possible association between systemic vasculitis and influenza vaccination.

**SA-PO042**

C3 Glomerulonephritis Associated with Monoclonal Gammopathy

**Case Description:** The patient is a 65-year-old Hispanic female who presented with lower extremity edema and dyspnea. She had acute kidney injury with nephritic urinary sediments. C3 and C4 were low. Hepatitis B & C profile, ANA, ANCA, anti-GBM and SPP were within normal limits. There was a faint monoclonal band on the gamma region of SPEP. CBG-Gammas were within normal limits. There was a faint monoclonal band in the gamma region of SPEP. C3 and C4 were reduced. Serological findings of a renal biopsy showed foamy change and numerous lamellar inclusions in the mesangium and glomeruli. C3 and C4 deposits were seen on immunofluorescence. No reactivity was seen for IgA, IgG, IgM, C1q, C4, fibrinogen and albumin. Electron microscopy showed subendothelial and mesangial immune complex deposits.

**Discussion:** C3 glomerulonephritis is related to dysregulation of alternative pathway of complement (AP) that can be associated with monoclonal gammopathy. Treatment of underlying monoclonal gammopathy may be of benefit in such a situation. Genetic studies for dysregulation of AP might be helpful.

**SA-PO043**

Late-Onset Fabry Disease with a R112H GLA Mutation and Mild Increase in Plasma Globotriaosylsphingosine

**Case Description:** A 42-year-old Japanese male was referred to our hospital due to acute kidney injury with a creatinine of 6.0 mg/dL. He was found to have acute kidney injury with nephritic urinary sediments. C3 and C4 were reduced. Serological findings of a renal biopsy showed foamy change and numerous lamellar inclusions in the mesangium and glomeruli. C3 and C4 deposits were seen on immunofluorescence. No reactivity was seen for IgA, IgG, IgM, C1q, C4, fibrinogen and albumin. Electron microscopy showed subendothelial and mesangial immune complex deposits.

**Discussion:** C3 glomerulonephritis is related to dysregulation of alternative pathway of complement (AP) that can be associated with monoclonal gammopathy. Treatment of underlying monoclonal gammopathy may be of benefit in such a situation. Genetic studies for dysregulation of AP might be helpful.

**SA-PO044**

Another Enemy for Kidneys: Synthetic Cannabinoids

**Case Description:** A 20-yr-old male without a medical history presented to ED with abdominal discomfort, nausea and vomiting for 3-4 days. On physical examination, arterial pressure was 150/60 mm/Hg, HR 86/min, without orthostatic signs. He denied any nephrotoxic drug use, OTC medication or contrast media exposure. He has been a synthetic cannabinoid (Bonzai) smoker for less than 2 weeks. On admission he was oliguric and creatinine was 7.7 mg/dL with normal creatinine kinase levels. Urinary analysis revealed pH 5.5, protein, +, blood trace, and granular casts. Bone marrow biopsy revealed atypical plasmacytosis without overt myeloma. Repeated kidney biopsy showed global proliferative changes along with splitting of glomerular basement membrane. C3 deposits were seen on immunofluorescence. No reactivity was seen for IgA, IgG, IgM, C1q, C4, IgG, fibrinogen and albumin. Electron microscopy showed subendothelial and mesangial immune complex deposits.

**Discussion:** Synthetic cannabinoids (SC) are widely used especially among young population. These substances have various physiological, metabolic and pharmacokinetic effects. In last few decades SC related acute kidney injury (SC-RAKI) is reported more often.

**SA-PO045**

A Unique Case of Granulomatous Acute Interstitial Nephritis from Fibrinolysis

**Case Description:** A 70 year old man with stage IV melanoma presented with low grade fever and malaise. He was found to have acute kidney injury with a creatinine of 6.0 mg/dL. Two months earlier, he had received a single dose of ipilimumab at which time his creatinine was 0.9 mg/dL. Laboratory data was notable for the absence of eosinophilia. Urinalysis showed 5-10 WBCs/hpf and many hyaline casts. A renal biopsy showed granulomatous interstitial nephritis with a component of granulomatous vasculitis (figure: H&E, Masson trichrome). He was treated with high-dose prednisone, which resulted in improvement of his renal function without the need for hemodialysis. After 10 weeks of steroid therapy, his creatinine had decreased to 1.6 mg/dL.

**Discussion:** Ipilimumab is a potent activator of T cells and can interfere with the immune system’s tolerance of self-antigens. This drug is known to cause a variety of immune-related adverse events including hypophysitis, hepatitis, colitis and dermatitis. Interstitial nephritis is a rare diagnosis, but has been reported to occur after exposure to ipilimumab.
Severe Rhabdomyolysis Secondary to Adenovirus Infection

**Introduction:** A 38-year-old male presented with renal failure in the setting of a flu-like illness. Urinalysis showed myoglobinuria and granular casts. His CPK was markedly elevated. He is diagnosed with rhabdomyolysis from adenovirus and requires hemodialysis.

**Case Description:** A 38-year-old AA male presented to the ER with a 4-day history of weakness, subjective fever, and diffuse myalgias as well as recent left eye viral conjunctivitis. He noted dark urine and poor urine output. On arrival to the ER his vitals were stable. He had full muscle strength and no neuro deficits. He was oliguric. His Sct 5.04, CPK 1,149,533 despite volume resuscitation including bicarb-containing fluid. He required HD. Workup was positive for adenovirus. Muscle biopsy was deferred in setting of known cause. He required 4 weeks of HD and was able to come off with improved GFR of 67.

**Discussion:** Two cases of rhabdomyolysis from adenovirus have been reported. Most commonly manifests as a febrile illness with pharyngitis. Management strategies have been adopted from studies on crush injury victims. Early volume resuscitation is recommended to mitigate renal failure. Despite the theoretical benefits of bicarbonate-containing resuscitation fluids, no consensus exists. Adenoviral infection can lead to rhabdomyolysis with severe acute kidney injury. Respiratory viral panel should be included in workup of rhabdomyolysis when no other cause is evident. Treatment relies on supportive care, intravenous fluid resuscitation, and hemodialysis in cases of severe renal failure.

**Acute Respiratory Distress Syndrome and Posterior Reversible Encephalopathy Syndrome following Rituximab Therapy**

**Introduction:** The anti CD20 monoclonal antibody Rituximab is an increasingly used therapy in modern medicine. It is associated with rare but potentially serious adverse events, notably Posterior Reversible Encephalopathy Syndrome (PRES), and Acute Respiratory Distress Syndrome (ARDS).

**Case Description:** A 60 year-old female was admitted with symptoms of peripheral oedema, arthralgia and muscle weakness. She was noted to have a widespread vasculitic rash, nephrotic range proteinuria and new acute kidney injury. Renal biopsy demonstrated mesangiocapillary glomerulonephritis with multifocal extraglomerular necrotising vasculitis, in keeping with cryoglobulinemia. She was commenced on plasma exchange, prednisolone and Rituximab. 2 days after the initial dose of Rituximab she developed acute respiratory distress and was found to be in florid pulmonary oedema. This was managed with ultrafiltration, furosemide and oxygen therapy. She received a second dose of Rituximab 1 week later, and rapidly developed toxic-acute seizures, a further episode of flash pulmonary oedema, encephalopathy and hyperreflexia. MRI brain revealed subcutaneous white matter high T2 and FLAIR signal in the occipital and posterior parietal lobes consistent with PRES. She received no further Rituximab. Her cryoglobulin levels remained detectable despite alternate day plasma exchange for 2 weeks, prompting the initiation of cyclophosphamide. Following 1 dose of cyclophosphamide the cryoglobulin titre fell to undetectable levels. All reported cases of PRES and ARDS were identified and as reviewed as a a study.

**Discussion:** There are 7 reported cases of PRES complicating rituximab use. The onset of PRES occurred from immediately to 21 days after administration. All patients recovered completely, and rituximab was reintroduced in half of the cases. Mean recovery time was 4 days, and an additional risk factor was present in 5 cases. The occurrence of ARDS in association with rituximab is rare, only 3 confirmed cases exist. ARDS may occur as a delayed reaction.

**SA-PO048**

**Atypical Hemolytic Uremic Syndrome Associated with Rituximab**

**Introduction:** Hemolytic uremic syndrome (HUS) is classified as a thrombotic microangiopathies (TMA). Atypical HUS (aHUS) occurs in 0.5 to 2 per million population per year, 50% progress to end-stage renal disease (ESRD), and 25% may die in the acute phase. Atypical HUS is linked to uncontrolled activation of the complement system. A variety of genetic abnormalities of the alternative pathway of complement have been described in aHUS, occurring in 60% of cases. aHUS is diagnosis when toxin producing bacterial infections, ADAMTS13 deficiency, and systemic-associate diseases are all excluded.

**Case Description:** A 57 year-old woman with a history of dermatomyositis and associated interstitial lung disease (ILD) was being treated for her ILD with Rituximab. She presented with altered mental status, shortness of breath, and fatigue after receiving an infusion of Rituximab. She was noted on physical exam to have peripheral edema and clubbing on lung exam. On laboratory evaluation, her creatinine was 4.3 (baseline 1), hemoglobin 7, and platelets 20 with schistocytes on peripheral smear and a low C3 and C4. ADAMTS13 showed normal activity. She was initially treated with high dose steroids and plasmapheresis. She was started on Eculizumab. She required hemodialysis. Renal biopsy showed thrombi consistent with thrombotic microangiopathy as well as mild acute tubular necrosis. She is still hemodialysis dependent.

**Discussion:** Overall outcomes of this rare diagnosis vary widely. Initial treatment is usually plasmapheresis and corticosteroids. Confirmed aHUS is usually treated with Eculizumab. Our unique case entertains Rituximab, a monoclonal antibody, as a possible trigger for aHUS. Knowing the mechanism of action of Rituximab is important to mediate a complement imbalance. More investigation is needed to determine Rituximab’s causality in inducing aHUS. Given the increasing use of Rituximab for various autoimmune conditions and malignancies it will be notable to see if more cases like this arise. 1. Norris M, Remuzzi G. Atypical hemolytic-uremic syndrome. *N Engl J Med*. 2009;361:1676-1687. 2. Constantinescu AR, Bitzan M, Weiss LS, et al. Non-enteropathic hemolytic uremic syndrome: Causes and short-term course. *Am J Kidney Dis*. 2004;43: 976-982.

**SA-PO049**

**Acute Renal Failure Associated with Parenchymal Involvement of Lambda-Restricted Neoplastic Plasma Cells**

**Introduction:** The pathogenesis of renal disease in multiple myeloma (MM) is diverse, but biopsies show that cast nephropathy, light chain amyloidosis and monoclonal Ig deposition are the most common causes. Renal function often correlates to the degree of cellular injury, not the degree of cast burden, amyloidosis or light chain deposition and direct involvement by plasma cells is rare. We present a case of diffuse interstitial involvement by neoplastic plasma cells, contributing to renal failure.

**Case Description:** A 70-year-old male with MM presented with acute renal failure. He was diagnosed with IgG lambda myeloma 8 years prior but refused therapy until 7 months ago. He failed CyBrd (M-protein remained at <9g/dl) prior to starting Carfilzomib-Revlimid.
On day 8 of therapy he was admitted with a Cr of 3.4, acutely elevated from 1.7. He denied hematuria, oliguria, fevers, edema or NSAID use. Renal ultrasound was without obstruction. He underwent renal biopsy. Pathology revealed diffuse interstitial involvement by lambda-restricted neoplastic plasma cells and minimal cast nephropathy, but no significant interstitial fibrosis, tubular atrophy or monoclonal deposition disease. Congo red studies were negative for amyloid. There were no features of TMA. Chemotherapy was resumed.

Discussion: Kidney disease with MM is common but is rare to see involvement of plasma cells in the renal parenchyma. Several review articles list renal parenchymal involvement of plasma cells as a cause of renal failure and, to our knowledge, one case report suggests the same. It is unknown the extent to which parenchymal involvement by plasma cells contributes to the pathogenesis of renal failure. To our knowledge, this is one of only a few cases of renal failure that can be attributed to neoplastic plasma cell involvement.

SA-PO050
AL Amyloidosis with Rapidly Progressive Renal Failure and Massive Liver Involvement: A Case Report

Matteo Floris,1 Maura Conti,1 Riccardo Cao,1 Anna Maria Asunis,1 Elisabetta Tamponi,1 Alice Atzeni,1 Patrizia Melis,1 Gianfranco Pili,2 Valeria Matta,1 Nicola Lepori,2 Doloretta Piras,1 Andrea Angioi,1 Antonello Pani,3 Nephrology, G. Broglio Hosp, Italy; Pathology, G. Broglio Hosp, Italy.

Introduction: AL amyloidosis is a plasma cell disorder clinically dominated by organized deposits of light chains, mainly in renal and cardiac tissues. Although hepatic disease is described, clinical manifestations are usually mild and frequently undetected. We report a severe case of AL amyloidosis with a massive hepatic involvement and rapidly progressive renal failure (RPPF).

Case Description: One month before coming to our attention, a 67 year old male was admitted to another institution for acutes and scrotal edema. Past medical history included hypertension, previous hepatitis B virus infection and estimated daily alcohol intake of 60g. Renal function was normal (serum creatinine [SCr] 0.7 mg/dL), while hepatic lysis indexes were moderately positive. A serum monoclonal component lgA kappa (0.21 g/dL) was detected and the bone marrow aspirate showed 10% plasma cell infiltration. Renal ultrasound showed hepatomegaly and portal hypertension. Final diagnosis was compensated alcoholic liver disease. After discharged, nephrotic syndrome (NS) (albumin 2.4 g/dL, proteinuria 12 g/24h), RPPF (SCr 1.6 mg/dL) and cholestasis appeared (ALP 1359 IU/L, GGT 462 IU/L, AST-ALT normal). The patient was admitted to our institution and renal biopsy was performed revealing AL amyloidosis, with prominent IgA(+) and Kappa(++) mesangial deposits, coherently with the serology. The hepatic disease was rediscussed, and the liver biopsy revealed coarse deposits of amyloid as for the kidney. Other organs, heart included, appear to be spared at the time. In accordance with hematologists, a CyBorD based regimen was started. Due to worsening kidney dysfunction, hemodialysis was initiated.

Discussion: This case highlights a rare presentation of AL amyloidosis with severe renal and hepatic involvement. Liver amyloidosis should be suspected in any patient with NS and unexplained cholestasis. Therefore, renal and hepatic biopsies should be considered when the clinical diagnosis is obscure, especially if rapid evolution to multiorgan failure is documented.

SA-PO051
Pulmonary-Renal Syndrome: A Rare Case

Joana Gameiro,1 Sofia C.A. Jorge,1 Miguel Bigote Vieira,1 Estela Nogueira,1 Maria Alice Fortes,1 Helena Sousa Viana,2 Fernanda Carvalho,2 Jose António Lopes,2 Antonio Gomes Da Costa.1
1 Service of Nephrology and Kidney Transplantation, Hospital Santa Maria, Portugal; 2 Service of Nephrology, Hospital Curry Cabral, Portugal.

Introduction: Pulmonary-renal syndrome (PRS) is characterized by acute renal and pulmonary involvement of immunological or non-immunological causes.

Case Description: A 35-year-old African woman with 6-month history of edema, bilateral arthralgias in her knees, shoulders and hands, creatinemia 2.6 mg/dL and nephritic proteinuria referred to Portugal for medical care presenting with bilateral erythematous non pruriginous macular lesions in both thighs. Investigation confirmed renal failure (creatinemia 7 mg/dL), nephrotic proteinuria (4.7 g/24h), haematuria, hypoalbuminemia, hyperlipidemia, normal sized kidneys with increased parenchymal echogenicity. She began hemodialysis and was transferred to ICU due to pulmonary hemorrhage requiring mechanical ventilation. Plasmapheresis and intravenous high-dose steroids were started. Pneumococal pneumonia was also diagnosed and began antibiotic. Immunologic and serologic tests were negative or normal range. Serum protein electrophoresis showed hypogammaglobulinemia. Echocardiogram revealed type II diastolic dysfunction. Renal biopsy showed nodular glomerulosclerosis. Investigation of haematological disease revealed serum kappa light chain band and urine Bence Jones kappa. Free kappa light chains, serum kappa/lambda ratio and serum Beta-2-microglobulin were elevated. Bone marrow biopsy and asparate showed 10% monoclonal plasmocytosis. No lytic lesions or masses were detected. Immunofluorescence of the renal biopsy revealed linear staining for kappa light chains along the tubular basement membrane and scarcer in the glomeruly. Electron microscopy is underway. Multiple myeloma was diagnosed and started chemotherapy with Bortezomib. Although there had been remission of pulmonary hemorrhage she remained on dialysis.

Discussion: Light chain deposits disease (LCDD) should be considered in the differential diagnosis of PRS. Renal involvement is typical in LCDD with nodular glomerulosclerosis as the common pathologic finding. Pulmonary haemnurea is usual and might suggest coexistence of fibrillary glomerulonephritis.
Phlegmasia Cerulean Dolens: Complication of Femoral Vein Catheterization

Dent’s Disease: An X-Linked Tubulopathy

SA-PO053

Dent’s Disease

Introduction: Dent’s disease is an X-linked recessive disorder of the proximal tubule characterized by low-molecular weight proteinuria, hypercalcuria, nephrocalcinosis/ nephrolithiasis, and progressive renal failure. This disorder is caused by mutations in either the CLCN5 gene, or less commonly the OCR1L gene, leading to disruption of tubulocortical endocytosis and the characteristic clinical findings.

Case Description: We describe an interesting case of a 24 year old Caucasian male with a longstanding history of excessive thirst and polyuria. He had no known history of renal disease. He denied history of urinary tract infections, nephrolithiasis, or NSAID use. Physical examination was unremarkable. Laboratory data showed a serum creatinine of 1.6. Hemoglobin A1c was normal. Urinalysis showed 2+ blood and 2+ protein. Urine osmolality was 277 mosm/kg. A 24 hour urine collection showed proteinuria of 1.7 g/day. ANA, ANCA, and hepatitis panel were all negative. Renal ultrasound showed multiple bilateral renal calculi and nephrocalcinosis. Further testing showed a daily urinary calcium excretion of 735 mg, phosphate 2150 mg and sodium 257 mg. His urine beta microglobulin level was significantly elevated at 2987 mcg/L. The presence of significant low molecular weight proteinuria, hypercalcuria, hyperphosphaturia, nephrocalcinosis/nephrolithiasis, hematuria/subnephrotic proteinuria, and chronic kidney disease fulfilled criteria for the diagnosis of Dent’s disease. No obvious X-linked pattern had been noted in his family history. Further genetic testing is pending at this time. On initiating hydrochlorothiazide, urinary calcium excretion reduced by 50%. Polyuria, which we attributed to nephrogenic diabetes insipidus in the setting of nephrocalcinosis, also improved significantly with the thiazide.

Discussion: This case report highlights the importance of recognizing this rare X-linked tubulopathy when presenting in adulthood. Commercially available genetic testing can be utilized for supporting the diagnosis and for appropriate genetic counseling for family members. The treatment focuses on reducing urinary calcium excretion and formation of nephrocalcinosis/nephrolithiasis with the ultimate goal of slowing progression to end stage renal disease.

SA-PO054

Phlegmasia Cerulean Dolens: Complication of Femoral Vein Catheterization

Introduction: There are three manifestations of acute massive venous thrombosis and obstruction of the venous drainage of an extremity. They are phlegmasia alba dolens, phlegmasia cerulea dolens (PCD) and venous gangrene.

Case Description: We present a 55-year-old hypertensive, presented with pedal oedema and breathlessness. About a month ago, she fell down and had dislocation of left patella. She was treated with a plaster cast and immobilization for 3 weeks. Her serum creatinine was 8.8 mg/dL. She was initiated on haemodialysis via two single lumen catheters placed in left femoral vein. The femoral vein catheters were removed after third session of haemodialysis. On fourth day, the patient complained pain and blue discolouration of up to ankle joint. The left dorsalis pedis and posterior tibial arteries were not palpable. Doppler revealed thrombosis of left common, external iliac, femoral, popliteal, anterior, posterior tibial vein and superficial veins. The left lower limb was elevated and anticoagulation was started but blebs increased and limb become blue. Below knee amputation of left lower limb was performed.

Discussion: The causative factor in phlegmasia is massive thrombosis and occlusion of major venous channels. Perkins et al reported that in 10 percent of patients no cause is found. It is common in women between fifth and sixth decades of age. Swelling, pain and cyanosis are the triad of PCD. Amputation rates are 12-50%. In our patient the effect of immobilization is compounded by femoral vein catheterization. PCD after femoral vein catheterization for haemodialysis has not been reported yet.

Phlegmasia Cerulean Dolens: Complication of Femoral Vein Catheterization

SA-PO055

Successful Treatment of Ischemic Hand Ulcer by Paclitaxel Coated Balloon

Jie Cui,1 Fengyou Liu,2 Zubin Irani.1

Introduction: Hand ischemia is a common complication in end stage renal disease (ESRD) patients. Steal syndrome from dialysis access is the most common cause of ischemic hand and is usually treated with banding procedure. However, exclusion of peripheral arterial disease (PAD) prior to banding is crucial.

Case Description: A 74 year-old women with history of ESRD due to diabetes mellitus on hemodialysis presented to access clinic for right hand ulcer. She had a right side brachiocephalic graft placement 3 years ago and has been dialyzed through this left without any issues. However, 3 months prior to the presentation, she started to notice severe right hand pain, especially during dialysis treatment. Four weeks ago, she developed an ulcer in the 2nd finger of her right hand.

Figure: The patient presented with a black ulcer on the second finger of her right hand. The ulcer completely healed 4 weeks later after paclitaxel-coated angioplasty balloon.

Given the concerns for steal syndrome, she was referred for a banding procedure. On physical exam, the graft had good thrill and bruits. Right radial artery pulse was very weak. A black ulcer was noticed on the 2nd finger of the right hand. Decreased sensation in the 1st, 2nd and 3rd fingers of the right hand. Fistulogram was performed which demonstrated occluded lesion in the proximal right radial artery, which was recanalized and angioplastied with 2mm, 3mm and 4mm balloon. However, at one-month clinic follow up, her ulcer only had minimal improvement. Repeat arteriogram showed moderate radial artery stenosis, which was angioplastied with 4mm paclitaxel coated-angioplasty balloon. The ulcer healed completely 1 month later.

Discussion: Paclitaxel coated balloon was recently approved by FDA to treat PAD in the lower extremities. This case report showed upper extremity PAD can also be treated successfully with paclitaxel coated angioplasty balloon.

Minimal Change Disease Associated with Invasive Ductal Carcinoma of the Breast: A Case Report and Literature Review

Siddhesh R. Lottikar,2 Julian D. Rose,1 Soumya Patnaik,2 Supakanya Wongrakpanich,3 Mary Carolina Rodriguez Ziccardi,2 Mark S. Morginstein,4 Rasib Raja,2 Eric J. Bloom.2

Introduction: Breast cancer mainly causes antibody-mediated paraneoplastic syndromes, the diagnosis of which may precede the detection of cancer. In an adult with Minimal Change Disease (MCD), paraneoplastic etiology should be explored. Here, we describe a rare case of MCD associated with breast cancer.

Case Description: Our patient is a 72-year-old Caucasian female who presented with bilateral lower extremity edema for 1 week. Home medications were notable for occasional diuretics. She denied history of urinary tract infections, nephropathy, or NSAID use. Two months later, she presented with a pulmonary embolus and CT showed concerning breast changes. Biopsy confirmed a stage IIIC invasive ductal adenocarcinoma. She was tapered off steroids, continued on furosamide and started on Paclitaxel.

Discussion: Breast cancer mainly causes antibody-mediated paraneoplastic syndromes. Yet, studies have shown intratumoral IFN-α expression correlates with induction of antitumoral T-cells, presenting a route for breast cancer to cause a T-cell mediated process such as MCD. Our patient had no lymphoma or thymoma and the lack of evidence of AIN and failure of improvement on discontinuation of NSAIDs argue against NSAID-induced MCD. The relationship of MCD with breast carcinoma is reinforced by her improved proteinuria with chemotherapy.

SA-PO056

Interventional Radiology, Chinese People' s Liberation Army General Hospital, Beijing, China; 3Interventional Radiology, Chinese People's Liberation Army General Hospital, Beijing, China; 4Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.

Introduction: Dent’s disease is an X-linked complication of femoral vein catheterization. Within next 12 hours, the signs extended to upper one-third of left leg and there were blebs. Ulceration rates are 12-50%. In our patient the effect of immobilization is compounded by femoral vein catheterization. PCD after femoral vein catheterization for haemodialysis has not been reported yet.
A Case of Donor-Derived Enterococcal Pyelonephritis in an HIV-Positive Kidney Transplant Recipient  

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Case Description:** 47 year old male with history of HIV infection (CD4 -534 cells/ mm3, VL -20 copies), ESRD on peritoneal dialysis, hypertension had deceased donor kidney transplantation. Post-op patient was given 1 dose of eflornithine as surgical prophylaxis. Basiliximab and intravenous immunoglobulin was used for induction therapy. Patient was started on intravenous ampicillin to complete a total of 6 days antibiotic course. POD #17 patient was readmitted to the hospital with urinary retention and elevated serum creatinine 2.2.

Renal ultrasound showed no hydrenephrosis. Urinalysis showed 2+ leukocyte esterase, 1+ blood, WBC 11-20, with occasional bacteria. Blood and urine culture grew Enterococcus faecalis. Our patient was started on intravenous ampicillin to complete a total of 14 days. Serum creatinine improved with treatment.

**Discussion:**  There is no clear consensus on treatment regimens for donor-derived infections. This case demonstrates transmission of donor-derived enterococcal infection despite timely initiation of appropriate antimicrobial therapy. Because of increased morbidity and mortality associated with post-transplant infection extended duration of antimicrobial therapy should be considered in these patients.

**SA-PO058**

Peritoneal Dialysis: A Better Modality of Renal Replacement Therapy for Liver Cirrhosis with End Stage Renal Disease?  

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Introduction:** Managing patients with end stage liver disease associated with portal hypertension, ascites and end-stage kidney disease (ESKD) in whom renal replacement therapy is challenging for a number of reasons including chronic hypotension, poor nutrition, coagulopathy, high infection rates, and encephalopathy. It is difficult to assess accurate dry weights because of the large variation patient weights depending on how much ascites they have at the time of dialysis, with weight fluctuations in excess of 10 kg. There is also a reluctance on the part of the transplant community to utilize PD because of the perception that these patients may not be able to go on to receive a successful liver transplant.

**Case Description:** Herein, we report our experience with 5 consecutive patients with decompensated cirrhosis who progressed to ESKD and required dialysis support. One patient did not tolerate HD and was switched to PD, the other 5 started with de novo PD. In each case, the patients were admitted to hospital for PD catheter placement with a surgeon experienced with patients who had advanced liver disease and stayed in the hospital for initial recovery period with IV albumin to support blood pressure. By our protocol, ascites fluid was drained in the OR and then drained each morning for the next 2 weeks before dialysis was initiated. Blood pressures ranged from 80/50-110/65 mmHg, patients remained asymptomatic. All patients received oral midodrine for BP support.

Adequate ultrafiltration achieved and edema improved. Serum albumin was monitored at regular intervals, ranged from 2.5-3. One patient had peritonitis from time of surgery, which was treated successfully; no other cases of peritonitis were noted.

**Discussion:** We suggest that PD should be considered in selected patients who have ascites and end-stage kidney disease. Further research is warranted regarding long term outcomes and potential effects of PD on the ability for these patients to get transplanted.
SA-PO061
Abdominal Compartment Syndrome: An Overlooked Culprit of Acute Kidney Injury in Immediate Post-Liver Transplantation
Ekamol Tantisattamo,1 Praveen Ratnasirimetha,2 Siwadon Pitukwearerakul,3 1Nephrology, Northwestern University; 2Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 3Present St. Francis Hospital, Evanston.

Introduction: Acute kidney injury (AKI) is a common complication after liver transplantation and often times, dialysis is required. Abdominal compartment syndrome (ACS) is a treatable cause of prerenal AKI without dialysis needed.

Case Description: A 60-year-old man with HCV and alcoholic cirrhosis underwent an ABO-identical liver transplantation. He presented with liver failure on postoperative day (POD) 2. On POD 4, his serum creatinine (SCr) was 2.5 mg/dL after 2 episodes of borderline changes detected from baseline. His sodium (Na+) and FE Na were 0.7% and 21%, respectively. Therefore, abdominal paracentesis was performed with an 8 L of yellowish clear ascites fluid removed. UOP significantly increased shortly after paracentesis. SCr had trended down and dialysis was not required.

Discussion: Our patient presented with prerenal AKI secondary to perioperative hypovolemia concomitant with superatherogenic tacrolimus level. Massive blood transfusion and fluid resuscitation in the setting of major abdominal surgery caused IAH and subsequently ACS contributing to worsening prerenal AKI. Bladder pressure is a bedside diagnostic tool to detect IAH. AKI could be reversed and dialysis could be avoided by abdominal paracentesis.

SA-PO063
Immune Complex MPGN Associated with Hashimoto’s Thyroiditis in a Young Female

Introduction: Glomerular disease associated with Hashimoto’s Thyroiditis (HT) is a rare occurrence infrequently reported in the literature. We present a case of membranoproliferative glomerulonephritis (MPGN) that was thought initially to be due to systemic lupus erythematosus (SLE) in a young woman.

Case Description: A 38 year old female presented in 2013 with leg edema and two grams of proteinuria. Creatinine (Cr) was 1.3 mg/dL. Of note, her thyroid function tests were consistent with severe hypothyroidism, with a TSH of 129 IU/ml and thyroid peroxidase antibodies >900 IU/mL. She had a history of Raynaud’s but did not fulfill clinical and immunological criteria for SLE. Kidney biopsy was consistent with immune complex MPGN with immunofluorescence positive for IgG and C3 only. Patient was non-compliant with thyroid replacement therapy and was lost to follow-up. She reappeared in 2015 with arthralgias, dyspnea, and leg edema. Her Cr had worsened to 1.7 mg/dL with 16 gram proteinuria. She was found to have a pericardial effusion. TSH was 174 IU/mL. Repeated testing for SLE was negative and a renal biopsy demonstrated immune complex-mediated MPGN with minimal staining for full house immunglobulins. She was placed on thyroxine hormone and also initiated on mycophenolate mofetil, given that both her thyroid and renal disease appeared to be driven by an autoimmune antibody mediated process.

Discussion: HT, immune complex MPGN and clinical findings in our patient were initially thought to be due to SLE however patient failed to fulfill any immunologic criteria for SLE. HT is rarely associated with MPGN and specific mechanisms remain unclear. Proteinuria in glomerular disease associated with HT is not correlated with levels of thyroid hormone. However, depositions of thyroglobulin and thyrotropin antibodies were noted on immunofluorescence prior to systemic lupus erythematosus (SLE) in a young woman.
SA-PO066
A Rare Case of Tubulointerstitial Nephritis Associated with Primary Biliary Cirrhosis Jatinder K. Hothi,1 Jingyin Yan,1 William F. Glass.1 1Dept of Nephrology, Baylor College of Medicine, Houston, TX; 2Dept of Internal Medicine, Baylor College of Medicine, Houston, TX; 3Dept of Pathology, Univ of Texas Health Science Center, Houston, TX.

Introduction: Primary biliary cirrhosis (PBC) is a chronic autoimmune liver disease characterized by positive antimitochondrial antibodies (AMA), immune-mediated epithelial damage of small bile ducts, which leads to liver cirrhosis as the disease advances. In addition to liver injury, other autoimmune diseases, such as Sjögren’s syndrome and Raynaud’s syndrome, are reported in approximately 2-20% patients with PBC. However, the association of PBC and renal injury is rarely documented.

Case Description: Here we present a case of tubulointerstitial nephritis (TIN) in a patient with PBC. A 35-year-old female with past medical history of PBC developed sub-nephrotic range proteinuria and chronic kidney disease stage 3. A renal biopsy showed moderate to severe renal cortical and focal medullary tubulointerstitial inflammation with infiltration of lymphocytes, plasma cells and occasional eosinophils, as well as significant tubulitis.

The patient was treated with a short course of oral prednisone and her renal function improved.

Discussion: This case highlights a very rare cause of TIN and suggests that steroid therapy is effective in this setting.

SA-PO067
Plasma Exchange as Adjunctive Therapy for Crescentic IgA Nephropathy Jicheng Wang, Xinfeng Xie, Fude Zhou, Minghui Zhao, Hong Zhang. Renal Div, Peking Univ Inst of Nephrology.

Introduction: Recent KDIGO guidelines recommend an aggressive immunosuppressive therapy in patients with crescentic IgA nephropathy (CedIgAN). While large cohort study from our center suggest that even with such a therapy, the 1- and 5-year renal survival rates remained low at 65% and 28%, respectively. Especially patients who present with serum creatinine (Scr)>580μmol/L hardly recovered from dialysis. In this study we aim to evaluate the efficacy of plasma exchange(PE) in severe CedIgAN.

Case Description: In this pilot study we give PE as adjunctive therapy to patients with severe CedIgAN on the back of high dose steroids and cyclophosphamide. Severe CedIgAN is defined as diffuse crescent forming with kidney failure that needs dialysis or presents severe CreIgAN on the back of high dose steroids and cyclophosphamide. Overall ten patients with severe crescentic IgA nephropathy received PE from 2011 to 2015.

Y: yes, N: No

Among them 7 patients reached dialysis at presentation with serum creatinine (768±176μmmol/L). Another 3 cases showed progressively kidney decline even after an aggressive immunosuppressive therapy. Patients received 5-10 PEs. After a mean 13 month follow-up, 4 of the 7 patients with dialysis successfully recovered from dialysis. One of the 3 patients with persistent kidney progression showed serum creatinine decline.

No severe adverse event was observed during the follow-up.

Discussion: Plasma exchange as adjunctive therapy may achieve benefit for patients with severe crescentic IgAN.

SA-PO068

Introduction: Fibrillary glomerulonephritis (FGN) is characterized by nonbranching randomly arranged fibrils along the mesangium and glomerular capillary walls that do not stain for Congo red, have a diameter of 16-24 nm, and usually show polyclonal IgG, C3, and light chain deposition by immunofluorescence. Found in ≤ 1% of native renal biopsies, FGN is usually idiopathic, although some cases are associated with malignancy, monoclonal gammapathy, and autoimmune diseases. Association of FGN with demyelinating neuropathy has been rarely described.

Case Description: A 38-year-old Indian man with 3-year history of hypertension and 10-month history of end stage renal disease attributed to hypertension, presented to our institution with a 3-week history of progressive, bilateral lower extremity weakness. During his hospital stay, he was diagnosed with non-infectious pleural and pericardial effusions. Lab work revealed normal Anti nuclear antibody, anti double stranded DNA antibody, serum complements, anti nuclear cytoplasmic antibodies. Serologies for hepatitis and human immune deficiency virus were negative. Electromyography revealed demyelinating sensorimotor polyneuropathy. Chest, abdomen and pelvis imaging was unrevealing for malignancy. No monoclonal peaks on serum and urine electrophoresis or immunofixation Fat pad biopsy negative for amyloid. Bone marrow biopsy showed 60% cellularity with tri lineage hematopoietic activity, no B cell clonality or T cell aberrancy. He was started on high dose steroids with gradual improvements of weakness. Renal biopsy showed findings of chronic FGN with IgG4 dominant deposition. 44 of 48 glomeruli were globally sclerosed with 80% fibrosis and no activity. Sural nerve biopsy results are still pending.

Discussion: FGN is a rare and leads to ESRD in the majority of cases. There are very few cases describing FGN in association with demyelinating polyneuropathy without associated plasma cell dyscrasias. Although FGN renal prognosis remains poor, early identification is important as it may help identify an underlying malignancy or systemic autoimmune disorder with potential for treatment. FGN may be a precursor for future lymphoproliferative disorder.

Acute Inflammatory Polyarthritis following Kidney Transplantation
Paul P. Maraj, Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: An acute inflammatory polyarthritis develops one month after deceased donor kidney transplantation in a 54 year old male. He had no prior diagnosis of any form of arthritis, crystalline, inflammatory or otherwise. Following workup he was diagnosed with Rheumatoid arthritis and improved with an increased dose of steroids. To date there are no case reports which described this disorder precipitated by kidney transplantation. This case report describes this unique clinical scenario and the dilemmas with diagnosis.

Case Description: 54 year old man with a medical history of end stage renal disease secondary to hypertensive nephrosclerosis who underwent deceased donor kidney transplant one month prior was admitted for joint pains. During kidney transplantation he had induction with thymoglobulin, plasmapheresis and rituximab as per institutional protocol for positive DSA. Maintenance immunotherapy consisted of tacrolimus, mycophenolate mofetil and prednisone taper dose. Following transplantation he was asymptomatic until one month after transplantation when he developed bilateral shoulder pains which then migrated to elbows and wrist; this was associated with significant morning stiffness and malaise. X-rays which were negative for bony abnormalities, MRI wrist revealed small to moderate joint effusion. Fluid analysis was negative for septic arthritis and crystals. Serum uric acid was within normal limits. Autoimmune workup negative including ANA, C3, C4. Rheumatoid factor was positive to titer 1:4, anti CCP was significantly positive at>250. He was treated with oral steroids which resulted in resolution of his symptoms.

Discussion: To date there have been no reports of rheumatoid arthritis in the immediate post-transplant period. There have been reports of an acute inflammatory syndrome related to mycophenolate use which improved on discontinuation, anti-CCP titers were unknown in these cases. Mycophenolate was continued in this patient and his symptoms did not recur after steroid taper making a reaction to mycophenolate less likely. Anti CCP is very specific but diagnosis of rheumatoid arthritis but its validity post transplant is unknown. The temporal relation with transplantation also raises the possibility of a drug induced reaction.

IgM Nephropathy: A Neglected Pathology of Nephrotic Syndrome
Krysthal Z. Andujar, Carlos Antonio Cortes Sanchez, Hector R. Cordova, Medical Service, VA Caribbean Healthcare System, San Juan, PR.

Introduction: IgM nephropathy is defined by the presence of immunoglobulin M (IgM) as the dominant immunoglobulin in the mesangium of the glomeruli in a diffuse and global distribution. Clinically, a poor response to steroids distinguishes this disease from Minimal Change Disease.

Case Description: An 80-year-old man with past history of Hypertension, Alzheimer’s dementia, and benign prostatic hypertrophy complained of progressive shortness of breath associated with severe bilateral lower extremity edema and decreased urine output. Vital signs revealed blood pressure of 171/77mmHg. Lung auscultation was remarkable for bibasilar rales. The patient had anasarca. Laboratory tests showed serum creatinine at 2.2mg/dL (baseline of 1.2mg/dL), BUN of 36mg/dL and albumin of 2.2g/dL. Urinalysis showed microscopic hematuria and proteinuria (> 500mg/dL). Renal sonogram revealed normal kidney size without hydronephrosis or nephrolithiasis. The 24-hour urinary protein excretion was 6.7gms/day. Serum creatinine rose to 7.7mg/dL a week later. Kidney biopsy was repeated and steroid pulse therapy was started. Hemodialysis was initiated. Renal biopsy results showed mild increase in mesangial matrix and interstitial fibrosis. Sections stained for IgG, IgA, albumin C1q and kappa and lambda light chains were negative. Staining for IgM showed granular deposits in the mesangial areas compatible with a diagnosis of IgM Nephropathy. Hemodialysis was discontinued after two sessions since the patient had rapid recovery of kidney function after the 3 day steroid pulse therapy. Steroid therapy was tapered and eventually discontinued. Three months later, 24 hour urinary protein excretion was normal and the serum creatinine was 1.6mg/dL.

Discussion: Patients with IgM Nephropathy are less likely to respond to immunosuppressive agents. The presence of mesangial IgM deposits and interstitial fibrosis entails a worse prognosis. However, in our case, the patient had a prompt response to steroid therapy with resolution of the nephrotic syndrome and recovery of renal function.

Renal Infarct from Traumatic Renal Artery Dissection
Eduardo J. Zouain, Isha Gupta, Karim El Hackem, Germaine Z. Chan, Steven D. Smith, Nephrology Dept, Mt. Sinai St. Luke’s Hospital and Icahn School of Medicine at Mt. Sinai, New York, NY.

Introduction: Renal infarction is an uncommon condition associated with a thromboembolic event (i.e., related to arterial fibrillation), hypercoagulable state, renal artery dissection or fibromuscular dysplasia. The 26 y/o male with no significant medical history presented with left flank pain for 3 days. The pain was described as 10/10 and accompanied with intermittent nausea. He fell from his motorcycle onto his left side 2 weeks prior. On exam there was a healing laceration over the left knee and tenderness to palpation over the left lower quadrant and L flank. The remainder of his exam including blood pressure was unremarkable.

Discussion: Renal infarcts are characterized by acute onset of flank or generalized abdominal pain, nausea, vomiting, and occasionally fever and hypertension. Elevated WBC, CRP and LDH have also been associated. Renal artery dissection secondary to trauma is rare and has been associated with anatomical variations and acceleration/deceleration injury leading to intimal tearing. The two goals of management are organ preservation and improvement of renovascular hypertension. The treatment options include surgical reconstruction, endovascular repair, or conservative treatment. Our patient was initially placed on empiric antiaggregation with heparin. After hypercoagulable disorder, vasculitis, and embolic source was ruled out, anticoagulation was stopped. The patient was discharged on conservative treatment.

Persistent Fever in a Patient with Wunderlich Syndrome
Marijeta Pekez,1 Kshitij Thakur,1 Dept of Medicine, Crozer Chester Medical Center, Upland, PA;1 ‘Clinical Renal Associates, Crozer Chester Medical Center, Upland, PA.

Introduction: Wunderlich syndrome is spontaneous, nontraumatic renal hemorrhage confined to the subcapsular and perirenal space. We present a case of a patient with a Wunderlich syndrome complicated by renal abscess.

Case Description: Patient was a 43 year old male who presented with nausea and generalized weakness, found to have sepsis secondary to urinary source. Ultrasound obtained during work up showed a old right perinephric hematoma. Patient continued to be febrile despite IV antibiotics. Repeat imaging with CT scan showed large abscess in place of the previously described subcapsular hematoma. Successful CT-guided drainage of the abscess led to marked improvement and resolution of fever.

Discussion: Wunderlich syndrome is secondary to neoplastic and non-neoplastic causes. It usually presents as mild flank pain, flank tenderness, or hematuria. Depending on blood loss, symptoms, of hypovolemic shock may develop. Treatment varies according to severity, ranging from monitoring of the hematoma to nephrectomy. Our case is interesting since Wunderlich syndrome provided a nidus for infection and eventual abscess formation causing persistent fevers and flank pain with preserved hemodynamic stability. It demonstrated the need for CT imaging in order to fully appreciate the extent of the hemorrhage which in this case converted into an abscess. In the right clinical scenario, Wunderlich syndrome should be evaluated as a possible factor in infectious presentations.

Gauker’s Disease and Lupus, Two Diseases in the Same Scope?

Introduction: Gauker’s disease is a rare inherited lysosome storage disease caused by genetic mutations that encodes for glucocerebrosidase enzyme. It’s deficiency leads to glucocerebrosidase (GC) accumulation in mononuclear macrophage system, including liver, spleen and bone marrow. Kidney involvement is usually rare. Systemic lupus erythematosus

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
(SLE) is an autoimmune disorder where similarly, splenoglandular accumulation occurs when there is glomerular disease. The authors describe a case of a woman with both Gaucher’s disease type 1 and SLE.

**Case Description:** A 32-year-old woman with Gaucher’s disease diagnosed at 17 years old, having valgus knees, presented several clinical clues suggesting SLE. Months later presented face and limbs edema and hypertension. She was admitted with microcytic and hypochromic anemia, 77000 platelets, creatinine serum levels of 1.38mg/dL and hypocalcemia. The urinalysis showed hematuria and proteinuria of 7628mg in the 24h urine collection. The patient had positive anti-nuclear antibodies, Anti-Sjögren’s syndrome-related antigen A and negative anti-double stranded DNA antibodies, anti-neutrophil cytoplasmic antibodies, viral serologies. Both complement levels were low. A kidney biopsy was performed.

It has been suggested that progressive accumulation of Gc may trigger macrophage activation resulting in enhanced cytokine secretion and subsequent clonal B-cell expansion leading to chronic stimulation of the immune system. GC changes natural killer T cell function, a regulatory lymphocyte that has a role in infectious, neoplastic and inflammatory processes, therefore having a potential role in inducing other autoimmune disease. NKT lymphocytes are considered to be a link between innate and adaptive immune responses processes, therefore having a potential role in inducing other autoimmune disease. NKT lymphocytes are considered to be a link between innate and adaptive immune responses processes, therefore having a potential role in inducing other autoimmune disease. NKT lymphocytes are considered to be a link between innate and adaptive immune responses processes, therefore having a potential role in inducing other autoimmune disease.

**Discussion:** This case highlights a possible immunologic proximity between Gaucher’s disease and SLE, bringing up the already existing doubt that the defects in lipid metabolism, could contribute to the development of autoimmunity.

SA-PO074

**Chronic Periaortitis, a Known Cause of Obstructive Uropathy**

**Margaret Daffy, 1 Smita Mahendrakar, 1 Manced Saam, 1 Michael Yudd. 2**

1 Nephrology, Rutgers-New Jersey Medical School, Newark, NJ; 2 Nephrology, East Orange Veterans Administration Hospital, East Orange, NJ.

**Case Description:** A 59 year-old man with hypertension presented with one week of gradually decreasing urine output, nausea, generalized weakness, and vague dull left lower quadrant pain with radiation to the left flank. He was afibrile with blood pressure of 170/90 mmHg, pulse of 79 beats per minute, respiratory rate of 16 breaths per minute, and oxygen saturation of 98% on room air. His abdominal exam was unremarkable except for non-tender scrotal swelling bilaterally. Laboratory studies were notable for the following values: WBC 12.1 x 10^9/L, BUN 63mg/dL, SCr 13.8mg/dL (baseline Scr 1.1mg/dL), ESR 57mm/hr, CRP 67mg/dL, U/A clear, yellow, specific gravity 1.01, pH 6, moderate blood, negative protein, leukocytoc esterase, or nitrates. A renal ultrasound showed moderate hydropnephrosis with patent renal arteries and veins bilaterally. CT of the abdomen and pelvis revealed moderate bilateral hydropnephrosis, an abdominal aortic aneurysm (3.6cm), and a periaortic soft tissue mass measuring 2 cm in diameter with associated ureteral obstruction. There was no intracranial intraparenchymal hemorrhage or suggestion of discrete malignancy. Based on combined clinical and radiographic evidence the patient was diagnosed with chronic periaortitis and retroperitoneal fibrosis. He was started on mycophenolate mofetil and prednisone taper with complete resolution of symptoms within 6 months.

**Discussion:** Retroperitoneal fibrosis (RPF) is a relatively rare condition characterized by the presence of fibrosis and inflammation of the retroperitoneal tissues that often surrounds the ureters and other abdominal organs and can lead to renal failure in advanced cases. Our case demonstrates the importance of considering RPF as an etiology of flank pain and renal failure as medical treatment is effective in reversing obstructive uropathy.

SA-PO075

**IgA Nephropathy in HIV Positive Patient with Acute Kidney Injury**

**Giovanna Y. Arteaga Muller, 1 Lilíaa Maria Rizo Toppede, 1 Elísa Maria Guerrero Gonzalez, 1 Gabriel Gómez, 1 Martha E. Galván, 1 Gabriela Alarcón-Galván. 2**

1 Dept. of Medicine, UANL, Monterrey, Mexico; 2 Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.

**Introduction:** Acute kidney injury is common in patients with HIV, being prerenal variety the predominant etiology. Among the intrinsic causes are thrombotic microangiopathy, the antiretroviral drugs associated and the immune complexes associated (3.5% -10%) being the collapsing focal segmental glomerulosclerosis the most frequently found.

**Case Description:** Male 41 year old, with use of cocaine, marijuana, benzodiazepines tattoos and high-risk sexual behavior, diagnosed with HIV nine years ago, treated with antiretrovirals which suspended two years ago. Begins 3 months before with malaise, a week prior to his admission presented progressive dyspnea on moderate to high stresses accompanied by productive cough and fever. Chest radiograph showed fine interstitial infiltrate, compatible with pneumocystis jiroveci, laboratories: Hb 9.4g/dl, creat 3.0 mg/dL, BUN 350 mg/dl, urine protein 4.7g/24 hrs, the urinalysis reported reddish urine, with granular casts, hematuria and pyuria. Hepatitis B, Hepatitis C, CMV and tuberculosis tests were all negative and the renal ultrasonography was normal. Renal biopsy revealed IgA nephropathy.

Direct immunofluorescence technique (400X) Mesangial granular staining (+) for IgA. Early treatment with anti-proteinuric general measures and prednisone improved renal function with a decreased in creatinine to 1.3mg/dL.

**Discussion:** The immune complexes associated nephropathy in patients with HIV is more common due to the start of antiretroviral therapy, however IgA nephropathy remains uncommon in this patients. In our patient the indication for renal biopsy was the erythrocyturia and the proteinuria in nephritic range. Early detection and treatment can prevent progression to ESRD.

SA-PO076

**Ketorolac Induced Mesangiolyysis: A Clinical Example of Anti-Thy 1.1 Model of Mesangio-Proliferative Glomerulonephritis**

**Fatima Khalid, 1 Dept. of Medicine, Univ of Rochester School of Medicine, Rochester, NY.**

**Introduction:** NSAIDS are known cause of acute kidney injury, but do not usually cause glomerulonephritis. We share an unusual presentation of glomerulonephritis after only one dose of ketorolac. No renal biopsy findings in acute ketorolac-related acute kidney injury appear to have been published based on an Ovid literature search.

**Case Description:** This is a 42 year old male with past medical history of nephrothiasis and urethral stricture, who presented to the hospital for a cystoscopy procedure. The patient had urinary obstruction after the procedure and developed oliguric acute kidney injury with serum creatinine of 3.1 mg/dL (baseline 0.8 mg/dL). Of note, the patient also received one dose of ketorolac during the procedure. Urinalysis showed 2+ blood with many red blood cells, and 9 grams of proteinuria as TP/creatinine ratio. Lab work demonstrated high LDH, low haptoglobin but stable hematocrit and platelet count. Periurethral smear did not reveal schistocytes. Urine microscopy showed RBC casts. Renal ultrasound showed normal sized kidneys with no hydropnephrosis. Kidney biopsy showed acute tubule-interstitial nephritis with tubular necrosis and mesangiolysis. Electron microscopy showed patent capillary loops with focal epithelial foot process effacement, visceral epithelial cells with cytoplasmic vacuolization, dilated capillaries with endothelial apoptosis and mesangial lysis. Glomerular basement membrane thickness was increased. There was evidence of acute tubular injury. No electron dense deposits, thrombi or crescents were identified. Immunofluorescence of glomeruli was negative. The patient remained oliguric and required renal replacement for short term followed by full recovery of renal function.

**Discussion:** Renal toxicity of ketorolac has been described, and appears generally to be reversible, but could lead to glomerulonephritis in a rare setting. The pathological findings in the glomeruli resembled those described in experimental animals with Thy-1 induced glomerulonephritis treated with rofecoxib (COX-2 inhibitors). In this model, glomerular disease is initiated by immune-mediated mesangial cell damage, resulting in mesangiolysis.

SA-PO077

**Disseminated Cytomegalovirus Disease in Induction Treatment with Mycophenolate Mofetil in a Lupus Nephritis Patient**

**Ana Pocinho Pimentel, Joana Vidinha, Teresa M. Jeronimo, Ana Cabrita, Ana Paula Silva, Pedro L. Neves. Nephrology, Centro Hospitalar do Algarve, Faro, Portugal.**

**Introduction:** Mycophenolate mofetil (MMF) is an immunosuppressive agent that exerts relatively selective antiproliferative effects on T and B lymphocytes and is increasingly being associated with higher incidence of tissue-invasive cytomegalovirus (CMV) disease in transplant receivers and other immune-mediated diseases. The case presented is a patient who developed CMV enteritis while receiving MMF and corticosteroids for lupus nephritis (LN).

**Case Description:** 59 year-old man with LN class IV (G7 + V under MMF (2.5mg/d) and prednisolone (60mg/d) at the time When started having weight loss; diarrhea, nausea, dysphagia and haematochezia. The blood count showed severe anemia and leucopenia. Comprehensive chemistry profile revealed Pcr 2.7mg/dL improving proteinuria from 11.7 to 2g/day and normal urinary sediment. CMV serology IgM came positive (PCR CMV: 834 copies/mL). Immunology tests were negative. Upper endoscopy and colonoscopy were performed. Biopsies showed CMV infection signs and esophageal candidiasis, MMF was tapered to 1g/day and prednisolone to 20mg/day. The patient was started on intravenous ganciclovir.
and fluconazole, with favorable clinical response. Proteinuria then worsened to 7.9g/day. Renal ultrasound revealed renal size decrease. Kidney biopsy revealed diffuse proliferation of PCr 1.6mg/dL having 2g MMF and prophylactic oral valganciclovir.

CMV virus directly infects the bowel causing mucosal erosions or ulcerations. We can only find little evidence that CMV disease explains the gastrointestinal adverse event profile associated with MMF but we bring up again the hypothesis that high local concentrations of MMF have a direct toxic effect on cells of the small intestine, causing gastrointestinal upset. Data on the incidence of CMV disease with the MMF induction protocol for LN are scarce.

Discussion: Similarly to transplant recipients receiving MMF, LN patients presenting gastrointestinal upset demand exclusion of CMV infection. This report highlights the importance of clinical follow-up of lupus patients with GI symptoms undergoing intense immunosuppression and accurate serological and histological diagnosis.

SA-PO078
Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy Mihoko Karube, Shinya Kaname, Kazuhiro Fukuda, Hideki Shimizu, Yoshinori Komagata, Yoshhiro Arimura. The First Dept of Internal Medicine, Kyorin Univ School of Medicine, 6-20-2 Shinkawa Mitaka-city, Tokyo, Japan.

Introduction: It is unknown whether pregnancy affects clinical course of cryoglobulinemic nephropathy and how to treat pregnant patients complicated with it.

Case Description: A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had been terminated for similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complements. The renal biopsy performed 10 days after the third termination revealed MPGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and Clq all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed by intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2.342kg on vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: We experienced a rare case of type III cryoglobulinemic nephropathy that usually developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. Although the pathogenesis of pregnancy-induced exacerbation of cryoglobulinemic nephropathy was not clear in this patient, aggressive treatment may have been helpful for ameliorating it, leading to successful delivery.

SA-PO079
Renal Recurrence of Acute Lymphatic Leukemia Anna Bertram, Jan H. Brascen, Ansgar Reising. 1Nephrology and Hypertensionology, Hannover Medical School, Hannover, Germany; 2Pathology, Hannover Medical School, Hannover, Germany.

Introduction: Renal complications of hematologic neoplasia can be therapy- or neoplasia-associated. We report a case of acute kidney injury (AKI) in the long term follow-up of a patient with acute lymphatic leukemia (ALL).

Case Description: The 42y old patient was diagnosed with ALL in 2009 and treated according to recommendations with chemotherapy and peripheral blood stem cell transplantation. In 2012, extramedullary ALL recurrence in his right knee was treated with chemotherapy and peripheral blood stem cell transplantation. Several urinalyses showed acute tubular necrosis. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: This exceptional case of isolated renal ALL recurrence highlights the importance of early evaluation with ultrasound and biopsy in patients with hematologic neoplasia and AKI. An empiric treatment for suspected interstitial nephritis would have delayed chemotherapy and thereby endangered the patient.

SA-PO080
A Rare Cause of Acute Kidney Injury in Non-Renal Solid Organ Transplantation Sameer Gupta, Wasy Hayumany, Ramapriya Sinnakruchanen, Liliana Osadchuk. Nephrology, Medical College of Wisconsin, Milwaukee, WI.

Introduction: Acute kidney injury (AKI) is a frequent complication of non-renal solid organ transplantation (SOT). Here we report a case of rapidly progressive renal failure leading to end stage renal disease (ESRD) due to acute oxalate nephropathy (AON) in a patient with non-renal SOT.

Case Description: A 63 year old female with past history of pulmonary fibrosis status post bilateral lung transplant, obesity status post Roux en Y gastric bypass (RYGB) surgery, and hypertension presented with worsening kidney function with BUN and creatinine of 55 mg/dl and 6.18 mg/dl respectively. She had normal kidney function with serum creatinine of 0.5mg/dl prior to transplant 8 months ago. Induction regimen included Basiliximab followed by tacrolimus, prednisone and mycophenolate (MMF) as maintenance therapy. Enoxaparin prophylaxis was used except for the first three postoperative days. Enoxaparin was subsequently substituted with fondaparinux. On postoperative day 26, she developed a palpable perinephric hematoma with declining creatinine to 1.9mg/dl. The hematoma resolved with conservative management. Despite withholding renin inhibitors for the following 3 weeks, she continued to have declining renal function. She was started on intravenous cyclophosphamide 6 times according to recommendations with chemotherapy and peripheral blood stem cell transplantation. In 2012, extramedullary ALL recurrence in his right knee was treated with chemotherapy and peripheral blood stem cell transplantation. Several urinalyses showed acute tubular necrosis. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: We experienced a rare case of type III cryoglobulinemic nephropathy that usually developed nephrotic syndrome during pregnancy, but finally bore a healthy baby after immunosuppressive therapy. Although the pathogenesis of pregnancy-induced exacerbation of cryoglobulinemic nephropathy was not clear in this patient, aggressive treatment may have been helpful for ameliorating it, leading to successful delivery.

SA-PO081
Paraneoplastic Membranous Nephropathy and Myelodysplastic Syndrome – A Rare Combination Krishna K R Manoh, Madhuri Manne, Dagmar Klinger. Renal Medicine, Univ of Massachusetts Medical School, Worcester, MA.

Introduction: We report a case of Membranous Nephropathy (MN) seen in association with Myelodysplastic Syndrome (MDS). This occurrence is rare and only 3 cases have been reported in literature previously. Up to 5-20% of adults with MN have been reported to have most commonly a solid tumor and less frequently, a hematologic malignancy.

Case Description: Our patient is a 58 y/o man who has chronic kidney disease of unclear etiology with serum creatinine (SCr) of 1.3 and MDS. He was admitted with acute kidney injury in the setting of pneumonia and had nephrotic range proteinuria along with dysmorphic red blood cells on the urinary sediment. Renal biopsy showed MN with relatively recent immune complex deposition. There was no colocalization of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and Clq all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed by tacrolimus, prednisone and mycophenolate (MMF) as maintenance therapy. Enoxaparin prophylaxis was used except for the first three postoperative days. Enoxaparin was subsequently substituted with fondaparinux. On postoperative day 26, she developed a palpable perinephric hematoma with declining creatinine to 1.9mg/dl. The hematoma resolved with conservative management. Despite withholding renin inhibitors for the following 3 weeks, she continued to have declining renal function. She was started on intravenous cyclophosphamide 6 times according to recommendations with chemotherapy and peripheral blood stem cell transplantation. In 2012, extramedullary ALL recurrence in his right knee was treated with chemotherapy and peripheral blood stem cell transplantation. Several urinalyses showed acute tubular necrosis. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: Acute kidney injury (AKI) is a frequent complication of non-renal solid organ transplantation (SOT). Here we report a case of rapidly progressive renal failure leading to end stage renal disease (ESRD) due to acute oxalate nephropathy (AON) in a patient with non-renal SOT.
lymphohistiocytosis by clinical criteria and therapy was initiated with high-dose steroids and etoposide. The patient responded to the treatment and SCr peaked at 1.45 mg/dL, but did not require renal replacement therapy. Following this treatment SCr improved to 0.7.

Discussion: MN is the most common cause of the nephrotic syndrome in nondiabetic adults. Histologic change on light microscopy is glomerular basement membrane thickening with little or no cellular proliferation. Patients without known cancer who are diagnosed with MN should undergo age-appropriate cancer screening and this could be life saving. MDS, a group of heterogeneous hematopoietic stem cell disorders, are characterized by abnormal bone marrow differentiation & maturation, morphologically and functionally characterized by ineffective erythropoiesis and a variable risk of evolution to acute leukemia. Paraneoplastic Glomerulonephritis (PGN), a rare secondary cause of glomerulonephritis and a complication of cancer remains a challenge to both nephrologists and oncologists. Studies to identify diagnostic biomarkers of PGN in blood, urine, or kidney biopsy samples by use of proteomic approaches or other approaches are critically needed to facilitate the early diagnosis of this disease.

SA-PO082

Eculizumab in Gemicitabine Induced Atypical Hemolytic Uremic Syndrome

Mohit Gupta, Rupesh Raina, Nathavath Tanphaichitr. Dept of Nephrology, Akron General Medical Center, Cleveland, OH.

Introduction: HUS (aHUS) is caused by endothelial damage due uncontrolled activation of complement system. Gemicitabine a nucleoside analog induced HUS (GiHUS) is rare. We report a patient with unetectable, locally advanced pancreatic cancer who developed a HUS after 1 month of gemicitabine.

Case Description: A 64 year-old female was diagnosed with 4 cm mass adenocarcinoma of the pancreatic head, after extensive evaluation of recurrent abdominal associated with clay colored stool. She underwent three cycles of gemicitabine at 1,000 mg/square meter. Her condition deteriorated over the following 1 week and developed microangiopathic hemolysis, rapidly declining renal function with proteinuria and hematuria, and renal biopsy of the last dose. Other markers of hemolysis namely LDH and bilirubin had dramatic improvement after 2 treatment of Eculizumab.

Pt was consequently treated with Eculizumab for management of atypical HUS. She received 1 dose of Eculizumab IV every week after which she was transitioned to once monthly for a total of nine doses. Pt’s Creatinine Clearance was closely monitored and had significantly improved from 34 mL/min at time of last dose to 60 mL/min of the last dose. Other markers of hemolysis namely LDH and bilirubin had dramatic improvement after 2 treatment of Eculizumab.

Discussion: HUS associated with gemicitabine is quite rare and no consistent risk factors have been identified. Conventional treatment with hemodialysis, or corticosteroids or plasmapheresis as minimal response. The rapid clinical response to eculizumab supports the concept that GiHUS might involve aberrant and autonomous complement activation.

The dramatic resolution of symptoms after eculizumab administration suggests that chemotherapy induce aHUS is an area deserving further careful investigation of therapeutic complement blockade.

SA-PO083

A Case of Rapidly Progressing Idiopathic Membranoproliferative Glomerulonephritis Effectively Treated with High-Dose Steroid Therapy

Bernice Kim, Kyung Soo Kim. Div of Nephrology, Dept of Internal Medicine, Dongsuk Univ Ilsan Hospital, Goyang, Republic of Korea.

Introduction: Membranoproliferative glomerulonephritis (MPGN) is an uncommon kidney disorder which can be idiopathic or secondary in etiology. As diagnostic methods improved over time, secondary cause of MPGN is increasingly defined and the truly idiopathic form is now a very rare condition. Because of the rarity of idiopathic MPGN, treatment guidelines are less commonly applied on case series and the natural history of the disease is unclear. We present a case of rapidly progressive idiopathic MPGN effectively treated with high-dose steroid.

Case Description: A 73-year-old male was admitted because of subtrochanteric fracture. On admission, he had normal kidney function with serum creatinine (CrCr) level of 1.02 mg/dL. 5 days after the operation of fracture, he was referred to the nephrology department due to abruptly increased level of CrCr. On postoperative day 10, despite adequate intravenous hydration, he became anuric and serum CrCr rose to 4.40 mg/dL requiring hemodialysis.

With little or no cellular proliferation. Patients without known cancer who are diagnosed with MN should undergo age-appropriate cancer screening and this could be life saving. MDS, a group of heterogeneous hematopoietic stem cell disorders, are characterized by abnormal bone marrow differentiation & maturation, morphologically and functionally characterized by ineffective erythropoiesis and a variable risk of evolution to acute leukemia. Paraneoplastic Glomerulonephritis (PGN), a rare secondary cause of glomerulonephritis and a complication of cancer remains a challenge to both nephrologists and oncologists. Studies to identify diagnostic biomarkers of PGN in blood, urine, or kidney biopsy samples by use of proteomic approaches or other approaches are critically needed to facilitate the early diagnosis of this disease.

SA-PO084

A Case of Advanced IgG4 Related Tubulointerstitial Nephritis Complicating Multiple Lymphadenopathy and Intrathoracic Nodule, Mimicking Malignant Lymphoma

Shigeto Horita, Hiroshi Fujii, Yuhei Fujisawa, Satoshi Hara, Yasunori Suzuki, Kazunori Yamada, Mitsushiro Kawano. Div of Rheumatology, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishikawa, Japan.

Introduction: Immunglobulin G4-related disease (IgG4-RD) is a systemic inflammatory disorder characterized by infiltration of lesions with IgG4-producing plasma cells. We describe a patient with IgG4-RD associated with advanced tubulointerstitial nephritis, membranous nephropathy, and multiple lymphadenopathy, mimicking malignant lymphoma.

Case Description: Four months prior to this admission, an 81-year-old male experienced anorexia and weight loss. Enhanced CT revealed gastric cancer, intrathoracic nodule, multiple defects of contrast medium in the kidneys and abdominal periaortitis. The patient’s serum Cr level was 1.1 mg/dL and IgG level was 390 mg/dL. One month prior to this admission, the patient had received gastrectomy. After gastrectomy, decreased renal function (Cr 2.09 mg/dL), elevation of IgG4, and hypocomplementemia were detected. A renal biopsy showed marked infiltration by IgG4-positive plasma cells, spiking and bubbling on PAM staining, and granular deposits of Ig on immunofluorescent staining. The patient was diagnosed with IgG4-related tubulointerstitial nephritis and membranous nephropathy. PET showed accumulation of fluorodeoxyglucose in the submucosal glands, lymph nodes, kidneys, abdominal aorta and prostate, which were hard to distinguish from malignant lymphoma. Biopsy of the largest lymph nodes in the axilla and intrathoracic nodule showed reactive lymphadenopathy with IgG4 positive plasma cell infiltration. One month after starting prednisolone (25 mg/day), Cr level was partially decreased to 1.1 mg/dL and, the size of the lymph nodes and intrathoracic nodule reduced.

Discussion: Finding of IgG4-RD often mimic those of malignancies, so the differentiation of malignancies from IgG4-RD is important. In this regard, pathological findings of the affected organs are important to make the correct diagnosis. As severe renal dysfunction might develop during a several month period, IgG4-related kidney disease should be considered as a cause of renal dysfunction of unknown origin, especially in elderly men.

SA-PO085

Presence of PLA2R Autoantibodies in a Patient with Clinical and Histopathological Evidence Suggestive of Secondary Membranous Nephropathy

Kristen P Tamura, Niti Madan. Nephrology, UC Davis Medical Center, Sacramento, CA.

Introduction: Differentiating between secondary membranous and idiopathic membranous nephropathy (IMN) is based on histopathology showing proliferative features in mesangium, full-house staining pattern, electron dense deposits in the mesangium and tubular basement membrane. Phospholipase A2 receptor (PLA2R) has been identified as a major target antigen involved in IMN pathogenesis. We describe here a patient with clinical history and histopathology suggestive of secondary membranous and positive anti-PLA2R antibody suggestive of IMN.

Case Description: A 56 year old Caucasian man with history of colon tubular adenoma, NHL- status post chemotherapy and radiation 30 years back, hypothyroidism presented with new onset nephrotic-range proteinuria. He was not taking any medications and physical exam noted generalized edema. Laboratory exam as noted in table 1.

A renal biopsy showed variable-sized electron dense deposits in subepithelial, intra membranous,mesangial and paramesangial locations. This finding strongly suggested a secondary etiology for the membranous nephropathy. Workup for infectious/autoimmune and neoplastic causes of membranous nephropathy was negative. Proteinuria worsened to 11 g/24h despite months of conservative therapy with lisinopril and low protein diet. Additional labs obtained came back positive for PLAR2 autoantibodies (IFA 1:1000, ELISA 97.6% R.U/ml). Kidney stained positive for PLAR2 glomerular deposits suggesting IMN.

The patient was then treated with a modified Ponticelli protocol using alternating monthly prednisone and oral cyclophosphamide (2 mg/kg/d) for six months. After three months, proteinuria, albumin and edema improved.

Discussion: Relying on histopathologic differences to distinguish between idiopathic and secondary membranous nephropathy may lead to incorrect diagnosis and delay in treatment. The presence of circulating and tissue PLA2R autoantibodies may be more reliable in diagnosing IMN than histopathology.
SA-PO086
Silent Malakoplakia in a Recipient of Kidney-Pancreas Transplant Diagnosed on Surveillance Biopsy of Kidney Allograft: A Patient-Centered Approach to Treatment of Malakoplakia Jun Shoji,1 Ravinder K. Walli,1 Dept of Kidney Disease and Hypertension, George Washington Univ, Washington, DC,1 Inova Transplant Center, Inova Fairfax Hospital, Falls Church, VA.

Introduction: Malakoplakia is an inflammatory disease leading to chronic morbidity and organ dysfunction. It was originally described in association with genitourinary tract infections with coliform bacteria and can manifest as acute pyelonephritis, acute or chronic renal failure, or renal mass. We present a case of a 40-year-old female recipient of simultaneous pancreas-kidney transplant who developed an acute rise in serum creatinine without apparent cause and found to have malakoplakia on kidney allograft biopsy. Patient-centered treatment resulted in reversal of allograft dysfunction and resolution of histological features of malakoplakia.

Case Description: 40-year-old Caucasian female with type 1 diabetes mellitus and end-stage renal disease on peritoneal dialysis underwent SPK transplant. After induction with basiliximab, she was maintained on tacrolimus and mycophenolate mofetil. Two months later, she was treated for acute T-cell mediated rejection (Banff Grade IA) with thymoglobulin. Serum creatinine returned to baseline and maintenance prednisone was added to her regimen. Her posttransplant course was complicated by multiple infections including parvovirus B19 infection, primary CMV infection, two episodes of urinary tract infections, and influenza A pneumonia. Due to an increase in serum creatinine without apparent cause, a kidney allograft biopsy was performed which revealed lesions consistent with malakoplakia.

Discussion: Treatment of malakoplakia in transplant recipient patients is not well established but include surgical resection and use of antimicrobial agents. In the era of cyclosporine and azathioprine, it was speculated that the use of azathioprine may be associated with the development of malakoplakia. Discontinuation of azathioprine was shown to result in return of more bactericidal activity of mononuclear cells. This case report illustrates that in the era of immunosuppression with tacrolimus and mycophenolate mofetil, the maintenance therapy with tacrolimus may be continued while treating for malakoplakia.

SA-PO087
Common Weight Loss Medication Pill—“Qsymia” Causing Hypokalemia and Renal Tubular Acidosis Iyotsana Thakkar, Mala Sachdeva. Div of Nephrology, North Shore-LI School of Medicine, Great Neck, NY.

Introduction: The obesity epidemic is growing. Aside from the traditional diet and exercise, weight loss pills are more commonly prescribed. Qsymia is one such weight loss pill consisting of topiramate and phentermine. We report potentially life threatening side effects of Qsymia causing severe hypokalemia, proximal renal tubular acidosis (pRTA), and cardiac dysrhythmia.

Case Description: A 68 year old female with history of hypertension presented with complaints of tingling of her left arm and jaw of one day duration. Her home medications included Aspirin and Hyzara (Losartan and Hydrochlorothiazide). She had self discontinued the Hyzaar five days prior to presentation. Patient was recently started on the weight loss medication “Qsymia” three months prior. She denied any alcohol use. On initial presentation, she was noted to be in atrial fibrillation (IR 150s) and hypotensive (BP 84/43 mmHg) requiring cardiovascular support. Subsequent cardiac catherization and echocardiogram were unremarkable. Initial lab data showed severe hypokalemia-2.4 mmol/L, creatinine 1.08 mg/dL, bicarbonate 22 mmol/L, phosphorus 2.1 mg/dL, magnesium 2.2 mg/dL, and calcium 8.9 mg/dL. Urinalysis showed pH 8 with glucosuria. Urine Lytes showed potassium 38 mmol/L, chloride 43 mmol/L, and sodium 141 mmol/L. It was suggested that patient’s clinical presentation and electrolyte disorders were due to the weight loss medication, and Qsymia was discontinued. Qsymia was approved by FDA in 2012 for weight loss. Most common side effects reported include paresthesia, dizziness, insomnia, constipation and dry mouth. In the U.S., drug label contains warnings for increased heart rate. Topiramate is known to cause pRTA. Our patient had mild acidosi, hypophosphatemia and glucosuria which we believe was a result of an early pRTA, induced by topiramate. Although hydrochlorothiazide is known to cause hypokalemia, our patient was not taking the medication for five days.

Discussion: Weight loss medications are now being more commonly used to treat obesity. Prescribers should be aware of the potential nephrotoxic side effects of Qsymia. Monitoring serum potassium and bicarbonate levels regularly should be taken into consideration.

SA-PO088
Multiple Myeloma as the Underlying Cause of Thrombotic Microangiopathy Venkata Buddhuraj,1 Liga Yusvirazi, Anastasios Papanagou, Savneek S. Chugh, Rahul N. Pawar. Nephrology, Westchester Medical Center, Valhalla, NY.

Introduction: Thrombotic microangiopathy (TMA) describes a pathological process of microvascular thrombosis, consumptive thrombocytopenia and microangiopathic hemolytic anemia, leading to end-organ ischemia and infarction affecting particularly the kidney and brain. TMA is a pathological feature of a number of clinical disorders including Hemolytic uremic syndrome (HUS) and atypical HUS. Rare but important, TMA may also occur in malignancy, connective tissue disease, malignant hypertension, and renal transplantation (rejection or drug toxicity). We present a rare case where patient developed AKI from TMA but found to have plasma cell dyscrasia as possible underlying etiology.

Case Description: A 42 y/o man with h/o myopathy, questionable mixed connective tissue disorder on prednisone and cellcept, Pulmonary Hypertension on home oxygen, CHF with preserved EF and Anemia requiring multiple transfusions went to an outside hospital with SOB and pedal edema found to have AKI with serum creatinine of 4 and 2+ proteinuria. Serologies were negative except for anti-RNP and ESR; with no improvement in renal function the patient had a renal biopsy which showed TMA, mild fibrosis and athero-sclerosis. The patient was Started on RRT and then transferred to Westchester medical center for treatment with Eculizumab for atypical HUS. After reviewing the labs we ordered Serum and urine protein electrophoresis which showed monoclonal Ig M spike, the patient underwent bone marrow biopsy which showed Plasmacytoma with 18% Plasma cells. The patient’s renal function improved in the hospital stay and stabilized with creatinine of around 2.0 mg/dl, but unfortunately the patient had a severe sepsis and passed away before initiation of management for Multiple myeloma.

Discussion: Multiple Myeloma accounts for 10% of hematological malignancies. Atleast 50% of patients with MM have evidence renal insufficiency and more than 80% have proteinuria. Multiple myeloma can present as has wide range of renal manifestations including myeloma cast nephropathy, Immune deposition disease, CKD Fanconi syndrome. Though rare Multiple myeloma can cause TMA and the Pathogenesis still remains unclear.

SA-PO089

Introduction: Pantoprazole (PPZ), a Proton Pump Inhibitor, is known to cause acute interstitial nephritis (AIN). We report a case of PPZ induced AIN in a young adult with just 3 doses of drug exposure.

Case Description: A 21 year old Asian American male with no past medical history was sent to the hospital by his Internist for elevated serum creatinine (Scr). He had nausea and abdominal pain 3 weeks earlier and was prescribed PPZ, which he took for 3 days. He denied use of any other medications including herbal supplements and NSAIDs. Laboratory data showed BUN of 82 mg/dL, Scr 15 mg/dL (baseline 0.6) , bicarbonate of 15 mmol/L and no creatinine or sodium gap. Urine showed sterile pyuria with no eosinophils, glycosuria with normal blood glucose , mild proteinuria (900mg/24 hrs). Serum and urine toxicology, protein electrophoresis, auto-immune work up were unremarkable. A Renal biopsy revealed diffuse expansion of the interstitium due to accumulation of cellular infiltrates consisting of lymphocytes, plasma cells and eosinophils with accompanying tubulitis consistent with AIN.

He received pulse steroids for 3 days and was continued on prednisone 1mg/kg/day with a plan to taper over 8-12 weeks. He required a few sessions of renal replacement therapy before his renal function started to recover, 6 weeks later his Scr was 1.4 mg/dL.

Discussion: Any drug can cause AIN, although the categories of antibiotics, diuretics and NSAIDs are most commonly implicated. Drug-induced AIN is not dose dependent, and recurrence can occur with a second exposure to the same or a related drug. The data on time of initiation, dosage and duration of steroids in drug induced AIN is limited due to lack of randomized control trials. On review of literature and our experience, we conclude that stopping the culprit agent and early steroid use confers better prognosis in drug induced AIN.

SA-PO090
Metastatic Sarcomatoid Carcinoma of Urothelial Origin in Failed Renal Allograft Venkata Buddhuraj,1 Rajat Lamba, Daniel G. Glicklich. Nephrology, Westchester Medical Center, Valhalla, NY.

Introduction: Renal cell carcinomas are more common in ESRD than the general population and renal transplant patients with enhanced longevity may be at particular risk. Sarcomatoid renal cell carcinoma represents 1-15% of all renal cell carcinomas but has been very rarely reported in transplanted renal allografts. The median age at diagnosis is 60 years with 45-77% of patients with locally advanced or metastatic disease at the time of diagnosis. We describe a case sarcomatoid tumor of urothelial origin in a transplanted renal allograft.

Case Description: A 54 y/o man with ESRD from polycystic kidney disease, HTN, aortic dissection repair, mechanical AVR, paroxysmal AFB, who had 2 failed renal transplants in the past and was on dialysis for past 12 years, was admitted for left lower quadrant pain, fever and leukocytosis for which he was started on vancomycin and...
Physicians should be aware of designer drugs use in ESRD patients. A patient developed (HAGMA), which could very well be related to synthetic marijuana use. Parathyroid hormone (PTH) levels with hypercalcemia. Some fail or cannot tolerate medical therapy. They eventually require parathyroidectomy. Tertiary hyperparathyroidism (3PTH) is the autonomous function of the parathyroid gland due to increased mass. Our case is unique as there are no reported cases of tertiary hyperparathyroidism in sickle cell patient, which we observed in our patient. The presentation of renal insufficiency and angina crisis which improved with parathyroidectomy. 25 year old man with sickle cell disease, ESRD on hemodialysis since 2012, (3PTH), presents after many admissions for sickle cell pain crisis. Cause of ESRD was unknown but attributed to sickle cell nephropathy. Current admission for knee pain, imaging of which showed “sclerotic appearance of the bones, likely due to renal osteodystrophy”. Intact PTH (iPTH) consistently > 4000 pg/mL, and patient non adherent to cinacalcet, agreed to parathyroidectomy after many admissions for presumed vaso-occlusive crisis. CT neck:“moderately enhancing foci inferior to the left and right thyroid lobes, and superior to the left thyroid lobes, could be compatible with parathyroid adenomas. “Sustami- scan:”equivocal slow washout focus in region of right lower pole of thyroid gland extending posteriorly. Suspicious for but not definitive for parathyroid adenoma”. On the day prior to surgery, iPTH = 4078 pg/mL with serum calcium (Ca) =10.3 mg/dL. Immediately after surgery imaging showed Ca of 8.9 mg/dL. The day after surgery, iPTH=36 pg/mL with Ca=7.6 mg/dL. Patient admitted for 3 days due to his requirement of intravenous calcium and daily hemodialysis. Since discharge, patient has had fewer admissions for pain. He has however, remained hypocalcemic and is on 5 grams of calcium carbonate, 4 mec of doxercalciferol, and is dialyzed with a 3 mEq/L calcium bath. 3PTH is common in ESRD patients that can leave them debilitated. Those who fail medical therapy may benefit from resection. In sickle cell disease symptoms of 3PTH was masked by vaso-occlusive crises and could be distinguished by marked reduction in symptoms after resection.

Synthetic Cannabinoid (SC) in End Stage Renal Disease. Chyi Chyi Chong, Pallavi D. Shirsat, Neville R. Dossabhoy. Synthetic cannabinoid (SC) are drugs of abuse especially among young adults. They are affordable, widely available and mostly importantly undetectable by standard urine toxicology screen. The avoidance of detection in the urine contributes to the autonomous function of the parathyroid gland due to increased mass. Our case is unique as there are no reported cases of tertiary hyperparathyroidism in sickle cell patient, which we observed in our patient. The presentation of renal insufficiency and angina crisis which improved with parathyroidectomy. 25 year old man with sickle cell disease, ESRD on hemodialysis since 2012, (3PTH), presents after many admissions for sickle cell pain crisis. Cause of ESRD was unknown but attributed to sickle cell nephropathy. Current admission for knee pain, imaging of which showed “sclerotic appearance of the bones, likely due to renal osteodystrophy”. Intact PTH (iPTH) consistently > 4000 pg/mL, and patient non adherent to cinacalcet, agreed to parathyroidectomy after many admissions for presumed vaso-occlusive crisis. CT neck:“moderately enhancing foci inferior to the left and right thyroid lobes, and superior to the left thyroid lobes, could be compatible with parathyroid adenomas. “Sustami- scan:”equivocal slow washout focus in region of right lower pole of thyroid gland extending posteriorly. Suspicious for but not definitive for parathyroid adenoma”. On the day prior to surgery, iPTH = 4078 pg/mL with serum calcium (Ca) =10.3 mg/dL. Immediately after surgery imaging showed Ca of 8.9 mg/dL. The day after surgery, iPTH=36 pg/mL with Ca=7.6 mg/dL. Patient admitted for 3 days due to his requirement of intravenous calcium and daily hemodialysis. Since discharge, patient has had fewer admissions for pain. He has however, remained hypocalcemic and is on 5 grams of calcium carbonate, 4 mec of doxercalciferol, and is dialyzed with a 3 mEq/L calcium bath. 3PTH is common in ESRD patients that can leave them debilitated. Those who fail medical therapy may benefit from resection. In sickle cell disease symptoms of 3PTH was masked by vaso-occlusive crises and could be distinguished by marked reduction in symptoms after resection.

SA-PO0093
Focal Segmental Glomerulosclerosis Associated with Cocaine Abuse: A Case Report

Introduction: Cocaine exists in two major forms: cocaine hydrochloride and alkaloid freebase (crack). Cocaine abuse causes many well recognized systemic adverse effects and acute kidney injury is usually due to thrombosis, malignant hypertension with thrombotic microangiopathy and renal infarction. In addition, it has been described ANCA-positive vasculitis induced by levamisole-adulterated cocaine causing nephrotic syndrome. We report a case of focal segmental glomerulosclerosis in a patient with history of cocaine use.

Case Description: A 49 year-old man of admixture race presented with progressive edema and dyspnea for the past five months. Lab tests showed Scr 7.0 mg/dL (baseline: 0.9 mg/dL), hypoalbuminemia, hypercholesterolemia and nephrotic range proteinuria (13g/24h). The patient had started using illicit drugs (marihuana and crack) three months before the symptoms begun. There was no sign of infection or hypovolemia. All serologic tests were normal or negative, including complement, antinuclear antibodies, anti-DNA antibody, c-ANCA, p-ANCA, hepatitis B and C, HIV, syphilis and there was no evidence of mononuclear leucocyte. Renal ultrasound was normal. The patient underwent hemodialysis and received methylprednisolone. Renal biopsy showed 13 glomeruli, 6 globally sclerotic with segmental sclerosis and synchiae of the glomerular tuft, tubular atrophy and moderate interstitial fibrosis. Immunofluorescence was negative. There was no recovery of renal function.

Discussion: Although it has been described nephrotic syndrome due to ANCA-positive vasculitis induced by levamisole-adulterated cocaine, we have reported a case that showed association between the use of cocaine and focal segmental glomerulosclerosis.

SA-PO0094
A Rare Case of Tumor Lysis Syndrome in a Patient with Angiosarcoma
Bilal J. Alturkmani, Michael A. Mao, Edward T. Casey. Afiaal Univ, Riyadh, Saudi Arabia; 1The Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Introduction: To report a rare case of tumor lysis syndrome (TLS) developing in a patient with angiosarcoma and metastasis to the liver.

Case Description: A 63-year-old male presented to his primary care physician complaining of fatigue, night sweats, fever, and newly developed RUQ pain. An ultrasound of the abdomen revealed hepatic lesions and a subsequent CT scan showed two large masses in the liver and a mass in the pancreas. A liver biopsy was obtained and findings were consistent with metastatic angiosarcoma and he was therefore initiated on palliative chemotherapy. The patient then presented to his local hospital with abdominal pain and abdominal bruises. His hemoglobin was 4.9 g/dL and he was found to be bleeding from the liver biopsy site. He was transferred to our institution for embolization in setting of intra-abdominal bleeding and multiorgan dysfunction. His clinical presentation, along with laboratory findings, was consistent with anuric renal failure secondary to TLS.

The patient was initiated on allopurinol, rasburicase, and continuous veno-venous hemofiltration (CVVH). He progressively deteriorated during his 11-day hospital course with recurrent episodes of arrhythmia, persistent encephalopathy, continued mechanical ventilator and hemodialysis dependence, and refractory septic shock with candidemia. The family elected for comfort care and the patient expired the next day.

Discussion: TLS is a constellation of laboratory and or clinical manifestations that can arise either spontaneously or secondary to cancer treatments. Patients with hematological malignancies have a higher tendency to develop this syndrome due to the rapid turnover of cell growth and death. However, patients with solid tumors occasionally present with TLS. To our knowledge, this is the first case report of TLS associated with angiosarcoma.
Leukocyte Chemotactic Factor 2 (LECT2)-Associated Renal Amyloidosis: A Case Report
Alejandro Pepen Romero, 1 James Drakakis, 2 Marius Fructus, 3 Tobias Hilscher, 2 Andreas Jeron, 2 Dunja Bruder, 2 Peter R. Mertens, 1 Christos D. Chatzkyrkou, 1 Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke Univ Magdeburg; 1Inst of Microbiology, Otto von Guericke Univ Magdeburg.

Introduction: LECT2 amyloidosis is a frequent form of systemic amyloidosis, representing 2.7-10% of all cases of renal amyloidosis. Most patients are elderly who present with chronic renal insufficiency and bland urinary sediment.

Case Description: We report a 76-year-old Egyptian male who presented after a recent hospitalization for self limited gastroenteritis and severe acute renal failure presumed secondary to acute tubular necrosis. Due to non-improving renal function and uremic symptoms, renal biopsy was done and showed patchy Interstitial amyloidosis deposits that did not stain for IgG, IgM, IgA, kappa, lambda chains or Amyloid A; sample was sent to Mayo Clinic where Liquid chromatography tandem mass spectrometry detected a peptide profile consistent with LECT2 Amyloidosis.

Discussion: This case suggests that LECT2 Amyloid can present with bland uroanalysis and non-nephrotic range proteinuria in elderly patients.

Monitoring Disease Activity in ANCA Associated Vasculitis (AAV): A Case for Activated Circulating Monocytes
1 Saman Sarangi, 1 Rachika Bhasin, 1 Abbas Haffarabarani, 1 Geetanjali Vali, 1 P.T. James, 1 Youshifumi Sadoh, 1 Department of Nephropathy and Hypertension, Olive View-UCLA Medical Center, Sylmar, CA; 2 Kidney Transplant, UCLA Medical Center, Los Angeles, CA.

Introduction: Patients with underlying glomerular diseases often present with acute kidney injury from either acute tubular necrosis (ATN) due to hemodynamic compromise such as diuretic overdose versus exacerbation of underlying disease. The clinician is often faced with the difficult decision to either provide fluids and supportive care vs. intensification of immunosuppressive therapy. Whereas proteinuria associated with ATN is presumably predominantly non-albumin protein, proteinuria associated with glomerular disease exacerbation is predominantly albuminuria. We follow a case with biopsy proven minimal change disease and concurrent ATN and evaluate sequential urine albumin to creatinine (MAC) ratio to protein to creatinine (PCR) ratio MAC/PCR over the course of treatment for changes.

Case Description: A 63 year old Hispanic male presented with anasarca and blood pressure 214/104 mm Hg. Routine evaluation was significant for a serum creatinine (SCr) of 1.4 mg/dl, peaked at 1.77 mg/dl, PCR of 12.8 g/g Cr, and MAC of 7.9 g/g Cr. Physical examination was significant for anasarca. There was no lymphadenopathy noted. Routine proteinuria evaluation for hepatitis B and C, RPR, HIV, C3, C4, CH50, ANCA, serua free light chains, serum and urine protein electrophoresis and immunofixation were negative. A kidney biopsy performed revealed minimal change disease with evidence of marked ATN. Patient was treated with a course of prednisone at 1mg/kg/day tapered over a 6 month period. Patient went into full remission with no complications. Over the course of disease, sequential MAC/PCR was noted to increase as PCR and SCr decreased. Presentation: Scr 1.4-1.77, MAC=7.9 g/g Cr, PCR=12.8 g/gCr, MAC/PCR=0.62, 2-month follow-up: Scr 1.3, MAC=1.6, PCR=12.7, MAC/PCR=0.95; 3-month follow-up: Scr 1.3, MAC=1.4, PCR=0.8, MAC/PCR=1.6.

Discussion: The current case indicates that a higher degree of albuminuria relative to proteinuria is noted with eventual resolution of ATN. We suggest that MAC/PCR may be used as a marker of associated ATN complicating underlying GN. Further studies are needed.

Idiopathic Eosinophilic Peritonitis After Peritoneal Dialysis Catheter Placement
Nader S. Baler, Charles W. Heilig. Nephrology and Hypertension, Univ of Florida, Jacksonville, FL.

Introduction: Idiopathic Eosinophilic peritonitis (IEP) typically occurs soon after initiation Peritoneal Dialysis (PD) with variable presentation mimicking bacterial or fungal peritonitis. The main etiology of IEP is currently unknown. It is speculated that IEP is an allergic reaction to possible plasticizers in the PD bags or catheter or an eosinophilic reaction to the solutions, methods of catheter placement or air exchanges during the exchanges.

Case Description: 42 year old female with a history of IIEP with ESRD from EMAF phase 1. After dialysis, she was brought in 9/2009 was started on hemodialysis (HD) via fistula. She underwent PD training and started CAPD on 9/18/2010 with Baxter Ultra bag dextrose solution after laparoscopic placement of Quinton C/url PD catheter on 9/20/2010. During follow up on 9/30/2010 cloudy PD fluid recognized. The patient didn’t have any symptoms of abdominal pain, nausea, vomiting, constipation, diarrhea or fatigue. Vital signs and physical exam didn’t show any evidence of site infection or abdominal tenderness and no skin allergic reaction. There were no new medications or any other antibiotic therapy since placement of PD catheter. PD fluid cell count showed total WBC count of 480/mm³ with 20% eosinophil 1% neutrophil. Gram stain and all bacterial, fungal and AFB cultures were negative. At this point the patient has switched to HD on 11/04/2010 via available fistula and PD catheter was kept in place. By 12/28/2010 a sample of peritoneal fluid obtained which showed declining of WBC count to 123/mm³ with 7% eosinophil with uric acid lowering agent successfully lowered uric acid level and possibly contributed to renal function recovery. In this case CPK level was not high enough to justify AKI and a very high serum myoglobin level established the diagnosis.

Case Description: A 37 years old man without known history was brought to ER with agitation and delusional/combative behavior. Vital signs included temp=100.4, BP=165/85, RR=32/min with 120-120 Bpm. On examination, he was mildly obtunded. Hospitalization for self limited gastroenteritis and severe acute renal failure presumed due to persistent metabolic acidosis and hyperkalemia. However uric acid level remained high at same range. We used a dose of Rasburicase at 3 mg which reduced uric acid level to 5.5 six hours later. After few days, renal function and clinical status started to improve and he was discharged in stable condition.

Discussion: There may be a therapeutic/prophylactic role for uric acid lowering agents in rhabdomyolysis induced AKI. In our case, Rasburicase successfully lowered uric acid level after it had remained high post-dialysis. Similar results have been reported in the past, however further research is needed in the future. Besides, Although AKI in rhabdomyolysis is usually seen with CPK levels>20000, our patient had much lower levels and a very high serum myoglobin established the diagnosis of severe rhabdomyolysis. Serum myoglobin is more accurate to determine the severity of rhabdomyolysis and predict the risk of AKI.

A Case of Rhabdomyolysis Induced AKI with Two Questions: Serum Myoglobin versus CPK and the Potential Role for Rasburicase
Mahdi Nourid kolour, Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: Rhabdomyolysis induced AKI is a common scenario. The mechanisms include myoglobin and uric acid crystal induced tubular injury. The role of uric acid lowering agents in such conditions remains to be defined. Here we describe such a case, in which
complete resolution of eosinophilia while the patient was on HD. In 3/28/2011, the patient resumed PD via same catheter and same solution, follow up PD fluid sample on 4/07/2011 showed normal WBC count and 4% eosinophil.

Discussion: Our case suggests IEP was a transient reaction to the catheter placement rather than a reaction to the PD set or solution.

SA-PO100

Post Renal Transplant Follow Up in Focal Segmental Glomerulosclerosis with 24 Hour Urine Protein Collection – Traditional and True
Rayinder Pal S. Bhatti, Manisha Singh, Lakshmi P. Nadimpalli, Sameh R. Abul-Ezz. Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.

Introduction: Random Urine Protein Creatinine Ratio (PCR) is commonly used to estimate proteinuria compared to 24 hour urine protein measurement (24-UP). However, there are concerns over the diagnostic accuracy and reliability of such an approach in post-transplant setting. We present a case of post-transplant focal segmental glomerulosclerosis (FSGS) illustrating this.

Case Description: A 39 year old male with primary FSGS, on peritoneal dialysis for 4 years received a cadaveric kidney transplant. His panel reactive antibody was 0% and HLA cross-match was negative. Peri-operative course was uneventful. Given the history of FSGS, PCR was monitored. By post-op day 5, serum creatinine had decreased from 7.3 mg/dl to 3.2 mg/dl and PCR from 4.3 to 2.8. However, his 24-UP came back 8 g, which was markedly different.

Early recurrence of FSGS was diagnosed. A biopsy was withheld to avoid delay in timely management and risk of bleeding with plasmapheresis which was immediately initiated. He was switched from tacrolimus to cyclosporine. He required plasmapheresis for 5 weeks and had satisfactory recovery in the ensuing months.

Discussion: Logistics have led to the widespread use of PCR in follow-up of kidney transplant recipients. However changing creatinine excretion with recovering renal function, lower precision with heavier proteinuria, and limited data on accuracy compared to 24-UP, potentially limit its utility at detecting early post-transplant recurrence of FSGS. Our case highlights marked discordance between the PCR and 24-UP, detection of which allowed a timely change in management. We conclude that it is prudent to monitor proteinuria by timed urine collection in preference to random PCR in the immediate post-transplant setting for recipients with primary FSGS.

SA-PO101

Introduction: Cadaveric kidneys account for a majority of transplants in the United States. However, only 10% of waitlisted patients receive one annually, making optimal utilization critical. Donor nephrolithiasis represent a small yet significant proportion of kidneys discarded. We present a patient who received such a kidney which otherwise could have been discarded.

Case Description: The donor was a healthy 31 year old female who suffered anoxic brain injury in a motor vehicle accident. Her CT abdomen showed 2 stones in the right kidney as represented in the figure’s inset. The kidney became available to us on a regional list after it was declined locally due to concerns over kidney quality. Our recipient was a 50 year old female with hypertensive nephropathy, on hemodialysis for the past 2 years. Her serum creatinine was markedly different.

We present such a patient developing peritonitis with an unusual pathogen.

Discussion: There were no perioperative complications and the recipient had excellent immediate graft function. Her creatinine progressively improved by time of discharge, remaining normal in subsequent months.

SA-PO102

A Peritoneal Dialysis Catheter Leak Complicated by Burkholderia Gladioli Peritonitis Rayinder Pal S. Bhatti, Dumitru Rotaru. Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.

Introduction: Dialysate leaks can occur any time after peritoneal dialysis (PD) catheter placement. Early leaks usually manifest as an exit site leak, though may also present with air in the PD catheter. Leaks increase the risk for exit site infections (ESI) and peritonitis. We present such a patient developing peritonitis with an unusual pathogen.

Case Description: A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for 3 years, presented with exit site erythema a week after trying to push in an extruded cuff. Prophylactic antibiotics were started but he declined surgery. The ESI recurred soon after completing 3 weeks of antibiotics. He agreed to catheter replacement with an exit site change. He was started on low volume exchanges. Two weeks later, he noted air bubbles in the PD catheter upon draining.

A small pinhole was found at the exit site, suspected to be from a sharp injury during dressing change. He was planned for surgical revision but soon started having turbid drainage. Instilled dialysate was cultured, broad spectrum intravenous antibiotics were started and he was switched to hemodialysis. During surgery, the damaged catheter was spliced to new tubing proximal to the exit site. The cultures grew Burkholderia Gladioli by now. PD was resumed the next day. The peritonitis resolved during the 3 weeks of antibiotics. He continued PD uneventfully over ensuing months.

Discussion: A rare observation, air in a PD catheter is almost pathognomonic of a dialysate leak. Our case highlights several key points in such a scenario. Firstly, use of sharps is a major risk factor and should be discouraged. Secondly, an increased risk of peritonitis...
including by rare pathogens warrants appropriate antibiotic prophylaxis and lastly a more limited approach than catheter exchange may be used even for leaks close to exit sites based on the location and local experience.

SA-PO103
Enteric Hyperoxaluria Related to Celiac Disease Causing Acute Kidney Injury After Kidney Transplantation

Ashvin Baru, Venkat Ramathan.
Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: Acute kidney injury (AKI) after kidney transplantation can occur from myriad of causes. We present an interesting case of a young woman with history of Celiac disease who developed AKI and biopsy-proven oxalate nephropathy within 3 months post-transplantation, as a result of enteric hyperoxaluria associated with gluten noncompliance.

Case Description: A 35 year-old woman with type 1 diabetes mellitus, and celiac disease underwent living unrelated kidney transplantation for ESRD related to biopsy-proven diabetic nephropathy. Her original renal ultrasound did not show nephrocalcinosis. After transplantation, nadir serum creatinine was 1.0 mg/dL. Three months later, she presented with six-day history of diarrhea and AKI. Serum creatinine peaked at 2.6 mg/dL. Since volume replacement did not improve her allograft function and she had high panel reactive antibody levels pre-transplant, a kidney biopsy was performed that showed acute tubular injury with significant oxalate crystalline deposits. Initial serum oxalate level was undetectable, but 24-hour urine oxalate excretion was elevated at 98 mg/dL. Pending gene testing, she was treated with intravenous fluids, low oxalate diet, gluten free diet, vitamin B6, oral alikali and calcium carbonate. Subsequent gene testing did not reveal an gene mutation in the oxalate pathway. Her urine output was maintained between 3 to 4L per day. With strict gluten avoidance and low oxalate diet, urine alkalization and oral calcium, her allograft function has improved to baseline.

Discussion: Celiac disease exacerbation and subsequent malabsorption can lead to significant gut oxalate absorption and hyperoxaluria. Resulting oxalate nephropathy is a rare cause of AKI after kidney transplantation.

SA-PO104
Unusual Presentation of Tumor Related Membranous Nephropathy

Tahir Zaman,1 Frederic Clayton,2 Josephine Abraham,1 Nephrology, Univ of Utah, Salt Lake City, UT;1 Pathology, Univ of Utah, Salt Lake City, UT. 

Introduction: The literature is laden with evidence of several solid tumors causing secondary membranous nephropathy. It is also described in the literature that solid tumors could also ANA positivity. 

Case Description: A 62-year-old male with a history of hypertension presented with oliguric renal failure following an episode of gastroenteritis. History was unremarkable except for celiac disease who developed AKI and biopsy-proven oxalate nephropathy within 3 months post-transplantation, as a result of enteric hyperoxaluria associated with gluten noncompliance. 

Sublingular mass was found which revealed squamous cell carcinoma. Bone marrow biopsy revealed smoldering multiple myeloma. The patient's ATN resolved and he subsequently underwent left partial glossectomy. His cancer was staged at T2N0 and he is undergoing chemotherapy and radiation therapy.

SA-PO105
A Case of Severe Adrenal Insufficiency due to Long-Term Glucocorticoid Administration for Pediatric Nephrotic Syndrome

Yuko Fujii,1 Akira Ashida,1 Hideki Matsumura,1 Akihiko Shirasu,1 Hyogo Nakakura,1 Motoshi Hattori,2 Hiroshi Tamai,1 Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan;1 Pediatric Nephrology, Tokyo Women's Medical Univ, Shinjuku, Tokyo, Japan.

Introduction: One of the adverse effects of long-term glucocorticoid therapy in supraphysiologic doses is suppression of the hypothalamic-pituitary-adrenal axis, although symptomatic adrenal insufficiency is considered to be an unusual complication of glucocorticoid therapy for nephrotic syndrome in pediatric patients. Here we describe a case of secondary adrenal insufficiency due to long-term glucocorticoid therapy for steroid-dependent nephrotic syndrome.

Case Description: A 12-year-old boy who had developed steroid-dependent nephrotic syndrome at the age of 2 years had been treated repeatedly with corticosteroid, cyclosporine and mizorbine. On relapse of the disease at 4 years of age, the nephrotic syndrome had been resistant to steroid therapy including 2 mg/kg prednisolone and 4 courses of methylprednisolone pulse therapy, but had responded to additional cyclophosphamide therapy at 7 months after relapse onset. During tapering of the glucocorticoid therapy, the patient had shown various symptoms, including general fatigue, facial edema, decreased urine volume, appetite loss, and dizziness from the age of 5 years. At that time, the basal value of cortisol was not detectable and a rapid ACTH loading test elicited a low response. In the CRH and insulin loading test, the basal value of ACTH was not detectable and an over-response of ACTH was demonstrated. Therefore the patient was diagnosed as having glucocorticoid-induced hypothalamic adrenal insufficiency and treated with cyclosporine, a decreased dose of prednisolone, and hydrocortisone supplementation. The serum ACTH and cortisol values increased gradually. An insulin loading test at the age of 12 years demonstrated normal responses of the ACTH and cortisol levels.

Discussion: The very long-term nature of the therapy for this patient with idiopathic nephrotic syndrome resulted in glucocorticoid-induced adrenal insufficiency. Periodic evaluation of adrenal function and re-evaluation of the treatment is important for patients with nephrotic syndrome receiving steroid therapy.

SA-PO106
Henoch-Schönlein Purpura in Adult from a Clinical Case

Miguel Goncalves, Pedro Vieira, Jose Darias, Luis Resende, Nuno Rosa, Jose Alves Teixeira, Gil Silva. Nephrology, Hospital Dr. Nélio Mendonça, Funchal, Portugal.

Introduction: Henoch-Schönlein purpura is a small vessel vasculitis mediated by IgA-immune complex deposition with multisystemic involvement. Rare in adults, is characterized by purpura, arthralgias, abdominal pain, and renal involvement. Viral infections have been reported as trigger.

Case Description: The authors present the case of a 25 years old male, without relevant medical history, admitted to the Nephrology Department in May 2014 by severe hypertension, renal failure (creatinine 6.7mg/dL), erythrocyturia and proteinuria. Renal ultrasound was normal. Renal biopsy revealed IgA nephropathy (M1E1S1T2). Our investigation revealed chronic hepatitis B virus (HBV) of vertical transmission origin (viral load 150 IU/mL). Corticosteroid therapy was started, with slight improvement in renal function. He was readmitted 2 months later by asthenia, epistaxis, weight loss, portal hypertension, splenomegaly, ascites, and oral and nasal ulcers. Laboratory tests revealed hemoglobin 9.2g/dL, creatinine 4.3mg/dL, normal transaminases, albumin 20g/L, urinary spot protein:creatinine ratio 1300mg/g, hypocoomplementemica, negative p-ANCAs, c-ANCAs and cryoglobulins, HBV load 379 980IU/mL. During hospitalization the patient initiated progressive pancytopenia, diffuse abdominal pain, generalized skin purpura and fever (with no identifiable infectious origin and interpreted as immunologic). We made clinical diagnosis of Henoch-Schönlein purpura and started with cyclophosphamide and entecavir. A few days later appeared hypoxemia and oliguria, requiring urgent dialysis. Cralian CT scan showed microangiopathic leucenoemphiaphathy of unspecified etiology and alveolar hemorrhage in chest CT scan. Due to life threatening multisystemic involvement we started methylprednisolone pulses, intravenous immunoglobulin and plasmapheresis. Patient completely recovered, but remained dependent on dialysis. 6 monthly cycles of cyclophosphamide were maintained, with no signs of recurrence.

Discussion: We emphasize the rare severe multisystemic involvement of a Henoch-Schönlein purpura in an adult, the onset of the disease with exacerbation of viral infection, and the therapeutic challenge of an HBV patient with an vasculitis.

SA-PO107
Rare Etiology for Chronic Kidney Disease: Bronchiectasis Related Secondary Amyloidosis

Alper Alp,1 Hakon Akdam,2 Aysegul Ornenci,3 Ibrahim Meteoglu,4 Alparslan Unsal,1 Yavuz Yenicerioglu.1 Nephrology, Van Education and Research Hospital, Van, Turkey; 2Nephrology, Adnan Menders Univ, School of Medicine, Aydin, Turkey; 3Pathology, Adnan Menders Univ, School of Medicine, Aydin, Turkey; 4Radiology, Adnan Menders Univ, School of Medicine, Aydin, Turkey.

Introduction: Here we present an elderly patient with a known posttuberculosis bronchiectasis, nephrotic-range proteinuria and renal failure was detected. Renal biopsy revealed AA amyloidosis. Tuberculosis and tuberculosis related systemic disorders still have clinical impact in nephrology practice especially in developing countries.

Discussion: The positive ANA raised the concern of concomitant connective tissue disease but C1q negativity on the biopsy made this diagnosis unlikely. Ultimately treatment of the underlying condition is paramount. 1. Imai, H. et al. Nucleolar antigens and autoantibodies in hepatocellular carcinoma and other malignancies. Am. J. Pathol. 140, 859–70 (1992).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: A 67 yo man was referred to our hospital with renal failure and proteinuria. PMHx was remarkable for tuberculosis(41 years age) and posttuberculosis- bronchiectasis for long years. On physical examination pretilial edema was evident. Chest X-ray, thorax CT revealed left sided total bronchiectasis and pulmonary nodules. Malignancy was excluded with PET/CT and bronchoscopy. On admission biochemical tests: urea: 220mg/dL, creatinine: 5.86mg/dL, potassium: 4.8mEq/L, GFR 10.3ml/min/1.73m2, ANA 1/100 positivity (cytoplasmic). Renal ultrasonography revealed bilateral echogenic kidneys with normal size and shape. 24 hour urinary proteinuria, albuminuria was 7924 mg/dL, 478mg/dL respectively. Renal biopsy was compatible with AA amyloidosis (segmental homogeneous deposits of amyloid in the glomeruli and interstitium). Immunohistochemistry was positive for staining of AA amyloid. There was no immunofluorescent staining with IgG/A/M, C3, fibrinogen.

Tunneled catheter was placed and hemodialysis was started.

Discussion: FMF and rheumatological disorders are the leading causes of amyloid AA in Turkey. However other rarely seen etiologies should not be missed in clinical practice. Secondary amyloidosis as a multisystemic disease has a high mortality risk. Renal manifestations include nephrotic syndrome and renal failure.

SA-PO108
Sunitinib Induced Acute Renal Failure and Nephrotic Syndrome in a Patient with Metastatic Neuroendocrine Tumor: A Case Report and Review of the Literature
Srijita Mukherjee,1 Carla L. Ellis,2 Nephrology, Emory Univ Hospital and School of Medicine, Atlanta, GA; 3Pathology, Emory Univ Hospital and School of Medicine, Atlanta, GA.

Introduction: Sunitinib is a chemotherapy agent used to treat advanced malignancies via inhibition of tyrosine kinase phosphorylation. We present a case of sunitinib-induced acute renal failure with nephrotic syndrome, occurring within one week of initiation for persistent carcinoid syndrome secondary to hepatic metastasis of a primary small intestinal neuroendocrine tumor.

Case Description: A 63 year old man with metastatic neuroendocrine tumor was initiated on sunitinib to treat persistent carcinoid syndrome despite initial therapy. Within one week of initiation, he developed new onset peripheral edema, 20 pound weight gain and acute renal failure with nephrotic range proteinuria. Baseline creatinine was 1.0, and on presentation, had increased to 3.0. There were over 10 grams of proteinuria on urine protein to creatinine ratio. Sunitinib was discontinued, but renal failure progressed, with peak creatinine of 7.1 prior to starting hemodialysis. A kidney biopsy was performed, which showed diffuse podocyte foot process effacement, focal global glomerulosclerosis and acute tubular injury. The patient remains dialysis dependent as of this report.

Discussion: Literature review reveals reports that vary both in time to onset and degree of resolution of renal disease after initiation and discontinuation of sunitinib therapy, respectively. Renal pathology also varies, including acute tubular necrosis, acute interstitial nephritis, diffuse podocyte foot process effacement and thrombotic microangiopathy. Our patient developed a greater severity of renal failure than most reported, including a higher protein to creatinine ratio. Sunitinib was discontinued, but renal failure progressed, with peak creatinine of 7.1 prior to starting hemodialysis.

There was no immunofluorescent staining with IgG/A/M, C3, fibrinogen.

SA-PO109
Cryoglobulinemic Glomerulonephritis After Successful Treatment of Hepatitis C
Nupur Gupta, Chad A. Zarse, Allon N. Friedman. Nephrology, IU School of Medicine, IN.

Introduction: The optimal treatment of cryoglobulinemic glomerulonephritis (GN) in the setting of Hepatitis C (Hep C) with sustained viral response (SVR) is unknown. Only expert opinion obtained from case reports provide guidance to the clinician. Some reports suggested a benefit with Rituximab which may be beneficial.

Case Description: 58yo male with h/o treated Hep C currently with an undetectable viral load, gastric ulcer, anemia, and HTN presented to clinic for evaluation of CKD. Hep C was initially diagnosed when he was found to have leuko(o)cystoclastic vasculitis on a skin biopsy of skin rash. Labs were positive for serum cryoglobulins, rheumatoid factor, low C4, and Hep C viral load. Renal function was normal and he was successfully treated for cryoglobulinemic vasculitis due to Hep C with interferon alpha, telaprevir and ribavirin and achieved a SVR. He presented 1 year later with renal insufficiency (creatinine -2.2 mg/dL) and proteinuria 2.6g/dL. He had no evidence of vasculitis. Spleen revealed IgM kappa monoclonal with negative UPEP. C4 was low and cryoglobulins remained positive. Kidney biopsy showed immune complex GN with organized deposits. Bone marrow biopsy was negative for lymphoproliferative disease. He was diagnosed with cryoglobulinemic GN with SVR. Initially, he was treated with prednisone followed by Rituximab and plasmapheresis. He failed the treatment and was started on hemodialysis.

Discussion: Cryoglobulinemic GN is frequently due to Hep C but is rare in patients achieving a SVR. In our case an underlying B cell lymphoma was ruled out and it was felt that B cell immune dysregulation due to Hep C was the culprit, in part due to prior published cases. However, in our case treatment with rituximab and plasmapheresis was unsuccessful. It remains possible, as others have demonstrated, that the virus may persist within the liver, macrophages, lymphocytes, and even kidney. The pathological basis for persistent vasculitis in setting of a SVR requires further study so that targeted and more effective treatment strategies can be designed.

SA-PO110
Diagnostic Intrapartum Dilemma: Distinguishing Glomerulonephritis from Preeclampsia in Pregnancy
Anamari L. Katsares, Fernanda Payan Schobel, William Franklin Pendergraft, Volker Nickeleit, JulieAnne G. McGregor, Harsharan Kaur Singh. UNC Kidney Center, Chapel Hill, NC.

Introduction: Distinguishing glomerulonephritis from preeclampsia intrapartum can be challenging due to overlap of clinical findings. Unfortunately, this diagnostic dilemma can result in unwarranted early delivery. Here we present 5 cases of glomerulonephritis (GN) complicating pregnancy.

Case Description: 3 patients (ages 22, 31 and 33) presented during pregnancy with proteinuria, dysmorphic hematua and, in 2 cases, acute kidney injury. In all 3 cases, the concern for preeclampsia prompted induction of labor (IOL), and postpartum kidney biopsy showed IgA nephropathy. 2 patients were treated with steroids and ACE inhibitors (ACEI) with improvement in proteinuria. The one with the most severe kidney dysfunction was treated with cyclophosphamide (CYC). Unfortunately, she became dialysis-dependent 1 month postpartum. The fourth patient (age 20) presented with HELLP syndrome at 25 weeks and underwent IOL. 5 months post-partum, she developed clinical symptoms of lupus in the setting of proteinuria, dysmorphic hematua and persistent kidney dysfunction. Kidney biopsy showed diffuse proliferative lupus nephritis, which was true proliferative lupus nephritis, which was subsequently treated with IV CYC. Unfortunately, she continued to have renal dysfunction despite treatment. The fifth patient (age 37) had minimal change disease (MCD) and was in remission at the time of pregnancy. She did well on cyclosporine until 25 weeks gestation when she developed hypocomplementemia, edema, and nephrotic-range proteinuria. It was unclear whether this represented preeclampsia or a MCD flare so she underwent IOL. Subsequent placental pathology failed to show signs of preeclampsia. She was treated postpartum with steroids and ACEI and re-entered remission.

Discussion: Here we show that pregnancy can aggravate (as in the case of our patient with MCD) or unmask (as in the other 4 cases) underlying glomerular disease. Diagnosis can be delayed due to risks related to kidney biopsy during pregnancy, and treatment is complicated by safety concerns for the developing fetus. Further work is needed to identify meaningful mechanisms to accurately differentiate preeclampsia from GN during pregnancy.

SA-PO111
A Case of Rapidly Progressive Glomerulonephritis Associated with Metastatic Lung Cancer
Eduardo J. D. de Sa Carneiro Filho, Victor Longo Silva, Lilian Cordeiro, Veronica T. Costa e Silva, Elieron Costalonga. Univ of Sao Paulo, Nephrology Division, Sao Paulo, Brazil.

Introduction: Several solid malignancies have been associated with glomerulonephritides. Rapidly progressive glomerulonephritis (rGN) has been reported in association in particular with renal cell carcinoma and lung cancers. We report a case of rGN associated with metastatic lung cancer treated with chemotherapeutic agents.

Case Description: A 57-year-old male with metastatic epidermoid lung cancer, treated previously with paclitaxel plus carboplatin, etoposide plus gemcitabine and four cycles of docetaxel, was admitted with dysuria and hematuria for last 1 week. Upon physical examination: edema of the lower limbs. Laboratory results demonstrated normal liver function, positive anti-Hbc, negative HbsAg and anti-Hbs, hemoglobin 6.5 g/dL, serum creatinine of 3.78 mg/dL (baseline 1.5), C3 154 mg/dL, C4 24.8 mg/dL, negative ANA. Urinalysis showed proteinuria (>1 g/L), more than 100 leukocytes per field and more than 100 red cells even after antibiotic treatment for presumed urinary infection. Due to persistent
proteinuria (3.7g/24h), evidence of dysmorphic hematuria and worsening of renal function (Cr 4.1 mg/dL), he received methylprednisolone 1g for three days and renal biopsy was proposed. It revealed pauci-immune crescentic glomerulonephritis. Immunofluorescence showed mesangial deposition of C3 (++) and lambda chains (++) . Treatment was followed by monthly i.v. cyclophosphamide and proteinuria decreased to 0.87 g/24h. cANCA became positive (1/160) 4 months after diagnosis.

Discussion: Membranous nephropathy is the most commonly reported glomerulonephritis especially with pulmonary cancer, but several reports suggest an association between rPGN and malignancies. The increased risk for malignancy has been confirmed in a retrospective review of 200 patients with ANCA-associated vasculitis, demonstrating a significantly increased relative risk (6.02) compared with age-matched controls. Biava et al reported seven cases of rPGN associated with a coexisting nonrenal malignancy (6 carcinomas and 1 lymphoma). The pathogenetic mechanisms by which neoplasms lead to the development of ANCA-associated vasculitidis and rPGN are largely unknown.

SA-PO112
A Case of Encapsulating Sclerosing Peritonitis in a Type I Diabetic on Peritoneal Dialysis
Zachary Freestone, Josephine Abraham, Akram M. Shaaban.
Nephrology, Univ of Utah, Salt Lake City, UT.

Introduction: Encapsulating sclerosing peritonitis (ESP) is a rare disorder associated with PD. It is characterized by peritoneal fibrosis and encasement of the bowel. Symptoms associated with ESP are non-specific and may be attributed to other etiologies. Abdominal imaging is required to evaluate ESP and diagnostic confirmation is achieved by laparoscopy. ESP should be considered in patients on peritoneal dialysis with symptoms involving the gastrointestinal tract, weight loss, or inadequate solute clearance.

Case Description: A 34 year old Caucasian male on PD presented to the clinic with complaints of nausea and abdominal pain. He had a history of type I DM, ESRD, hypertension, and gastroesophageal reflux disease. On examination, he was febrile and tender to palpation over the abdomen. An abdominal x-ray indicated that he had calcification in the abdomen and pelvis. CT imaging showed calcification of the parietal peritoneum, abdominal cavity, omentum, and bowel. The patient underwent exploratory laparotomy with simultaneous PD catheter removal. The visual examination revealed a brown, inflamed rim encompassing the peritoneum, omentum, bowel, and colon. Peritoneal dialysis was discontinued and the patient was transitioned to hemodialysis.

Discussion: Encapsulating sclerosing peritonitis (ESP) is a condition associated with peritoneal dialysis. Its presenting symptoms are often non-specific and may be attributed to other causes. Abdominal imaging is necessary to evaluate for suspected ESP, CT being the preferred method. ESP is characterized by peritoneal thickening and fibrosis that encases the bowel. Treatment includes cessation of PD with transfer to hemodialysis and bowel rest. Other attempted treatments of this disease have included steroids and total enteralory.

SA-PO113
Acute Kidney Injury from Enterovesicular Fistula Secondary to Squamous Cell Carcinoma of Bladder
Eleni Chelioti, Evdokia Efthimiou, Alexia Papalexandrou, Maria Sotiraki, Ioannis Xatrakis, Maria Tsiviligou.
Dept of Nephrology, General Hospital of Piraeus, Athens, Greece.

Introduction: Squamous cell carcinoma (SCC) of the bladder is a relatively rare tumor. Predispousing factor is chronic irritation of the bladder by urinary infection, calculi and long-term indwelling catheterization. Enterovesicular fistula (EVF) usually has flow from intestine to the bladder and commonly manifests with recurrent urinary tract infections(UUTI), fecaluria and pneumaturia. We report a case with SCC of bladder who developed EVF, leading to acute kidney injury(AKI).

Case Description: A 56 year old Caucasian female with hypertension, diabetes mellitus and recurrent UTI was admitted in a uremic state that necessitated the immediate start of hemodialysis. Further clinical and laboratory findings revealed hematuria, pyuria, bacteriuria and fecaluria after placing a Foley catheter. Ultrasound scan of the abdomen showed hydrated kidneys of normal size and parenchymal thickness. CT scan of the abdomen and pelvis showed a markedly contracted and nodular bladder with a large bladder wall defect and the Foley catheter extending through the bladder wall into a small bowel loop. A diagnosis of EVF with reverse flow from the bladder to intestine was made. She subsequently underwent to a long surgery with total cystectomy, a ileo-hemicolectomy and creation of an ileal conduit. Histopathology examination of specimens revealed SCC of bladder and metastasis in the colon. After surgical intervention, she became hemodialysis dependent, received further therapy and died further months later.

Discussion: In the western world SCC represent less than 5% of all bladder tumors. There are no specific diagnostic tests and it is usually diagnosed in advanced stage. Although distant metastasis is infrequent but the prognosis is poor and most patients die. In our case the only proved predisposing factor is chronic irritation of the bladder by UTI. EVF rarely can have reverse flow leading to urine excretion via GI tract in patients with diminished bladder capacity. The diverted urine stimulates metabolic disorders causing AKI.

In order to confirm the diagnosis of these bilateral ureteroenteric fistulas, a sample of colostomy fluid was checked for Creatinine levels. The Creatinine level from the colostomy fluid was equivalent to the urine creatinine level hence confirming the diagnosis. Patient was further treated with intravesical Polymyxin for cystitis.

Discussion: Lower urinary tract infections are a serious complications in patients undergoing abdominopelvic surgeries. However, they are mainly associated with patients undergoing chemotherapy and radiation therapy for colorectal malignancies. These complications can be lethal and have a very poor prognosis.

SA-PO115
Clinicopathological Feature of a Patient with IgD-Lambda Type Multiple Myeloma Showing Kidney Involvement
Koari Yamaguchi,1 Toshiya Okamura,1 Kengo Furuichi,2 Takashi Wada,1 Yasunori Iwata,2 Taichiro Minami.1
1Nephrology, Tonami City Hospital, Tonami, Toyama, Japan.2Nephrology, Kanazawa Univ, Kanazawa, Ishikawa, Japan.

Introduction: Kidney involvement sometimes occurs in patients with multiple myeloma (MM). MM associated kidney diseases encompass diverse manifestations, such as cast nephropathy, amyloidosis and immunoglobulin deposition disease. Since the frequency of IgD type MM is relatively low, renal manifestation, especially, renal pathology has not been fully understood. Here, we report the autopsy case of IgD type MM with kidney involvement.

Case Description: A 81 years old women admitted the hospital because of systemic pain and appetite loss. Laboratory data showed serum Cr 5.14 mg/dl, urea nitrogen 57.2 mg/dl and corrected Ca 16mg/dl. Urine protein was 1+ with dipstick analysis and 9.7 g/gCr. Serological test revealed a monoclonal IgD-lambda chain. Proliferated plasma cells with the positivity of IgD-lambda chain was increased (16%) in bone marrow. After the Ca lowering therapy, desamethason (20mg/day X 5 days) was administrated to the patient. While serum levels of IgD was decreased by the therapy, renal function deteriorated, requiring dialysis. She died of infection at 64 day after admission. Autopsy specimen of kidney showed cast

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
formation in tubular lumens with severe tubular atrophy. Cell accumulation and fibrotic lesion were also detected in interstitium. Meanstinal matrix was mildly expanded in glomeruli. Amyloid deposition was not observed.

Discussion: Herein, we showed clinical course and renal pathology of the patient with IgD-lambda type MM. Although steroid pulse therapy decreased serum levels of IgD, renal function did not improve. Renal pathology showed cast nephropathy, interstitial fibrosis and cell infiltration. The renal manifestation of IgD-type MM requires further investigation.

SA-PO116

Sunitinib-Induced Nephrotic Syndrome and Acute Kidney Injury in a Malignant Insulinoma Patient: A Case Report

Wokana Shoda, Naofumi Yui, Shohtarou Naito, Soichiro Iimori, Koichiro Sasa, Takayasu Mori, Naohiro Nomura, Eisei Sohara, Tomokazu Okado, Tatemitsu Rai, Shinichi Uchida; Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan.

Introduction: Sunitinib, a tyrosine kinase inhibitor targeting vascular endothelial growth factor receptors (VEGFR), has been proven to be effective in the treatment of several types of cancer, including pancreatic neuroendocrine tumors. However, its risk of renal complications, such as proteinuria, renal dysfunction, and hypertension, are underestimated. Case Description: A 71-year-old man with malignant insulinoma treated on sunitinib for six months, developed proteinuria, acute kidney injury and hypertension. Kidney biopsy showed thrombotic microangiopathy (TMA) like lesions such as double contour, edematous endothelial cells and microaneurysms, suggesting injuries induced by sunitinib. Decreased VEGF expression in podocytes was demonstrated by immunohistochemistry, supporting the diagnosis. Sunitinib was discontinued and partial remission of the renal complication was achieved in two weeks. However, the patient mandatorily needed to restart sunitinib because of poor control of blood glucose level due to pancreatic cancer exacerbation. By reducing the dose of sunitinib and administering losartan concurrently, the patient was able to maintain stable renal function with serum creatinine level of 1.4 mg/dl and urinary protein level under 1.0 g/day.

Discussion: VEGF blockade by sunitinib is featured by adverse effects including hypertension and renal injury. In the present case, renal injury partially improved after discontinuing sunitinib. Reducing the dosage of sunitinib and administering losartan made it possible to restart sunitinib treatment while controlling its renal side effects. VEGF, which is expressed and secreted by podocytes, is an important factor for development and maintenance of glomerular endothelium. Renal biopsy in this case showed down regulation of postoperative renal recovery.

SA-PO117

Liver-Kidney versus Liver Transplant Alone: Decision Making in the Operating Room

Ekamol Tantisattamo, 1 Siwadon Pitutweerakul, 2 Praveen Ratanasrimethe, 3 Nephrology, Northwestern Univ; 1 Presence St. Francis Hospital, Evaston; 2 Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Acute kidney injury (AKI) is a common complication of decompensated chronic liver disease and hepatorenal syndrome (HRS) is one of the leading causes. Liver transplantation (LT) is a definitive treatment for HRS; however, simultaneous liver-kidney transplantation (SLK) is pursued due to the severity of preoperative AKI with uncertainty of postoperative renal recovery.

Case Description: A 60-year-old Caucasian woman with ESLD due to alcoholic cirrhosis had been readmitted twice over 2.5 months with AKI from HRS. Even though, she was treated with albumin, mimosdine, and octreotide, serum creatinine (SCr) had been elevated from the initial baseline of 1 mg/dL and had never returned to the baseline. Instead, it was worse every times she had AKI (Figure 1). After the last episodes of AKI, Scr had been stable at 2.5 mg/dL and she was listed for SLK. One week later, she was offered for SLK. After the LT, she started making a significant amount of urine immediately; therefore, the kidney was not transplanted and transferred to other potential kidney transplant recipient in another transplant center. Postoperatively, Scr had trended down to 1.1 mg/dL.

Discussion: Even though, our patient had recurrent episodes of AKI from HRS and was on dialysis for 3 months, we were able to cancel AKI in the last episode. We do not believe this was renal life-threatening. Also, our patient had a longer period of time on waiting list than usual, and we thought that it was the chance of meaningful renal recovery was small and SLK was initially planned. Fortunately, her renal function was recovery immediately after the LT alone. Preoperative evaluation for SLK versus LT alone sometimes becomes uncertain. Intraoperative finding of signs of renal recovery after LT is crucial as to avoid unnecessarily kidney transplantation and provide the opportunity to utilize kidney organ to other potential kidney transplant recipients.

SA-PO118

Is Portopulmonary Hypertension Patient a Good Candidate for Liver Transplantation?

Ekamol Tantisattamo, 1 Praveen Ratanasrimethe, 2 Siwadon Pitutweerakul, 3 Nephrology, Northwestern Univ; 2 Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; 3 Presence St. Francis Hospital, Evaston.

Introduction: Portopulmonary hypertension (PPH) is one of the most feared complications of end-stage liver disease (ESLD). Liver transplantation (LT) may reverse this complication with uncertain outcomes. We report a case of ESLD women complicated by severe pulmonary arterial hypertension (PAH) secondary to PPH and acute kidney injury (AKI) who had prolonged pre- and post-operative simultaneous liver-kidney transplantation (SLK) with partial liver improvement, un-meaningful renal recovery, and bed bound with reconditioning.

Case Description: A 48-year-old woman with ESLD from cryogenic cirrhosis complicated by portal hypertension, PAH-related to PPH and sarcoidosis presented with AKI requiring CRRT. She was treated with treprostinil, sildenafil, and ambisentan until suitable for SLK. Postoperatively, liver and renal allografts worked well and PA pressure was decreased. However, she still required treprostinil and diuresis to control PAH and volume status. After 5 months of ICU stay, she developed severe deconditioning and malnutrition. She had AKI with Scr of 0.5 mg/dL up to 1 mg/dL over 3 weeks. Calculated average clearance from 24-hour urine collection was 15 ml/min. Transplant renal allograft biopsy revealed moderate ATN and borderline changes. Diuretic dose was decreased and Scr was improved to 0.7 mg/dL. She still required treprostinil as well as intensive rehabilitation and nutritional supplementation. She remains in ICU for the majority of the time posttransplantation.

Discussion: PPH is one of the challenging scenarios for ESLD requiring LT. Reversibility from PPH after LT is uncertainty. It is still a dilemma in managing this difficult situation between LT to prolong life with poor quality and conservative management. LT is a life-saving surgery but may not always reverse a severe complication of ESLD such PPH and thus prolongs no postoperative quality of life. Therefore, LT in such a complex underlying condition needs to be individualized.

SA-PO119

Flash Pulmonary Oedema in Renal Artery Stenosis: An Indication for Stenting?

Elise Chiu, Martine David, Neil Chapman; Medicine, Imperial College, United Kingdom.

Introduction: Renal artery stenosis (RAS) is an unusual but potentially treatable cause of flash pulmonary oedema. Although national guidelines recommend percutaneous revascularization (level of evidence B), we present a case of recurrent flash pulmonary oedema oedema which suggests a need for further evidence to support use of revascularization therapy in elderly patients with multiple comorbidities.

Case Description: A 78-year-old woman presented with a fourth episode of sudden onset dyspnoea in 4 months. Her medical history included CAD, AF, hypertension (HTN) and severe pulmonary HTN due to heart failure with preserved ejection fraction (HFPEF). On admission, there were bilateral respiratory crackles and pulmonary congestion on chest XR. BP was 140/95, creatinine 110umoL/L, eGFR 42. Echocardiogram showed concentric LVH, preserved EF and raised PAP. Because of recurrent symptoms despite apparently adequate medical management of HFPEF, she underwent CT angiography which revealed bilateral ostial RAS (70% right, 40% left). Following multidisciplinary team discussion, bilateral balloon angioplasty with stent insertion was performed with radiologically successful results and she was discharged on tivardenaxan for stroke prevention. Since then, she has had no further episodes of pulmonary oedema. However, renal function has deteriorated post-procedure (max creatinine 226umoL/L, eGFR 18 at 6 weeks; no evidence of in-stent thrombosis) and she has diuretic-resistant pedal oedema severely impacting quality of life.
**Complement Mediated Hemolytic Uremic Syndrome Secondary to SLE**

**Introduction:** Complement-mediated hemolytic uremic syndrome (CM-HUS) is a life-threatening disease. Rapid diagnosis and early treatment impact patient outcomes. CM-HUS is often caused by defects in the complement regulatory system leading to uncontrolled activation of the alternative complement pathway, resulting in systemic thrombotic microangiopathy (TMA).

**Case Description:** 64-year-old female with well-controlled HIV on HAART, presented with new pancytopenia, thrombocytopenia and acute kidney injury. On examination she had no neurological symptoms and no diarrhea. Preliminary blood tests revealed WBC 2.9K/UL, hemoglobin 6.6g/dl, platelets 64K/UL, and serum creatinine at 4.0 mg/dl. LDH was elevated at 600U/L, haptoglobin was undetectable, with Coombs test negative. Peripheral blood smear revealed numerous schistocytes. Further work up revealed an elevated ANA (>1:2560), and hypocomplementemia. Anti-Smith antibody elevated at >8. These laboratory studies and the presence of lymphadenopathy and pancytopenia established a diagnosis of SLE. Patient received pulse methylprednisolone, but creatinine increased to 6 mg/dl. A kidney biopsy revealed TMA. The patient was treated with plasma exchange but developed uremia and was started on hemodialysis. Neither renal function nor hemolysis improved.

**Discussion:** This case emphasizes the importance of early consideration of CM-HUS as well as prompt initiation of treatment to block terminal complement upon recognition of the syndrome. As clinicians, this class of diseases is challenging and complicated, requiring our rapid attention to aid timely identification and rapid management.

**SA-PO121**

**Idiopathic Nodular Glomerulosclerosis Presenting with Nephrotic Range Proteinuria and Normal Renal Function**

**Introduction:** Idiopathic Nodular Glomerulosclerosis (ING) is a well-established but uncommon entity that has been described in 1985 by Chan JY et Al. It is common in older white men with history of long-standing hypertension, obesity, and smoking and typically presents with renal Insufficiency & Nephrotic Range Proteinuria. Multiple reports and meta-analyses of patients with ING demonstrate an average creatinine > 2.0 mg/dl and progressive kidney dysfunction leading to ESRD.

**Case Description:** We report a case of a 57 year old Caucasian obese female who presented with edema and heavy proteinuria (9 grams/day). She is a 40-pack year smoker with long-standing hypertension with variable control. Serum Creatinine on presentation was 0.7 mg/dl. Hba1c was 6.0% and fasting/random sugars never met criteria for overt Diabetes Mellitus. Urine showed 3-10 rbc/hpf and none was dysmorphic with an otherwise bland urine sediment. She had a negative work up for paraproteinemias and all other causes of proteinuria. Kidney biopsy showed Class III nodular sclerosis (KW lesions) and moderate atherosclerosis by light microscopy. Immunofluorescence and Congo red staining were negative andmunoclonal kappa light chain in the urine. Work up was negative for hepatitis B and C. Kidney biopsy done showed MPGN, with positive immunofluorescence for IgM, C3, kappa, along with large subendothelial and mesangial deposits. Both C3 and C4 were normal. The patient was diagnosed as having MGUS by the hematology center, Boston, MA.

**Discussion:** A-HFR has dynamic profiles of ultrafiltration and conductivity of the dialysate: this aspect creates an iso-osmolar dialysate, ensuring a better periferal refilling and improving compliance during the dialysis treatment. This is due to the use of biosensors. A-HFR also reduces the Amino acids loss. This report has numerical limitations but provides encouraging data on the use of AHFR in malnutrition and disequilibrium syndromes. This experience underlines the importance of further efforts towards customized dialysis procedures.

**SA-PO123**

**Monoclonal Gammapathy of Renal Significance: The Significance Is Not Always Unknown**

**Introduction:** Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury noted on microscopy. It is less commonly associated with monoclonal gammapathies, including monoclonal gammapathy of unknown significance (MGUS).

**Case Description:** Patient is a 67 years old female, with a history of rheumatoid arthritis, on Methotrexate, who presented to an outside facility with progressively worsening fatigue for four months. Investigations showed pancytopenia, following which she was transferred to our hospital for further management. On arrival at our hospital, patient was noted to have an acute kidney injury. A random urine protein/creatinine ratio showed 5.5 g/mmol proteinuria. Serum protein electrophoresis showed a monoclonal spike, with an Ig M kappa clone. Immunoglobulin (Ig) G was low at 161 mg/dl, while Ig M was increased at 378 mg/dl. Bone marrow biopsy done showed 5 % plasma cells, with no morphological features of a plasma cell neoplasm, leukemia or lymphoma. Kidney biopsy done showed MPGN, with positive immunofluorescence for IgM, C3, kappa, along with large subendothelial and mesangial deposits. Both C3 and C4 were low. Work up was negative for hepatitis B and C. Serum cryoglobulin levels were normal. No evidence of lupus was noted. Infectious work up was also unremarkable. Patient was diagnosed as having MGUS by the hematology service. MPGN was assessed to be secondary to MGUS in the absence of other possible etiologies. Patient was started on high dose steroids for 3 days followed by a taper, along with intravenous Rituximab 375 mg/m2 weekly for 4 weeks. Due to worsening renal functions patient was started on hemodialysis. Unfortunately due to lack of renal recovery, patient was declared as having end stage renal disease.

**Discussion:** MGUS is the most common plasma cell disorder and may be a precursor for myeloma. It is characterized by a lack of end organ damage. A small subset of patients, however, may rarely have renal involvement, with MPGN being noted on renal biopsy. MGUS can therefore be associated with morbidity and mortality, and therefore its significance may not always be unknown.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

A Case of Chronic Unilateral Hematuria Treated by Segmental Renal Artery Embolization

Han'sae Kim,1 Joon Seok Oh,2 Yong Ki Park,2 Dongyeol Lee.1 1Nephrology, Bongseong Memorial Hospital, Busan, Korea; 2Nephrology, Dongrae Bongseong Memorial Hospital, Korea.

Introduction: Chronic unilateral hematuria is characterized by intermittent or continuous hematuria that cannot be diagnosed using standard radiographic and hematologic methods. Unilateral hematuria is probably a benign condition that seldom requires surgical treatment, but some cases were managed with partial or total nephrectomy. Recently, a variety of treatments, including the ureteroscopic interventions have been attempted if the bleeding focus is identified. However, if not identified on ureteroscopy, surgical treatment has been considered a priority. We report the case of chronic unilateral hematuria with subtotal segmental renal artery embolization.

Case Description: We experienced a case of chronic unilateral hematuria in a 42-year-old woman who was admitted to our hospital due to intermittent gross hematuria and anemia for 31 months. About 29 and 19 months ago she already underwent CT scan, renal angiography, and renal biopsy at other tertiary hospitals, but didn’t found any other specific abnormalities repeatedly except some blood clots in left renal pelvis on ureteroscopy. She underwent CT urography, renal arteriography, cystoscopy and ureteroscopy again. Ureteroscopic findings only showed bleeding in the upper third of left renal calyces but definite bleeding focus could not be identified. Thus we decided to manage with segmental renal artery embolization than partial nephrectomy to minimize the reduction in renal function and to reduce operational risk. The superior and superoanterior segmental renal arteries were successfully embolized with 3mm coils and gelatin sponge. Gross hematuria disappeared on the 4th day after the procedure, microscopic hematuria disappeared on the 5th day. In 11th day, infarction in the upper third portion of left kidney was confirmed on CT scan. In 13th day, the patient was discharged. Thereafter serial urinealysis showed no hematuria.

Discussion: Patients with chronic unilateral hematuria often require surgical or upper urinary tract endoscopic procedures. Segmental renal artery embolization will be a better treatment for patients unable to identify the bleeding focus on the upper urinary tract endoscopy.

A Case of Chronic Unilateral Hematuria Treated by Segmental Renal Artery Embolization

Han’sae Kim,1 Joon Seok Oh,2 Yong Ki Park,2 Dongyeol Lee.1 1Nephrology, Bongseong Memorial Hospital, Busan, Korea; 2Nephrology, Dongrae Bongseong Memorial Hospital, Korea.

Introduction: Chronic unilateral hematuria is characterized by intermittent or continuous hematuria that cannot be diagnosed using standard radiographic and hematologic methods. Unilateral hematuria is probably a benign condition that seldom requires surgical treatment, but some cases were managed with partial or total nephrectomy. Recently, a variety of treatments, including the ureteroscopic interventions have been attempted if the bleeding focus is identified. However, if not identified on ureteroscopy, surgical treatment has been considered a priority. We report the case of chronic unilateral hematuria with subtotal segmental renal artery embolization.

Case Description: We experienced a case of chronic unilateral hematuria in a 42-year-old woman who was admitted to our hospital due to intermittent gross hematuria and anemia for 31 months. About 29 and 19 months ago she already underwent CT scan, renal angiography, and renal biopsy at other tertiary hospitals, but didn’t found any other specific abnormalities repeatedly except some blood clots in left renal pelvis on ureteroscopy. She underwent CT urography, renal arteriography, cystoscopy and ureteroscopy again. Ureteroscopic findings only showed bleeding in the upper third of left renal calyces but definite bleeding focus could not be identified. Thus we decided to manage with segmental renal artery embolization than partial nephrectomy to minimize the reduction in renal function and to reduce operational risk. The superior and superoanterior segmental renal arteries were successfully embolized with 3mm coils and gelatin sponge. Gross hematuria disappeared on the 4th day after the procedure, microscopic hematuria disappeared on the 5th day. In 11th day, infarction in the upper third portion of left kidney was confirmed on CT scan. In 13th day, the patient was discharged. Thereafter serial urinealysis showed no hematuria.

Discussion: Patients with chronic unilateral hematuria often require surgical or upper urinary tract endoscopic procedures. Segmental renal artery embolization will be a better treatment for patients unable to identify the bleeding focus on the upper urinary tract endoscopy.

An Unusual Cause of Acute Kidney Injury in a Patient Several Months Post Renal Transplant

Sweta Carpenter, Karthik M. Ranganna. Nephrology, Drexel Univ.

Introduction: Urinary anastomotic leaks after kidney transplants are no longer a common phenomenon. Due to advancements in reconstruction techniques, urologic complications after renal transplant are now reported to occur in only 2-2.5% of patients. If a urinary anastomotic leak were to develop, it frequently occurs within one month of the transplant and is usually due to technical error or ischemia to the ureter. However, her best functioning kidney on right side likely had spontaneous recovery.

Case Description: We present a case of a 60 year male with a history of a living unrelated kidney transplant who developed acute kidney injury 5 months after transplant. He had a baseline creatinine of 1.5-1.7 mg/dL, and initially presented to the hospital with fevers and a creatinine of 2.96 mg/dL. A fungal urinary tract infection with Candida was diagnosed, and right kidney stent was placed with improvement of his symptoms. Subsequently patient was readmitted to the hospital with severe abdominal pain, radiating from loin to groin. CT abdomen and pelvis showed multiple bilateral kidney stones, largest measuring 7mm, and a 5mm stone at the ureterovesical junction on the left with hydroureter. His serum creatinine (SCr) increased from 1.2 to 4 mg/dL.

Patient underwent cystoscopy, left retrograde pyelogram for renal stone extraction and stent placement with improvement of creatinine. A 24-hour urine collection 4 weeks after stent placement showed normal high urinary calcium and oxalate excretion but 20% citrate excretion. A repeat 24 hour collection 8 weeks after the remission of UC showed normal both calcium and oxalate excretion but citrate excretion remained low and urine of pH 6.5. Patient was told to increase fluid intake to 3L/day and potassium citrate was added to the diet.

Discussion: This case suggests that stone formation may be an early phenomenon in UC. We think there might be a benefit in obtaining 24-hour urine collection for stone analysis following diagnosis of IBD, as this may help us identify patients at increased risk of stone formation. Early simple intervention like increasing fluid intake can help prevent stone formation. Benefits from empiric treatment with potassium citrate are not well known. Further studies need to be done for the better understanding and preventing renal stones formation in patients with active and severe IBD.

SA-PO126

Bilateral Renal Artery Stenosis due to Takayasu Arteritis Complicated by Complete Renal Artery Occlusion with Complete Spontaneous Renal Recovery

Sofiullah Kazi, Ghulam Akbar, Paul Robbins. Nephrology, Lankenau Medical Center, Wynnewood, PA.

Introduction: 53 year old female who had established diagnosis of severe bilateral renal artery stenosis from unknown cause, admitted for elective repair of the aortic root aneurysm and aortic valve replacement for severe aortic regurgitation developing acute renal failure from complete renal artery occlusion post operatively due to ischemic insult followed by spontaneous recovery.

Case Description: 53 year old female with past medical history of multiple CVA and negative embolic workup, presented with syncope at an outside hospital. Workup with echocardiogram revealed severe aortic regurgitation. CT angiography showed multiple small ulcerations within the aorta starting from ascending aorta until iliac artery bifurcation with severe stenosis of superior mesenteric artery, celiac artery and bilateral renal arteries. Her serum creatinine was at 0.9 and an ultrasound revealed right and left kidneys size to be 9x9cm and 8x8cm respectively. She was referred to our hospital for evaluation and management of severe aortic regurgitation. She underwent elective repair of the aortic root and aortic valve. Immediately in post operative period, patient became anuric due to complete occlusion of the right renal artery based on CT angiography. She was taken to catheterization laboratory with unsuccessful attempt to open right renal artery. She was started on hemodialysis next day. A week later, reattempt to open right renal artery was again unsuccessful. She was placed on prednisone as her biopsy revealed Takayasu Arteritis. After 2 weeks into her course, patient started to have spontaneous recovery with renal function and she was taken off the hemodialysis.

Discussion: Renal artery stenosis as a manifestation of systemic vasculitis is rare. With an aggressive surgical approach, combined with glucocorticoid therapy, mortality due to Takayasu arteritis is less than 10%. In our patient, it is most likely that slow progression of renal artery stenosis occurred over time with an acute embolic occlusion postoperatively. However, her best functioning kidney on right side likely had spontaneous recovery after ischemia based on renal angiograms and potential benefit of steroids by reducing inflammation.

SA-PO128

A Case of Kidney Dysfunction and Visual Loss

Patrick Koscielniak,1 Muhammad Sohaib Karim,1 Micah R. Chan,1 Anthony Krentz.2 1Div of Nephrology, University of Wisconsin School of Medicine and Public Health; 2PreventionGenetics.

Introduction: Senior-Loken syndrome is a rare hereditary nephropathy (ophtho-renal syndrome) often presenting with autosomal recessive inheritance, a reduction in urinary concentrating ability with bland urinary sediment, and chronic tubulo-interstitial nephritis with typical progression to end-stage renal disease (ESRD) in individuals younger than 20 years old. It was first described in 1961 by Senior et al., and Loken et al.

Case Description: A 29 year old male and his seeing eye dog presented to the kidney clinic with uncontrolled hypertension, creatinine of 2.6mg/dl and a history of Leber congenital amaurosis since the age of four. Physical exam was unremarkable except newly diagnosed ulcerative colitis with severe pancolitis on barium enema. He was referred for screening ultrasound which revealed 38% of Cronh’s disease and 37% of Ulcerative Colitis(UC) patients had asymptomatic renal calciuli mostly calcium oxalate and uric acid stones. Active inflammation was the important risk factor for renal calculi.

Case Description: In our case report we describe a 40 year old male with no significant past medical history except newly diagnosed ulcerative colitis with severe pancolitis on colonoscopy 3 months ago. His pancolitis was treated with steroids and Infliximab therapy with significant improvement of his symptoms. Subsequently patient was readmitted to the hospital with severe abdominal pain, radiating from loin to groin. CT abdomen and pelvis showed multiple bilateral kidney stones, largest measuring 7mm, and a 5mm stone at the ureterovesical junction on the left with hydroureter. His serum creatinine (SCr) increased from 1.2 to 4 mg/dL.

Patient underwent cystoscopy, left retrograde pyelogram for renal stone extraction and stent placement with improvement of creatinine. A 24-hour urine collection 4 weeks after stent placement showed normal high urinary calcium and oxalate excretion but 20% citrate excretion. A repeat 24 hour collection 8 weeks after the remission of UC showed normal both calcium and oxalate excretion but citrate excretion remained low and urine of pH 6.5. Patient was told to increase fluid intake to 3L/day and potassium citrate was added to the diet.

Discussion: This case suggests that stone formation may be an early phenomenon in UC. We think there might be a benefit in obtaining 24-hour urine collection for stone analysis following diagnosis of IBD, as this may help us identify patients at increased risk of stone formation. Early simple intervention like increasing fluid intake can help prevent stone formation. Benefits from empiric treatment with potassium citrate are not well known. Further studies need to be done for the better understanding and preventing renal stones formation in patients with active and severe IBD.

Clostridioides Difficile Associated Peritonitis in a Patient on Peritoneal Dialysis
Dimpus M. Patel, Gaurav Jain. Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

Introduction: Culture negative infectious peritonitis (CNP) is a common and serious complication in peritoneal dialysis (PD) patients. It is usually a result of samples failing to reach the threshold of microbiological detection, recent antibiotic exposure, or simply unusual scenarios of PD fluid leak. Stool C. difficile infections have become more frequent, and more refractory to treatment, and dialysis patients are often affected by C. diff secondary to repeated exposure to antibiotics, as well as hospitalizations.

Case Description: A 41 AA male on PD since 2012 presented to PD unit with complaints of abdominal pain and cloudy fluid. He was started on intraperitoneal antibiotics (Vancomycin and Cefazidime) as an outpatient, though his symptoms of abdominal pain were persistent. On hospitalization day 2, he was noted to have cloudy PD fluid with a WBC count of 7,130 with 85% polys and he was started on IV metronidazole. His abdominal pain persisted, and a recheck of PD fluid cell counts on Day 3 revealed a WBC count of 17,671 with 79% polys. The PD fluid cultures from the PD unit as well as the hospital were negative for any growth. Microbiology lab at the hospital was asked to check his PD fluid for C. diff, and the C. diff PCR from the PD fluid was positive.

Discussion: Our case study describes culture negative peritonitis in a patient with C. difficile that did not respond to broad spectrum IV antibiotics. This prompted further investigation of C. difficile peritonitis that was confirmed on lab testing. This case highlights the importance of suspecting C. difficile peritonitis in PD patients with CNP.

SA-PO130
Adequacy of Australian Nephrology Training Nicholas A. Gray, 1 Thomas Joseph Beaton, 2 Rathika Krishnasamy, 1 Nigel David Toussaint, 1 Richard K S Phoon. 2
1 Renal Unit, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; 2 Renal Unit, Westmead Hospital, Westmead, New South Wales, Australia; 3 Renal Unit, Royal Melbourne Hospital, Parkville, Victoria, Australia

Background: There has been an increase in the number of doctors training in nephrology in Australia. This study aimed to assess the adequacy of nephrology training by measuring self-determined competency and skill relevance among recently graduated nephrologists.

Methods: A survey was developed by the Nephrology Advanced Training Committee of the Royal Australasian College of Physicians. The survey was administered on-line in 2015 via the annual subscription to the Australian and New Zealand Society of Nephrology. Nephrologists who were awarded Fellowship after 2002 were invited to participate.

Results: 113 of a 306 eligible Fellows (37%) completed the survey. 8 respondents had trained overseas and were excluded. Median age was 41 years (interquartile range 37-44) and 63% were male. Medical school was completed in Australia (59%), India (15%), and New Zealand (7%). 35% received at least some training in a rural area and 25% were qualified for research careers (30%). Respondents indicated good training and competency in most clinical skills that were relevant to their practice. The activities were mapped to 1-4 NAS milestones. The evaluations were built in Google Forms and delivered daily to supervising faculty members. In an effort to translate into competency-based training, the ACGME has developed 24 milestones specific to fellowship. While the milestones are comprehensive, they are challenging to determine an individual’s rating through faculty evaluations; many of whom are untrained in this system. We aimed to create a simple scoring system that translates the milestones into observable nephrology activities that can be completed daily on a handheld device.

Methods: For each nephrology rotation, a list of 5-10 frequent activities was developed. For every activity, a description for the five levels of competency was written to standardize the score. The activities were mapped to 1-4 NAS milestones. The evaluations were built in Google Forms and delivered daily to supervising faculty members. Using a four-click system, the observer can submit a fellow evaluation with most done on mobile devices. If faculty members wish to express a narrative, a free-text response box is provided for comments.

Results: Of the 914 possible evaluations over a nine-month period of time 727 evaluations were returned. This provided data points to distinguish scores among all fellows in all of the NAS milestones.

Pediatric Nephrology Workforce and Training: An International Perspective
Dorey A. Glenn, 1 Adam R. Weinstein, 1 Maria E. Ferris. 2 1 Univ of North Carolina at Chapel Hill; 2 Dartmouth Hitchcock Medical Center; 3 Univ of North Carolina at Chapel Hill

Background: There is a shortage of pediatric nephrology providers in a number of areas around the world. We sought to determine pediatric nephrologists’ perspectives on this issue.

Methods: A voluntary web-based survey was deployed via the Qualtrics™ survey engine. Members of the International Pediatric Nephrology Association responded anonymously to questions about their geographic location, time spent on training, practice setting, and impressions on local workforce challenges and opportunities.

Results: The number of responses to date was 38, representing 21 countries from all continents. Six percent of the respondents treat both children and adults. The number of years required to train in pediatric nephrology was reported as: 2 years (35%), 3 years (58%) and 4 years (8%). Nearly 80% of practices were associated with academic settings. Specialty training programs are reported in 63% of the respondents’ institutions and 50% of those with training programs stated that it was difficult or very difficult to recruit trainees. Forty two percent of the respondents stated that it was difficult or very difficult to find a job after training. The themes most frequently cited on qualitative analysis include low availability and interest in the field by trainees, poor compensation, demanding schedule and competing family demands.

Conclusions: In this preliminary study of an international cohort of pediatric nephrologists, our data suggests a perception of a decreased pediatric nephrology workforce. There is also a perceived shortage of available positions in the field. Further data collection on workforce issues as it pertains to country-related factors is needed.
Methods: ITE annual reports provided by the National Board of Medical Examiners were reviewed and summarized. Results: Scale score for all was 480:104 (mean ± SD); 1st-year fellows (n=1,202) 445±96, 2nd-year (Y2, n=2,005) 515±100, and 3rd-year and higher (n=112) 509±113. Standard error of the mean ranged 41-45. The 2010 ITE had 150 core items only. 2011 and 2012 ITE had separate 50-item urinalysis and renal pathology modules administered to Y1 and Y2 respectively (not included in total test statistics). In 2013 and 2014, all completed two 10-item modules on these topics (included in statistics). A mean of 6.6 core items (4.4%) were deleted per year after adjudicating items with high difficulty or negative faculty feedback with American Board of Internal Medicine Certification Exam: General Aspects of Chronic Kidney Disease (CKD), Glomerular/ Vascular (GV), Tubulointerstitial/Cystic (TUC), Acute Renal Failure/ICU Nephrology (ARF/ICU), Kidney Transplant, Hypertension, Sodium/Water (Na/H2O), Acid-Base/ Potassium Balance (ABP/K), and Mineral Metabolism and Endocrine Syndromes (MME). Ethics. Though examinee abilities typically vary yearly, overall total test average p value was 0.67. ARF/ICU, Na/H2O, MM, and CP tended to be less difficult (average p value 0.7) and T/C more difficult (average p value 0.58). Total test mean item discrimination bias-corrected correlation averaged 0.21, highest for A-BK (0.28) and lowest for CKD (0.18). Total test item difficulty (a) averaged 0.81; highest for GY (0.46) and lowest for T/C (0.25). Conclusions: As expected, scale scores were higher for Y2 than Y1 fellows. Over 95% of administered items were scored; among those, mean item difficulty, item discrimination, and reliability varied among content areas.

**SA-PO134**

**What Are We Doing? A Survey of U.S. Nephrology Fellowship Program Directors**

Background: Recent years have seen a decrease in Nephrology fellowship applicants. Low fellowship numbers may be partially responsible, and may affect the educational mission of the fellowship. Our survey addresses fellow work load and educational experiences to further explore these issues.

Methods: We distributed a survey for nephrology program directors via the Training Directors’ website. The survey addressed fellows’ service load and the scope of educational activities offered by the fellowship.

Results: 57 out of 147 programs responded (39%). Most are 2 years long, with a mean of 7 fellows, and are “front loaded”—64% require ≥ 7 months of inpatient service during year one. Inpatient services are usual (93%) covered by one fellow with significant resident involvement. NP’s and PA’s help cover about 15% of services. The busiest services have about 21-25 patients, although 13% of programs averaged ≥ 26 patients. At their busiest, these services have more than 30 patients, occasionally surpassing 50 patients. About one quarter of programs cap the number of patients per fellows. Although a fellow can cover more than one service, on call typically covers 10 nights over a three month period and 1-weekend/month. Most fellows do one weekly half day clinic, averaging 4-6 patients per session with a faculty: fellow ratio typically ≤ 2:1. Clinic structure is not usually modified during fellows’ inpatient service.

Longitudinal coverage of HD and PD patients is provided by 82% and 61% of program respectively. Educational conferences ranged from 2-6 hours per week. Faculty didactic teaching varies from < 1 hour per week to 5 hours per week; one hour is typical. Fellows usually give 2-6 formal presentations yearly, although in some programs this is significantly more.

Conclusions: Our survey underscores the large variety in work load, practice patterns and frequency of educational conferences at different institutions and provides a framework to help address the service/education balance during nephrology fellowship.

**SA-PO135**

**Perceptions of Nephrology Among Internal Medicine Residents**

Michael N. Daniels,1 Ivan E. Porter,2 Nabeel Aslam,3 Deepti Jain,4 Charity Curtis,5 Hope Kneidel,6 Sharon E. Maynard.1 1Div of Nephrology, Lehigh Valley Health Network/Univ of South Florida, Allentown, PA; 2Div of Nephrology and Hypertension, Mayo Clinic College of Medicine, Jacksonville, FL; 3Network Office of Research and Innovation, Lehigh Valley Health Network/Univ of South Florida, Allentown, PA.

Background: As interest in nephrology declines, we sought to identify factors influencing career interest among internal medicine (IM) residents.

Methods: This is a repeated cross-sectional survey of IM residents to assess perceptions of nephrology and the impact of these perceptions on career decisions. All categorical internal medicine residents in programs in the southeast and southwest were invited to participate in 2012, prior to the initiation of a nephrology fellowship program (Group 1); and in 2015, three years following initiation of a nephrology fellowship program (Group 2).

Results: 131 of 156 residents (84.0%) completed the survey. A total of 14.8% (19/131) of residents indicated an interest in a nephrology career, with a 6.25% (8/131) indicating Nephrology as their first choice. Cardiology (21.1%) and Hospitalist (12.5%) were the most popular career choices. The presence of a Nephrology Fellowship program did not increase resident career interest in nephrology (14.5% in Group 1 vs. 15.1% in Group 2). In perceptions of nephrology were not significantly different in Group 1 vs. Group 2. Negative perceptions of nephrology most commonly endorsed by residents were: renal pathologyophy is too complex (22.9%), poor preparation in medical school (22.14%), few opportunities for procedures (26.7%), long work hours (24.4%), and long hours/lonely call for nephrology fellows (27.5%). The majority of residents (83.2%) reported exposure to positive role models in nephrology. Experiences cited as having a high impact on career choice included: mentors/role models in the field (71.65% of residents) and rotations during residency (57.14%).

Conclusions: The presence of a nephrology fellowship program had no effect on IM residents’ interest in nephrology careers. Residents endorsed several negative perceptions of nephrology which may affect career choice.

**SA-PO136**

**Insight into the Declining Interest in Nephrology**

Sherry Mansour, Yeunjung Kim, Mark A. Perazella. Nephrology, Yale School of Medicine, New Haven, CT.

Background: The decline of interest in nephrology is very concerning with an increasing number of unfilled fellowship spots every year. Identifying the reasons behind such decline is crucial to reverse this trend and preserve the future nephrology workforce. Several surveys have attempted to isolate this problem but none targeted US IM residents.

We present the results of a survey targeting IM residents.

Methods: A web-based survey was conducted using survey monkey. 10 questions designed to help understand the reasons behind the decline of interest in nephrology were utilized. The survey link along with recruitment letter and consent form were sent to all US IM residency programs. Email addresses were obtained from the Alliance for Academic Internal Medicine website.

Results: 531 residents responded to the survey. 81% of those who completed the survey answered “No” to the question asking if they had interest in nephrology. The most common reason cited was a disheartening patient population, followed by salary, work hours & lack of understanding. 50.9% found nephrology “difficult” with the most challenging topics being glomerulonephritis (GN), acid base & transplant. The respondents noted that exposure to interventional nephrology; transplant & GN might increase their nephrology interest. Of those interested, more exposure to GNS during residency was felt to likely reinforce their interest.

Conclusions: These survey results demonstrate that most IM residents aren’t interested in nephrology and that restructuring of nephrology electives in residency programs to include enhanced exposure to GNS, transplant, and nephrology procedures might increase interest.

Nephrology rotations are primarily an inpatient experience with exposure to critically ill AKI patients or complicated ESRD patients with significant recidivism. This experience leads to the perception that the nephrology population is disheartening. Since this is the most common reason why residents lack interest, changing the structure of nephrology electives in IM residencies to allow for more outpatient exposure with emphasis on GNS and transplant might be crucial for enhancing interest in nephrology fellowship training and a career in this subspecialty.

**SA-PO137**

**Challenges and Workforce in Developing Countries: A Review of the Current Trends and Implications for Optimal Kidney Disease Care**

Julius Oluoch Okel,1 Bilal Qurni,1 Timothy Olusugen Olarewaju,2 Aminu K. Bello.1 1Univ of Alberta, Canada; 2Univ of Ilorin, Nigeria.

Background: Nephrology education has undergone rapid advancement leading to the development of comprehensive curricula and standards towards a high quality patient-centered care. These standards are often lacking on issues critical to the practice of nephrology in developing countries.

Objectives: We evaluated how nephrology training programs within the context of the healthcare systems across 25 upper-middle and high income countries to identify best practices and opportunities for adoption in developing nations. We further reviewed training guidelines from the major professional societies (ISN, major national societies) on content and process of training. Data were obtained from multiple sources (government reports, published literature, and websites of professional/licensing authorities, World Federation for Medical Education (WFME) and its Regional branches. The WFME 3-set of Global Standards on medical education at all levels were applied in evaluating training programs on the domains of training process, assessment, and evaluation.

Results: We found 5 key thematic problems with the current training model in developing countries that included 1)an emphasis on factual information, memory and recall (core knowledge content), 2) absence of needs assessment and evaluation, 3) structure and organization of training is a product of established tradition than of evidence and not in congruent with health system changes and dynamics, 4) a didactic and opportunistic instructional model with other core areas of competencies (professionalism, collaboration, advocacy, managerial skills and of scholarship are not formally taught, and 5) application of knowledge rather than formal assessment methods.

Conclusions: There are similarities and differences in structure, content and process of training programs across both developed and developing countries. The results have implications for re-design of training programs in the developing world for kidney education and better clinical care delivery in patients with kidney diseases addressing local needs and priorities.
SA-PO138
Creating and Enhancing Interest in Nephrology Careers: A Novel Nephrology Elective Experience for Medical Students
Hitesh H. Shah, Kenan D. Jhaveri.

**Background:** Interest in nephrology careers continues to decline in the United States (US). The type of nephrology elective that US medical students experience may play an important role in creating and enhancing interest in nephrology careers.

**Methods:** At our institution, we created a novel 4-week nephrology elective experience for medical students. Our redesigned elective included both 2-week inpatient (IP) and 2-week outpatient (OP) nephrology experiences. The OP rotation included 10 half-days of various nephrology clinic experiences, 2 half-days of immediate post-transplant clinic, 1 half-day of dialysis clinic, 2 half-days of peritoneal dialysis clinic, 1 half-day of outpatient hemodialysis unit rounding. The redesigned elective also included education conferences. From 7/2012 to 2/2015, nine 4th year medical students (all from different US medical schools) completed our redesigned nephrology elective. To evaluate the novel elective experience, all medical students were asked to complete an anonymous on-line survey upon completion of their rotation.

**Results:** All students responded to our survey. All reported adequate OP nephrology exposure during their elective. 89% had worked with 1 or 2 faculty members during the IP setting. In comparison, 78% were exposed to at least 4 different faculty members during the OP experiences. All students had interacted with at least 3 fellows. All reported that the elective experience enhanced their exposure and knowledge in nephrology and that they would recommend this elective to other medical students. They also thought that this elective experience enhanced their exposure and knowledge in nephrology and that the elective experience enhanced their exposure and knowledge in nephrology.

**Conclusions:** We believe that the restructured nephrology elective provides the medical student with a much needed and realistic exposure to nephrology careers. Based on our experience, we recommend all training programs to consider this elective structure for medical students.

SA-PO139
Journal Publication of Nephrology Fellows Case Report Presentations at ASN Kidney Week 2012-2013

**Background:** The inception of the fellows case report (CR) category at the ASN Kidney Week (KW) occurred in the year 2012. However, the number and types of CR abstracts accepted for publication at the conference is not known. We reviewed journal publication (JP) of these previously presented CR abstracts at ASN KW is also not known.

**Methods:** All previously accepted fellows CR abstracts from ASN KW 2012-2013 were reviewed and further categorized as follows: glomerular diseases (GN), tubulointerstitial diseases (TIN), acute kidney injury (AKI), fluid-electrolyte and acid-base disorders (FEAB), dialysis (D), kidney transplant (KT), genetic disorders (GD), mineral diseases (MD), and other (O) cases. To determine the PR-JP rate of these CR abstracts, a literature (PubMed) search was performed in May 2015.

**Results:** A total of 415 abstracts were presented in the fellows CR category at the ASN KW 2012-2013. Compared to KW 2012, there was a 7.5% increase in CR abstract presentations at KW 2013. Over these previous two KW meetings, nearly one-third (31.6%) were CR abstracts. The remaining abstracts were FEAB (15.2%), AKI (14.4%), KT (11.8%), D (11.8%), TIN (5%), MD (4%), O (4%), and GD (2.2%) related presentations. Compared to KW 2012, there was increase in GN related presentations (from 55 to 76) at KW 2013. So far, only 72 (17.3%) out of the 415 abstracts have been published as papers in peer-reviewed journals. One abstract was published as a letter to the editor format. Of those that were published, 31.5% were GN related case reports. Interestingly, 22% of these journal publications did not list the lead author of the KW CR abstract as the primary author of the paper.

**Conclusions:** Based on our study, it seems that there is an increased interest among fellows to present CR abstracts at ASN KW. Nearly one-third were GN related case presentations. However, so far, less than one-fifth of the fellows CR abstracts presented at KW 2012-13 have been published in peer-reviewed journals. Reasons for this low publication rate is not known. Measures to enhance CR publications need to be considered.

SA-PO140
Analysis of Published Medical Student Related Nephrology Medical Education Research

**Background:** Undergraduate (medical student) related medical education research in nephrology is not well studied. This analysis aims to assess the rigor of the research of the studies describing teaching methods used in medical student education in nephrology.

**Methods:** A review of the English literature on nephrology education of medical students was conducted on two major online academic search engines (PubMed and ERIC). References of abstracts were also reviewed. Conference abstracts were not investigated. The empirical studies were categorized by subject within nephrology. The research design of each study was then recorded.

**Results:** 26 original studies were found in which a method of teaching nephrology to medical students was described. The studies dated from 1977 to 2015. The focus of these teaching experiences was as follows: anatomy (3.3%), physiology (23.3%), pathophysiology (26.7%), pathology (10%), treatment (20%), and general nephrology (16.7%). 4 of the pathophysiology studies were also classified under other categories, so there were 30 total studies. The papers were also categorized into types of assessments. Participants containing two different types of studies for a total of 28 types of assessment. 14.2% had either no assessment of the educational experience or had a description too vague to categorize it; 3.6% involved a questionnaire about the existing educational approach but did not implement any changes. Methods to improve the educational experience included 28.5% that had open ended questions, 28.5% that had numerical assessment data, and 12% that had a mixed approach.

**Conclusions:** Rigor is lacking in most studies done in medical student education research in nephrology. Over 50% of the studies done had a survey-based design. More randomized controlled trials are needed to assess reliably the effectiveness of the educational techniques in nephrology medical education research.

SA-PO141
Participation in the Open, Online, Twitter-Based, Nephrology Journal Club, NephJC.
Joel Topf, Matthew A. Sparks, Edgar V. Lermnr, Thomas Oates, Paul J. Phelan, Francesco Iannuzzella, Swapnil Hiremath.

**Background:** We established an online nephrology journal club, NephJC, in April 2014 that meets twice monthly to discuss emerging research and clinical practice guidelines. We invite content experts and manuscript authors to the discussion. The meeting occurs on the public forum Twitter, allowing any interested individual to join. The purpose of NephJC is to provide a recurring, academically-minded event on Twitter that students could consider as part of their 3 top career choices as a result of this elective experience.

**Conclusions:** We believe that the restructured nephrology elective provides the medical student with a much needed and realistic exposure to nephrology careers. Based on our experience, we recommend all training programs to consider this elective structure for medical students.

SA-PO142
Three Years' Experience with the Online Educational Game, NephMadness

**Background:** NephJC is to provide a recurring, academically-minded event on Twitter to help establish this communication channel as one for serious nephrology discourse. In addition, online journal clubs are becoming a critical route for post publication peer review. In order to assess the impact of NephJC we reviewed participation in the discussions over the first year. This analysis aims to assess the rigor of the research of the studies describing teaching methods used in medical student education in nephrology.

**Results:** There were 342 entries in NephMadness (25% increase over 2014) nephrology in 25 countries with three quarters from the US. Gender breakdown was 31% female, 69% male. 46% of the contestants were attendings, 24% fellows, 10% residents and 9% medical students. The hashtag #NephMadness was tweeted 4,297 times (190% increase) by 401 people (144% increase) between Jan 16 and June 16. Web traffic to the hosting site was triple its monthly average and included the single highest traffic day ever. A blue ribbon panel of nephrologists determined the winners of each match-up.

**Conclusions:** Rigor is lacking in most studies done in medical student education research in nephrology. Over 50% of the studies done had a survey-based design. More randomized controlled trials are needed to assess reliably the effectiveness of the educational techniques in nephrology medical education research.

SA-PO143
Awareness of AKI in Low Resource Settings: A Global Survey
Joseph Lunyera,1 Kajiru Kilonzo,2 Andrew J.P. Lewington,3 Karen E. Yeates,4 Fredric O. Finkelstein.5 1Duke Univ; 2KCDC; 3Leeds Teaching Hospitals; 4Queen’s Univ; 5Iale Univ.

Background: The ISN has set a goal of eliminating preventable deaths from AKI by 2025—the “0x235” initiative. However, there is limited awareness of the challenges presented by AKI in terms of diagnosis, treatment and management in low resource settings (LRS).

Methods: We reached out to nephrologists working in LRS using a web-based instrument of 18 questions. Responders were asked what strategies should be considered to increase the awareness of AKI in LRS and recommend approaches to heighten this awareness. 206 respondents from 5 WHO world regions, including 54% from Africa.

Results: The major barriers to raising awareness cited by all were inadequate training; shortage of adequately trained health workers and lack of awareness of the significance of AKI by healthcare workers, government officials and the general public. Additional factors cited were limited patient access to health facilities, limited diagnostic and treatment facilities, lack of support for up AKI programs, lack of clinical practice guidelines for AKI, poor communication systems, limited research funding and lack of linkages of AKI programs to other health projects. Health centers (HCs) were broken down into rural, district and regional HCs. Supplies available for diagnosis (serum creatinine and BUN) and management (IV fluids, antibiotics, anti-venom) of AKI are limited in rural HCs. All noted that hemodialysis services were available but only in selected, large urban centers. Peritoneal dialysis was limited to regional HCs.

Conclusion: Increasing the awareness of AKI in local, district, and regional HCs requires a multi-faceted approach, reaching out to government officials, hospital administrators, physicians, nurses, local health care workers, community leaders, international organizations and the general public. The success of this initiative involves the development of meaningful and targeted educational programs, training materials, and treatment guidelines tailored to the local situations. Alliances will need to be formed with governmental agencies, non-profit organizations and global health programs. Support needs to be provided for additional research programs.

SA-PO144
Acute Kidney Injury Education to Nursing and Assistant Health Care Staff
Mansoor N. Ali. Renal Medicine, Calderdale and Huddersfield Hospitals NHS Foundation Trust, United Kingdom.

Background: Acute kidney injury (AKI) is a global healthcare problem. It carries significant mortality and incurs heavy costs to the National Health Service. Extensive work has been done recently both at undergraduate and postgraduate level to ensure front line medical staff have better understanding in managing AKI. One such important area of focus involves the need for training nursing and assistant healthcare staff who care for patients presenting with AKI.

Purpose of the study: To gauge the understanding of AKI amongst nursing and healthcare assistants working on busy acute medical admissions unit.

Methods: The anonymous questionnaire was aimed at the nursing and assistant health care staff working on the admissions unit at two large district hospitals. The length of time since qualification ranged from few weeks to 16 years. The questionnaire was followed by planned teaching, simulation training and workshop sessions. The process was carried out within a period of 2 months.

Results: The Questionnaire was completed by 50 staff members. It included series of questions aimed at defining and managing AKI from a nursing perspective. 24 out of 50 were able to define AKI. Only 5 out of 50 have never cared for patients with AKI. Not many were aware of the symptoms of AKI; common answers given by 40 respondents were “reduction in urine output” and “dehydration.” All participants answered “yes” to monitoring urine output and understood the significance of fluid monitoring but all admitted more needed to be done to ensure accurate documentation in the patient’s notes. Other questions asked were if nurses check patient’s blood results on the system server to which most replied “no” and if medications were regularly reviewed during drug rounds. Surprisingly, not all were aware of nephrotoxic medications and only 20 respondents would regularly review drug charts in the context of renal failure.

Conclusions: The questionnaire and the training sessions identified lack of better understanding of AKI and its management. There needs to be a stronger emphasis on the introduction of AKI and its management during their training years and development of mandatory online e-learning modules.

SA-PO145
Evaluation and Management of Acute Kidney Injury – A Trainee Survey

Background: AKI occurs in 1 in 3 hospitalized patients, and majority of those are managed by non-nephrology specialists, including trainees.

Methods: The renal fellowship program designed an online anonymous survey, distributed to trainees (students, residents, fellows), to understand their level of knowledge in recognition and management of AKI. 37 questions were classified into following categories: knowledge of guidelines; prognostic factors; and drug safety. Results are represented as agreement percentage.

Results: 104 trainees responded to the online survey; 50% were male, 84% US medical graduates and 70% were residents/fellows. 50% were affiliated to medical specialties, and 53% had spent at least one elective in nephrology. In terms of AKI definition: 51% use serum creatinine (SCr) as the most important factor to diagnose AKI, whereas 20% use urine output. Majority (76.1%) agreed that rise of 0.3 mg/dl or 1.5 times of baseline SCr was clinically relevant, in concordance with current guidelines. RIFLE criteria were most commonly used (42%), followed by KDIGO (13%); and 90% agreed that guidelines help in standardization, and management of patients. 85% concurred that AKI impacts short and long-term outcomes, however, majority (60%) felt dialysis requirement was the most important clinical predictor of outcome. Majority (67%) felt that early involvement of nephrology services is helpful in AKI management; 66% sought nephrology input to determine the cause of AKI/co-management, and 7% viewed nephrology role purely for procedural delivery of dialysis. As for drug safety, 89% reported to pay attention to renal function while drug dosing, but 70% felt that this was the responsibility of either pharmacy or ordering team. In terms of follow-up 61% of subjects felt that follow-up was only needed in moderate to severe AKI cases or in non-recovery, 86% preferred that in n = 30 days, and 64% preferred that to be with primary care.

Conclusions: Most of the trainees displayed good knowledge of AKI guidelines (RIFLE), seek timely nephrology involvement and view it to be beneficial. More work needs to be done in terms of improving knowledge/practice about drug safety and follow-up care in AKI.

SA-PO146
Adherence to Care Bundles for AKI – Challenges in Supporting Education and Measuring Compliance
Melanie Louise Sally, Christopher J. Mulgrew. Renal Medicine, Royal Devon & Exeter Hospital, Exeter, Devon, United Kingdom.

Background: AKI typically occurs as a consequence of intercurrent illness in patients with multiple comorbidities and risk factors. The use of clinical guidelines to assist medical and nursing staff in AKI management has been adopted by most secondary care institutions in the UK. We have previously presented our use of e-alerts for AKI as a prompt to improve AKI care (Mulgrew et al, ASN, 2013). Clinical guidelines were prompted by the e-alart and widely publicised to staff.

Methods: In a model similar to the NHS Safety Thermometer, snapshots of compliance with 6 key elements of the AKI guidelines on 4 medical wards was measured by identifying patients from AKI e-alerts. These included documentation of AKI, medication review, clinical diagnosis and ongoing investigation monitoring. Awareness was supported by an AKI Education nursing team, working with medical and nursing staff. Monthly compliance was assessed over a period of one year.

Results: Mean compliance for all elements of the guidelines improved from 52% to 69% over the year. Significant variability was seen, often associated with notable workforce challenges such as new medical staff or periods of increased activity.

Conclusions: Supporting medical and nursing teams to manage AKI in secondary care in order to prevent progression and treat promptly remains challenging. A number of external factors frequently impact upon adherence to guidelines and support needs to be planned in order to continue to maintain high standards and optimise patient care. The use of a Safety Thermometer, allowing performance to be analysed and comparisons made between clinical areas, may continue to be useful in improving performance and patient outcomes in AKI.

SA-PO147
Internal Medicine Residents Knowledge of Vein Preservation in Chronic Kidney Disease Patients
Sandesh Joshi, Jamie Alton Green, Maria C. Bermudez. Nephrology, Geisinger Medical Center, Danville, PA.

Background: Vein preservation is important among CKD patients for future arteriovenous fistula potential. House staff plays critical role in managing these patient population and preserving their vein for future arteriovenous fistula. Their knowledge and current practices directly affects the outcome for vein preservation among these patients.

Methods: We conducted a survey among 44 internal medicine residents to understand their baseline knowledge and current practices regarding vein preservation. The survey was conducted at Geisinger Medical center, Danville, PA.

Results: 44 residents were included in the survey. Only 6.8% (3) were able to correctly identify patient population, on whom we should avoid particular arm for IV draws, BP measurements, peripherally access or peripherally inserted central catheters. Two-third (27) answered non-dominant arm to avoid for these procedure and 13.5% (6) responded side does not matter. 81.8% (36) answered that nephrology should be consulted prior to peripherally inserted central catheters placement for CKD 4 patient. 93.1% (41) answered...

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

658A
correctly that peripherally inserted central catheters can damage peripheral veins. 52% (23) knew arterial of PICC line was tunneled internal jugular catheter, 34% (15) answered tunnelled subclavian catheter as an alternative. 55% (24) did not know preferred site for peripheral access, blood draws, 63% (28) has never written orders for nurse to request to avoid particular arm for IV draws, BP measurements in advanced CKD patients or patients on HD, 90%(31) have never requested a bedside sign to avoid particular arm for these patients.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.

SA-PO148

Vascular Access and Transplant Referral Rates in CKD: An Ongoing Performance Improvement Project for Nephrology Fellows

Background: Referral for vascular access (Ac) and kidney transplantation (Tx) are important management facets of CKD. We previously conducted a performance improvement project assessing Ac and Tx referrals rate (RR) in CKD patients from the Nephrology fellows’ clinics. Following an educational intervention, there was an improvement in transplant RR (JASN 25.786A, 2014). To evaluate the sustainability of this initiative, we conducted a follow-up analysis.

Methods: This performance improvement project was conducted in 3 phases at the Charlie Norwood VAMC; Phase 1, baseline (1/1-4/30, 2013), Phase 2 (post-intervention, 8/1-11/30, 2013) and Phase 3 (follow-up, 1/1- 4/30, 2015). Data extraction was conducted by three, 2-fellow teams, each reviewing the other’s RR for all patients seen in the previous 4-month period. The analysis was sorted by eGFR (ml/min/1.73m2); for eGFR<15, both Ac and Tx RR were recorded. In addition, Tx RR for eGFR 15-20 was documented.

Results: 1114 total records were reviewed (349, 361, and 404 for Phases 1, 2 and 3, respectively). Table 1 indicates the number of patients and RR in those with Ac and Tx RR. For Ac RR through all 3 phases were steady at 72-75%. Tx RR were improved after intervention and were sustained in Phase 3.

Table 1. Referral in patients with GFR <20 in different study phases. Results presented as number of patients (%).

Conclusions: Referral rates for kidney transplantation by Nephrology fellows improved with a chart review and educational intervention were performed. Vascular access referrals from this study remained stable. This work suggests that outpatient performance improvement projects conducted by Nephrology fellows confer peer review accountability for outpatient practice habits, heightens trainee awareness of key referral issues, and appears to help sustain or improve referral rates for vascular access and kidney transplantation.

SA-PO149

Impact of Standardized Electronic Documentation in an Academic Nephrology Setting

Leslie P. Wong, Emilio D. Poggio, 1,2 "Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; 1Transplant Center, Cleveland Clinic, Cleveland, OH."

Background: Reimbursement depends on documentation and billing based on complexity of care. Academic nephrologists are under pressure to improve productivity measured by revenue and relative-value-based units (RVUs). Incorrect documentation or billing may result in loss of revenue and RVUs due to services that have been provided. Standardized electronic templates were introduced in an academic nephrology setting to help address this issue.

Methods: Standardized templates based on Medicare 1997 Guidelines were introduced in July 2014 for all inpatient nephrology encounters. A training presentation was provided to teach nephrologists proper use of the templates. 7.314 inpatient charges submitted by 22 academic nephrologists between January 2012 and March 2015 were reviewed. Data included patient identity, clinical presentation, primary diagnosis, procedural terminology (CPT) code specifying the type of service, the identity of the nephrologist and any adjustments made by the coding department. Adjusted charges were accompanied by the reason for adjustment, the corrected CPT code and a revenue change based upon Medicare reimbursement. RVUs were calculated using the Medicare National Physician Fee Schedule.

Results: Before July 2014, 4.2% of charges were adjusted compared to only 2.8% after July 2014. The mean work RVU loss per adjustment decreased from 1.15 to 1.00 (p<0.01). The mean revenue loss per adjustment improved from $270.88 to $229.56 (p<0.05). Multivariate regression identified factors associated with worse productivity adjustments: encounters before July 2014, more than 10 years of academic experience and transplant nephrology (all p-values <0.01). Factors associated with improvement in RVUs included endorector after July 2014, ICU encounters and less than 10 years of academic experience (all p-values <0.01).

Conclusions: Standardized templates led to significant reductions in revenue/work RVU losses per encounter at a large academic nephrology center. Nephrologists with more than 10 years of academic experience and transplant nephrologists performed worse than their peers. Efforts to improve documentation and billing may have important implications for academic nephrologists.

SA-PO150

Nephrology Documentation and Billing Educational Needs at an Academic Medical Center

Leslie P. Wong, Emilio D. Poggio, 1,2 "Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; 1Transplant Center, Cleveland Clinic, Cleveland, OH."

Background: Reimbursement in nephrology depends on accurate documentation and billing. Academic nephrologists are under increasing pressure to meet financial productivity targets. An analysis of nephrology reimbursement was performed at an academic medical center to identify deficiencies and identify targets for education.

Methods: 75,097 inpatient nephrology encounters by 22 nephrologists from January 2012 and March 2015 were reviewed. Data included the current procedural terminology (CPT) code specifying the type of service and any charge adjustments made by the coding department. Adjusted charges were accompanied by the reason for adjustment, the corrected CPT code and a gross revenue adjustment based upon Medicare reimbursement. Relative value units (RVUs) were calculated using the Medicare National Physician Fee Schedule. Multivariate regression analysis was performed to identify factors associated with RVU adjustments.

Results: 5615 (7.5%) of encounters were adjusted by coders. 3832 (68%) were due to incorrect documentation or billing and 1683 (32%) were due to services performed but not billed by nephrologists. For submitted charges, revenue was reduced by $995,976 and 4227 work RVUs as a result of incorrect documentation or billing. The potential loss of revenue from unbilled services was $603,014 and 2823 work RVUs. Inadequate documentation of physical exam (p<0.01) and inadequate documentation of supervision of medical students/residents/fellows (p<0.01) were independently associated with RVU adjustments. Incorrect charge selection, duplicate charges, competing charges from another nephrologist and conflicting discharge/observation/post-operative care CPTs were also independently associated with RVU adjustments (p<0.01).

Conclusions: There was a substantial loss in gross revenue and work RVUs due to incorrect documentation and billing in an academic nephrology setting. These reductions in reimbursement and productivity might be avoided through better physician education and training. Specific targets include documentation of physical exam and supervision of trainees, correct CPT charge selection and ensuring all services performed are billed.

SA-PO151

Reaching Renal Goals – A Quality Improvement Project

Mihran V. NaIjayan, Oksana I. Nimkevych, Vecheslav Fedorchenko, Sara Jacob Coulon, Kimberly Cox Fremin, Zohary M. Al Shaila. Medicine, LSUHSC School of Medicine, New Orleans, LA.

Background: The purpose of this study was to improve our patient care in a renal clinic at a large university hospital by using three of the core competencies- patient care, systems based practice, and practice based learning and improvement.

Methods: A check-out sheet was developed and given to all trainees in the nephrology clinic at a large university hospital by using three of the core competencies- patient care, systems based practice, and practice based learning and improvement. Specifically, targets include documentation of physical exam and supervision of trainees, correct CPT charge selection and ensuring all services performed are billed.
Conclusions: Our project was helpful in educating trainees in the treatment goals and strategies for patients in the renal clinic, and standardized an approach to patient care. Overall, the results show a trend towards improvement in all goal areas except for renal education. This study did not account for patients who were new to our clinic and therefore had never received renal education previously.

SA-PO154
Improving Pathology Curriculum for Nephrology Fellows

Enrica Fung,1 Orlando Camacho,1 Michelle M. O’Shaughnessy,1 Adetokunbo A. Taiwo,1 Gabriela Velez,1 Neeraja Kambham,2 Timothy W. Meyer.1
1Nephrology, Stanford; 2Pathology, Stanford; 3Nephrology, VA Palo Alto

Background: Stanford fellows were previously exposed to renal pathology through attendance at monthly hour-long “biopsy conferences” where faculty and fellows discussed difficult cases; and informal quarterly “fellows-only conferences” where fellows asked pathologists questions on core topics. Our project sought to improve fellows’ education in renal pathology.

Methods: Twelve first to third year fellows participated in this project. Two renal pathologists led five orderly review sessions, dedicated to fellows only: 1. Common renal pathologies; 2. Primary glomerulonephritis; 3. Secondary glomerulonephritis; 4. Plasma cell dyscrasia-related renal disease; 5. Renal transplant pathology. Second year fellows helped in preparation of teaching material. Fellows were encouraged to ask questions. Participants completed a survey to measure their satisfaction with renal pathology teaching and their confidence in interpreting renal biopsies before and after this project. Five 10-question pre-session quizzes and a comprehensive 40-question post-project final measured knowledge acquisition.

Results: Prior to our project, 53% of fellows felt “somewhat satisfied” to “satisfied” with the current pathology conferences, and 10% of fellows felt “somewhat confident” in their abilities to interpret biopsy findings. Most fellows (83%) viewed renal pathology to be an “important” or “very important” part of their overall nephrology training. After the project, 100% of fellows felt “somewhat satisfied” to “very satisfied” with the project, and 60% of fellows felt “somewhat confident” in their abilities to interpret biopsy findings. To date, fellows answered 63% of quiz questions correctly prior to the project and 60% of final questions correctly after the project.

Conclusions: Survey of nephrology fellows revealed poor confidence in interpreting renal pathology prior to our project despite perceived importance of the topic. To date, post project evaluation suggested improved confidence in renal pathology but lack of significant change in knowledge base. This may be due to issues with knowledge acquisition, inter-test comparability or instruction method.

SA-PO155
Improving the Communication Skills of Nephrology Fellows by Utilizing MBTI Training

Anna Marie Burger, Julia Lewis. Vanderbilt Univ School of Medicine, Nashville, TN.

Background: Communication skills can both positively and negatively affect the patient-physician relationship. Although many things impact successful communications, individuals’ personality types affect the way they communicate and the way they interpret the communications of others. It has been suggested that a lack of understanding of the basic difference between personality types contributes to poor communication and unsuccessful interactions. Nephrologists work in a unique environment in the dialysis unit with a complex interdisciplinary team and a “captured” audience of anywhere from 10-40 patients in a single room. In the dialysis unit, communication between the multi-disciplinary team and the patients and between the multidisciplinary team’s individual members impacts the successful achievement of dialysis outcomes.

Methods: Eleven nephrology fellows underwent a curriculum designed to increase their awareness of their own Myers Briggs Type Indicator (MBTI) personality preferences, their knowledge of the different basic personality preferences, and how those differences impact communication. Knowledge of the MBTI preferences was tested pre-intervention, immediately post intervention, and 8 weeks post intervention. Communication skills were measured pre-intervention, post intervention, post dialysis nurse teaching, and during fellow-real patient interactions. Fellows were also asked to describe how they used their knowledge at 8 weeks post intervention.

Results: The intervention led to a sustained increase in the fellows’ MBTI personality preference knowledge. At 8 weeks post intervention, fellows reported utilizing their personality preference knowledge to improve their communication with their patients as well as with members of their team. However, nephrology fellows’ communication skills, as measured by the Kalamazoo Essential Elements Communication Checklist Adapted (KEECC-A), did not change.

Conclusions: Although training in MBTI personality preferences led to a significant, sustained increase in MBTI knowledge and fellows continued to report utilizing their knowledge at 8 weeks post intervention, there was no change in their measurable communication skills utilizing nurse observations.

SA-PO156
Lung Ultrasound: A New Skill for Nephrologists for Volume Overload Quantification in End Stage Renal Disease Patients on Hemodialysis

Marc M. Saad, Wissam Mansour, Elias Moussaly, Jeanne Karam, Boutros Karam, Cara Brown, Monica Kapoor, Elic El-Charabaty, Suzanne E. El Sayegh. Internal Medicine/Nephrology, Staten Island Univ Hospital, Staten Island, NY.

Background: Many methods have been tried to assess the volume status in patients on hemodialysis (HD). While the estimated dry weight is still the only method widely used, it is often inaccurate and poses a clinical challenge. Pulmonary congestion detected as B lines on ultrasound (BLUS) is rising as a novel parameter for assessing volume status; we evaluate the accuracy and reliability of measuring BLUS performed by residents following the Trento course.
Biopsy Diagnosis | Pre-biopsy diagnostic accuracy (%)  
---|---  
ANCA vasculitis | 100  
MCD | 100  
DM | 86  
Lupus class II | 80  
Amyloidosis | 57.14  
Lupus class III + IV | 50  
Idiopathic Membranous | 45.45  
HIVAN | 42.85  
IgA | 38.46  
Lupus class V | 33.33  
HTN | 33.33  
Fibrillary GN | 25  
Normal | 0

Nephropathologists with > 10 years’ experience tended to more accurately predict the diagnosis than those with < 10 years’ experience (64.4 vs. 48.3%, p=0.07).

Conclusions: Nephropathologists more accurately diagnosed ANCA vasculitis, MCD & Diabetes by clinical gestalt, but were less accurate for stages of lupus and other seronegative GNs. Regardless of training and experience kidney biopsy is still the diagnostic tool of choice in patients with kidney disease.

SA-PO158

Out-Patient Clinic Based Multidisciplinary Patients’ Education for Advanced DM Nephropathy Is Effective and Efficient for Reducing ESRD

Fumiko Takai, Takuya Fujimura, Masataka Hasegawa, Miyuki Futasuyama, Yuki Heath, Masahiko Nagahama, Yasuhiro Komatsu. Nephrology, St. Lukes International Hospital, Tokyo, Japan.

Background: Diabetes Mellitus (DM) is the most common etiology of CKD. Patients educations for these patients are known to be important, however, effectiveness and efficiency of them are still unclear. We established multidisciplinary out-patient clinic based education system, specialized for advanced diabetes nephropathy, and assessed their clinical outcomes.

Methods: Education system were started from May 2012, in St. Lukes’ International Hospital, Tokyo, Japan. All CKD patients with DM were asked to meet nurse and diettian, before seeing physicians, on every visit of the CKD clinic. Nurse and diettian give the specific advice for each patients, within 15 minutes, by using our original short text or materials. Initiation of renal replacement therapy (RRT) were assessed for the primary and secondary of morbidity, HbA1c, eGRA, type of RRT were. 

Results: From May 2012 to March 2015, total 372 individual patients were participated. Their baseline eGFR were 36.5 ±12.5ml/min, mean age 65.5 ±13.2 y.o. and 68% of them were male. Two hundred and ninety seven, 82% of patients were educated and their average of frequency of education was 4.3 ±2.1 times/year. Comparison of educated and non-educated groups, baseline eGFR, HbA1c or other comorbidity did not differ. However, preservation of renal function were better in educated group ; delta eGFR: Educated vs. Non-educated: -3.26e±1.21 vs. -8.2±3.25 ml/min/1.73m²/year, p=0.04, T-Test. More, incidence of ESRD in non-educated group ; Initiation of Dialysis: Educated vs. Non-educated: 9.4% vs. 33.3%, p=0.033, Chi-Square test. Furthermore, in non-educated group, none of the patient selected peritoneal dialysis or transplants for the RRT.

Conclusions: Our out-patient clinic based education system is simple and useful for diabetic CKD patients for reducing ESRD.

SA-PO159

Our Studies Our Way: Creation of a Digital Story CKD Educational Intervention

Marcia Oleyar, Ashwini R. Sehgal. General Internal Medicine, Cleveland Clinic, Cleveland, OH; Missouri Breaks Diabetes Research Institute, Center for Reducing Health Disparities, MetroHealth Medical Center, Cleveland, OH.

Background: Chronic Kidney Disease and End Stage Renal Disease disproportionately affects American Indian communities, yet there are few culturally appropriate educational interventions for this population.

Methods: Digital storytelling combines first person narrative with digital images and music and can be done with a community-based, learner-centered approach. With these digital tools, people create personal narratives that are powerfully compelling, emotionally engaging, and provide another view or perspective on a topic. We recruited 10 men and women with diverse life experiences related to health and kidney disease from an American Indian community to create digital stories. Each participant was mailed a pre-workshop information sheet about digital storytelling and were encouraged to bring pictures.

Results: We held a 3 ½ day digital story workshop with our partner nDigiDreams, LLC in Nov 2013 at a tribal college. Participants, their family members, and research staff worked together with the facilitators to create their personal digital story related to health and kidney disease in their words. A total of 10 digital stories were created encompassed four areas: develop story idea, gather media such as pictures and music, record the voice parts/edit the digital story, and share or screen the digital stories among the group. Five stories about life on dialysis, having a kidney transplant, and making changes to control diabetes were selected to be in the final DVD.

Conclusions: We created a unique educational tool in the form of digital stories. The DVD has been used in an ongoing pilot observational educational trial looking at the impact on chronic kidney disease knowledge and health behaviors among American Indians.

Funding: NIDDK Support

SA-PO160

The Effect of Nephrology Specialty Clinics on Patient Care and Trainee Experiences

Frederick H. Kuo, Rajeev Raghavan, Wolfgang C. Winkelmayer, Jolly Jolly, Marcia Oleyar, Ashwini R. Sehgal. Dept of Medicine-Nephrology, Baylor College of Medicine, Houston, TX.

Background: As medicine evolves, there has been a trend towards the creation of special clinics which streamline care in hopes of improving patient survival through clinical trials and increased time with “super-specialists”. From a trainee perspective, a Nephrology clinic focused on a particular disease affords a unique perspective on disease pathophysiology and treatment and can be a wonderful tool to recruit residents or students into Nephrology. We hypothesized that a major advantage of nephrology clinics across the US utilize such subspecialty clinics, and we aimed to characterize the patient and trainee experience by conducting a nationwide survey.

Methods: An e-mail detailing the study’s aims and an anonymous ?-question online survey was sent to the 139 program directors of ACGME-accredited nephropathy fellowship programs in July 2014.

Results: 54 of 139 program directors (39%) replied. We found Transplant clinics to be the most common subspecialty clinic (83%), followed by Stone clinic (63%), Advanced CKD clinic (58%), and Glomerulonephritis clinic (38%). The course encompassed four areas: develop story idea, gather media such as pictures and music, record the voice parts/edit the digital story, and share or screen the digital stories among the group. 10 out of 10 digital stories were created encompassed four areas: develop story idea, gather media such as pictures and music, record the voice parts/edit the digital story, and share or screen the digital stories among the group. Five stories about life on dialysis, having a kidney transplant, and making changes to control diabetes were selected to be in the final DVD.

Conclusions: We created a unique educational tool in the form of digital stories. The DVD has been used in an ongoing pilot observational educational trial looking at the impact on chronic kidney disease knowledge and health behaviors among American Indians.
for lupus, polyzystic kidney disease, and genetics. Regarding patient compliance within specialty clinics, 40% indicated it to change, 40% improved, and 20% much improved. On patient satisfaction, 32% indicated no change, 49% improved, and 19% much improved. No respondents perceived decreased patient compliance or satisfaction. Trainees participated in 98% of specialty clinics with a 91% satisfaction rate; 29% were very satisfied. 45% of specialty clinics had ongoing research projects, with an average of 5.5 research projects in those clinics.

Conclusions: Subspecialty clinics can be an invaluable tool for both trainees and patients; both groups reported high satisfaction levels. These clinics also enable research by providing an established database of patients with specific disease processes. Access to such information is essential to quality research and may streamline the development of key clinical trials.

SA-PO161

Background: The distribution of renal replacement therapy (RRT) modalities among patients varies from country to country, and is often influenced by non-medical factors. In our department, patients progressing towards end-stage renal disease (ESRD) go through a structured Pre-Dialysis Education Program (PDEP). This PDEP is conceived with patients association and nursing educator.

Methods: Forty-nine patients with CKD who were receiving care in a multidisciplinary predialysis clinic (mean age 73.5, 63% men). The participants were accompanied by family members. They have attended educational classes, followed by two workshops in groups and a final educational evaluation. The workshops are carried out in groups of 6 to 10 patients. The PDEP consisted of: (1) psychosocial assessment, (2) education about dialysis and choice of modalities, (3) counseling sessions with patient, family members, (4) education about dietetic and dialysis.

Results: Choice of the substitution method at the end of the workshops: 61% peritoneal dialysis, 18% haemodialysis and 21% absence of choice. 94% of the patients began the substitution treatment with a chosen modality. 100% Satisfaction of the patients. 26% decrease of the anxiety. (p<0.0005), 25% (p< 0.0001) increase in the consent for the treatment, 61% increase in the engagement in the treatment (patient ready to receive treatment) (p<0.00001), 47% increase knowledge of RRT (p<0.0001).

Conclusions: Most studies dealing with the pre-dialysis information show a balanced choice of the RRT, but only 50% of the patients actually begin DF. Our workshops of help and assistance to the choice enable to significantly reduce the anxiety linked to the dialysis and thus increase the adherence and engagement for the chosen method RRT. A two-phase educational intervention can increase the proportion of patients who intend to initiate dialysis with self-care dialysis. In our centre offering all treatment RRT modalities, a high percentage of patients exposed to a structured PDEP start with a self-care RRT modality.

SA-PO162

Frequency of Use of Social Media in CKD Patients on Hemodialysis: Pilot Study in Ecuador Fabian A. Ortiz-Herbergen, Juan Carlos Calderon, Walter Marin, Jorge J. Elizalde, Juli Figueroa, Byron Josu, Ivan Manuel Cherecz, 3

1Inst Ecuatoriano de Diálisis y Transplantes, Guayaquil, Guayas, Ecuador; 2Respiralab, Guayaquil, Guayas, Ecuador; 3School of Medicine, Univ de Especialidades Espirito Santo, Samborondon, Guayas, Ecuador.

Background: CKD on dialysis is defined as <15% of kidney function. In Latin America, 461 per million are on dialysis. Region is the third largest user internet. Social media includes communications spread electronically, shared by individuals and discussed by a connected population. Hispanic Americans with CKD used it, to inform and be informed, and supporting each others.

Methods: Observational, cross sectional, pilot study. Patients were recruited in dialysis center in Guayaquil. Survey included demographical and clinical items, Charlson score and 4 questions about frequency of use of social media were included. Also, questions about obtaining information; and interest in receiving or asking physician questions related to illness in social media. Frequencies and mean (SD) were employed. Chi-square, ANOVA and M-W U was used for comparisons. Also, Cronbach were calculated.

Results: 34 patients participated, with mean age of 56.5 (SD 16.3), mean years on dialysis of 3.9 (SD 4), 52% were women. Comorbidity’s rate was very high (82.4%). 70.6% of patients believed that dialysis control symptoms of disease. 11.8% hadn’t got cellular-phone neither Internet. 61.8% hadn’t got SMS. Almost half of patients had smartphones. Women had a high comorbidity (41.2%), p<0.05. Around 30.0% reported using SMS, Facebook, YouTube, internet at least once a week. 46.7% use Internet as principal source of information, YouTube (20.0%) and email (16.7%). 40% of patients reported high interest in receiving information by SMS, Facebook (33.3%) and email (26.6%). 33.3% reported high interest in asking by SMS, email (26.7%) and Facebook (20.0%). 63.3% reported high interest in receiving information and asking by whatsapp. Conробаха was 0.884.

Conclusions: Internet use is very common for searching information related to disease. WhatsApp, SMS, Facebook and email were reported as new tools for providing illness related information to the patient. The survey had a good reliability and consistency.

SA-PO163

The Impact of Predialysis Education on Patient Understanding, Preparedness, and Decisional Conflict Regarding Renal Replacement Therapy Options Syed Amir Hamid Ali Shah, 1 Ion D. Bucaloiu, 1 Amanda Young, 2 Jamie Alton Green. 3 ‘Nephrology, Geisinger Medical Center, Danville, PA; 1 ‘Center for Health Research, Geisinger Medical Center, Danville, PA.

Background: Predialysis education is recommended to prepare patients with advanced chronic kidney disease (CKD) for initiation of renal replacement therapy; however, the impact of various approaches to the decision-making process is not well known.

Methods: We surveyed 91 advanced CKD patients before and after a 2-hour nurse led group education class to assess patient understanding of renal replacement therapy options (1=poor to 5=excellent), preparedness to make a decision (1=not at all to 5=very prepared), and decisional conflict using a validated scale (0=no decisional conflict to 100=extremely high). The class included a combination of direct verbal instruction and video presentation, tailored to patients with a low literacy and sociodemographic backgrounds. Content included the advantages/disadvantages of hemodialysis (HD), peritoneal dialysis (PD), transplant, and conservative care.

Results: Mean age was 66.5, 58% male, 94% white, 44% had a high school or lower level of education, and 46% had low health literacy. Mean level of understanding increased significantly for all modalities pre-post (2.02 ± 0.10 for HD, 1.95 ± 0.44 for PD, 2.35 ± 0.45 for transplant, and 2.10 ± 0.42 for conservative management; all p<0.001). Decision preparedness also increased significantly from 2.44 to 3.50 (p<0.001). Improvements were similar regardless of age, gender, educational level, or health literacy. At the end of the class, overall decisional conflict was low (median score 10; IQR 0, 20). Equal proportions of patients preferred HD (24%) or PD (22%), compared with transplant (12%) and conservative management (4%), yet nearly (30%) of patients remained unsure of their decision.

Conclusions: Despite significant improvements in patient understanding and preparedness about renal replacement therapy options, a substantial number of patients remained unsure of their decision after routine predialysis education. Additional decision supporting interventions may be needed to improve decision-making in advanced CKD patients.

SA-PO164

Chronic Kidney Disease Knowledge Among English and Non-English Speakers Anushya Jeyabalan, Pranav S. Garmiella, Lesley Inker. Nephrology, Tufts Medical Center, Boston, MA.

Background: Patient education regarding CKD is an important part of pre-dialysis care. While educational interventions have also shown to improve clinical outcomes among dialysis patients, there is little information however, on health literacy in CKD populations.

Methods: We performed a cross-sectional survey of patients identifying themselves as primarily English or Chinese (Mandarin or Cantonese) who were visiting an outpatient nephrology clinic at a single tertiary hospital. A validated Kidney Knowledge Survey (KiKS) that has been used to assess CKD knowledge in previous studies was translated into Chinese and then self-administered in English or Chinese. All patients had at least 1 prior visit with a nephrologist.

Results: 102 participants completed the survey of which 70 were English speakers and 32 were Chinese speakers. Chinese speakers were older, more likely to have less than high school education and had a greater prevalence of diabetes (Table). Estimated glomerular filtration rate and urine protein were not different between groups. Mean KiKS score was lower in Chinese speakers compared to English speakers (11.9 ± 17.2; p=0.001). Chinese speakers scored lower in all domains of the KiKS; general kidney knowledge (6.2 ± 4.5), knowledge of kidney function (5.5 ± 4.0) and knowledge of medications (0.4 ± 3.7).

Conclusions: While our results for CKD knowledge among English speakers are comparable to previously published data (mean score 18.6), scores among non-English speaking CKD patients is lower than English speakers. Whether this finding is associated with differences in care management and clinical outcome needs to be evaluated. Furthermore, educational material and programs may need to be tailored to specific populations to improve health literacy.

SA-PO165

Follow-Up with Doppler Ultrasound of Asymptomatic Arteriovenous Fistula (AVF) After Renal Biopsy (RB) maize Rivera, 1 Saul Enrique Pampa, 1 Virginia López de la Manzanara Pérez, 1 Victor Burguera, 2 Nuria Rodriguez Mendiola, 1 Cristina Galeano, 1 Ingrid Viviana Racho Michaels, 1 Rodrigo Hernandez Loyola, 1 Fernando Liano. 1 Nephrology, Hospital Univ Ramon y Cajal/UAH, Madrid, Spain; 2 Nephrology, Hospital Univ San Carlos, Madrid.

Background: RB is an essential percutaneous technique in Nephrology that entails major and minor complications, one being the AVF which is usually asymptomatic and undetected, and because of the absence of routine Doppler examination post RB. We analyzed the natural history of asymptomatic AVF post RB of native kidney (NK) and transplanted (RT) detected by Doppler examination following RB.

Methods: We analyzed the presence of AVF on 327 RB between January 2011 and December 2011, included in our database, 47 (14%) RB developed AVF detected by Doppler ultrasound performed at 24th post RB. We studied the following data: AVF size and its relation to the needle caliber and time to spontaneous closure and its relationship to the AVF size. All RB were real-time ultrasound-guided RB performed with a biopsy gun (Acuson, Tsk, Japan), the RT caliber 16G and 14G in the NK.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: 45 AVF were asymptomatic (96%), whereas 2 (4.2%) had to be embolized by the angiographer. Of the 45 asymptomatic AVF, 28 were of RET (62.2%), 69% were male. AVF 28 (62%) were followed until its closure with Doppler. 75% sized <1cm and correspond to RT (16 G-needle). We noticed that the 50% of AVF had closed at 3 months post RB at an average of 49 days. AVF with a size between 1.1 and 1.9 cm (17.7% of the total) took longer time to close (mean 67 days). Among the 17 patients without follow-up five had died, 3 lost the renal graft and 9 were lost in the evolution. Seven of the 9 patients without follow-up were studied by Doppler after contacting them by phone, 28 months post-biopsy. In the seven AVF had spontaneously closed.

Prior to the establishment of the LN Clinic, AVF after RB is a frequent complication but asymptomatic and rarely requires surgery. All asymptomatic AVF closed spontaneously. The size of AVF were related with the caliber of the needle and with the time to close. No AVF grew in evolution. The routine use of Doppler following RB is essential to identify and standardizing management of AVF.

SA-PO166

The Role of Post Biopsy Ultrasound in Predicating Complications After Percutaneous Renal Biopsy of Native Kidneys

Umar Hayat, Hafiz I. Ahmad, Syed Rizwan Bokhari, Syed A. Khalid. Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital Lahore, Lahore, Pakistan.

Background: The percutaneous renal biopsy (PRB) of native kidneys has been an essential tool in the diagnosis and management of renal diseases. Despite all advances, clinically evident bleeding complications do occur in up to 50% of patients after PRB of native kidneys. Traditionally patients are kept under observation for 24 hours after the procedure. An earlier investigation to anticipate the likelihood of complications will help to reduce the time limit of stay for these patients and thus the resource burden.

Methods: 46 patients undergoing renal biopsy at department of Nephrology, Jinnah Hospital were considered for this study. Renal biopsy was performed using a 16-gauge automatic core biopsy needle. After the biopsy, patients were closely monitored in the recovery room and after 1 hour, the biopsied kidney was examined by ultrasound. These patients were admitted and were kept under observation to assess any complications for next 23 hours.

Results: Of these 46 patients, 24 (52%) were males with mean age 39 (16 to 60 years). More than 3 cm hematoma was seen in 2 (4.3%) patients at 1 hour post biopsy ultrasound scan. Of these 2 patients, only 1(2%) patient had major complications including hypotension, decreased in hemoglobin etc. Thus 45 (97.8%) patients had uneventful recovery. Sensitivity of more than 3 cm hematoma formation at 1 hour post biopsy in predicting major complications was 100% with specificity of 97.7%.

Conclusions: Our study showed that the frequency of major complications was minimal in patients without >3 cm hematoma formation at one hour post-PRB. Post-PRB ultrasound is a non-invasive, accurate diagnostic tool in predicting procedure related major complications.

A Multidisciplinary Clinic for Children with Lupus Nephritis (LN) – A Step Towards Personalized Medicine?

J. Emory, D. Bland, S. Schoenfelder, J. Abedi, T. Rubinstein, H. Sabucedo, R. Zhang, Y. Huang, and D. Hayat. 1Pediatric Nephrology, Children’s Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY; 2Pediatric Rheumatology, Children’s Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY.

Background: Most children with SLE develop LN, which significantly worsens morbidity and mortality. Progression to ESRD occurs in 5-10%. Early diagnosis and treatment improve long-term outcomes, thus prompt evaluation is essential. Therefore, a combined pediatric nephrology/rheumatology clinic (LN Clinic) was started in 2013. The primary aim was to evaluate the number of days between onset of proteinuria (first-ami urine p/c >0.2) and performance of a renal biopsy (bx) for SLE patients (pts), pre- and post-establishment of the LN Clinic. We aimed for a 20% reduction in time to renal bx

Methods: Of these 46 patients, 24 (52%) were males with mean age 39 (16 to 60 years). More than 3 cm hematoma was seen in 2 (4.3%) patients at 1 hour post biopsy ultrasound scan. Of these 2 patients, only 1(2%) patient had major complications including hypotension, decreased in hemoglobin etc. Thus 45 (97.8%) patients had uneventful recovery. Sensitivity of more than 3 cm hematoma formation at 1 hour post biopsy in predicting major complications was 100% with specificity of 97.7%.

Conclusions: Our study showed that the frequency of major complications was minimal in patients without >3 cm hematoma formation at one hour post-PRB. Post-PRB ultrasound is a non-invasive, accurate diagnostic tool in predicting procedure related major complications.

SA-PO168

Antidepressant Efficacy and Safety Observations: USRDS ACTIVE-ADIPOSE Study

Nancy G. Kutner, Rebecca H. Zhang, Yijian Huang, C. Barrett Bowling. 1Temory Univ, Atlanta, GA; 2Atlanta VA Medical Ctr.

Background: Although depression is a prominent issue, depression management in advanced CKD and ESRD patients is not well understood. Antidepressants are the most frequent therapy, but efficacy and safety data are limited (Hedayaati et al. 2012).

Methods: The primary exposure of interest was use of antidepressant medications among 771 maintenance hemodialysis (MHD) patients ages 20-92 in 14 outpatient clinics who were enrolled 2009-2011 in the ACTIVE-ADIPose special study (median ESRD treatment 3.2 years). Gender distribution and ESRD etiology were similar to the overall MHD population, but the proportion non-white and younger than age 65 was higher in the study cohort. Medication efficacy was defined by participants’ scores (<18 vs. >18) on the Center for Epidemiologic Studies-Depression (CES-D) scale (Hedayaati et al. 2006). Adjusted odds for recent falls observed in association with antidepressant use and CES-D score provided an indicator of safety.

Results: Antidepressants were prescribed for 15% of study participants. 40% of those with prescribed antidepressants had an elevated CES-D score, suggesting lack of drug efficacy. Efficacy did not appear to vary by patients’ age or vintage, but more whites had elevated CES-D scores. Recent falls were more frequent among patients on antidepressants with elevated CES-D score (adjusted odds ratio 2.27 [1.05, 4.90]), p = 0.04, compared with patients not on antidepressants and CES-D score <18. Fall risk was similar across type of prescribed antidepressant (SSRI, atypical, and tricyclic drugs).

Conclusions: Efficacy of antidepressant medications was unclear for 40% of those with these drugs prescribed, and safety hazard was suggested by increased fall risk. Continued evaluation of nonpharmacologic as well as pharmacologic options for depression management in MHD patients, the focus of a current PCORI trial, is important.

SA-PO169

Sofosbuvir Use in Patients with Hepatitis C Virus Infection and Severe Chronic Kidney Disease

Alberto J. Sabucedo, Marie Essie Antoine, Delvis Jorge, Aileen Andreu, Fernando E. Pedraza, Maria Del Pilar Hernandez, Lennox Jeffers, Marco A. Ladino/Avellaneda. Dept of Medicine. Divs of Nephrology and Hepatology, Miami VA Medical Center/Univ of Miami, Miami, FL.

Background: Chronic hepatitis C virus (HCV) infection is a major health problem. The use of new direct acting antiviral (DAA) based regimens has been shown to provide a high sustained virologic response with less adverse reactions compared to interferon-ribavirin regimens. The American Association for Study of Liver Diseases recommends expert consultation on patients with eGFR less than 30 mL/min because safety and efficacy data are not available on these patient populations. We propose that these DAAAs are safe to use in patients with advanced kidney disease.

Methods: A total of 23 patients with HCV and estimated glomerular filtration rate (eGFR) less than 45 mL/min were treated with sofosbuvir and simprevir, dose of sofosbuvir to use in patients with advanced kidney disease. Chronic hepatitis C virus (HCV) infection is a major health problem. The use of new direct acting antiviral (DAA) based regimens has been shown to provide a high sustained virologic response with less adverse reactions compared to interferon-ribavirin regimens. The American Association for Study of Liver Diseases recommends expert consultation on patients with eGFR less than 30 mL/min because safety and efficacy data are not available on these patient populations. We propose that these DAAAs are safe to use in patients with advanced kidney disease.

Results: A cohort of 23 HCV positive patients had the following descriptive statistics, 20 males (87%) and 3 females (13%). 15 patients had Genotype 1a (65%), 7 patients had Genotype 1b (31%) and 1 patient had Genotype 2b (4%). 3 patients (13%) had End Stage Renal Disease (ESRD) and were on hemodialysis, 9 patients (39%) had Chronic Kidney Disease grade IV (CKD IV - eGFR <30 mL/min) and 11 patients (48%) had Chronic Kidney Disease grade IIIIB (CKD IIIIB - eGFR >< 45 mL/min) The HCV viral load of the 23 patients (100%) had a statistically significant decrease as the therapy progressed through completion with a statistically significant T-test with a p < 0.05. No side effects were present on the patients during DAA therapy. Patients with CKD grades IIIIB and IV on DAA treatment had a preserved kidney function by the end of therapy.

Conclusions: Efficacy of antidepressant medications was unclear for 40% of those with these drugs prescribed, and safety hazard was suggested by increased fall risk. Continued evaluation of nonpharmacologic as well as pharmacologic options for depression management in MHD patients, the focus of a current PCORI trial, is important.

Funding: NIDDK Support
Conclusions: Sofosbuvir is safe and effective in patients with Hepatitis C Virus infection and severe Chronic Kidney Disease, confirming its recent approval and close monitoring by Hepatology and nephrology services due to the lack of data in safety and efficacy.

SA-PO170
Exonuclease as Bridging Therapy in Veterans with Advanced Kidney Disease Chui L, Low Renae A. Minnema. Pharmacy, VA San Diego Healthcare system, San Diego, CA.

Background: Patients with CrCl <30 mL/min on anticoagulation require temporary bridging anticoagulants. Low-molecular weight heparins (LMWH) have longer half-lives and predictable anticoagulant effect but require anti-Xa monitoring in CKD. This study aims to evaluate the safety and efficacy of lovenox as a bridge therapy in patients with CrCl< 30 mL/min. 

Methods: A retrospective study was conducted from Jan 1, 2012 to Dec 1, 2014. Patients with CrCl < 30 mL/min, received enoxaparin 1 mg/kg as a bridge therapy to warfarin, and had at least one anti-Xa level checked were included in the study. Patients were excluded if they had major bleeding or thromboembolism in previous 3 months before enoxaparin, history of bleeding disorders, or used enoxaparin for other indications.

A dosing nomogram was used to guide dosage adjustment to keep anti-Xa levels within the target range (0.5-1.0 mcg/ml). The primary outcomes are # of minor/major bleeds and thromboembolic events. The proportion of anti-Xa levels within goal range was assessed. Descriptive statistics were used to compare outcomes to the literature.

Results: 12 patients met inclusion and exclusion criteria. The mean age was 62.4 ± 11.9 years, 91.7% were male, 58% were diabetic and 46% had congestive heart failure. 50% were on both warfarin and aspirin. The mean treatment duration of enoxaparin was 11.4 ± 6.4 days, the average CrCl was 17.6 ± 5.5 mL/min. A total of 19 anti-Xa levels were included for analyses. There were 2 (16.7%) bleeding events, 1 (8.3%) major and 1 (8.3%) minor bleed. None of the patients developed thromboembolic complications. The most common adverse event was bruising at the injection site that did not lead to any early discontinuations of therapy. Seven (49.4%) were within the target range.

Conclusions: Majority (83.3 %) of patients had minimal or no adverse events and none with thromboembolic outcomes. In patients with bleeds, no correlation was seen with the anti-Xa levels. The dosing protocol is effective, with 89.4 % of anti-Xa levels within goal range. The results have the support the safety and efficacy of the enoxaparin dosing protocol as a bridge therapy peripherally in patients with CKD.

Funding: Veterans Administration Support

SA-PO171
Thiopurine Methyltransferase (TPMT) Genotyping to Predict Myelosuppression Risk in Chinese Patients with Nephropathy Xuemei Li, Jie Ma. Nephrology, Peking Union Medical College Hospital, Beijing, China.

Background: Pharmacogenetic study in nephritis is mainly focused on genes involved in the metabolism of Azathioprine (AZA). Use of AZA is limited by its toxicity. Variants in the Thiopurine S-methyltransferase (TPMT) have been associated with AZA toxicity. The aim of this study was to determine the contribution of TPMT variants in the development of AZA-related myelosuppression in Chinese patients with nephropathy.

Methods: Variants associated with the decrease of enzyme activity in TPMT genes were genotyped in 4 nephritis patients treated with AZA, and correlated with the clinical response and development of adverse drug reactions in a retrospective case-control study. Three common mutation alleles of TPMT (TPMT* 3A (G460A/T179G), TPMT*3B (G460A), TPMT*3C (T179G)) were detected by polymerase chain reaction-high resolution melting and sequencing in 12 patients, included 4 patients with myelotoxicity and 8 patients without myelotoxicity.

Results: Genetic analysis showed only one of the 4 patients with myelotoxicity was detected TPMT*3C polymorphisms, no TPMT*2, *3A, *3B or *3C polymorphisms were detected in any of the 11 patients.

Conclusions: Single-nucleotide polymorphisms of TPMT could not explain the azathioprine-related adverse events.

SA-PO172
Lanthanum Carbonate-Induced Granulomatous Gastritis Francesco Iannuzzelli, 1 Loredana De Marco, 2 Sonia Pasquali. 1 Department of Internal Medicine, Nephrology and Dialysis Unit, Aretespedica Santa Maria Nuova, IRCCS, Reggio Emilia, Italy; 2 Department of Human Pathology, Aretespedica Santa Maria Nuova, IRCCS, Reggio Emilia.

Background: Long-standing non-calcium based phosphate binders administration has been recently associated with a number of different gastrointestinal lesions. We describe a rare case of lanthanum carbonate-induced granulomatous gastritis.

Methods: A 58-year-old woman was admitted to our hospital because of nausea, vomiting, weight loss. Because of a well-known stage 3 chronic kidney disease, she was started on peritoneal dialysis. About one month later, CAPD was well-tolerated with an adequate dialysis dose. Nevertheless, she continued to complain of nausea, vomiting and dyspepsia. A gastroscopy revealed chronic gastritis with superficial erosions and an histopathology consisting of non-necrotizing, sardoid-like granulomas with aggregates of multinucleated giant cells. Orange cristalloid material was seen within granulomas. Special stains for fungi and mycobacteria were negative. Her previous medical history was only significant for hypertension and type 2 diabetes mellitus. Physical examination was unremarkable. A chest X-ray was normal. A tuberculin skin test was negative. ANCA titers were negative and serum angiotensin converting enzyme (ACE) level was in the laboratory reference range. At the time of our evaluation, she had been receiving lanthanum carbonate 1 g bid for about 6 months.

Conclusions: At the best of our knowledge, so far, only 7 cases have been described in the literature.

The histopathologic picture in our patient was compatible with a lanthanum carbonate-induced gastritis with some peculiar characteristics: a granulomatous reaction and the appearance of lanthanum carbonate crystals not only within histiocytes/multinucleated giant cells but also inside the cytoplasm of the epithelial glandular cells.

SA-PO173
Relative Incidence of Adverse Events with Ferumoxytol versus Other Intravenous Iron Products in Non-Dialysis-Dependent Chronic Kidney Disease Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.

Background: All intravenous (IV) iron products confer risk of hypersensitivity reaction (HSR). The relative safety of ferumoxytol versus other IV iron products is not established. We used Medicare claims to assess relative safety of ferumoxytol versus other IV iron products in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: We analyzed a 20% sample of Medicare Parts A and B claims in 2009-2012. Patients received a first dose of IV iron between Jan 1, 2010, and Nov 30, 2012, and had diagnosed NDD-CKD without IV iron treatment during the 1 year before first dose. For each ferumoxytol user, we identified 1 propensity score-matched control who used another IV iron product, the score included demographics, comorbidity, and concomitant IV medication. Patients were followed until change in IV iron product, end stage renal disease, death, or Dec 15, 2012. With Cox regression stratified by matched pair and cumulative number of prior IV iron doses, we assessed relative incidence of anaphylaxis, HSR symptoms, serious anaphylaxis, emergency room (ER) visit, hospitalization, and death within 1 day of first dose and within 1 day of each subsequent dose.

Results: We identified 7358 ferumoxytol users and 7358 matched controls. Baseline characteristics were balanced across groups. There were too few cases of anaphylaxis and death to permit comparisons. However, after first dose, hazard ratios (ferumoxytol users vs. matched controls) were 0.90 (95% confidence interval, 0.80-1.01) for HSR symptoms, 1.06 (0.66-1.72) for hypotension, 0.72 (0.55-0.94) for ER visit, and 0.78 (0.60-1.02) for hospitalization. After subsequent doses, corresponding hazard ratios were 1.07 (0.90-1.27) for HSR symptoms, 0.91 (0.80-1.07) for hypotension, and 0.86 (0.64-1.15) for ER visit, and 0.97 (0.70-1.35) for hospitalization.

Conclusions: Relative to other IV iron products, ferumoxytol was not associated with excess risk of adverse events in NDD-CKD patients, following both first dose and subsequent doses. The incidence of anaphylaxis and death was very low in ferumoxytol users and matched controls.

SA-PO174
Efficacy, Safety and Pill Burden of Sucroferric Oxydroxide, an Iron-Based Phosphate Binder, Over 52 Weeks in African American Dialysis Patients Stuart M. Sprague, 1 Anjay Rastogi, 2 Markus Ketteler, 1 Adrian C. Covic, 1 Jürgen Floege, 1 Viatcheslav Rakov, 4 Elera Armando Samuels. 1 NorthShore Univ Health System, Chicago; 2 Univ of California; 3 Cleveland Clinic & KHI-Dialysis Center, Germany; 4 Gr T. Popa University of Medicine and Pharmacy, Romania; 5 RWTH Univ Hospital Aachen, Germany; 6 Vifor Pharma; 7 Temple Univ, Philadelphia.

Background: A post hoc analysis of data from a randomized, open-label, Phase 3 study and its extension investigated the efficacy and safety of the iron-based phosphate binder sucroferric oxyhydroxide (SFOH; VELPHOR®) vs sevelamer carbonate (SEV; Renuvel®) in African American dialysis patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

664A
**Methods:** Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks’ dose titration then 12 weeks’ maintenance. Eligible patients enrolled in a 28-week extension study.

**Results:** Of the 549 patients who completed the extension study, 100 were African American patients, equally distributed between the treatment groups despite the 2:1 randomization (n=48, SFOH; n=52, SEV). Serum phosphorus decreased rapidly and to a similar extent with SFOH and SEV, and remained relatively constant thereafter (Table). Mean ± standard deviation number of tablets/day was lower for SFOH (3.4 ± 1.35) vs SEV (7.6 ± 2.92) over 52 weeks. The incidence of serious or severe treatment emergent adverse events and deaths were similar in both treatment groups. Gastrointestinal-related disorders were the most frequently observed adverse events for SFOH and SEV.

**Conclusions:** SFOH efficacy was maintained long-term, with a lower pill burden than SEV and similar safety profile, in African American dialysis patients. **Post hoc** results reflect those from the overall study population.

**Intergated Dialysis Unit Module and Module Compartment Structure**

**Background:** Conventional set-up of hemodialysis (HD) center requires intensive manpower and tedious workload due to the intricate fluid and electricity layouts, and the fixed partitions structure. It is vital to design an integrated module considering rapid manpower and tedious workload due to the intricate fluid and electricity layouts, and time-series studies were completed in 50 and 28 randomly selected HD patients, respectively. Multi-trait multi-method scale and time-series studies were completed in 50 and 28 randomly selected HD patients, respectively.

**Methods:** The Integrated Dialysis Partition System was designed for HD center. To ensure patient privacy, an easy-assembled partitions with a herringbone seating arrangement was used to position the HD seats partially and equally askew in one direction. The mobile modules of fluid pipes and electricity lines allow easy access for routine maintenance. Eighty uremic patients were enrolled to examine the differences between conventional and new HD unit in terms of psychological adjustment including depression, anxiety, mood, and illness intrusiveness.

**Results:** The state-of-the-art HD center with 40 seats could be established within one day.

**Conclusions:** The integrated dialysis unit module allows for rapid assembly, easy pipeline maintenance, and improved patients’ quality of life.

**Funding:** Pharmaceutical Company Support - Vifor Pharma

**SA-PO176**

**Safety and Adherence in End Stage Renal Disease Patients on Chronic Hemodialysis**

**Background:** Missed hemodialysis and abbreviated hemodialysis sessions are common in end stage renal disease patients on maintenance hemodialysis. Dialysis non-adherence has been associated with increased mortality and morbidity in chronic hemodialysis patients. Our quality assessment performance improvement data revealed that on an average 15% of patients missed and abbreviated hemodialysis (HD) sessions over a period of 6 months.

**Methods:** We evaluated patients’ perception about missed and abbreviated sessions, and safety during HD sessions at our dialysis center. A questionnaire regarding patients’ views about missed, abbreviated and safe hemodialysis sessions using a visual analog scale (0-100 mm, where 0 means ‘No’ and 100 means ‘Yes’) was conducted in-person by a nephrology fellow or a social worker on all HD patients. Data are presented as mean ± standard deviation (SD).

**Results:** Ninety patients participated in the survey. Sixty eight (75.6%) patients with a mean score of 78±29.6 felt like coming for their HD sessions during the last one month. Fifteen of 89 (16.9%) did not know why they came for HD sessions. Twenty two percent came because they wanted to live while 18% came because they did not want to die. Eighty nine (98.9%) patients with a mean score of 94.5±17.3 felt safe during the HD sessions. Seventeen (18.8%) patients indicated missing the HD sessions. Thirty six of 83 (43.4%) patients with a mean score of 71±37.6 wanted to miss HD sessions during the last one month. Fifteen of 89 (16.9%) signed against medical advice for the abbreviated HD sessions during the last one month.

**Conclusions:** Data suggest that safety of HD sessions does not appear to be a factor for missing HD sessions. Lack of patients’ understanding of importance of HD treatments as well as lack of adherence likely leads to non-adherence and abbreviation to HD sessions. The safety of HD treatment was not the core issue behind increasing patients’ absenteeism. Active patients’ participation and individualization of HD sessions may improve adherence to HD sessions.

**SA-PO177**

**Validation of a Tool to Assess Nursing Workload in Hemodialysis**

**Background:** Patient classification scales (PCS) to assess nursing workload predict staffing needs and facilitate transparency in assignments resulting in improved work environment, patient safety and quality of care. Few validated PCS tools exist for hemodialysis (HD). This study validates a point-of-care PCS developed for in-centre HD at a Canadian tertiary care centre.

**Methods:** Using LEAN framework, from Sept 1, 2013 to Mar 1, 2014 at the Health Sciences Centre in Winnipeg, Canada, iterative consultations with stakeholders resulted in creation of a PCS consisting of 9 domains and 67 subdomains. At each HD session between April 7-21, 2014, bedside HD nurses completed both a visual analogue scale (VAS), which assessed general level of nursing care required, and the PCS tool. Karnofsky scale and time-series studies were completed in 50 and 28 randomly selected HD patients, respectively. Analysis: Internal consistency and reliability were assessed using Cronbach’s alpha and Intraclass Correlation Coefficient (ICC), respectively. Multi-trait multi-method analysis (MTMM) determined item homogeneity. Spearman’s correlation of PCS with VAS, Karnofsky score and time-series studies assessed criterion and predictive validity. Linear regression was performed to determine the association of each subdomain with PCS score.

**Conclusions:** Preliminary results suggest excellent reliability and validity of this PCS tool. Validation studies at other HD centres with expanded time-series and reliability studies continue.
Feasibility of a Hemodialysis Safety Checklist for Nurses and Patients

Samuel A. Silver, Alison Thomas, Andrea Rathe, Pamela L. Robinson, Ron Wald, Chaim Bell, Ziv Harel. Nephrology, St. Michael's Hosp, Toronto, ON, Canada; Medicine, Mt.Sinai Hosp, Toronto, ON, Canada.

Background: In 4% of ESRD patient deaths, the cause of death is a result of a preventable hemodialysis complication. These include errors related to communication, organization and human factors. We recently developed a hemodialysis safety checklist (Hemo Pause) to be completed by nurses and patients at specified intervals throughout a hemodialysis session, with the goal to improve dialysis unit safety culture. Our objective was to determine the feasibility of using Hemo Pause during every hemodialysis session for 3 months.

Methods: We conducted a single-center, prospective time series study. A convenience sample of 14 nurses and 22 prevalent in-center hemodialysis patients participated. All participants were trained in the administration of Hemo Pause, completed the checklist at every hemodialysis session for 3 months and were free to suggest checklist modifications consistent with quality improvement methodology. The primary outcome was Hemo Pause completion, which was determined weekly using the percentage of checklists in the patient chart with all 17 items assessed. We also measured Hemo Pause acceptability using local patient safety surveys.

Results: There were 799 hemodialysis treatments pre-intervention and 757 post-intervention. The checklist was completed for 556 of 757 (73%) treatments. The most common reasons for non-completion were the availability of nursing staff trained in Hemo Pause and patient admission to hospital. Among hemodialysis nurses, 93% (15/16) agreed that Hemo Pause was easy to use and 79% (11/14) agreed it should be expanded to other patients. Among hemodialysis patients, 73% (16/22) agreed that Hemo Pause made them feel safer and should be expanded to other patients. Negative comments by nurses or patients occurred on 4% (7/200) of survey responses.

Conclusions: A hemodialysis safety checklist (Hemo Pause) was acceptable to both nurses and patients over a 3 month period. Our next step is to spread Hemo Pause locally and conduct a mixed methods study to determine mechanisms by which Hemo Pause may improve safety culture, patient engagement, and reduce adverse events.

Community-Based Parenteral Anti-Infective Therapy (COPAT) for ESRD Patients

Evamaría Anvari, Reza Anvari, Laura Ferreira Provenzano, Juan C. Calle. Nephrology, Cleveland Clinic Foundation, Cleveland, OH.

Background: Infections are the leading cause of hospital admissions for patients with ESRD. The majority will need to continue antimicrobial therapy when discharged. Community-based parenteral anti-infective therapy (COPAT) refers to the practice of administering antimicrobial therapy in the outpatient setting. It requires a multidisciplinary intervention. Occurred on 4% (7/200) of survey responses.

Methods: We investigated the policies from the main dialysis providers in our area. We discovered that COPAT is not common in our setting.

Results: Among hemodialysis nurses, 93% (16/16) agreed that Hemo Pause made them feel safer and should be expanded to other patients. Negative comments by nurses or patients occurred on 4% (7/200) of survey responses.

Conclusions: A hemodialysis safety checklist (Hemo Pause) was acceptable to both nurses and patients over a 3 month period. Our next step is to spread Hemo Pause locally and conduct a mixed methods study to determine mechanisms by which Hemo Pause may improve safety culture, patient engagement, and reduce adverse events.

Improving Emergency Room (ER) to Dialysis Flow in a Busy Inner City ER

Anjali Rayman, Todd Mcclinton, Raymon Mcclinton, Naheed Ansari, Bonnie Carnes.

Background: Delays in access to hemodialysis during hospitalization are not uncommon and negatively impact on quality of patient care and lead to avoidable complications and unnecessary hospitalizations. Triple Aim is a sought after goal for health organizations to optimize health system performance. We hoped to target one of the three components which is to improve the experience of care.

Methods: The objective was to ensure initiation of dialysis for all non-emergent patients within four hours of ER triage. We analyzed retrospectively in a 8 week observation period, Electronic Medical Record (EMR) data on all hemodialysis patients >18 years of age presenting to the ER, with emphasis on time from triage to initiation of dialysis (TID). We also analyzed factors contributing to delays in dialysis initiation. Data were collected daily on each patient and tabulated weekly. We instituted two measures to address the obstacles.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

166A
These were i) educating the ER staff about timeliness of informing the renal team and ii) the second was to institute a tracking system to systematically gather detailed data on patient transport metrics such a time to patient pick up from initial contact with the transport office.

**Results:** Baseline data revealed average TID from triage was 8 hours. Two major contributory factors identified were late notification by ER to renal team and delays in transport. By instituting measures targeting these, we were able to achieve being able to provide dialysis within 4 hours of triage in over 80% of our non-urgent hemodialysis patients.

**Conclusions:** We were able to improve the patient experience and care with simple measures. This has a positive impact on patient safety by minimizing late treatments and staff fatigue. Though Triple Aim is a goal at the population and health care delivery level, we believe processes can be implemented at a local level that align with the CMS goals of triple aim. In today’s environment it is incumbent upon us to make efforts to innovate for better patient care and to minimize health care costs.

**SA-PO183**

**Quality Improvement Project in Dialysis: Improving Access to Dialysis for Patients Presenting to the Emergency Room (ER)**

Nikulkumar Chaudhari,1 Bonnie Carnes,2 Cherrylly Moore,3 Roshni Upputalla, Parikshit Thakur,4 Naheed Ansari,5 Anjali Acharya,1 Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; 2Nephrology, Atlantic Dialysis, Queens, NY.

**Background:** Hemodialysis patients presenting to the emergency room are a vulnerable patient population. Majority of them have significant comorbid conditions. Delays in evaluation and institution of dialysis are common in busy emergency rooms. We undertook a project to improve quality of patient care as well as the patient experience with a goal to provide timely dialysis.

**Methods:** We analyzed baseline data from electronic medical record (EMR) pertaining to all hemodialysis patients presenting to the ER in a specified 8 week period. After period, within the team we identified a few factors that were seen as obstacles in providing timely dialysis. One of them was the time from patient triage to notification of the renal team. We instituted an educational program with the ER staff with focus on the timeliness of informing the renal team, establishing “triage to renal team notification time” of less than 30 minutes as a meaningful metric. Data was collected at pre and post intervention. The objective was to meet this goal >80% of the time over the 2 month intervention period.

**Results:** There was a positive impact on the triage to renal notification time. The percentage of timely notifications as defined, rose to >85% from a baseline of <25% and this effect was sustained over the 8 weeks. Most patient notifications happened within 10 minutes of triage.

**Conclusions:** A simple intervention on educating the ER staff made a significant impact on timely evaluation of dialysis patients presenting to the ER. There was an observable positive impact on patient experience. We view this as a simple first step in optimizing patient care and experience towards a seamless journey through the hospitalization. Simple innovative steps such as this could contribute to cost control by avoiding/minimizing dialysis treatments during off hours. In addition it could help mitigate staff fatigue and treatment errors thus improving patient safety.

**SA-PO184**

**Diagnostic Reference Values for Cerebrospinal Fluid May Not Be Useful in Haemodialysis Patients Suspected of Having Central Nervous System Infection**

Thomas Oates,1 Damien Ashby. Imperial NHS Trust, London, United Kingdom.

**Background:** Invasive investigations in haemodialysis (HD) patients can be associated with complications due to bleeding, and standard diagnostic tests, such as pleural fluid biochemistry, have been shown to be of limited value in this patient group. As a result, we examined the utility of cerebrospinal fluid (CSF) analysis in HD patients suspected of central nervous system (CNS) infection.

**Methods:** We used electronic records to retrospectively examine laboratory data from HD patients who had CSF analysis in a 5 year period. All patients were initially suspected of having a CNS infection based on relevant culture and polymerase chain reaction tests ultimately proved negative for bacterial, mycobacterial, fungal or viral infections in all cases.

**Results:** 30 CSF samples from 29 patients were identified in the study period. CSF protein concentration was available for 16 samples (median 0.40g/L, range 0.19-1.06g/L, corrected for number of red cells in sample) and paired CSF and plasma glucose concentrations, allowing calculation of CSF:serum glucose ratio, for 25 samples (median ratio 0.58, range 0.21-1.40). Using the accepted normal CSF protein concentration of 0.23 to 0.38 g/L (see Figure shaded region), 8 out of 16 samples showed an elevated protein concentration suggesting CNS infection. Additionally, 13 out of 25 samples had a CSF:serum glucose ratio of less than the normal value of 0.6 (see Figure horizontal line) which is also suggestive of CNS infection.

**Conclusions:** CSF biochemistry is frequently used in the diagnosis of CNS infection. Our preliminary results suggest CSF protein and glucose concentrations should be interpreted with caution in HD patients and may not add diagnostic information in suspected CNS infection. We are currently investigating the hypothesis that CSF biochemistry may be influenced by duration of chronic kidney disease and HD vintage.

**Continuous Renal Replacement Therapy (CRRT) and Hypoglycemia: A Retrospective Study on Patients Undergoing CRRT and Development of Hypoglycemia in Diabetic and Non-Diabetic Individuals**

Mamtha Ball,1 Adam Lyons,1 Mary C. Naglak,1 Doron Schneider,1 Robert A. Sirot,2 Internal Medicine, Abington Jefferson Health, Willow Grove, PA; 2HTN Nephrology Associates, Abington Jefferson Health, Willow Grove, PA.

**Background:** Hypoglycemia is a little known complication of CRRT. There are no studies available to evaluate the prevalence or intensity of hypoglycemia during CRRT. This study attempts to determine the frequency, timing, and severity of hypoglycemia as a complication of CRRT in diabetic and non-diabetic patients in the intensive care unit.

**Methods:** This was a retrospective observational study to assess the effect of CRRT on plasma glucose in diabetic and non-diabetic individuals who were admitted to Abington Jefferson Health. A chart review was used to complete a detailed data collection form for patients who underwent CRRT for several diagnosis (sepsis, medication overdose, acute renal failure) in 2013 and 2014 who met the selection criteria. Hypoglycemia is defined as Blood sugar less than 70mg/dL. Dialysate contained 100mg/dL glucose.

**Results:** After reviewing the charts for 218 CRRT events in 119 patients admitted to Abington Jefferson Health, 100 patients were studied based on selection criteria. The mean age of the study population was 66.3 ± 15.3 years. Thirty-six of the 100 patients studied had hypoglycemia during CRRT. The number of episodes was as follows: 14/36 (38.9%) had one episode, 7/36 (19.4%) had three and 5/36 (13.9%) had five episodes (mean number of episodes was 2.7±1.9). Hypoglycemia occurred on average 9.9±6.1 hours from start of CRRT. Patients who had hypoglycemia during CRRT were more likely to have it again after CRRT (53%; 19/36) (p=0.0005). Of the 36 patients with hypoglycemia, 78% (28/36) had sepsis vs. 22% (8/36) who did not have sepsis but had hypoglycemia (p=0.05). No association was found between development of hypoglycemia and history of diabetes and CKD.

**Conclusions:** Our study showed that hypoglycemia is a frequent complication during CRRT. In order to prevent hypoglycemia from being under-recognized protocols including frequent blood glucose monitoring during CRRT should be in place.

**SA-PO186**

**The Safety of Intravenous Hydration for the Prevention of Contrast Induced Nephropathy**

Yvonne R.P. de Waal,1 Corinne E.A. Balemans,2 Marc A.G.J. Ten Dam,2 Louis J.M. Reichert,2 Jack F. Wetzel.1 Nephrology, Radboud University Medical Center, Nijmegen, Netherlands; 2Nephrology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; 3Nephrology, Rijnstate Hospital, Arnhem, Netherlands.

**Background:** Contrast-induced nephropathy (CIN) is associated with marked morbidity and mortality. To prevent CIN, current guidelines advise intravenous hydration in high risk patients. Thus far, the possible side effects of hydration have received little attention. We evaluated the incidence of (serious) adverse events (SAEs) after intravenous hydration.

**Methods:** In a retrospective study we analyzed the incidence of (SAEs) after intravenous hydration in two Dutch hospitals. In one hospital (Rijnstate Hospital Arnhem) we evaluated all SAEs related to hydration. In the other hospital (CWZ Nijmegen) the analysis was limited to SAEs, i.e. those necessitating prolonged hospital stay. Patient and outcome characteristics were retrieved from the hospital records.

**Results:** In the Rijnstate Hospital Arnhem we evaluated 233 records of patients hydrated in the period from February till July 2013. AE’s occurred in 18 patients (8%). The most common AE was overhydration, which occurred in 11 patients (5%) and necessitated

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
prolonged hospitalisation in 4 (2%). Admission to the coronary care unit was needed in one patient. Almost all patients with overhydration (91%) had pre-existent cardiac disease and used diuretics. Infusion related AEs also occurred, like extravasation and phlebitis, in one case leading to S. Aureus bacteremia. In the CWZ Nijmegen we evaluated 257 medical records of patients hydrated from May 2013 till January 2014. Prolonged hospitalisation due to overhydration was necessary in 10 patients (4%).

**Conclusions:** Our study demonstrates that overhydration is a common adverse event after intravenous hydration and necessitates prolonged hospital stay in 2-4% of these patients. These data provide arguments against routine hydration in patients with moderate increased risk of CIN. Patients with pre-existent cardiac disease are most prone to overhydration; however, these patients are also at highest risk for the development of CIN. Risk and benefits must be weighed when choosing strategies to prevent CIN.

**SA-PO187**

**Cystatin C in Predicting Cardiorenal Syndrome Type 1 and Mortality in Patients with Acutely Decompensated Heart Failure with Preserved Renal Function**

Carlos Federico Varela, 1 Ivan Constantin, 2 Gustavo Cristian Grenoli, 3 Griselda Bratti, 4 German Barrera Hugalde, 5 Cesar Belziti, 6 Rodolfo Pizarro, 7 Guillermo Javier Rosa diez. 8 9Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 10Cardiology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

**Background:** Cardiorenal Syndrome type 1 (CRS 1) is defined as a worsening renal function that complicates acutely decompensated heart failure (ADHF). These patients experience higher mortality and morbidity. Serum creatinine (SC) is slow to reflect changes in kidney function. Cystatin C (CysC) has emerged as a novel biomarker with a stronger correlation with cardiovascular disease than SC. The aim of our study was to evaluate Cys C in predicting CRS 1 and outcomes in patients admitted with ADHF and preserved renal function.

**Methods:** We conducted an observational and prospective study. We included patients above 18-years old with ADHF with preserved renal function defined as a SC below 1.3 mg/dL. We excluded patients with heart valvular disease and acute coronary syndrome. Cys C blood samples were collected on admission. We defined CRS 1 as a rise in creatinine by 0.3 mg/dL or more during five days.

**Results:** 166 patients aging 85 median (IQR 77-89) years old were enrolled. The incidence of CRS 1 was 29.7%, with an in-hospital mortality of 3.1%, and a total mortality (TM) of 24.4%. The median follow-up was 193 days. Cys C was significantly higher in patients with CRS 1 compared to those without (1.72±0.58 vs 1.51±0.41; p=0.03) and predict TM but did not predict in-hospital mortality (1.69±1.57±0.48; p=0.58) or readmission (1.47±0.4 vs 1.6±0.5; p=0.58). In the multivariable analysis Cys C was an independent predictor of mortality (OR 3.31 CI 1.38-7.93) while SC at admission was not (OR 0.48 CI 0.05-3.48). The area under the receiver-operating characteristic curve of Cys C for CRS 1 was 0.60 and for TM was 0.65. The best cutoff value was 1.6 mg/dL for both end points. It had a sensitivity and specificity of 61.2 % and 60.3 % for CRS 1, and 61.5 % and 62 % for TM, respectively.

**Conclusions:** Above a cut-off value of 1.6 mg/dL, Cys C predicts CRS 1 and mortality in patients admitted with ADHF with preserved renal function.

**SA-PO188**

**Is Cystatin C a Better Biomarker of AKI in ICU to Compare NGAL?**

Itir Yegenag, Fatih Kamis. Internal Medicine, Kocaeli Univ Medical School, Kocaeli, Izmit, Turkey.

**Background:** Serum creatinine levels can be affected with many variable factors. We concluded that better bio-marker is needed to recognize AKI as early as possible. We studied Cystatin C (CysC) and Neutrophyl Gelatinase Associated Lipocalin (NGAL) in ICU patients to determine which is more predictable.

**Methods:** Hundred and eighty three (85 male; mean age: 65) critically ill patient with no previous chronic renal failure history were included to this study. Clinical, laboratory evaluations were noted and blood was taken in 48 hours for CysC and NGAL and followed for 7 days, if they meet the RIFLE criteria.

**Results:** CysC and NGAL values for every stages RIFLE and serum CysC value were significant only for RIFLE-L stages (p=0.25) but not urinary CysC. NGAL in serum and also in urine were significantly different in RIFLE-L. Biomarkers were compared when fulfilled the RIFLE criteria in first 48 hour and following 3-7 days to non-AKI values.

**Conclusions:** In our cohort NGAL obtained in 48 hours is more predictable biomarker than CysC for early AKI diagnosis following 7 days. But CysC levels were fairly predictive for mortality.

**SA-PO189**

**The Effect of Point of Care (POC) Creatinine/eGFR Measurement on the Incidence of Contrast-Induced Acute Kidney Injury (CI-AKI) following Primary Percutaneous Coronary Intervention (PPCI) for the Treatment of ST Elevation Myocardial Infarction (STEMI)**

**Background:** Contrast-induced acute kidney injury (CI-AKI) is a predictor of mortality, morbidity and length of hospital stay. During STEMI treatment with primary percutaneous coronary intervention (PPCI) there are a number of predictors of AKI including existing renal dysfunction (eGFR < 60) and contrast volume used.

**Methods:** A retrospective audit over 6 months at the Essex Cardiothoracic Centre identified 348 patients who had presented with STEMI and had PPCI. These patients formed the standard care group. Prospectively 131 consecutive patients presenting with STEMI and under-going PPCI had a point of care creatinine measurement (STATSENSOR, Nova Biomedical). A comparison in rates of AKI was made between the two groups.

**Results:** In the standard care group, 9.7% of patients with normal renal function and 26.6% of patients with impaired renal function developed AKI. When creatinine was measured pre-PPCI, 8% of patients with normal renal function and 16.1% of patients with renal impairment developed AKI; a 39.5% reduction in AKI in those with renal dysfunction in the POC creatinine group. The average contrast volume in the standard care group was 159 ml, compared to 117.5ml when renal function was found to be impaired (eGFR < 60) pre-PPCI. 186ml was used on average in the POC group when creatinine was found to be normal.
Conclusions: Measuring the POC creatinine of 131 patients presenting with STEMI and undergoing PCI reduces the rates of AKI by 39.5% in those with renal dysfunction. This appears to be mediated in part by a reduction in contrast volume in those patients identified with renal dysfunction (117.5 ml) compared to normal renal function (186 ml).

Serum Creatinine Variability Predicts Progression to CKD4

Carlos E. Palant,1,2 Lakhmir S. Chawla,1,2 Ping Li,1,2 Paul L. Kimmel,1,2 Charles Faselis,2,1 Richard Amundr,1,2 1 Medicine, Washington DC VA Medical Center, Washington, DC; 2 Medicine, George Washington Univ Medical School, Washington, DC; 1 NIDDK, National Insts of Health, Bethesda, MD.

Background: Pre-dialysis patients have high serum creatinine (SC) variability. SC variability is associated with high death rates. We examined the association between SC variability and CKD progression in a large cohort of US veterans with a wide range of baseline eGFR.

Methods: VA patients admitted 10/1999 - 12/2005 with at least 4 months with SC and initial eGFR>30 ml/min/1.73 m2 (using CKD-EPI) were selected. Autoregression-based slope was computed for each patient using monthly peak SC. SC variability was root mean-square residual of peak SC readings from the regression line. CKD4-date was the first date when eGFR permanently fell below 30 m/min/1.73 m2. Logistic regression was used to predict CKD4 using: initial SCGFR, SC variability, SC slope; age, race, months with SC readings, and comorbidities (DM, CAD, PNE, MI, angina, AKI, COPD, CHF). Kaplan-Meier (KM) analysis was used to examine time from first admission to entry into CKD4, stratified by SC variability quartile and baseline eGFR, and Cox regression was used to adjust survival estimates for the covariates above.

Results: Of 342,066 patients, 36,108 (10.6%) reached CKD4. The logistic model had strong prediction accuracy (c=94) with sensitivity and specificity both 86. SC variability was strongly associated with entry into CKD4 (adjusted OR 3.79 [3.67-3.91], p<0.001). Time to CKD4 differed by level of SC variability in KM (p<.0001; Figure) and Cox (HR was strongly associated with entry into CKD4 (adjusted OR 3.79 [3.67-3.91], p<.001).

Conclusions: SC variability is strongly independently associated with rate of decline in renal function, at all baseline eGFR levels, after accounting for covariates, and is an important risk factor for entry into CKD4.

Assessment of Methods Used to Substitute for Missing Preadmission Creatinine Values in the Diagnosis and Staging of Acute Kidney Injury

Amelie Bernier-Jean,1,2 Anatolie Duca,1,2 Francois Madore,1,2 Remi Goupil,1,2 Stephan Troyanov,1 Josee Bouchard.1,2 Nephrology, Hospital du Sacre-Coeur de Montreal, Canada.

Background: Missing preadmission serum creatinine values (SCV) are a common obstacle to the diagnosis and staging of acute kidney injury (AKI). As a workaround, the KDIGO guidelines suggest using a baseline SCV computed from the MDRD formula assuming a baseline estimated glomerular filtration rate (eGFR) of 75 ml/min per 1.73m2. We hypothesized that surrogates for preadmission SCV will misclassify AKI incidence and severity when compared to a known preadmission SCV.

Methods: Over a 12-month period, we performed a retrospective single-center study of critically ill patients with known preadmission SCV to identify the most accurate method to estimate baseline SCV for AKI diagnosis and staging (KDIGO criteria). We assessed three surrogate methods: 1) the first hospital admission SCV, 2) the minimal SCV after ICU admission and 3) SCV computed for a eGFR of 75 ml/min per 1.73 m2 using MDRD.

Results: Of 1001 randomly selected patients, a preadmission SCV was available for 498 and 14 were excluded for requiring acute renal replacement therapy. Median age was 65 (IQR 58-76), 60% were male and 98% were Caucasian or Asian. The median time between SCV measurement and admission was 116 (IQR 78-179) days. AKI incidence according to preadmission SCV was 24.8%. We reported in table 1 the AKI incidence, sensitivity, specificity and kappa values for each surrogate method.

For AKI staging, we found the following kappa values: 0.75 using the first SCV upon admission, 0.43 using the minimal SCV, and 0.66 using the computed MDRD eGFR of 75ml/min/1.73m2.

Conclusions: In our cohort, the MDRD computed SCV for a eGFR of 75ml/min per 1.73 m2 was the best surrogate method for diagnosing AKI. Using the minimal SCV significantly overestimated the incidence of AKI. Concerning AKI staging, the first hospital admission SCV was the most accurate method.

SA-PO192

Fluid Balance and Oliguria in Early AKI Diagnosis After Liver Transplant

Camila Lima1,2, Luciana Haddad1,2, Luiz M. Malbouisson1,2, Luiz Augusto Carneiro1,2, Etienne Macedo1,2, 1 Nephrology, Univ of Sao Paulo, Brazil, 2 Gastrointestinal Surgery, Univ of Sao Paulo, Brazil, 3 Anesthesiology, Univ of Sao Paulo, Brazil.

Background: AKI is a frequent complication of liver transplant (LT), associated with increased morbidity and mortality. Early diagnosis can translate into secondary preventive measures and improve outcomes. We hypothesized that adjusting Scr for positive fluid balance (FB) and applying urine output(UO) criterion would improve timing of AKI diagnosis. In addition, we investigate whereas sequential assessment of urinary biochemistry after LT can improve prediction of early post-operative AKI development.

Methods: In a prospective cohort study, we recorded UO, FB and labs of patients undergoing LT. We assessed urine and blood biochemistry peripheric (before induction of anesthesia, after portal reperfusion, 6, 18, 24 hours after surgery). AKI diagnosis was based on UO and the Scr KDIGO criterion before and after correcting scr for FB (FB adjusted, using the formula: (weight*0.6)/(FB/weight*0.6).

Results: Fifty-five patients >18 years undergoing LT from Jun13 to Oct14 were included in the analysis. Twenty-seven percent (15) of patients developed AKI based on Scr criterion within 72h after surgery (early AKI). By adjusting Scr for fluid balance 38%(21) patients were classified as early AKI. Applying the UO criterion, 43 patients were classified exclusively by this criterion as early AKI. All patient showed a decline in FeNa and the FeU after portal reperfusion. Patients developing early AKI had a higher decline and maintained lower levels for 24h. FeU/reva values were significantly different 6 hours after surgery in early AKI patients. Patients with early AKI based on both criteria or exclusively by UO had a higher mortality and longer ICU and hospital stay than non-AKI patients.

Conclusions: Applying UO criteria and adjusting Scr for FB can help in the early identification of patients developing AKI after liver transplant. Tubular function assessment could be utilized along with biomarkers of kidney injury to identify patients with increased risk of developing AKI. Standardized approach for early AKI diagnosis in high-risk patients could improve outcomes.

SA-PO193

Renal Angina Index a Practical Tool to Identify Patients at Increased Risk of Acute Kidney Injury

Rolando Claro-Del Granado1, Andrea Pero1, Josec Bouchard,2 Ravindra L. Mehta3. 1IBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; 2Hospital do Sacre-Coeur de Montreal, Canada; 3Univ of California San Diego Medical Center.

Background: Reliable prediction of acute kidney injury (AKI) has the potential to optimize treatment. Recently Goldstein SL et al. proposed an empiric clinical model of renal angina using patient demographic factors and early signs of injury to identify critically-ill children who would be at higher risk of AKI. We test the hypotheses that in a cohort of adult critically-ill patients, a modified renal angina index (RAI) will identify patients at high risk of developing AKI, and could be related to in-hospital mortality.

Methods: We included 124 consecutive patients admitted to our medical ICU. We measured serum creatinine (scr) every 24 h for 7 consecutive days after ICU admission. AKI was defined as a 50% increase in S.C. (using KDIGO criteria). AKI was defined using the following formula: Risk level (vasopressors and invasive mechanical ventilation = 5; diabetes mellitus = 3; and sepsis = 1) X Injury level (decreases in eGFR: no change=1, 0-24.9%=2, 25-49.9%=3, and ≥50%=4). The composite range of the RAI is therefore: 1, 2, 3, 4, 5, 6, 8, 10, 12, 20, 24, 40. We analyzed the value of a RAI score ≥8 to predict subsequent AKI (after 48 h, day 3) and survival.

Results: We identified 50(40.3%) patients with AKI (KDIGO guidelines scr criteria), and 74(59.7%) patients who did not develop AKI. Patients with a RAI ≥8 were at higher risk of developing AKI within 7 days of follow-up (RR 1.64 95% CI 1.31–2.05; p<0.0001). A RAI ≥8 at ICU admission (day 1) and 24h after admission (day 2) was able to identify individuals who developed AKI (day 3-7) with an AUC of 0.86 (95% CI 0.770-0.945); p< 0.0001 and an AUC of 0.891 (95% CI 0.815-0.946); p< 0.0001, respectively. No difference was found in terms of 28 day in-hospital mortality in patients with a RAI ≥8 vs a RAI ≤8.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents author.
Conclusions: The RAJ provides a clinically feasible methodology to identify critically-ill patients at high risk of developing AKI before a rise in sCr occurs. This tool would permit the early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

SA-PO194

The Renal Angina Index Identifies Patients at High-Risk of Acute Kidney Injury – Analysis from AWARE: A Prospective Multinational Study of AKI in Critically Ill Children Rajaï K. Bassu, 1,2 Ahmad Kaddourah, 1,2 Stuart Goldstein, 1,2 1Pediatics, Center for Acute Care Nephrology, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2On Behalf of the AWARE Study Investigators, Multinational Pediatric ICU.

Background: We conducted a global, prospective observational study of critically ill children to study the epidemiology of pediatric acute kidney injury (AKI). We analyzed the association of the renal angina index for prediction of AKI and patient outcomes.

Methods: Data from 32 centers (5 continents, data collection for 3 consecutive months in 2014) from children (aged 3 months to 25 years) admitted to a pediatric intensive care unit were analyzed. The renal angina index (RAI) was calculated on the day of admission (Day 0) as previously described. A cut-off of > 6 on Day 0 was used to define fulfillment of absence of renal angina (RA+ vs. RA-). The primary outcome was the presence of severe AKI on Day 3, defined by change in serum creatinine from baseline using KDIGO stage 2-3 criteria (Day 3 AKI). Other patient outcomes were assessed at 28 days.

Results: 9.6% (501/5231) of children were RA+ on Day 0. The area-under-curve receiver operating characteristic of the Day 0 RAI for Day 3 AKI was 0.797 (95% confidence interval 0.759-0.836). RA+ was associated with higher net fluid balance on Day 3 than RA- (p=0.001). Compared to RA-, Day 0 RA+ was associated with prolonged duration of mechanical ventilation, longer length of stay, increased use of extracorporeal therapies, and higher incidence of mortality.

Conclusions: In AWARE, the largest prospective multi-center epidemiologic assessment of AKI in critically ill children, we demonstrate the ability of the renal angina index to identify patients at high risk of AKI, three days in advance. Fulfillment of renal angina early in the ICU course is associated with poor patient outcome.

SA-PO195

Background: The bioelectrical impedance analysis (BIA) is a noninvasive and painless technique and easy to perform, which is used for determining body composition. Can offer assessment of AKI in critically ill children, we demonstrate the ability of the renal angina index to identify patients at high risk of AKI, three days in advance. Fulfillment of renal angina early in the ICU course is associated with poor patient outcome.

Methods: We include a cohort of 83 patients (mean age 64 years SD 1.8, and male 72.3 %) with AKI and BIA. We evaluate clinical prognostic index (individual severity index –ISI–), inflammatory and protein metabolism analytical parameters (C-reactive protein, albumin, prealbumin) and chronic health index (Karnofsky –K-).

Results: Exits 14.5%, PA and ECW/ICW was associated with prognosis in AKI.

PA was associated with protective risk mortality OR 0.425, p=0.007, CI 0.95% 0.229-0.870 and ECW/ICW with risk mortality OR 2.247 CI 95% 1.266-3.98. The AUC with PA was 0.770 (p=0.003, CI 95% 0.652-0.888) and with ECW/ICW was 0.778 (p=0.001, CI 95% 0.678-0.879).

Conclusions: BIA is a useful technique to evaluate AKI. Lower PA and higher ECW/ICW are associated with worse prognosis in AKI. Therefore, BIA can be useful tool for early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

SA-PO196

Preoperative Renal Resistive Index Predicts the Risk of Acute Kidney Injury in Patients Undergoing Cardiac Surgery Daniel P. Olsson Hertzberg, 1 Ulrik Sartipy, 2 Martin Holzmann. 1' Dept of Medicine, Karolinska Inst, Stockholm, Sweden; 2'Department of Anesthesiology, Surgical Services and Intensive Care Medicine, Karolinska Univ Hospital, Stockholm, Sweden; 3Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden.

Background: Previous studies have indicated that Renal Resistive Index (RRI), an ultrasound-based measurement, can predict AKI in a variety of settings. To our knowledge, there are no studies investigating the predictive value of preoperative RRI and the risk of AKI in cardiac surgery patients. The aim of this study was to investigate whether an elevated preoperative RRI predicts AKI in a general cardiac surgery population.

Methods: Patients undergoing elective cardiac surgery were included prospectively between September 21, 2014 and April 22, 2015 at the Karolinska University Hospital. RRI was measured before surgery. An elevated RRI was defined as >0.7. The outcome AKI was defined as an absolute increase in post-compared to preoperative serum creatinine by 0.3 mg/dL (>26 µmol/L) or a relative increase by >50%. The odds ratio for AKI was calculated by logistic regression in patients with a RRI >0.7 versus those with a RRI ≤0.7.

Results: 98 patients were included. In patients with a RRI ≥0.7, 6 (15%) patients developed AKI, compared to 19 (33%) in patients with a RRI ≤0.7. The mean increase in postoperative serum increase in patients with RRI ≥0.7 was 0.12 mg/dL (11 µmol/L) compared to 0.34 mg/dL (30 µmol/L) in those with RRI >0.7 (p=0.03). The odds ratio for developing AKI in patients with a RRI >0.7 compared to those with a RRI ≤0.7 was 2.76 (9.99-77).

Conclusions: We found that patients with an elevated RRI before cardiac surgery had an increased risk of developing AKI postoperatively. RRI might be a valuable tool for identifying patients with an increased risk of developing AKI connected to cardiac surgery.

SA-PO197

Development of a Postoperative Risk Stratification Tool via Bayesian Model Averaging for Acute Kidney Injury After Cardiac Surgery Allison Meisner 1, Kathleen F. Kerr, 1 Heather Thiessen Philibrown, 2 Francis Perry Wilson, 3 Amit X. Garg, 4 Michael Shlipak, 5 Peter Kavsak, 6 Richard P. Whitlock, 7 Steven G. Coca, 8 Chirag R. Parikh. 1 'Univ of Washington, Seattle, WA; 2Western Univ, ON, Canada; 3Yale School of Medicine, New Haven, CT; 4UCSF; 5McMaster Univ; ON, Canada; 6Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Acute kidney injury (AKI) is a frequent complication of cardiac surgery. We sought predictive combinations of biomarkers measured 0-6 hours after surgery, potentially in combination with cardiopulmonary bypass (CPB) time (to account for the degree of insult).

Methods: The primary endpoint was sustained mild AKI, defined as an increase of 50% or more in serum creatinine over preoperative levels lasting at least two days during the hospital stay. We defined AKI (secondary endpoint) was defined as a serum creatinine increase of 100% or more or dialysis during hospitalization. Data were from a cohort of 1219 adults undergoing cardiac surgery at 6 medical centers; among these, 117 developed sustained mild AKI and 60 developed severe AKI. We considered CPB time and 22 biomarkers as candidate predictors. We used Bayesian Model Averaging (BMA) methods to develop center-adjusted combinations for sustained mild AKI by (1) maximizing the posterior model probability and (2) retaining predictors with posterior variable probabilities above 0.5.

Results: The maximum posterior model probability combination included plasma NT-proBNP, plasma h-FABP and change in serum creatinine; the median probability and (2) retaining predictors with posterior variable probabilities above 0.5.

Conclusions: We found predictive combinations of biomarkers measured 0-6 hours after surgery, potentially in combination with cardiopulmonary bypass (CPB) time (to account for the degree of insult).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.
SA-PO198
Low Pre-Operative Serum Bicarbonate Levels Predict Acute Kidney Injury After Cardiac Surgery
Jong Hyun Jheg, Kyoung Sook Park, Hyung Jung Oh, Seung Hyeok Han, Taehyun Yoo, Jung Tak Park. Dept of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea.

Background: Low serum bicarbonate levels are known to be risk factors for renal function deterioration in chronic kidney injury patients. However, it is not well known whether preoperative low serum bicarbonate levels are associated with the development of acute kidney injury (AKI) in patients who undergo cardiac surgery. Therefore, clinical implications of preoperative serum bicarbonate levels on AKI occurrence after cardiac surgery were evaluated.

Methods: The patients who underwent coronary artery bypass or valve surgery at Yonsei University Health System from January 2013 to December 2014 were enrolled. The patients were categorized into three groups according to pre-operative serum bicarbonate levels (group 1 <23 mEq/L, group 2 23-24 mEq/L, group 3 >24 mEq/L). Multivariate logistic regression analysis was performed to determine the effect of pre-operative serum bicarbonate levels on development of AKI at 48 hours after cardiac surgery.

Results: Among 452 patients, 228 patients (26.1%) developed AKI at 48 hours after cardiac surgery. Incidence of AKI was higher in group 1 (34.6%) than group 2 (26.3%) and group 3 (39.0%) (P<0.001). The duration of post-operative intensive care unit (ICU) stay was longer in AKI patients (AKI vs. non-AKI, 6.2 vs. 2.7 days, P<0.001). In addition, post-operative ICU stay was longer in the low pre-operative serum bicarbonate level groups (group 1 4.4 days, group 2 3.6 days, group 3 3.3 days, P<0.001). In multivariate logistic regression analysis, low pre-operative serum bicarbonate levels were significantly associated with pre-operative AKI development even after adjusting for age, sex, hypertension, diabetes mellitus, operation type, hemoglobin, and glomerular filtration rate (group 3 as reference, odds ratio=2.36, 95% confidence interval=1.57-3.54, P<0.001).

Conclusions: Low serum bicarbonate levels were associated with higher incidence of AKI and prolonged ICU stay. Correction of low serum bicarbonate levels before cardiac surgery may reduce the risk of AKI development.

SA-PO199
Admission Hyperuricemia Increases the Risk of Acute Kidney Injury in Hospitalized Patients
Wisit Cheungpasitporn,1 Charat Thongprayoon,2 Stephen B. Erickson.1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; Internal Medicine, Bassett Medical Center, Cooperstown, NY.

Background: The association between elevated admission serum uric acid and risk of in-hospital acute kidney injury (AKI) is limited. The aim of this study was to assess the risk of developing AKI in all hospitalized patients with various admission serum uric acid (SUA) levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients who had admission SUA available from January 2011 through December 2013 were analyzed in this study. Admission SUA was categorized based on its distribution into six groups (less than 3.4, 3.4 to 4.5, 4.5 to 5.8, 5.8 to 7.6, 7.6 to 9.4, and greater than 9.4 mg/dL). The primary outcome was in-hospital AKI occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of AKI of various admission SUA levels using the most common SUA level reference range (5.8 to 7.6 mg/dL) as the reference group.

Results: Of 1,435 patients enrolled, AKI occurred in 263 patients (18%). The incidence of AKI and need for dialysis was increased in patients with higher admission SUA levels. After adjusting for potential confounders, SUA greater than 9.4 mg/dL was associated with an increased risk of developing AKI with odds ratios of 1.79 (95% CI 1.13-2.82). Conversely, admission SUA of less than 3.4 mg/dL and 3.4 to 4.5 mg/dL were associated with decreased risk of developing AKI with odds ratios of 0.38 (95% CI 0.17-0.75) and of 0.50 (95% CI 0.28-0.87) respectively.

Conclusions: Elevated admission SUA was associated with an increased risk for in-hospital AKI.

SA-PO200
Hypoalbuminemia Is a Strong Risk Factor for Acute Kidney Injury Progression in Elderly Patients in Intensive Care Unit
Yu Kurata,1 Keita Hirano,2 Fumio Omata,2 Yasuhito Komatsu.1 1Div of Nephrology, Mitsu Memorial Hospital, Chiyoda-ku, Tokyo, Japan; 2Div of Nephrology, St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan; 3Center for Clinical Epidemiology, St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan.

Background: Population aging is a global issue; especially, Japan is experiencing rapid aging, at a faster speed than any other developed country, and those aged 65 or older comprised 25.9% of Japan’s population as of September 2014. Previous studies showed elderly patients are at high risk for developing acute kidney injury (AKI). AKI is also a common clinical syndrome in the ICU setting, but its clinical presentation varies from mild to severe. Predicting whether AKI progress or not is difficult but can guide clinical decision making. The aim of the present study is to elucidate risk factors of AKI progression among elderly patients in ICU.

Methods: A retrospective study of patients age 65 and older and developed AKI during ICU stay between January 2004 and September 2013. AKI was defined as increase in serum creatinine (sCr) of ≥1.1 times baseline. The primary outcome was the progression to AKIN stage 3 (increase in sCr of 3 times over baseline or need for renal replacement therapy (RRT)) within 14 days after AKI development. Prerenal AKI, postrenal AKI, and AKIN Stage 3 at diagnosis of AKI are excluded; prerenal AKI is diagnosed when serum BUN-to-creatinine ratio ≥ 2 and postrenal AKI is diagnosed based on clinical situation.

Results: 418 patients were included. The mean age of was 80.6 ± 8.2 years, baseline sCr 0.89 ± 0.40 mg/dL, and baseline eGFR 66.1 ± 32.3 ml/min/1.73m2. Among 418 patients, 77 (18.4%) experienced AKI progression and 83 (19.9%) died. Of the 77 patients with AKI progression, 25 (6.0%) patients received RRT. AKIN stage 2 at diagnosis (OR=2.33, 95%CI=1.23-4.36), RAS inhibitor use (OR=2.84, 95%CI=1.33-5.93), bacteremia (OR=1.69, 95%CI=0.89-3.14), hypoalbuminemia (OR=5.10, 95%CI=2.94-9.06) were risk factors for AKI progression.

Conclusions: Hypoalbuminemia is a strong risk factor for AKI progression in older patients in ICU. Further study is needed to evaluate whether correction of hypoalbuminemia could prevent AKI progression or not.

SA-PO201
Impact of Preexisting Serum Prealbumin on All-Cause Mortality in Community-Acquired and Post-Operative Acute Kidney Injury Patients
Yanfang Zou,1 Dan Wen,1 Jingyuan Xie,1 Xiaonong Chen,1 Wen Zhang,1 Nan Chen.1 Nephrology, Ruijin Hospital, Shanghai, China; Nephrology, Ruijin Hospital; Nephrology, Ruijin Hospital.

Background: To explore the impact of pre-existing prealbumin concentration on all-cause mortality in AKI (acute kidney disease, AKI) patients.

Methods: From 2000 to 2010, 477 patients diagnosed with community-acquired AKI (CA-AKI) and treated in the Department of Nephrology, Ruijin Hospital, Shanghai Jiaotong University were enrolled in the CA-AKI group. 138 patients diagnosed with AKI after cardiac operations were enrolled in the post-operative AKI (PO-AKI) group. Data were collected at the time point of AKI onset and one year after the discharge.

Results: Patients with CA-AKI were younger than PO-AKI patients. Compared with PO-AKI patients, more patients in CA-AKI group suffered from chronic kidney disease, obesity and hyperlipidemia and less patients with cerebrovascular disease (CVD), anemia, myocardial infarction and so on. Levels of LMA were higher in CA-AKI patients than PO-AKI group (CA-AKI group 0.91, 95% CI 0.84-0.99). In CA-AKI group, cumulative survival rate of patients in normal PA group (PA>20mg/dL) was higher than that in lower PA(<20mg/dL) group (95.4% vs 88.3%, P=0.031). Similarly, in PO-AKI group, normal PA level was associated with a higher survival rate (74.1% vs 47.8%, P=0.019).

Conclusions: A significant difference was detected between CA-AKI group and PO-AKI in general characteristics, comorbidities, laboratory examinations, outcome, and risks. Patients with PA>20mg/dL showed better survival rate.

Funding: Government Support - Non-U.S.

SA-PO202
Usefulness of Serum Ischemia-Modified Albumin Levels to Predict Dialysis Requirement in Patients with Acute Renal Injury
Mehmet Uzun, Harun Akar. Internal Medicine, Izmir Tepecik Education and Research Hospital, Turkey.

Background: Ischemia-modified albumin is a promising biomarker for early diagnosis of diseases related with ischemia. Ischemia leads to modification in albumin molecule by reducing its binding to cobalt. The aim of this study was to evaluate the levels of ischemia-modified albumin in patients with acute kidney injury (AKI).

Methods: Serum levels of ischemia-modified albumin were estimated in 51 patients with AKI.

Results: The mean age of 28 female and 23 male patients were 65.39±15.28 and 71.41±13.28, respectively. Levels of LMA were found to be high in 75.5% of the patients (48/60) and were found to be normal in 25.5% of the patients (<400). Kaplan-Meier survival analysis showed that the survival was not different between IMA groups. Urine amounts were significantly different between IMA groups. The urine volume was lower in patients with higher IMA levels (<400).
Conclusions: In the present study, the levels of IMA were found to be significantly higher in those who needed hemodialysis treatment. IMA levels do not predict mortality. Taking these results together, serum IMA levels might give an idea about dialysis requirement in patients with AKI. More studies with larger sample groups may help to establish the role of IMA on decisions regarding dialysis initiation.

SA-PO203
Urinary TIMP-2 and IGFBP7 Elevate Early After Vancomycin Administration in Critically Ill Patients Who Develop AKI Maria Osterrmann,1 Lui G. Forni,2 Lakhmir S. Chawla,1 Jing Shi,3 Kianoush Banac-Kashani,1 John A. Kellum,4 ’King’s College London, London; ’Royal Surrey County Hospital, Guildford; 3George Washington Univ, Washington; 4Wallk Biocience, Carlbad; 5Mayo Clinic, Rochester; 6’Univ of Pittsburgh, Pittsburgh.

Background: We previously validated a biomarker combination of tissue inhibitor of metalloproteinase-2 (TIMP-2) and insulin-like growth factor binding protein 7 (IGFBP7) for risk stratification of acute kidney injury (AKI).1 A cutoff of 0.3 (ng/mL)/1000 for [TIMP-2][IGFBP7] indicated AKI stage 2-3 at least 24h prior to serum creatinine. We also showed that nephrotoxic drug use was common in patients developing AKI and that the [TIMP-2][IGFBP7] test could have identified patients earlier.2 In this sub-analysis of the Sapphire study,3 we examined the temporal changes in [TIMP-2][IGFBP7] following vancomycin.

Methods: We identified patients who received vancomycin and grouped them according to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the median daily [TIMP-2][IGFBP7] value from day prior to 1st dose of vancomycin until 5 days after. A bootstrap analysis was used to calculate 1-sided p-values for comparison to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the [TIMP-2][IGFBP7] test could have identified patients earlier.

Conclusions: Immediate post-operative serum IL-33 concentrations were higher in matched AKI cases compared to non-AKI controls. Further studies are needed to clarify the role of serum IL-33 in human AKI.

Funding: NIDDK Support

SA-PO205

Background: We previously demonstrated AKI duration improves risk-stratification for AKI prognosis in addition to the magnitude of serum creatinine rise. We evaluated whether kidney injury biomarkers within 6 hours after cardiac surgery associate with post-operative AKI duration.

Methods: We included 1199 adults undergoing cardiac surgery in TRIBE-AKI cohort that survived to discharge and examined association between five urinary biomarkers: neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP) and albumin with duration of serum creatinine-based AKI criteria for AKI (0=no AKI), 1-2, 3-6, >7 days).

Results: Overall, 406 (34%) patients had AKI, of which 48 had stage 2/3 AKI. Of 358 with stage 1 AKI, 115 (32.1%) had AKI duration >3 days. An additional 41 (85%) with stage 2/3 AKI had duration of >3 days. Concentrations of all biomarkers increased with AKI duration and each log increase in biomarker was independently associated with greater odds of longer duration category (IL-18 OR 1.21, 95% CI 1.10-1.33; L-FABP 1.14, 95% CI 1.07-1.21; NGAL 1.10, 95% CI 1.03-1.17).

Peri-Operative Serum IL-33 Concentrations in Matched AKI and Non-AKI Patients Undergoing Cardiac Surgery Charles L. Edelestein,1 Heather Thiessen Philbrook,2 Jay L. Koyner,3 Michael Shlipak,4 Steven G. Coca,5 Chirag R. Parikh,5 ’Univ Colorado Denver; 2Yale Univ; 3Univ Chicago; 4UCSF.

Background: Endothelial cell damage and death in the nephron is an early feature of AKI. Damage-associated molecular patterns (DAMPs) are endogenous molecules released by damaged cells including endothelial cells. IL-33, a DAMP, has been shown to be present in blood vessels in the kidney and released into the blood, but not the urine, in cisplatin-induced AKI in mice before the increase in serum creatinine. We sought to determine whether serum IL-33 levels are a biomarker of AKI in humans in a nested case-control study.

Methods: Perioperative plasma samples were obtained from patients enrolled in the TRIBE-AKI cohort. 35 cases of AKIN Stage 2 AKI or higher within the first 4 post-op days were matched to 70 controls with no AKI by pre-op GFR, age, sex, site and cohort. Blood samples were available pre-op, day 1 (6-6 hours), days 2 and 3. Serum IL-33 was measured by ELISA.

Results: The pre and post-operative levels of IL-33 are shown in Table 1. Using a mixed model accounting for the matching in the data, the first post-operative value of IL-33 was significantly different (p=0.005) between cases and controls after adjusting for pre-op values. There was a non-significant trend towards higher IL-33 levels on day 2.

Conclusions: While most patients in the TRIBE-AKI Cohort experienced stage 1 AKI when classified by peak serum creatinine increase, one-third of those have duration of AKI of >3 days. Elevated urinary kidney injury biomarker within 6 hours of surgery may help in identifying of patients at risk for longer AKI duration, which may serve as a reliable metric for drug development trials.

Urinary Biomarker Evaluation in Cancer Patients Receiving Cisplatin

Blessy George,1 Amanda Roque-Atlano,2 Cara A. Chang,3 Nickie L. Johnston,2 Madeleine Gomez,2 Lucas Ellison,3 Xia Wen,2 Lauren Aleksunes,1 Daniel Bowles,2 Cindy L. O’Bryant,4 Melanie S. Joy.1 1School of Pharmacy, Rutgers Univ, NJ; 2Schools of Pharmacy and Medicine, Univ of Colorado, CO.

Background: The study explored the time dependency of urinary biomarker changes and correlations between the biomarkers and traditional markers of kidney injury in a cohort of patients receiving cisplatin.

Methods: Urine was obtained at 2baseline, 2Day 3 and 3Day 10 from patients (n=42) receiving cisplatin (25 mg/m2). Urinary kidney injury molecule-1 (Kim-1), calbindin, beta-2 microglobulin (B2M), clusterin, monocyte chemotactic protein-1 (MCP-1), cystatin C, trefoil factor 3 (TFF3), tissue inhibitor of metalloproteinase 2 (TIMP2), and insulin growth factor binding protein 7 (IGFBP7) were measured with multiplex or ELISA.

A: baseline vs. Day 3 p<0.05, B: baseline vs. Day 10 p<0.05, C: Day 3 vs Day 10 p<0.05.

The biomarker-GFR correlations were: TFF3 (r: -0.2590), B2M (r: -0.2017), Kim-1 (r: -0.1758), MCP-1 (r: -1.390), cystatin C (r: -0.0936), IGFBP7 (r: -0.0764), clusterin (r: -0.0767), calbindin (r: -0.0647), and TIMP2 (r: -0.0619). The biomarker-albumin correlations were: calbindin (r: 0.7813), TFF3 (r: 0.5949), clusterin (r: 0.5869), Kim-1 (r: 0.3166), TIMP2 (r: 0.3016), MCP-1 (r: -2.304), IGFBP7 (r: 0.2217), cystatin C (r: 0.1375), and B2M (r: 0.1149).

Conclusions: Urinary biomarkers display time dependent increases post cisplatin and exhibit variable degrees of correlation with GFR and urinary albumin. TFF3 had high concordance with both GFR and urinary albumin, which may be a favorable characteristic.

Prediction of Long-Term Renal Outcomes in AKI Survivors by Urinary Biomarkers

Rei Ishihki,1 Kent Doi,2 Maki Sumida,1 Yoshifumi Hamasaki,1 Naoki Yahagi,2 Masaoi Nanagak,1 Eiset Noiri.1 1Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.

Background: Although several epidemiological studies suggested that acute kidney injury (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to evaluate the carbonyl and oxidative stress in these group and their pathogenesis link and (II) prognostic predictability of carbonyl and oxidative stress marker in this AKI.

Methods: We conducted an observational study examining the association of three biochemical data were analysed and were followed from hospitalization to discharge/discharge of AKI (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to (I) evaluate the carbonyl and oxidative stress in these group and their pathogenesis link and (II) prognostic predictability of carbonyl and oxidative stress marker in this AKI.

Results: Among the enrolled 495 patients, 393 patients discharged from the hospital without MAKE. Of them, 175 patients were followed up for two years after ICU discharge and 63 patients (36.4%) were positive for long-term renal outcomes (Outcome 1). A step-wise logistic regression analysis demonstrated that only urinary NGAL showed a positive response.

Conclusions: Urinary biomarkers measured at ICU admission were significantly associated with long-term renal outcomes after hospital discharge in MAKE-free AKI survivors.

SA-PO208

Significance of Serial Measurement of Acute Kidney Biomarker in Intensive Care Unit

Rei Ishihki,1 Kent Doi,2 Maki Sumida,1 Naoki Yahagi,2 Masaoi Nanagak,1 Eiset Noiri.1 1Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.

Background: AKI biomarkers have been developed with the concept of earlier detection of kidney damage than serum creatinine. However, single time point measurement appears not to provide sufficient information for detecting and predicting AKI in ICU patients who frequently suffer from multiple and transient/persistent renal insults. This study was aimed to evaluate whether serial measurement enables to predict AKI progression and recovery in these patients.

Methods: Serial measurements of AKI biomarkers including plasma and urinary NGAL, urinary L-FABP, and urinary NAG at ICU admission (day 1) and 24 hr after (day 2) were conducted in adult critically ill patients who were treated in a ICU.

Results: Among the enrolled 272 patients, 33 were determined as newly developed AKI after ICU admission, 64 showed worsening of kidney function and 63 recovered from AKI. ROC analysis showed that biomarkers at day 2 showed no significantly additional benefit in predicting these three AKI outcomes compared with those measured at day 1. However, net reclassification improvement (NRI) analysis demonstrated adding AKI biomarkers at day 2 to the clinical model comprised of clinical variables and biomarker at day 1 significantly improved prediction of these AKI outcomes.

Conclusions: Serial measurement of AKI biomarkers involved in clinical models could contribute to prediction of AKI outcomes in a heterogenous cohort of adult mixed ICU.

SA-PO209

Role of Carbonal Stress Revisited in Pathogenesis of Tropical Acute Kidney Injury

Pinaki Mukhopadhyay. Nephrology, NRS Medical College, Kolkata, West Bengal, India.

Background: Malaria and snake bite are two common causes of Acute Kidney Injury (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to (I) evaluate the carbonal and oxidative stress in these group and their pathogenesis link and (II) prognostic predictability of carbonyl and oxidative stress marker in this AKI.

Methods: All cases of falciparum malaria mediated AKI (FM/aki) (n=50) confirmed by antigen and/or in peripheral blood smear and snake bite mediated AKI (SAKl) (n=58) were included. AKI was calculated as per RIFLE criteria. Demographical, clinical and biochemical data were analysed and were followed from hospitalization to discharge/death. Oxidative and carbonyl stress markers [advanced oxidation protein product (AOPP), advanced glycation end product (AGE), pentosidine, dityrosine, thioarbituric acid reactive substance (TBARS) and methyl glyoxal (MG)] were measured consecutively according to standard protocol. Predictive importance was assessed from trend analysis, receiver operated characteristic (ROC) curve analyses and multiple logistic regression with AKI as the outcome.

Results: The Oxidative stress index (OSI) of FMAKI patients were 1.89 higher than controls. The TBARS, MG level were 6.49 and 5.56 times higher indicating a significant carbonal stress in these patients. AOPP level was 2.33 times higher indicating proteins being highly insulted in FMAKI. Similarly in SAKl significantly elevated total oxidant stress with decreased total antioxidant stress leads to net oxidative stress in SAKl patients depicted by increased OSI values (p<0.001). MG was increased by 3.48 times (p<0.001). Only AOPP (p<0.001) and MG (p=0.004) were found to be significantly elevated in expired patients than the survived indicating their predictive power for adverse outcome. At univariate level,
all parameters can differentiate between AKI and the non-AKI group. At multivariate level, methylglyoxal, AOPP and dityrosine appeared to be independent predictor of AKI in snake bite and malaria infected patients (p<0.05).

**Conclusions:** 1.MG, the carbonyl stress marker along with oxidative stress are significantly raised and possibly linked to the pathogenesis of AKI. 2.MG and AOPP can be used as a surrogate marker in these tropical AKI.

**Prediction of Short-term and Long-term Outcomes of AKI-Based on Plasma NGAL**

**Karina Soto,¹ Fernando Pereira,¹ Liliana Maria goncalves Cunha,² Jola Pinto,² Ana Luisa Papoila,² Prasad Devajaran.¹**

**Nephrology, Hospital Fernando Fonseca; ²Inst Superior de Engenharia de Lisboa; ³Nova Medical School/FCM, Univ Nova de Lisboa, Portugal; ⁴Nephrology, Cincinnati Children’s Hospital Medical Center, OH.**

**Background:** We have previously shown a good performance of Plasma NGAL (pNGAL) as an AKI biomarker in emergency settings. Now we investigated a new AKI classification based on pNGAL for prediction of kidney dysfunction at discharge and at the end of follow-up.

**Methods:** Patients from a previous study at ED were followed for >5y. During the study period, 599 patients were admitted with new AKI (21.7% were based on SCr). All significant clinical variables were included in multivariable analysis at discharge.

**Results:** Of 599 patients admitted, 97.8% were available at discharge and 54.4% at last follow-up. At admission 42.6% were reclassified as AKI-pNGAL+ whereas only 21.7% were based on SCr. All significant clinical variables were included in multivariable analysis at discharge.

*p<0.001 unless CVD=0.007

Having pNGAL>110 at ED corresponded to 4-fold increased odds for eGFR<60 mL/min (p<0.001 ROC-AUC 0.82). The cumulative incidence of CKD showed that most of AKI-pNGAL+ developed CKD at 60 mo (the highest proportion 77%) (figure 1) HR for CKD: 2.4 for patients AKI-pNGAL+ in long-term (p=0.001 ROC AUC 0.74) NRI 56.3 and IDI 0.03.

**Conclusions:** Patients who were AKI-pNGAL+ had significant lost kidney function at discharge and more than 2-fold risk of developing CKD in long-term evolution. Plasma NGAL is a useful tool for CKD prediction, independent of serum creatinine.
SA-PO213

At Myeloma Diagnosis, Age and Free Light Chain Level Predict Renal Function and These Factors with Free Light Chain Response Predict Renal Outcome

Punit Yadav,1,2 Mark Trehan Drayson,1,2 Mark Cook,1,2 Jennifer H. Pinney,1 Hannah V. Giles,1 Yu sandar Aung,1,2 Paul Cockwell,1,2 Univ Hospital Birmingham, UK; 1,2 Univ of Birmingham, UK.

Background: Elevated involved immunoglobulin light chain (FLC) is a major cause of renal impairment (RI) in myeloma. Relationships between presentation and post-admission renal function and serum FLC levels are not established.

Methods: We used central laboratory data from the MRC Myeloma IX trial which compared bisphosphonate and thalidomide-based therapies. Patients were divided into 3 categories: eGFR ≥60 ml/min, normal renal function; eGFR 30-59 ml/min, mild-moderate RI; eGFR <30 ml/min, severe RI. Linear regression and logistic regression modelling were used to explore independent determinants of renal function.

Results: 52.8% had an eGFR ≥60 ml/min; 37.3% had an eGFR 30-59 ml/min and 9.8% had an eGFR <30 ml/min. Median eGFR in patients with involved FLC was significantly lower than those with xFLC (58 [IQR 42-77] vs 63 [IQR 46-80]; P<0.001). Median eGFR for light chain only myeloma (LCO) was also significantly lower than those with IgG and IgA myeloma (49 [IQR 28-78] vs 62 [IQR 47-79] vs 63.5 [IQR 42.2-82.0]; respectively; P<0.0001). Patients with a difference between involved and uninvolved FLC (dFLC) ≥500 mg/L had a lower eGFR compared to those with dFLC 100-499 mg/L and dFLC <100 mg/L (52 [IQR 35-72] vs 66 [IQR 52.0-82.6] vs 67 [IQR 54.2-80.2]; respectively; P<0.0001). A dFLC level of 700 mg/L was the optimal cut-off value for prediction of severe RI, with an AUC of 0.80. Factors associated with eGFR at presentation were: age, log dFLC, male gender and LCO myeloma. On censoring those with dFLC <700mg/L; age and log dFLC were still associated with eGFR at presentation but not male gender and LCO myeloma. Factors that were independently associated with RI at PI were: age (odds ratio [OR] 1.033, P=0.044); presentation eGFR (OR 0.93, P<0.0001) and attainment of VGPR (very good partial response) compared to <PR (partial response) serum FLC response (OR 0.52, P=0.005).

Conclusions: Age and serum FLC level predict eGFR at presentation and age, presentation eGFR, and serum FLC response predict RI outcome.

SA-PO214

Urinary Biomarkers Improve the Prediction and Prognostic Assessment of Acute Kidney Injury in Critically Ill Patients

Patrick T. Murray, Teresa Martin, Eoin J. Cotter. UCD Clinical Research Centre, School of Medicine, Univ College Dublin, Dublin, Ireland.

Background: Acute kidney injury (AKI) is common in intensive care unit (ICU) patients, and is diagnosed late by serum creatinine. New biomarkers may permit earlier detection and better management.

Methods: All patients admitted to the ICUs of two university hospitals were screened for this prospective cohort study. Clinical information and urine were collected on admission and daily for 7 days. Urine biomarkers analysed were neutrophil gelatinase-associated lipocalin (NGAL), α- and ʌ- glutathione-S-transferases (GSTs), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP), creatinine, and albumin. AKI was defined by modified KDIGO criteria, using IU admission creatinine as reference. Values were compared between those who did or did not develop AKI or 30d adverse clinical outcomes (RRT or death). ROC curves were generated for prediction of AKI and outcomes by a clinical score (including age, gender, serum creatinine & urea, urine output) and urine biomarker values on admission. In patients developing AKI, ROC curves were similarly generated for the prediction of clinical outcomes with values obtained at time of AKI diagnosis.

Results: 659 patients were enrolled; 181 patients (27%) developed AKI within 7d of ICU admission. AKI stages at diagnosis were:Stg1(n=81,45%),Stg2(n=17,9%),Stg3(n=83,46%). Of the 42 patients who developed AKI, 37 (88.1%) had an AUC of 0.77 (0.7 to 0.8), with the highest validity for predicting AKI. Early recognition of septic patients at risk for AKI developing within the first 48h in ICU (AUC 0.79±0.12), compared to clinical score alone (0.77±0.11; p=0.0001). AKI biomarkers similarly improved the prediction of AKI developing within the first 7d (0.73±0.15), compared to clinical score alone (0.69±0.07; p=0.0003); and marginally improved the prediction of 30d RRT or death (0.7±0.1 vs 0.69±0.1; p=0.05). In patients developing AKI, AKI biomarkers at the time of diagnosis significantly improved prediction of 30d adverse clinical outcomes (RRT or death): 0.77±0.19, compared to clinical score alone (0.68±0.13;p=0.01).

Conclusions: Urinary biomarkers combined with standard clinical tests improved prediction of AKI and outcomes in ICU patients, on admission and at AKI diagnosis.

SA-PO215

Association of Growth Factor Biomarkers with Acute Kidney Injury and Long-Term Mortality in Adults following Cardiac Surgery

Background: Following the structural damage and functional impairment from acute kidney injury (AKI), the kidney undergoes a coordinated process of repair involving regenerative growth factors. We conducted an ancillary analysis of a large, prospective study of adults undergoing cardiac surgery to investigate the utility of epidemial growth factor (EGF) and vascular endothelial growth factor (VEGF) in predicting kidney injury and mortality.

Methods: Patients undergoing cardiac surgery at high risk for AKI were enrolled at six academic centers. AKI was defined as a doubling in serum creatinine from baseline or receiving acute dialysis during the hospital stay. Postoperative plasma levels of EGF, VEGF, and a combination model of the two growth factors were evaluated for association with outcomes of AKI or long-term, all-cause mortality at a mean follow-up of 3 years.

Results: First postoperative and peak plasma EGF were not associated with AKI. Elevated peak plasma VEGF was independently associated with increased risk of AKI (adjusted odds ratio [OR] 7.4, 95% confidence interval [CI] 1: 1.47-47.9). Elevated first postoperative EGF was inversely associated with a lower risk of mortality (adjusted HR=0.67; 95% CI: 0.47-0.97). Elevated first postoperative VEGF was likewise associated with a lower risk of mortality (unadjusted HR=0.36; 95% CI: 0.16-0.82), though the association was attenuated following adjustment (adjusted HR=0.36; 95% CI: 0.15-1.04). When used conjunctively, elevated levels of first postoperative EGF and VEGF together were independently associated with a lower risk of mortality (adjusted HR=0.28; 95% CI: 0.11-0.72).

Conclusions: Postoperatively, EGF and VEGF are released in response to AKI, and their concentrations were inversely associated with long-term mortality. These growth factors may serve as biomarkers of long-term outcomes in adults undergoing cardiac surgery.

Procalcitonin as a Predictor of AKI in Patients with Sepsis

Jonathan Chavez1, Maria de la luz Alcantar Vallin,2 Guillermo Garcia-Garcia,3 Luis Arnoldo Muñoz.2 1Nephrology Service, Hospital Civil de Guadalajara, Guadalajara, Mexico; 2Internal Medicine, Hospital Civil de Guadalajara, Guadalajara, Mexico.

Background: Sepsis is a common cause of AKI. Identifying patients at risk for AKI could improve clinical outcomes. Procalcitonin (PCT) reflects accurately the presence of sepsis and its severity. We evaluated the role of PCT as predictor of AKI in septic patients.

Methods: Cross-sectional study of 72 septic patients between January to December 2014. Patients with SCR ≥1.5 mg/dl before admission, ESRD patients and those with autoimmune comorbidity were excluded. PCT, Scr, urea, and WBC were measured on admission, and at 24 and 48 h of hospitalization. X2 and t-test were used when appropriate. A ROC curve for PCT value on admission as well as the area under the curve (AUC), the standard AUC error, and sensitivity and specificity of PCT values were determined.

Results: Patients’ mean age was 50.8 y (18-79); 37 (51.4%) were women. 18 (25%) patients had PCT value <0.5 mg/L (negative) and 54 (75%) 0.5 mg/L (positive) on admission. Forty-two (58.3%) patients developed AKI, 19 (42.5%) KDIGO 1, 12 (26.6%) KDIGO 2, and 11 (26.2%) KDIGO 3. Of the 42 patients who developed AKI, 37 (88.1%) had a positive value of PCT at admission (p<0.01, OR 5.659, 95% CI 1.738 to 18.425). The ROC PCT presented an AUC of 0.75 (p<0.0001, 95% CI 0.639 to 0.862). The cutoff of 2.565 mg / ml of PCT had the highest validity for predicting AKI with an SE of 61.9%, one SP of 80%, a PPV of 44.52%, NPV of 56.18%.

Conclusions: We found a significant association between levels of PCT and development of AKI in patients with sepsis. A cutoff PCT value of 2.565 mg / mL on admission had the highest validity for predicting AKI. Early recognition of septic patients at risk for AKI with PCT could improve clinical outcomes in this population.

SA-PO217
Elevated Erythropoietin Concentration in AKI Is Associated with IGFBP-1 Rather Than Hemoglobin Tetsushi Yamashita, Eisete Noiri, Yoshihumi Hamasaki, Naoki Yahagi, Masanori Nagaku, Kent Doi. The Univ of Tokyo, Tokyo, Japan.

Background: EPO expression will be increased by hypoxia in the kidney and hypoxic injury plays a crucial role in pathogenesis of AKI. However, little is known about blood EPO levels in critically ill patients complicated with AKI.

Methods: This study prospectively enrolled 98 adult critically ill patients who admitted to the adult ICU. We measured plasma EPO and also measured plasma IGFBP-1 as a hypoxic marker, which is produced mainly by liver, and plasma NGAL and urinary NAG as renal damage biomarkers on ICU admission. This study was conducted to evaluate whether plasma EPO levels in AKI patients was regulated by other factors than anemia.

Results: AKI occurred in 42 (42.9%) patients. Significantly higher plasma EPO in the AKI group was detected compared with the non-AKI group (16.13 [9.87–28.47] mIU/mL versus 27.81 [10.16–106.02] mIU/mL, p<0.05). Plasma EPO concentration was strongly and negatively correlated with hemoglobin in the non-AKI group but not in the AKI group. Plasma IGFBP-1 was strongly and positively correlated with plasma EPO. Multiple logistic regression analysis revealed plasma EPO in the AKI group was significantly associated only with plasma IGFBP-1 and complication of diabetes mellitus.

Conclusions: Plasma EPO had a predictive value for diagnosing AKI but itself had a limited value for distinguishing prerenal AKI from other causes of AKI.

Funding: Government Support - Non-U.S.

SA-PO218
Predictive Value of Plasma Neutrophil Gelatinase-Associated Lipocalin (NGAL) to Distinguish Prerenal AKI to Other Causes of AKI Chae Ho Lim, Young-II Jo. Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center, Gwangjin-gu, Seoul, Republic of Korea; Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center, Gwangjin-gu, Seoul, Republic of Korea.

Background: Plasma Neutrophil gelatinase-associated lipocalin (NGAL) is a promising biomarker for acute kidney injury, but it’s role for distinguishing prerenal AKI from other causes are not well known. The aim of this study was to evaluate the predictive value of plasma NGAL to distinguish prerenal AKI to other causes of AKI.

Methods: We reviewed all NGAL test from December 26, 2011 to February 28, 2015 in Konkuk University Medical center (Seoul, Republic of Korea) and subtract patients who taken factional excretion of sodium(FENa) test at the same time. Patients were first grouped with Acute Kidney Injury Network (AKIN) stages and evaluated it’s diagnostic role for AKI and second divided with prerenal AKI and other causes of AKI.

Results: Total 5814 NGAL test were done from December 26, 2011 to February 28, 2015 in Konkuk University Medical center, and 495 patients taken FENa test at the same time. 36 patients (12.2%) developed AKI and 26 (9%) died. Mean NLR was measured at presentation to the ER.AKI was defined as a new-onset 1.5-fold or more increase in serum creatinine or a 25% decrease in estimated GFR sustained for at least 3 days despite volume resuscitation. The primary outcome was AKI. Secondary outcome was in-hospital mortality. Receiver operating characteristics curve revealed AUC 0.715 (95% CI 0.63-0.8) sensitivity 0.78, specificity 0.65, OR 6.423 (CI, 2.659 to 16.026) for a cutoff value of NLR 5.5. The association between NLR and in hospital mortality was not statistically significant (p = 0.92).

Conclusions: Plasma NGAL had a predictive value for distinguishing AKI but it itself had a limited value for distinguishing prerenal AKI from other causes of AKI.

SA-PO219
Neutrophil/Lymphocyte Ratio for Early Detection of Acute Kidney Injury (AKI) in Patients Admitted to the Emergency Room Mohsen Abu Alhefia, Ntsho N. Slotki, Linda Shavit. Adult Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.

Background: Neutrophil to lymphocyte ratio (NLR) is a readily available biomarker of systemic inflammation. Several studies have provided evidence of an association between elevated NLR and adverse outcomes in a variety of medical and surgical conditions, including CKD. In this study, we evaluated the predictive capacity of single Emergency Room (ER) measurement of NLR for early diagnosis of acute kidney injury (AKI).

Methods: We prospectively studied 294 patients aged 71.6 ± 17. NLNR was measured at presentation to the ER.AKI was defined as a new-onset 1.5-fold or more increase in serum creatinine or a 25% decrease in estimated GFR sustained for at least 3 days despite volume resuscitation. The primary outcome was AKI. Secondary outcome was in-hospital mortality. Results: 36 patients (12.2%) developed AKI and 26 (9%) died. Mean NLR was significantly higher in AKI compare to non-AKI patients (11.7 ± 5.2 vs 6.4 ± 5.8; p=0.008). A multivariate model adjusted for age, gender, blood pressure, and plasma albumin levels confirmed that NLR is higher in AKI patients (p=0.048). Receiver operating characteristics curve revealed AUC 0.715 (95% CI 0.63-0.8) sensitivity 0.78, specificity 0.65, OR 6.423 (CI, 2.659 to 16.026) for a cutoff of NLR 5.5. The association between NLR and in hospital mortality was not statistically significant (p = 0.92).

Conclusions: Single ER measurement of NLR can be a useful tool for early diagnosis of AKI. This finding is particularly important in light of the widespread availability and low cost of NLR, especially compared with other biomarkers currently under study in the context of AKI.

SA-PO220
Urine Klotho in Human AKI Javier A. Nevra, Xilong Li, Beverley Adams-Huet, Carolina De La Flor, Ming Chang Hu, Robert D. Toto, Orson W. Moc. Nephrology, UT Southwestern; Clinical Sciences, UT Southwestern; Mineral Metabolism, UT Southwestern, Dallas, TX.

Background: AKI is associated with increased morbidity and carries increased risk for subsequent CKD. Klotho deficiency has been observed in experimental AKI and low Klotho post-AKI is associated with progression to CKD in rodents. We report the first study of Klotho in human AKI.

Methods: We conducted a prospective study of 29 AKI patients and 29 controls without AKI in the ICU setting. We excluded patients with baseline GFR<60 or kidney transplant. Urine samples were obtained within 24h of peak serum creatinine (SCr) or at RRT initiation

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

676A
in AKI cases, and within 24h of ICU admission in frequency-matched controls. AKI was defined by KDIGO criteria. Longitudinal data from AKI cases were obtained throughout hospital stay. Renal recovery was defined as the ratio of follow-up SCr/baseline SCr £1.5. Urine Klotho was measured by immunoprecipitation-immunoblot. Mixed-effects linear models were constructed to assess longitudinal trends of Klotho in AKI survivors.

Results: Mean (SD) age was 58 (17) years, 62% were men and 75% white. Patients with AKI had higher critical illness scores than controls without AKI. Five (17.2%) patients died and 8 (27.6%) required RRT in the AKI group. Only 3.5% patients died in the control group. Urine Klotho adjusted by urine creatinine (uKlotho/Cr) was significantly lower in AKI cases than in controls, median 10 [IQR 4–20] vs 28 [14–52] fmol/mg, p=0.003. Furthermore, uKlotho/Cr significantly increased with time in patients that exhibited renal recovery (n=7, Δ+216%, p=0.05) but not in those that did not (n=7, Δ+8%, p=0.91), median follow-up 24 days.

Conclusions: uKlotho/Cr is significantly lower in patients with AKI when compared to ICU controls without AKI. uKlotho/Cr recovered only in patients that recovered kidney function. Klotho may serve as a prognostic marker for AKI recovery.

Funding: Other NIH Support - University of Texas Southwestern Medical Center O’Brien Kidney Research Core Center (NIH, P30 DK079328-06) and the National Center for Advancing Translational Sciences of the National Institutes of Health (NIH, UL1TR001005).

Biomarkers of Acute Kidney Injury in Children Treated with Cisplatin

Kelly McManahon,1 Shahrad Rod Rassekh,2 Kirk Raymond Schultz,3 Maury N. Pinsk,4 Tom D. Blydt-Hansen,2 Cherry Mammen,4 Ross T. Tsuyuki,5 Prasad Devarajan,4 Michael Zappitelli,1 1 McGill U, Montreal; 2 U British Columbia, Vancouver; 3 U Alberta, Edmonton, Canada; 4 Cincinnati Children’s Hosp, Cincinnati.

Background: Cisplatin(CisP) causes acute kidney injury(AKI) and may cause chronic kidney disease(CKD). Biomarker(Bio) may allow early AKI diagnosis and treatment. Applying BioM to Long-Term Effects in Child/Adolescent Cancer Treatment(ABLE) is a Canadian study of cancer treatment toxicities, including nephrotoxicity. We study BioM of child CisP treatment for early and late renal outcome prediction. This analysis evaluates neutrophil gelatinase-associated lipocalin(NGAL), kidney injury molecule-1(KIM-1) and serum Cystatin C(CysC) with CisP therapy in the first 1/3 of subjects.

Methods: Ongoing, 8-site, prospective cohort of 150 children receiving CisP. Excluded: severe CKD. Protocol includes 2 “acute” visits[AV] around CisP infusion(pre, post, discharge urine/blood) for serum creatinine(SCr), CysC, urine NGAL, KIM-1. Outcomes: AKI(Kidney Disease Improving Global Outcomes[KDIGO]) Scr criteria; AKI by National Cancer Institute(NCI) criteria(based on serum electrolytes).

Results: Data available in 44/60 (mean/SD age 7.6yrs; AV1/AV2 hospital stay 16±27/12±26 days; 55% male). AV1: 11% KDIGO AKI, 46% NCI AKI, 50% with either. AV2: 14% KDIGO AKI, 72% NCI AKI, 75% with either. BioM drop immediately post-CisP(n=23), followed by a rise at discharge.

Conclusions: A similar pattern is seen in AKI and non-AKI groups and when expressing BioM/urine creatinine(not shown).

Funding: Government Support - Non-U.S.

Elevated Renal Injury Biomarkers Fall Transiently After Stenting in Human Atherosclerotic Renal Artery Stenosis (ARAS)

Wei Wang1,2, Ahmed Saad,1 Sandra Herrmann,1 Alfonso Eirin,1 Hui Tang,1 Lilach O. Lerman,1 Stephen C. Textor1,1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Nephrology, Dalian Municipal Central Hospital, Dalian, Liaoning, China.

Background: ARAS reduces blood flow and perfusion pressures to the post-stenotic kidney (STK), ultimately producing inflammatory injury. The aim of our study was to identify and track renal injury biomarkers for 24 hours and 3 months after combined CT imaging and stent revascularization.

Methods: 12 patients with severe ARAS scheduled for revascularization for clinical indications were enrolled in a 3 day inpatient and restudied 3 months later. All subjects maintained ACE/ARB Rx and fixed Na+ intake, and were compared with Essential Hypertensive(EH) (n=12) undergoing the same biomarkers and imaging studies. Glomerular filtration rate (GFR) was measured by iothalamate clearance, blood flow and perfusion by Multidetector Computerized Tomography (MDCT) and NGAL, MCP-1, IL-10, TNF-α, KIM-1, IGFBP7 and TIMP-2 in renal vein and peripheral blood/IVC samples every 6 hours for 24 hours and after 3 months.

Results: Kidney perfusion, whole kidney blood flow, single kidney iohalamate GF were reduced in the STKs compared to kidneys from EH and increased after stent revascularization.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

date, it is unclear which intrinsic factors trigger the onset of SIRS and associated AKI. We investigated the role of mtDNA during systemic inflammation and AKI and the role of platelets herein.

Methods: Human platelets were stimulated with mitochondrial DNA, genomic DNA or unmethylated CpG-enriched oligonucleotides (CpG ODN). Platelet activation was measured using FACs. In a single centre prospective observational study we included 37 patients diagnosed and classified for the onset of SIRS with or without the development of AKI that were admitted to the ICU. As a control we included (n=25) patients after elective major surgery without a diagnosis of either SIRS or AKI. Blood and urine samples were isolated and processed. Free circulating plasma and urinary mtDNA was determined by RT-PCR. Inflammatory mediators and PF4 in urine were measured using specific ELISA.

Results: Mitochondrial DNA, but not genomic DNA triggered platelet activation. Unmethylated CpG ODN, dose dependently stimulated platelet activation. Compared to ICU-controls, critically ill patients with SIRS demonstrated elevated levels of plasma and urinary mtDNA and proinflammatory cytokines. Compared to SIRS patients without AKI, the patients with AKI displayed elevated levels of urinary PF4—indicative of platelet activation.

Conclusions: The development of AKI in critically ill patients is associated with platelet activation, possibly triggered by mitochondrial DNA.

Invaders in the Night: Sleep Apnea and Sub-Clinical Renal Injury
Aaron A. Rampal,
Shahab Bozorgmehr, 1 Areef Jihani, 2,3 F. David Weiner, 1 Satish P Ramachandrarao, 1 Rebecca Belay, 1,4 Muna T. Canales. 1,4
1 Univ of Florida, Gainesville, FL; 2 Minneapolis VAMC; 3 Univ of Minnesota, Minneapolis, MN; 4 Malcom-Randall VAMC, Gainesville, FL; 3 Univ of California, San Diego, CA.

Background: Sleep apnea is common in patients with CKD. We postulated that sleep apnea may cause renal injury through repeated ischemia-reperfusion. The current study correlated overnight changes in urinary excretion of renal injury biomarkers with severity of sleep apnea.

Methods: 39 consecutive participants in the SNORE Study. A longitudinal study of sleep apnea and kidney function decline, underwent overnight sleep study and provided spot urine samples before and after sleep. We measured urinary NGAL, L-FABP, KIM-1, and urinary cystatin C levels, and correlated differences between AM and PM levels (AM-PM) with severity of sleep apnea or hypoxia. Sleep apnea was defined by the apnea-hypopnea index (AHI, events/hour); hypoxia was % total sleep time <90% SaO2 (%TST90). Data were log-transformed to normalize distribution.

Results: Patient characteristics: Mean age, 73.6 ± 8.4 years; 90% male; 78% Caucasian, 13% black; BMI 29.4 ± 4.2 kg/m2; MDRD eGFR, 34.3 ± 18.1 ml/min/1.73m2; Median urinary albumin/creatinine ratio, 46 mg/gCr [IQR 9-357 mg/g Cr]. 69% had sleep apnea (AHI ≥ 5); median AHI 10 [IQR 2-23]; median %TST90, 15 [IQR 2-23]; with 34% %TST90 < 10%.

Conclusions: The correlation of KIM-1 with hypoxia suggests that SA may contribute to CKD through ischemic renal injury. Future studies with larger sample size and in non-CKD populations are needed to further test this hypothesis.

SA-PO226

Body Mass Index and Acute Kidney Injury in Hospitalized Patients
Yan Lun Allen Liu, Milind Nikam, Lee Ying Yeoh. Dept of Medicine, Khoo Teck Puat Hospital, Singapore.

Background: Acute kidney injury (AKI) is common in hospital settings. The association between AKI and Body Mass Index (BMI) in general hospitalized patients is not known. This study is to explore the incidence of AKI and the impact of BMI on AKI in hospitalized patients.

Methods: This was a single centre, retrospective, case-control study. All patients aged 21 or above under in-hospital care from January to December 2013 were recruited for analysis. We calculated the incidence of AKI according to the Kidney Disease: Improving Global Outcomes (KDIGO) criteria among different BMI groups (underweight [BMI < 18], normal [BMI 18-23], overweight [BMI 23-25] and obese [BMI ≥ 25]), and then analyzed the risks of developing AKI within and between groups. Baseline creatinine was defined as the most recent value obtained in hospital up to 12 months before admission. If no previous serum creatinine was available, the lowest serum creatinine during hospitalization was used instead. If only one serum creatinine result was known during hospital stay, the baseline creatinine was estimated by the use of simplified Modification of Diet in Renal Disease (MDRD) eGFR (assuming a correction factor for white ethnicity). Underweight patients (BMI < 18) had statistical significantly more stage 1 AKI than the rest of the population, while patients with BMI ≥ 25 had more stage 2 AKI (stage 1 AKI for underweight, normal, overweight and obese patients was 15%, 10.2%, 9.4% and 10.3% respectively; stage 2 AKI, 7.6%, 6.3%, 6.4% and 5.2% respectively). There was no difference in frequency of stage 3 AKI among different BMI groups.

Results: A total of 12567 patients were recruited for analysis. Mean age was 62.5 ± 18.5 years. Male patients constituted 53.8% of the study population. 61.9% were Chinese ethnicity. There were 2656 patients suffered from AKI (21.1% of the whole study population), with 10.7% of them having stage 3 AKI. Underweight patients (BMI < 18) had statistically significantly more stage 1 AKI than the rest of the population, while patients with BMI ≥ 25 had more stage 2 AKI (stage 1 AKI for underweight, normal, overweight and obese patients was 15%, 10.2%, 9.4% and 10.3% respectively; stage 2 AKI, 7.6%, 6.3%, 6.4% and 5.2% respectively). There was no difference in frequency of stage 3 AKI among different BMI groups.

SA-PO224

AKI Development Upon SIRS Is Associated with Platelet Activation, Possibly Triggered by Mitochondrial DNA Derived from Damaged Cells
Marcel Jansen, 1 Wilco P. Pulsken, 1 Diba Emaai, 1 Sandrine Florquin, 1 Joris J. Roelofs, 1 Jaklien Leemans. 1 Nephrology, Academic Medical Center, Amsterdam, Netherlands; 1 Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: Multiple inflammatory pathways are activated by non-infectious agents during Systemic inflammatory response syndrome (SIRS) leading to collateral damage, including the development of acute kidney injury (AKI). Pattern recognition receptors (PRRs) of the innate immune system sense Damage-Associated Molecular Patterns (DAMPs) leading to an immune response. Components of mitochondria e.g. unmethylated CpG-enriched mitochondrial DNA (mtDNA) that leak upon cell injury, are a source of DAMP. Platelets express several PRRs and play an important role in innate immunity. To
Conclusions: Preliminary results revealed underweight hospitalized patients had increased risks of developing stage 1 AKI. Stage 2 AKI was more commonly seen in patients with BMI ≤ 25. BMI status was not associated with the development of severe AKI (stage 3).

SA-PO227

Hypermagnesemia as a Risk Factor for the Mortality in Intensive Care Unit Patients with Acute Kidney Injury

Shunichi Shibazaki, 1 Makoto Araki, 1 Kohei Miura, 1 Dajo Inaguma, 2 Dept of Nephrology, Sawa Central Hospital, Chino, Nagano, Japan; 2 Dept of Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.

Background: We need an easily measured biomarkers predicting for the mortality in acute kidney injury (AKI) because of high mortality rate. Therefore, we paid attention for serum magnesium (sMg) levels which reflects the renal tubular damage, and study the relationship sMg and prognosis in intensive care unit (ICU) patients with AKI.

Methods: A cohort study was conducted by collecting data from January to December 2014 in Nagoya Daini Red Cross Hospital. According to sMg at ICU 1st day, three groups were divided; low Mg group (sMg<1.8mg/dL), normal Mg group (1.8mg/dL≤sMg<2.6mg/ dL), and high Mg group (sMg≥2.6mg/dL). AKI was defined as serum creatinine (sCr) abrupt (within 7 days) increase to ≥1.5 times baseline or sCr increase by ≥ 0.3mg/dL. The primary endpoint was 28 days mortality after ICU admission. The secondary endpoint was the renal recovery rate, the renal replacement therapy (RRT) induction rate, and the transition rate to maintenance dialysis. Renal recovery was defined as an absence of AKI.

Results: Out of 1614 ICU patients, 200 patients were included. The number of each groups are following; low Mg group was 55, normal Mg group was 115, and high Mg group was 30. The mortality was higher in high Mg group than in other Mg group (p =0.011). A multivariate analysis identified high Mg group as an independent risk factor for the mortality (p=0.041). High Mg group had 2.39-fold increased odds of mortality against normal Mg group (95% CI 1.04 -5.50). Kaplan-Meier curves showed the high Mg group (within 7 days) increase to ≥1.5 times baseline or sCr increase by ≥ 0.3mg/dL. The primary endpoint was 28 days mortality after ICU admission. Kaplan-Meier curves showed the high Mg group was associated with higher mortality.

Figure 1: Kaplan-Meier curves for the mortality (p =0.003)

There was no significant association between each groups and the secondary endpoints. Conclusions: Hypermagnesemia is an independent risk factor for the mortality in ICU patients with AKI.

SA-PO229

Contribution of Drugs versus Risk Factors in Drug-Induced Renal Injury

Celia D. Capella, 1 Linda Avadish, 1 Etienne Macedo, 1 Dina Cruz, 2 Stuart Goldstein, 1 Jorge Cerda, 1 David T. Selewski, 6 Michael Zappitelli, 3 Andrew J.P. Goldstein, 7 Ravindra L. Mehta. 1 Nephrology, Univ of California San Diego, San Diego, CA; 2Nephrology, Univ of Cincinnati, Cincinnati, OH; 3Nephrology, Albany Medical College, Albany, NY; 4Nephrology, Univ of Michigan, Ann Arbor, MI; 5Nephrology, Univ of Montreal, Montreal, QC, Canada; 6Nephrology, Care HS Hospital India, Hyderbad, India; 7Nephrology, St. James’ Univ Hospital, Leeds, London, United Kingdom.

Background: Drug-induced renal injury (DIRI) is an increasing cause of acute kidney injury (AKI). Attribution of DIRI requires consideration of the drug exposure, the number of drugs involved and underlying or concomitant risk factors (RF). We hypothesized that underlying RF would influence attribution of DIRI.

Methods: The drug induced renal injury (DIRECT) study is an ongoing prospective multicenter study evaluating genetic determinants of the drug exposure. Each enrolled case was adjudicated for causality by two independent nephrologists. We analyzed the first consecutive 86 adult and pediatric AKI cases. We evaluated the percent agreement, kappa statistic, and contribution of each drug (in setting of multidrug injury) and AKI RF.

Results: Adjudicators agreed 87.2% (n=75) had DIRI. For non-DIRI cases, causality could not be established because of competing AKI RF. RF contributed to AKI in 86% of adults and 70% of children. Adjudicators disagreed on the percent attribution for each drug in 52%. For DIRI cases, inter-rater agreement on percentage attributed to drug 1 was 48% with kappa=0.239 (p<0.001). For non-DIRI cases, inter-rater agreement for drug 1 was 81.8% and RF attribution was 96%.

Conclusions: Underlying RF are common in DIRI associated AKI. Causality assessment in DIRI is complex due to difficulty in determining the attribution of drug and RF. CAT for DIRI should incorporate AKI RF and their interaction with drugs. Funding: Private Foundation Support

SA-PO230

Reduced Incidence of Post-Operative Acute Kidney Injury After Cardiovascular Surgery

Dadi Helgason, 1 2 Martin I. Sigurdsson, 2 Ravindra L. Mehta. 1 Dept of Anesthesia, Brigham and Women’s Hospital; 2 Div of Nephrology, Brigham and Women’s Hospital, Boston; 1 Dept of Cardiothoracic Surgery, Landspitali, Reykjavik; 2 Dept of Anesthesia, Brigham and Women’s Hospital, Boston.

Background: Acute kidney injury (AKI) is a serious complication of cardiac surgery. The aim of this study was to examine time trends in incidence and survival of patients diagnosed with AKI following cardiac and thoracic aorta surgery.

Methods: This was a retrospective study of all heart and thoracic aorta operations performed on adults in Iceland from 2007 to 2014. AKI was diagnosed according to the KDIGO criteria based on serum creatinine values in the electronic database of the clinical laboratory at the institution. Survival status was verified at Statistics Iceland. The incidence of AKI and its outcome was compared between the first and second half of the 8 year study period using Chi squared and the Kaplan Meier method. Outcome between AKI and non-AKI patients was compared by propensity score matching (1:2, non-replacement matching).

Results: A total of 2224 patients underwent 2502 operations during the study period, of which 238 (9.4%) were acute operations (range 18-97) years and 70.7% of patients were men. AKI occurred after 417 operations (16.7%). Of these 302 (12.1%), 69 (2.8%) and 46 (1.8%) were of stage 1, 2 and 3, respectively. Incidence of AKI creatinine level was 1.8 mg/dL (range 0.8-17). In 6 patients, renal TMA was biopsy-proven. Renal replacement therapy was required in 10 (12%) patients, plasma exchanges (PEx) were performed in 17 (21%), 8 (10%) received fresh frozen plasma infusions, 9 (11%) corticosteroids, and 3 (4%) eculizumab (after PEx failure). Evolution data were available for 59 (73%) patients, among which the 17 treated with PEx. Hematological and renal remission was achieved in 35% with PEx versus 50% without, hematological remission without renal improvement in 18% with versus 26%, and no improvement was observed in 47% with versus 24% without PEx. Only one patient improved with eculizumab.

Conclusions: Gemcitabine treatment can be associated with TMA and severe renal adverse effects. The benefit of plasma exchange or eculizumab in this setting remains uncertain.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

679A
decreased from 19.2% in the first period to 14.5% in the second period (p=0.002). Survival of AKI patients at 30 days and 1 year did not differ between time periods, being 82.6% vs. 83.8% and 79.5% vs 76.8%, respectively (p=0.10). Survival was worse for patients with AKI compared with the propensity score matched control cohort, both at 30 days (86.1% vs. 96.5%, p=0.0001) and at 1 year postoperatively (81.2% vs. 91.5%, p=0.0001).

Conclusions: The incidence of AKI following cardiac and thoracic aorta surgery is decreasing. Nevertheless it still affects one in seven patients and even though most patients have mild AKI, it is associated with increased mortality which remains unchanged over the past decade. Funding: Private Foundation Support

SA-PO231

Acute Kidney Injury in Patients with Chronic Kidney Disease: Aetiology and Survival Comparisons to Non-Acute Kidney Injury Chronic Kidney Disease Population Akib Khan,1 James Ritchie,2 Smeeta Sinha,3 ‘Senior House Officer, Imperial NHS Foundation Trust, London, United Kingdom; ‘Renal Medicine, Univ of Manchester, Manchester, United Kingdom; ‘Nephrology, Salford Royal Foundation Trust, Salford, United Kingdom.

Background: AKI, described by an acute (hours to days) fall in kidney function, is associated with significant morbidity and mortality. Poor outcomes exist when AKI is superimposed on CKD, a disease involving structural or functional renal abnormalities in a chronic setting (>3 months). We present a single-centre prospective observational study; retrospectively analysed. We determine the factors surrounding AKI on CKD. Aetiology, length of stay, specialist review and medication data were examined. We compare AKI on CKD patients’ survival to matched non-AKI CKD patients.

Methods: CRISIS database CKD patients matching inclusion criteria treated at Salford Royal Foundation Trust were studied (n=542). A 2.0-3.0 and >3.0 times serum creatinine increase from last measurement was used to define Acute Kidney Injury Network stages 2 (n=17) and 3 (n=10) events respectively. Controls were matched by age, eGFR and blood pressure. Logistic Regression, Cox-Hazard Ratio and Kaplan-Meier Survival Plots were used.

Results: Aetiological factors associated with AKI included sepsis (48.1%), drug-induced (29.6%) and dehydration (25.9%). Septic-AKI had a 1.405 odds ratio (95%CI:1.009-19.936,p=0.801) of death compared to non-Septic events. Hazard ratio for death due to AKI on CKD compared to non-AKI CKD was 1.77 (95%CI:0.72-4.33, p=0.207). Kaplan-Meier survival function clearly demonstrates this.

Conclusions: Aetiology of AKI in our patient group was similar to that seen in non-CKD studies. There was a clear trend towards increased all-cause mortality in patients with AKI on CKD in comparison to non-AKI CKD patients. Renal function decline rate following AKI on CKD should be explored in the future.

SA-PO232

Prospective Study of Incidence and Early Detection of Acute Renal Failure in Preterm Babies in a Tertiary Center in South India Indira Agarwal, Nithya Ponmudi, Anil K. Kuruvilla, Vijayakumar Theophilus-Sunder. Pediatric Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; Neonatology, Christian Medical College, Vellore, Tamil Nadu, India; Nephrology, Christian Medical College, Vellore, Tamil Nadu, India.

Background: Preterm babies are at risk for ischemia, hypovolemia and hypotension and thus vulnerable to Acute kidney injury (AKI). We aimed to study the incidence and predisposing factors for AKI in preterm babies and to assess the usefulness of urinary NGAL as a predictor of kidney injury.

Methods: Babies born < 32 weeks to 6 weeks were recruited; those with abnormal antenatal renal scans and major congenital anomalies were excluded. Weekly monitoring of urine output, clinical progress, interventions, ventilation, unexpected events and use of nephrotoxic drugs was done. Serum creatinine and urine NGAL was collected at 72 hours of age and weekly thereafter. Descriptive statistics using mean +/- SD for continuous variables and Fisher's exact test for categorical variables and Risk factor analysis using log binomial was performed.

Results: Of the 4823 live births, 80 fulfilled inclusion criteria (10.14%). The incidence of AKI was 12.6%. The risk factors included oligosomia, PDA, nephrotoxic drugs, low Apgar, mechanical ventilation, CPAP and abnormal antenatal scans. Urine NGAL was estimated in 31 babies. It rose earlier and was significantly elevated in those on mechanical ventilation by week 2 while Creatinine rose only by week 3.

NGAL was inversely proportionate to gestational age and birth-weight. Both NGAL rise and creatinine were higher in babies with AKI associated with NSAIDS, umbilical lines and asphyxia.

Conclusions: NGAL holds promise as an early marker of AKI and a non invasive test for serial monitoring of renal function in preterm babies. A study with a larger sample size is required to establish reference values for NGAL in preterm babies.

SA-PO233

Acute Kidney Injury Electronic Alerts in Primary Care Conor Patrick Moran,1 Ying C. Kuan,2 Patrick Lm Lynch,1 Francis Mccarroll.1 1Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; 2Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-46%). A UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition. AKI is regarded as the remit of Secondary care and there have been few studies examining Community Acquired AKI, (CA-AKI). Guidelines have recommended the use of electronic alerts (e-alerts) in both Primary and Secondary care. We examined the incidence and mortality of CA-AKI.

Methods: We introduced AKI e-alerts with accompanying e-guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI in Primary, 1 and Secondary care environments. Data collection was carried out for 3 months. The demographics of both cohorts were compared.

Results: Median age, (74.5 years vs. 75 years), gender distribution, (M:F: 48% / 52%), and median time to death, (8 days vs. 11 days), were comparable. 44 Alerts were from Primary Care and 77 from Emergency Department. Of the Primary Care Alerts, 20 patients were subsequently admitted. Of those who were not, 3 died within 30 days, (1. Died at 5 days, 2. Died at 8 days, 3. Died at 21 days). Despite this, Community-acquired AKI was associated with a 30-day mortality of 10.7%. Hospital-acquired AKI, (HA-AKI), was associated with a 28.2% 30-day mortality, (p=<0.001). Sub-group analysis showed Primary care alert associated with 13.64% mortality and Primary Care alerts with 9.76%, (p=<0.001). Median Age at Death; CA-AKI 80 years. Median time to death; CA-AKI 5 days, HA-AKI 11 days.

Conclusions: AKI is common and associated with a significant morbidity and mortality. CA-AKI is common opportunities at diagnosis and intervention are often missed with grave
consequences. Appropriate management of CA-AKI could help reduce the economic and physical burden associated with AKI and reduce the long-term burden of CKD. Further work is required to expand the role of AKI e-Alerts in Primary Care.

SA-PO234

Acute Kidney Injury Causes and Outcome: A Single Center Experience from Sudan

Background: Acute kidney injury (AKI) is a challenging problem in Africa—a diverse continent with regards to population and financial and medical resources. There are no reliable statistics about the incidence of AKI in Africa. Based on sporadic regional publications the incidence has been estimated at 150 per million population. In addition to infectious diseases, toxins play a major etiologic role in AKI.

Methods: In this study we analyzed data from Omer Belal Renal Center in Soba University Hospital, Sudan, a tertiary referral center with a catchment area of 3 million citizens. All hemodialysis (HD) patients treated for AKI in the period between 1/1/2013 and 12/31/2014 were included in the study.

Results: Out of 520 hemodialysis patients we identified 69 patients with AKI; 39 (56.5%) were males. The mean±SD age was 40.5±17.4 years. Serum creatinine and blood urea levels on admission were 14.7±6.7 and 245±125 mg/dL, respectively. Serum creatinine and blood urea levels at discharge were 2.5±2.1 and 53±32 mg/dL, respectively. 29 patients (42%) experienced recovery of normal renal function; the recorded mortality was 13 %. AKI causes.

Conclusions: AKI has become increasingly prevalent in developing countries, and is associated with severe morbidity and mortality. Many causes of AKI can be prevented by interventions at the individual, community, and regional levels. Efforts should be directed to eradicate causes of AKI, expedite diagnosis, and aggressively manage pre-renal conditions and specific infections.

SA-PO235

Usefulness of Pressepin, Procalcitonin and IL6 as a Biomarkers of Adverse Renal Outcome and Mortality After Cardiac Surgery

Background: Cardiac surgery (CS) is now possible in increasingly high-risk patients. CS: accurate evaluation of surgical risk is crucial. Mortality and negative impact on outcomes in this population. It is possible that a combination of these three biomarker in an inflammatory multi-biomarker panel as opposed to a single biomarker should betaken into account.

Methods: Male Wistar rats were injected intramuscularly with 5mg/Kg body weight(BW) of either 50% glycerol(Gly) or 0.9% saline(S).Five groups were studied: S(n=5), S+Allo(n=6), Gly(n=7), Gly+Allo(n=7), Gly+ivAllo(n=7). S+Allo rats received Allo(300mg/L) in drinking water 7 days prior to and for 24h after Gly/S injection.Gly+ivAllo: intravenous Allo(50mg/Kg BW) 30’ after Gly injection and 30mg/L in drinking water thereafter.

Results: Gly rats showed markedly reduced glomerular filtration rate(GFR,imulin clearance) associated with renal vasoconstriction,renal tubular damage,increased oxidative stress,apoptosis and inflammation.Allo treatment ameliorated all these alterations.Allo reduced muscular oxidative stress and accelerated its recovery.

Conclusions: Prophylactic and therapeutic Allo attenuates Gly-induced AKI by reducing oxidative stress (systemic, muscular and renal),inflammation and apoptosis.It may represent a new therapeutic approach for rhabdomyolysis and myoglobinuric AKI (FAPESP). Funding: Government Support - Non-U.S.

Allopurinol Attenuates Rhabdomyolysis-Induced Acute Kidney Injury: Renal and Muscular Protection

Background: Myoglobinuric acute kidney injury(AKI) is the most severe complication of rhabdomyolysis.Aim: To evaluate the efficacy of allopurinol(Alo) on rhabdomyolysis-induced AKI.

Methods: Male Wistar rats were injected intramuscularly with 5mg/Kg body weight(BW) of either 50% glycerol(Gly) or 0.9% saline(S).Five groups were studied: S(n=5),S+Allo(n=6),Gly(n=7),Gly+Allo(n=7),Gly+ivAllo(n=7). S+Allo and Gly+Allo rats received Allo(300mg/L) in drinking water 7 days prior to and for 24h after Gly/S injection.Gly+ivAllo: intravenous Allo(50mg/Kg BW) 30’ after Gly injection and 30mg/L in drinking water thereafter.

Results: Gly rats showed markedly reduced glomerular filtration rate(GFR,imulin clearance) associated with renal vasoconstriction,renal tubular damage,increased oxidative stress,apoptosis and inflammation.Allo treatment ameliorated all these alterations.Allo reduced muscular oxidative stress and accelerated its recovery.

Conclusions: Prophylactic and therapeutic Allo attenuates Gly-induced AKI by reducing oxidative stress (systemic, muscular and renal),inflammation and apoptosis.It may represent a new therapeutic approach for rhabdomyolysis and myoglobinuric AKI (FAPESP). Funding: Government Support - Non-U.S.

Cell Cycle Progression in the Early Phase of Septic Kidney

Background: The recovery of renal function after acute kidney injury (AKI) is likely controlled by proliferation of surviving tubular cells in damaged nephrons containing cell death or sloughing. However, recent studies revealed that AKI concomitant with sepsis had significantly less tubular cell death than other forms of AKI, such as ischemic- and drug-induced AKI. It has not been examined whether septic AKI accelerates tubular cell proliferation in the condition with less cell death. In the present study, we examined the time-course changes in tubular cell proliferation after sepsis.

Methods: Lipopolysaccharide (LPS) and ceum ligation and puncture (CLP) model were used to induce sepsis in mice. Cell cycle progression was assessed by intravital imaging of Tg(FucCeI)().fluorescent reporter (FucCeI) mice, which express monomeric Kusabira-Orange in G1/G0 phase cells, and immunohistochemistry for Ki67 or bromodeoxyuridine in young (8-12 weeks of age) and old (18-20 months of age) C57Bl/6 mice.

Results: Fucci mice (8 weeks of age) showed an increase in G10 to S transition of tubular cell cycle in the early phase of sepsis (within 2 hours in LPS and 4 hours in CLP). Ki67 and bromodeoxyuridine staining were increased only in young mice (Ki67 cell number: 1.5±0.1 fold increase in both LPS and CLP mice compared to normal control), not in old mice (Ki67 cell number: 0.8±0.1 fold in LPS mice and 1.0±0.1 fold in CLP mice compared to control) at a similar time point observed in Fucci mice. Etoposide, an anti-cancer drug, abolished the cell proliferation after LPS injection in young mice. Importantly, old mice or etoposide-treated young mice showed much worse AKI as compared to young mice at 24h after sepsis. Moreover, mice lacking p21, a cyclin-dependent kinase inhibitor, showed a marked increase in Ki67 cells after LPS (2.2±0.1 fold increase vs. WT mice).

Conclusions: These results indicate that sepsis induces tubular cell proliferation in the early-phase of septic kidney. This situation may be a compensatory mechanism against the development of AKI since the frequency of cell proliferation is inversely correlated with the severity of sepsis. Moreover, cell senescence may worsen this complication leading to an increased risk of AKI.

Hepcidin Mitigates Endotaxin-Induced AKI
Yogesh M. Scindia, Paromita Dey, Sundararaman Swaminathan. Medicine, Univ of Virginia, Charlottesville, VA.

Background: Sepsis is a common cause of acute kidney injury (AKI). Sepsis-associated inflammation induces hypoferremia and thereby limits iron availability to pathogens. It has been shown that hepcidin-induced degradation of ferroportin and consequent iron restriction are key for this hypoferremic state. Since, iron has been implicated in the pathogenesis of both sepsis and AKI, we hypothesized that hepcidin pretreatment would mitigate bacterial endotoxin-induced AKI.

Methods: C57BL/6 were treated with saline or 50 mg of hepcidin, 24 hours prior to LPS (Escherichia coli O111:B4) injection (6.5 mg/kg). Renal function, injury and inflammation markers were examined up to 24 hours post LPS injection. Mouse glomerular endothelial cells (MGEC) were cultured with 100 ng/mL LPS for 6 hours after treating them with and without 1 mg/mL hepcidin for 12 hours.

Results: Kidney function (as measured by serum BUN) significantly declined 2 hours post LPS injection and progressively deteriorated for 24 hours. This was prevented by hepcidin treatment (BUN: LPS; 83.55 Vs Hepcidin + LPS; 32.33, p < 0.001). Renal injury markers were examined up to 24 hours post LPS injection. Mouse glomerular endothelial cells (MGEC) were cultured with 100 ng/mL LPS for 6 hours after treating them with and without 1 mg/mL hepcidin for 12 hours.

Results: Kidney function (as measured by serum BUN) significantly declined 2 hours post LPS injection and progressively deteriorated for 24 hours. This was prevented by hepcidin treatment (BUN: LPS; 83.55 Vs Hepcidin + LPS; 32.33, p < 0.001). Renal injury markers were examined up to 24 hours post LPS injection. Mouse glomerular endothelial cells (MGEC) were cultured with 100 ng/mL LPS for 6 hours after treating them with and without 1 mg/mL hepcidin for 12 hours.

Blockade of KCa3.1 Potassium Channels Protects against Cisplatin-Induced Acute Kidney Injury
Cheng-Lung Chen, Li-Heng Pao.1,2,3,4 Graduated Inst of Life Sciences; 1School of Pharmacy, National Defense Medical Center; Taipei, Taiwan; 2Graduate Inst of Health-Industry Technology; 3Research Center for Industry of Human Ecology, Chung Guang Univ of Science and Technology, Taoyuan, Taiwan.

Background: Anti-tumor efficacy of cisplatin chemotherapy is mainly limited by its toxicity to normal tissues, particularly the kidney toxicity. Tubular apoptotic cell death significantly contributes to the pathogenesis of cisplatin-induced acute kidney injury (AKI). KCa3.1, a calcium-activated potassium channel, has been reported to participate in cell apoptosis. However, the involvement of KCa3.1 in cisplatin-induced AKI is unknown.

Methods: We examined KCa3.1 mediates cisplatin-induced tubular apoptotic cell death in vivo, as well as the development of cisplatin-induced AKI in KCa3.1-/- and pharmacological blockade mouse models in vivo.

Results: Cisplatin treatment triggered an early induction in KCa3.1 expression, which is associated with apoptotic cell death in HK-2 cells, as well as with the development of renal tubular damage and cell apoptosis in mice. By treating with highly selective blocker TRAM-34, we found KCa3.1 inhibition suppressed cisplatin-induced apoptotic cell death in HK-2 cells. In the in vivo study, KCa3.1 deficiency reduced renal function loss, renal tubular damage and apoptotic marker caspase-3 induction in kidneys after cisplatin administration in KCa3.1-/- mice. Pharmacological blockade of KCa3.1 by TRAM-34 similarly attenuated cisplatin-induced AKI in mice. Furthermore, we dissected the underlying mechanisms in which KCa3.1 blocking reduces cisplatin-induced apoptosis. We found KCa3.1 inhibition attenuated the cytochrome c release and the increase of intrinsic apoptotic mediator Bax, Bax cleavage-97, caspase-3 and caspase-9 after cisplatin treatment. We also found KCa3.1 blocking inhibited cisplatin-induced the increase of ER stress mediator caspase-12, which is independent of calcium-dependent protease m-calpain activation.

Conclusions: Blockade of KCa3.1 protects against cisplatin-induced AKI through the attenuation of tubular apoptosis downstream of Bax activation. We propose that a potassium channel that interferes with Bax-NPM interaction in an effective treatment for ischemic AKI.

Bax Mimotope Therapy: Effective Treatment for Ischemic Acute Kidney Injury (AKI)
Zhiyong Wang, Ryan M. Mulhern, Andrea Havasi, Ramon G. Bonegio, Steven C. Borkan. Renal Section, Boston Univ Medical Center; Boston, MA.

Background: Ischemic AKI causes renal cell death partly by Bax-mediated apoptosis. Recent studies show that Bax requires the chaperone nucleosphosmin (NPM) for mitochondrial targeting and apoptosis. We propose that a mimotope that interferes with Bax-NPM interaction is an effective treatment for ischemic AKI.

Methods: To assess mimotope efficacy, 2 mg control or therapeutic Bax mimotope was administered by a single tail vein injection in 6-week old B6 mice either before or after renal ischemia caused by 2 min of bilateral renal pedicle clamping, an insult that produces severe AKI. BUN/Cr, histologic injury score, caspase 3 activity, Bax activation and Bax-NPM interaction were compared in each experimental group at the above time points (n = 8 each group).

Results: Compared to control, Bax mimotope administration 15 min before or 15 min, 1.2 or 3 hr after ischemia significantly improved renal function. No protection was observed if Bax mimotope exposure was delayed for 4 or more hours after ischemia. Although 12% of controls died of AKI, only 2% of animals died in the Bax mimotope groups. Despite equivalent Bax activation in both groups, the Bax mimotope improved histologic injury score, reduced caspase 3 activation and decreased Bax-NPM interaction as assessed by co-immunoprecipitation.

Conclusions: Selective interference of Bax-NPM interaction with a Bax mimotope within several hours of acute ischemia improves survival, significantly reduces the severity of AKI (lower BUN and Cr), decreases histologic injury score and inhibits Bax-mediated apoptosis downstream of Bax activation.

Role of AMPK in Aristolochic Acid-Induced Acute Kidney Injury
Anne-Emilie Deleveys.1 Inês Jadot,2 Vanessa Colombaro,3 Eric De prez,1 Isabelle Habsch,4 Kumar Sharma,5 Nathalie Caron,6 Joelle L. Nortier.7 Free Univ of Brussels; 1,2 Universite Libre de Bruxelles, 3Univ degli studi di Modena e Reggio Emilia, Modena, Italy.

Background: Experimental aristolochic acid nephropathy (AAN) is a pertinent model of tubulo-interstitial nephritis characterized by an early phase of acute kidney injury (AKI) and progression to chronic kidney disease (CKD). In the AAN model, the expression of Klotho, a kidney-specific nephroprotective and recovery. The activation of AMPK represents a potential strategy to prevent the transition from AKI-to-CKD.

Methods: We studied three groups of rats: 1) Sham (S) 2) rats undergone 2.5 mmol/24-h. In contrast, I/R+PFN group showed restoration of CrCl 5.7 ml/day; p<0.05), RBF 5.2 ml/min/100 g BW; p<0.05), and a marked increase in the number and thickness of injured tubules per field.

Conclusions: Activation of Nrf2 alleviates IRI-induced tubular loss through enhancing the antioxidant response system. Nrf2 inducers are one of prospective therapeutic candidates for preventing AKI-to-CKD transition.

Acute Kidney Injury in the Rat Is Prevented by Pirfenidone
Izabel Quezalzatti Lima Posada,1,2 Francisco Fontana,1,2 Nathan Berman,1,2 Claudia Reppel,1,2 Norma Posada,1,2 Inst de Investigaciones Biomédicas, UNAM e Inst Nacional de Ciencias Médicas y Nutricion Salvador Zubiran, Mexico, Mexico; 1Univ Panamericana, Mexico, Mexico; 2Univ degli studi di Modena e Reggio Emilia, Modena, Italy.

Background: Pirfenidone (PFN) is an orally active small molecule which acts mainly through an anti-fibrotic effect, but also possesses antioxidant and anti-inflammatory properties. This study was designed to evaluate the effect of the prophylactic treatment with PFN on acute kidney injury (AKI) due to bilateral renal ischemia (IR) in the rat.

Results: Three groups of rats: 1) sham, 2) S (2) 12 rats undergone 20 min of ischemia and 24-h of reperfusion and, 3) rats treated with PFN (700 mg/kg, 24-h before ischemia (IR), 3) rats treated with PFN (700 mg/kg, 24-h before ischemia (IR)). Serum creatinine, creatinine clearance (CrCl) protein excretion, urinary levels of Hsp72 (UHsp72V) and nitrates and nitrites (UNO2/NO3V) were assessed. Mean arterial pressure (MAP) and renal blood flow (RBF) were recorded 24-h after surgery. Tubular injury (TI) was evaluated in fixed kidneys by counting the cast number and the number of injured tubules per field.

Conclusions: Our results revealed that pre-treatment with PFN prevents AKI in the rat. Part of its renoprotective effects seems to be related with the restoration of NO production. These findings suggest that PFN could be a promising tool in the prevention of AKI in the rat.

HDAC8 Plays a Critical Role in the Epigenetic Activation of Fibroblasts and the Pathogenesis of Renal Fibrosis
Scott R. Manson, Quisha Guo, Katelynn H. Moore, Paul F. Austin. Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.

Background: The development of renal fibrosis is associated with changes in the expression of approximately 10% of the genome, suggesting widespread transcriptional dysregulation. Nonetheless, the roles of critical epigenetic pathways in disease progression remain poorly understood. Here, we examine the biological and therapeutic importance of histone deacetylases (HDACs) in the function of fibroblasts and the pathogenesis of renal fibrosis.

Methods: Renal fibrosis was modeled in vitro by treatment of NRK-49F fibroblasts with the pro-fibrotic cytokine TGF-β and in vivo in mice by unilateral ureteral obstruction (UUO). The role of HDAC proteins was assessed by treatment with the broad spectrum HDAC inhibitor Trichostatin A (TSA) and the HDAC8-specific inhibitor PCI-34051. The translational relevance of these findings was assessed in patients who underwent a nephrectomy following UPI obstruction.

Results: UUO leads to a 6.1-fold increase in HDAC8 expression that localizes specifically to myofibroblasts. In NRK-49F cells, treatment with PCI-34051 promotes myofibroblast differentiation and apoptosis, but suppresses proliferation and matrix synthesis. These findings extend to the injured kidney in vivo, where HDAC8 inhibition results in a 41.6% decrease in COL1A1 and a 61.6% decrease in α-SMA. Furthermore, there is a 77.9% decrease in the interstitial proliferative response, a 43.0% decrease in myofibroblast number, and a 31.1% decrease in renal fibrosis. Finally, the development of renal fibrosis in patient with obstructive kidney disease is associated with a 32.1% increase in the number of HDAC8-positive cells.

Conclusions: Together, these findings demonstrate that HDAC8 plays a critical role in regulating fibroblast activation. Treatment with HDAC inhibitors is also an effective therapeutic approach to reverse the epigenetic changes associated with the pathogenesis of renal fibrosis. Finally, since an increase in HDAC8 expression occurs in patients during disease progression, HDAC8-targeted therapies have therapeutic potential for the treatment of chronic kidney disease.

Renoprotective Effect of Long Acting Thio-redoxin by Modulating Oxidative Stress and Macroglue Migration Inhibitory Factor against Rhabdomyolysis-Associated Acute Kidney Injury
Hiroshi Watanabe, Kento Nishida, Masafumi Fukagawa, Toru Maruyama. Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan.

Background: Rhabdomyolysis-associated acute kidney injury (AKI) is a serious life-threatening condition. As such, more effective strategies are needed for its prevention and treatment. Although thioredoxin-1 (Trx) possesses superior biological activities, such as anti-oxidative and anti-inflammatory effect via the modulating macrophage migration inhibitory factor (MIF), its short blood retention limits the therapeutic application. To overcome this, we engineered long acting Trx by genetically fused with human serum albumin (HSA-Trx), and examined its renoprotective effect against glyceral-induced AKI.

Methods: HSA-Trx was prepared by using Pichia expression system. The mouse model of rhabdomyolysis-associated AKI was induced by the administration of a 50% glycercol solution.

Results: An intravenous HSA-Trx pre-treatment attenuated the glycercol-induced decline in renal function, compared to a PBS, HSA or Trx alone. HSA-Trx caused a reduction in the tubular injuries and in the number of apoptosis-positive tubular cells. Renal superoxide, 8-hydroxy deoxyguanosine, nitrotyrosine and the plasma Cys34-cysteinylated albumin were clearly suppressed by the HSA-Trx treatment. Prior to decreasing TNF-α and IL-6, HSA-Trx suppressed an increase of plasma MIF level. In LLC-PK1 cells, HSA-Trx decreased the level of reactive oxygen species and lactate dehydrogenase release induced by myoglobin. HSA-Trx treatment resulted in a threefold increase in the survival of lethal glycercol-treated mice. The post-administration of HSA-Trx at 1 and 3 hr after glycercol injection exerted a significant renoprotective effect.

Conclusions: HSA-Trx, a long acting Trx, has potential for use in the prevention and treatment of rhabdomyolysis-associated AKI via its extended effects of modulating oxidative stress and MIF.

Reciprocal Effects of HDAC1 and HDAC2 Deletion on Renal Ischemia-Reperfusion Injury
David Dean Authurhouse, Zhonglin Wang, Guanghu Ge, Tricia Bhatti, Wayne W. Hancock, Matthew H. Levine. Surgery, Hospital of the Univ of Pennsylvania, Philadelphia, PA; 1Pathology and Laboratory Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA; 1Pathology and Laboratory Medicine, Hosp of the Univ of Pennsylvania, Philadelphia, PA.

Background: Histone/protein deacetylase proteins (HDACs) have been implicated in renal ischemia-reperfusion injury (IRI). HDAC1 and 2 are highly homologous Class 1 HDACs thought to have similar function.

Methods: This study included wild type C57BL/6 (B6) and inducible HDAC1- or 2- gene deleted mice (HDAC1KO and HDAC2KO). Renal-specific or extra-renal gene deletion was achieved with transplantation, native nephrectomy, and subsequent gene deletion. Warms IRI consisted of unilateral clamping of the renal pedicle and contralateral reperfusion. Cold IRI was achieved through procurement, controlled interval of cold storage, and transplantation.

Results: HDAC1KO mice had impaired renal IRI tolerance compared to controls with higher BUN levels (p<0.01; Figure 1A) and increased fibrosis post-injury. HDAC2KO mice had improved early renal function (p<0.01; Figure 1B) and decreased fibrosis (p<0.01) compared to controls and tolerated extended periods of ischemia. In transplant models, renal-specific HDAC2KO mice had superior IRI tolerance with less renal impairment (p<0.01) and decreased fibrosis (p<0.01) compared to extra-renal HDAC2KO controls. After transplantation with 18 hours of cold ischemia, HDAC2KO donor kidneys had improved BUN (p=0.02) and survival compared to controls.

Conclusions: HDAC1 and 2 have reciprocal effects on murine renal IRI tolerance, with HDAC1 deletion increasing vulnerability and HDAC2 deletion providing protection. The effect of HDAC2 deletion is profound, is intrinsic to the kidney, and extends to cold ischemia and renal transplantation.

Kim-1 Overexpressing Transgenic Zebrafish Identify mTOR as an Effector of Kim-1-Mediated Kidney Injury in Fish and Mice

Wensheng Yin, Said Movahedi naini, Dirk M. Hentschel, Benjamin D. Humphreys, Joseph V. Bonventre. Renal Div, Brigham and Women's Hospital, Boston, MA.

**Background:** Mammalian kidney injury molecule 1 (Kim-1), an epithelial phagocytic receptor, is markedly upregulated in the proximal tubule in various forms of acute and chronic kidney injury in humans and many other species. Here, we characterized the zebrafish Kim-1 homologue, called Kim-1, Kim-3 and Kim-4. By genetically expressing constitutive or tamoxifen-induced Kim-1 in zebrafish kidney tubules, we identified mTOR as an effector in Kim-1-mediated kidney injury. We then validated mTOR as a therapeutic target for kidney injury and fibrosis in Kim-1 overexpressing transgenic mice.

**Methods:** We created two transgenic zebrafish models of Kim-1 overexpression in neoplasms employing the cdh1 promoter. One model utilized a constitutively active promoter while the other utilized a tamoxifen-induced Cre-ERT2 recombinate to express Kim-1 in neoplasms in a temporally-controlled manner. The role of mTOR signaling was evaluated using the inhibitor rapamycin. Zebrafish GFR was determined using the elimination rate of fluorescein-labeled dextran.

**Results:** Kim-1 was markedly upregulated after gentamicin-induced kidney injury and had conserved phagocytic activity in zebrafish. Both constitutive and tamoxifen-induced expression of Kim-1 in zebrafish kidney tubules resulted in shedding of the tubule brush border, reduced GFR, pericardial edema and increased mortality rate. Kim-1-induced kidney injury was associated with inhibition of growth of adult fish. Kim-1 expression led to mTOR inhibition in zebrafish kidney tubules resulting in shedding of the tubule brush border, reduced GFR, pericardial edema and increased mortality rate. Kim-1 and mTOR expression in zebrafish was similar. VAP-1 inhibition resulted in significantly lower mRNA levels of CXCCL1 and CXCCL2 in the kidney without affecting chemokines involved in macrophage recruitment, such as MCP-1, or major adhesive molecules, VCAM-1 and ICAM-1.

**Conclusions:** These data suggest that VAP-1 plays an important role in renal ischemia-reperfusion injuries by controlling neutrophil infiltration, and offer a promising view that its inhibition can be a novel therapeutic target in ischemic acute kidney injury. *Funding: Government Support - Non-U.S.*

Treg and ILC2 Contribute to IL-233 (a Novel Fucosylation-Cytokine)-Mediated Protection in AKI

Maria Stremiska,1 Liping Huang,2 Sheetal Jose,1 Ameadeep Bajwa,1 Diane L. Rosin,1 Mark D. Okusa,1 Rahul Sharma.1 1CHIR, Univ of Virginia, Charlottesville, VA; 2Dept of Pharmacology, Univ of Virginia.

**Background:** Inflammation is an early event in AKI and studies have shown regulatory T cell (Treg)-mediated protection in inflammation driven injuries. Since we found that intraglomerular and tubular hydrostatic pressures in IL-233 (a cytokine expressed in CD4+ cells) were hypothesized to be protective to the kidneys by conduction of renal function. IL-233 is a cytokine which is produced by macrophages and other immune cells and is known to be protective against kidney injury. We sought to determine whether IL-233 and IL-33 cooperate to expand endogenous Tregs. Indeed, a proportion of Tregs constitutively expressed ST2 and IL-33 contributed to promote Tregs. IL-2 and IL-33 in combination or as IL-233 fusion cytokine, but not alone protected mice from IRI, with IL-233 being more efficient than the combination.

**Methods:** We designed a fusion cytokine (IL-233) containing the activities of IL-2 and IL-33 for better targeting of Tregs. The cytokines were expressed in E.coli, purified to homogeneity and tested in a mouse model of ischemia reperfusion injury (IRI). C57BL/6 male mice were pretreated (ip) with different doses of cytokines prior to 26 min of bilateral renal ischemia and 24 hours of reperfusion. Kidneys were characterized for function, acute tubular necrosis and the profile of infiltrating cells.

**Results:** IL-2 and IL-33 in combination or as IL-233 fusion cytokine, but not alone protected mice from IRI. We also hypothesized that IL-233 being more efficient than the combination first increases splenic levels of Tregs followed by their mobilization. Since both IL-2 and IL-33 also promote Th2 response, an increase in IL-4 and IL-5, and a decrease in Th1 cytokines IFNγ and TNFα was seen, indicating a shift towards a protective Th2 response. Protected mice had a higher proportion of neutrophils and lymphoid cells 2 (ILC2) in the blood and the kidneys. Neutrophil infiltration in the kidneys was significantly lowered in IL-233 treated mice. Treg adoptive transfer studies revealed higher degree of protection in mice injected with Tregs obtained from mice pretreated with IL-233. Adoptive transfer of IL-233, pretreated with IL-233 also protected against IRI. In vitro experiments with IL-233 pretreated Tregs revealed their higher suppressive function.

**Conclusions:** Thus, IL-233 cytokine attenuates kidney inflammation to protect from IRI and bears strong potential to be a therapeutic agent for AKI. *Funding: NIDDK Support*
GFR in Conscious Mice After Sepsis: Role of Tubuloglomerular Feedback
Jonathan Street, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. NIDDK, Bethesda, MD.

Background: Reabsorption of glomerular filtrate by the tubules is an energy intensive process. During sepsis the ability of the tubules to meet this energy demand may be impaired. To prevent renal salt wasting during sepsis it is hypothesized that activation of tubuloglomerular feedback reduces GFR and subsequently the metabolic demand on the tubules – “acute renal success”. Mice without tubuloglomerular feedback should maintain higher levels of GFR. In conscious mice we detected early changes in GFR using a novel transcutaneous measurement of a fluorescent filtration marker. Because adenosine A1 receptor (A1AR) signaling is required for tubuloglomerular feedback we directly measured GFR following sepsis in A1AR knockout mice.

Methods: Sepsis was induced in male A1AR knockout mice and littermate controls by cecal ligation and puncture. GFR was monitored in awake mice for 5 hours byplasma disappearance of FITC-Sinistatin, injected at 0 and 90 minutes after surgery, and its transcutaneous fluorescence measured by a miniaturized fluorimeter attached to the mouse back.

Results: The baseline GFR was similar in A1AR WT and KO mice. In WT mice, GFR was stable during the first hour following induction of sepsis. GFR slowly declined over hour two, and then fell rapidly to <10% of normal and remained low for 5 hours. In contrast, the GFR was lower in KO mice than in WT mice in the first hour following sepsis (p < 0.0226), then fell gradually to 27% of normal, with a smaller decrease observed after 2 hours compared to WT mice (p < 0.0286).

Conclusions: In mice lacking tubuloglomerular feedback, unexpectedly, GFR begins to decrease earlier after sepsis suggesting impaired autoregulation. The sudden decrease in GFR in WT mice at 2 hours after induction of sepsis does not occur in A1AR KO mice. Tubuloglomerular feedback modestly supports, not suppresses, GFR in the first hour following sepsis, and only later acts to suppress GFR.

Renal Functional Reserve May Be Inferred from Variation of Renal Resistive Index: Preliminary Evidence
Sara Samoni,1,2 Federico Nalessi,2 Gianluca Villa,3 Silvia De Rosa,1 Ilaria Petrucci,1 Massimo de Cal,1 Fiorenza Ferrari,1 Alessandra Brendolan,2 Mario Meola,1 Claudio Ronco,1 Sant’Anna School of Advanced Studies, Pisa,1 IRRI, Vicenza,3

Background: The increase of glomerular filtration rate (GFR)after a protein load represents the renal functional reserve (RFR). Mechanical abdominal stress (MAS), through the compression of renal arteries and the consequent reduction of renal blood flow, can activate the autoregulation mechanism to maintain glomerular perfusion. Both phenomena are related to the afferent vasodilation, which can be displayed by the drop of renal resistive index (RI) measured by color Doppler. We hypothesized that the variation of RI during MAS may predict the RFR.

Methods: In 15 healthy volunteers, MAS was performed through the application of a saline bag on abdominal wall. According to the performed dose-response curve, we used bags which weigh 10% of subject’s BW. We recorded RI in mesorenal interlobar arteries each min for the 10 min of MAS. The RI reduction was defined by the difference between baseline RI and the lowest RI reached during MAS and expressed as percentage reduction (pDRI).

Results: RFR was measured through a standardized protein loading test. Spearman’s correlation was applied to evaluate if pDRI correlates with RFR.

Conclusions: We enrolled 9M and 6F with a median age of 30[24-57] yrs old. The median baseline CrCl was 99.2[70.3-132.8] ml/min/1.73 m². The RFR ranged between 11.55% and 9.0%; M60’-72.1% ±3.25%. These changes were accompanied by 5 fold increases of MDA levels and GSH depletion. LDH release and MDA production were iron and NAPH oxidase (Nox) dependent since they were blocked by deferoxamine or the Nox1/4 inhibitor GKT 137831.

Conclusions: ALA has renoprotective effects in glycerol-injected AKI. ALA is already used in clinics for this indication. ALA has the potential to prevent cisplatin-induced AKI via the induction of HO-1, and prevention of tubular apoptosis. We hypothesize that ALA plays a renoprotective role via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

5-Aminolevulinic Acid Attenuates Rhabdomyolysis-Induced Acute Kidney Injury in Mice
Atsushi Uchida, Minoru Satoh, Tamaki Sasaki, Naoki Kishihara. Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.

Background: Rhabdomyolysis often occurs after severe skeletal muscle injury, and high mortality has been reported with the acute kidney injury (AKI) that develops subsequently. Thus, the establishment of effective prevention and treatment is a pressing problem. 5-Aminolevulinic acid (ALA) is the naturally occurring metabolic precursor of heme, and serves as protein material related to energy production. Previous study demonstrated that ALA has the potential to prevent cisplatin-induced AKI via the induction of heme oxygenase (HO)-1, and prevention of tubular apoptosis. We hypothesize that ALA plays a renoprotective role via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

Conclusions: ALA has renoprotective effects in glycerol-injected AKI. ALA is already used in clinics for this indication. ALA has the potential to prevent cisplatin-induced AKI via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

SA-PO257
Ferroptosis as a Cause of Proximal Tubule Injury
Joel M. Weinberg,1,2 Andreas Linkermann,3 1Nephiology, VA Healthcare System Ann Arbor, Ann Arbor, MI; 2Nephrology, Univ of Michigan, Ann Arbor, MI; 3Nephrology, Christian Albrechts Univ, Kiel, Germany.

Background: “Ferroptosis” has recently been described as a form of iron-dependent, lipid peroxidation-mediated cell death with a distinct injury pattern relative to other forms of necrosis and there is evidence that it contributes to AKI in vivo (PNAS 111:16835.2014, Nat. Cell Biol. 16:1180,2014). Here, we have refined approaches to study ferroptosis in freshly isolated proximal tubules (PT) and assessed new agents being developed to ameliorate it.

Methods: Freshly isolated rabbit (R) and mouse (M) PT were treated with either tert-butylhydroperoxide (IBHP, 5 mM) or hydroxynolinone + ferrous ammonium sulphate (HQ+Fe,10 μM each) followed by incubation for 120 min, then measurement of LDH release, malondialdehyde (MDA) production, mitochondial membrane potential, and GSH.

Results: IBHP and HQ+Fe induced progressive LDH release that was more severe in M PTs (R: HQ+Fe: R60'-35.5±6.8%, B20’-51.4±9.6%; M60’-72.1±2.6%, M20’- 87.4±3.2%). These changes were accompanied by 5 fold increases of MDA levels and GSH depletion. LDH release and MDA production were iron and NAPH oxidase (Nox) dependent since they were blocked by deferoxamine or the Nox1/4 inhibitor GKT 137831. Feri-1, the prototypical ferroptosis inhibitor, attenuated mechanical stress-induced cell death, strongly alleviated both forms of injury and associated MDA production at concentrations of 0.1 to 2 μM as did a panel of 23 other ferrostatin analogs with potencies similar to those seen in isolated non-renal cell systems. Interestingly, the lipidic antioxidant, diphenyl-p-phenylendiamine (DPPD), was even more potent than the highly active ferrostatins. Ferrostatins were not effective against acute cell killing and energetic deficits induced by hypoxia/reoxygenation, indicating that the benefit seen during in vivo ischemia/reperfusion does not target that phase of injury.

Conclusions: Ferroptosis is strongly expressed in fully differentiated PTs, is suppressed by both newly developed ferrostatins and the classical lipidic antioxidant, DPPD, and is an injury process that can be targeted to alleviate AKI.

SA-PO260
Identification and Characterization of IGFBP7 and TIMP2 Expression in Human Proximal and Distal Tubule Cells
David R. Emlet,1 Nuria M. Pastor-Soler,1 Allison L. Marciszyn,2 Xiaoyan Wen,1 Jacob K. Volpe,1 John A. Kellum,1 1Center for Critical Care Nephrology, Dept of Critical Care Medicine, Univ of Pittsburgh, Pittsburgh, PA; 2Renal Electrolyte Div, Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.

Background: Interleukin-1α (IL-1α) and tumor necrosis factor-α (TNFα) expression are increased in human proximal tubule cells. 5-Aminolevulinic acid (ALA) is the naturally occurring metabolic precursor of heme, and serves as protein material related to energy production. Previous study demonstrated that ALA has the potential to prevent cisplatin-induced AKI via the induction of heme oxygenase (HO)-1, and prevention of tubular apoptosis. We hypothesize that ALA plays a renoprotective role via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

Conclusions: ALA has renoprotective effects in glycerol-injected AKI. ALA is already used in clinics for this indication. ALA has the potential to prevent cisplatin-induced AKI via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.
Methods: The cortex of human kidneys were dissociated and viable cells cultured. Proximal and distal tubule epithelial cells (PTECs and DTECs) were isolated with antibodies against CD13 and CD227 using the Dynabead pan-mouse IgG system. Isolated cells were cultured on transwell supports and characterized by immunoblot and immunofluorescence.

Results: CD13 isolated cells were positive for the PTEC markers Gamma Glutamyl Transferase and Aquaporin1. CD227 isolated cells were negative for GGT and AQP1 but positive for the distal tubule markers CD227 and E-cadherin. Microscopy demonstrated that both PTECs and DTECs formed tight junction monolayers with a low percentage of cells in cycle as identified by Ki-67. Analysis of conditioned media demonstrated that the conditioned media secreted IFNβ and TNFα. 2. Important proteins involved in the secretion of IFNβ and TNFα were identified as extracellular DNA.

Conclusions: We have developed a novel cell culture model system of PTECs and DTECs for the cellular/molecular analysis of AKI. We confirmed that IFNβ and TNFα can be expressed and secreted by these cells, and we have identified differential expression and secretion of these proteins across cell types and spatially within cells. These systems and knowledge will now allow for investigation of the potential role of these biomarkers in the molecular etiology of AKI.

Klotho and S100A8/A9 as Discriminative Markers Between Pre-Renal and Intrinsic AKI

Ji Yong Jung.1 Eun Sik Jung.2 Byoungho Choi.1 Jun Jung Oh.1 Chungsik Lee.1 Hyun Hee Lee.1 Wookyoung Chung.1

1 Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; 2 Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.

Background: Early detection and accurate differentiation of the cause of acute kidney injury (AKI) is essential for the prognosis of the patient. However, to date, there are few reliable biomarkers for the discrimination of pre-renal and intrinsic AKI. The purpose of this study was to determine whether AKI is associated with an altered level of klotho and S100A8/A9 (an endogenous toll-like receptor 4 ligand), and NGAL (neutrophil gelatinase-associated lipocalin) protein that may contribute to differentiate between pre-renal and intrinsic AKI.

Methods: Volume depleted pre-renal AKI model was induced by male Sprague-Dawley rats were fed a low-salt diet (0.03%) without water 96hr before two times at intraperitoneal (IP) injection of sodium fluoride (20 mg/kg) at 24hr intervals. In contrast, cisplatin-induced intrinsic AKI model were given by a single IP injection of cisplatin (5 mg/kg). All animals were euthanized 72hr after first IP injection. We also performed a proof of concept cross-section study to measure serum and urinary biomarkers in 77 hospitalized patients with established AKI.

Results: Compared with intrinsic AKI group, pre-renal AKI group caused a marked depression of urinary klotho level (13.21 ± 17.32 vs. 72.97 ± 19.76 pg/ml, P = 0.002). In addition, intrinsic AKI group caused a marked elevation of S100A8/A9 level than those of pre-renal AKI group (25929.97 ± 598.05 ng/ml vs. 685.09 ± 111.85 ng/ml, P = 0.002 in serum; 1361.11 ± 230.86 ng/ml vs. 741.72 ± 101.96 ng/ml, P = 0.003 in urine). Serum and urinary NGAL showed no difference between pre-renal and intrinsic AKI group. The proof of concept study with hospitalized AKI patients also demonstrated decreased urinary klotho in pre-renal AKI patients and increased urinary S100A8/A9 concentrations in intrinsic AKI patients.

Conclusions: The attenuation of urinary klotho and increment of urinary S100A8/A9 may contribute to discriminate the pre-renal AKI and intrinsic AKI.

Release of Extracellular DNA Contributes to Renal Ischemia Reperfusion Injury Through Platelet Activation and Formation of Neutrophil Extracellular Traps

Marcel Jansen.1 Diba Emal.1 Sandrine Florquin.1 Joris J. Roelofs.1 Pathology, Academic Medical Center Amsterdam, Amsterdam, Noord Holland, Netherlands.

Background: Renal ischemia reperfusion injury (IRI) results from a complex interplay between platelet activation and neutrophil extracellular traps (NETs) leading to tissue damage. It has been shown that platelet inhibition protects from IRI. How platelets are activated upon renal IRI is not entirely known. In this study we investigate renal cell death, extracellular DNA release and neutrophil extracellular traps (NETs) as potential triggers for platelet activation and renal IRI injury.

Methods: We stimulated platelets with necrotic renal cells in presence or absence of DNAse1. Supernatant from necrotic renal cells stimulated platelet activation and formation of neutrophil extracellular traps (1066 pg/ml, P<0.05). The highest expression of proinflammatory factor significantly decreased and anti-inflammatory factor significantly decreased in -1h and 0h groups compared with other point time groups in 1h, 12h and 14h groups.

Conclusions: Mice were subjected to renal I/R and treated with DNAse1 or vehicle, and sacrificed after 1 day. As marker for NET formation in tissue we stained renal tissue for citrullinated histone H3 and granulocyte marker Ly6G. In blood we measured Platelet Factor 4 (PF4), DNA, creatinine and urea.

The Role of Senescence of Bone Marrow Cells in Acute Kidney Injury

Hoon Kyung Kim.1 Sung Yoon Lim.1 Jihyun Yang.1 Young Ju Na.1 So-Young Lee.2 Sang-Kyung Jo.1 Won-Yong Cho.1

1 Dept of Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea; 2 Dept of Internal Medicine, Eulji Univ Hospital, Seoul, Republic of Korea.

Background: There have been considerable growth in older population and age-related kidney disease in the world. It was demonstrated that the impairment in the potentiality to repair and regenerate of renal resident cells is a hallmark of biological processes associated with aging. However, the impact of senescence of bone marrow derived cells (BMDC) on kidney injury is not known. Here, we investigated the role of senescence of BMDC in the development and progression of ischemic acute kidney injury (AKI).

Methods: Seven wk-old female mice were subcutially irradiated and reconstituted with bone marrow from 12-mo-old (old-to-young, old BMT) or 7-wk-old (young to young, young BMT) mice. Then we performed renal ischemia reperfusion injury (IRI) in old or young BMT mice, and functional, histological kidney damage and inflammation were compared.

Results: The Y chromosome was detected in peripheral blood of BMT mice indicating successful reconstitution of female mice with male bone marrow. Although the population of immune cells was in spleen between old and old BMT mice was significantly different, old BMT mice showed less renal functional deterioration and histological damage after IRI. This was associated with less infiltration of F4/80 macrophages and lower level of tissue cytokine (IL-12). In vitro study with BMDCs also revealed that LPS-induced cytokine production (IL-12, MCP-1 and IL-10) were significantly suppressed in old BM cells than young BM cells.

Conclusions: Our data shows that senescence of BMDC could affect susceptibility and response to renal ischemic injury possibly via immune modulatory effect. A better understanding of these processes may help to develop new strategies that are specifically tailored for treatment of the elderly population.

SA-PO266
Optimal Transplantation Timing of Mesenchymal Stem Cell in Rat Model of Renal Ischemia Reperfusion Injury

Xiaojuan Liu.1 Xiaofang Yu.1 Jieru Liu.1,2 Young Ju Na.1 Eulji Univ Hospital, Seoul, Republic of Korea.

Background: To investigate whether timing of mesenchymal stem cells (MSCs) transplantation can determine the survival and therapeutic potential of MSCs in ischemic kidney.

Methods: The model of renal IRI was induced by the release of bilateral renal pedicle clamping for 60 min. 60 rats were divided into 5 groups, 4 groups were sacrificed at 1h, 12h, 24h after reperfusion, the remaining one group was sacrificed at 0h, 1h, 12h, 24h, 48h, 72h and 1 week post-IRI respectively. Passage 3 rat MSCs were cultured with different time points kidney homogenate supernatants. After reperfusion, CM-Dil-labeled MSCs or vehicles only were administered through the carotid artery of the animals. 1h before reperfusion(-1h) and immediately(-0h), 12h, 24h after reperfusion. The animals were sacrificed after 48h after reperfusion and 24h after MSCs transplantation.

Results: The survival rate was 47% at 24h of reflow(470.6±41.65/mm, P<0.05) and NGAL peaked at 12h(7607±1066 pg/ml, P<0.005). The highest expression of inflammatory factor was in the 1h, 12h and 24h groups. Significant kidney function and histological damage improvement was observed after the treatment of MSCs in -1h and -0h groups. Meanwhile, the expression of proinflammatory factor significantly decreased in -1h and -0h groups compared with other groups. Significant kidney function and histological damage improvement was observed after the treatment of MSCs in -1h and -0h groups. Significant kidney function and histological damage improvement was observed after the treatment of MSCs in -1h and -0h groups.

Conclusions: MSCs transplantation 1h before reperfusion or immediately after reperfusion produces the most dramatic improvement in renal function and morphology in a model of renal IRI injury. It is the optimal timing to transplant MSCs in IRI before the inflammatory response is established.

Renoprotective Role of Par1β in Acute Kidney Injury

Abhijit Pal.1 Natalie S. Uy.1 James M. Pullman.2 Zhongfang Du.1 Kimberly J. Reidy.1 1Pediatric Nephrology, Children’s Hospital at Montefiore, Montefiore Medical Center/Albert Einstein Medical College, Bronx, NY; 2Pathology, Montefiore Medical Center/Albert Einstein Medical College, Bronx, NY.

Background: Partitioning defective Par1β (aka MARK) is a member of the Par polarity protein family and that localizes to the basolateral aspect of renal tubular cells. Defects in apico-basal polarity and cell-cell adhesion occur in acute kidney injury (AKI). Mammalian homologues Par1a and 1b are serine threonine kinases that

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
are functionally redundant on kinase assays. We have identified Par1a and Par1b expression in mouse models of tubular injury and human kidney tissue (leftover from clinically indicated renal biopsy). Proximal tubular injury was induced by in wild-type(WT) and Par1b knockout mice by injecting cisplatin (30mg/Kg, ip) or folate acid (250 mg/kg, ip). The degree of histological damage was assessed by light microscopy. The expression of Par1a was decreased in cisplatin or folate acid treated mice compared to WT. Immunohistochemistry failed to reveal increased expression of mouse terminal deoxynucleotidyl transferase deoxyuridine triphosphate nick end labeling assay. Our data demonstrates that Par1 proteins have a nemo-protective role in tubular injury. Further studies of the mechanisms of this effect and interaction with Notch signaling are ongoing.

Small Heat Shock Protein Beta-1 (HSPB1) Is Upregulated and Regulates Mitophagy and Apoptosis of Renal Tubular Cells in Acute Kidney Injury

Tatsuki Matsumoto, Kazu Hamada-Ode, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Taro Horino, Yoshinori Taniguchi, Shimeji Fujimoto, Yoshio Terao. Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan.

Background: Heat shock protein beta-1 (HSPB1, also known as HSP27) is a small heat shock protein involved in many cellular processes and reportedly protects cells against oxidative and inflammatory stresses. Autophagy promotes cell survival and is thought to play a key role in preventing stress in acute kidney injury (AKI). However, little is known about the role of HSPB1 in autophagy and apoptosis in the pathogenesis of AKI.

Methods: We used a rat ischemia/reperfusion AKI model and cultured renal tubular cells as an in vitro model. To elucidate the regulation of HSPB1, we evaluated the promotor activity and expression of HSPB1 in normal rat kidney (NRK)-52E cells in the presence of H2O2. To examine the regulation of autophagy by HSPB1, we established NRK-light chain 3 (NRK-LC3) cells that were stably transfected with a fusion protein of green fluorescent protein and LC3.

Results: The results of immunohistological examination showed that HSPB1 was expressed in proximal tubule cells after AKI. Real-time quantitative reverse transcription-polymerase chain reaction and western blot analysis showed that HSPB1 mRNA and protein expression were upregulated 6-72 h and 12-72 h, respectively, after ischemia/reperfusion injury. HSPB1 promoter activity as well as mRNA and protein expression indicated dose-dependent induction by H2O2. HSPB1 overexpression-induced autophagy in NRK-LC3 cells under normoxic conditions was confirmed with confocal microscopy, which revealed the presence of LC3-positive granules. Furthermore, H2O2-induced autophagy was inhibited by the transfection of small interfering RNAs for HSPB1. Overexpression of HSPB1 reduced BAX activation and H2O2-induced apoptosis, as measured by caspase 3 activity and terminal deoxynucleotidyl transferase deoxyuridine triphosphate nick end labeling assay.

Conclusions: These results indicate that HSPB1 upregulation plays a role in the pathophysiology of AKI.

SA-PO268

Developing a More Clinically Relevant Mouse Model of Cisplatin-Induced Acute Kidney Injury

Background: Cisplatin, a commonly used chemotherapeutic for the treatment of many solid cancers is known to induce acute kidney injury (AKI) in 30% of patients. Patients that develop cisplatin-induced kidney toxicity must either have the dose severely reduced or be switched to an alternative therapy to prevent long-term renal damage. In many cases the alternative therapy may be less effective at treating the tumor. Due to cisplatin’s complex nephrotoxic profile, the development of renoprotective agents remains a challenge. Currently there are no FDA approved drugs for the protection of cisplatin-induced AKI. The standard mouse model of cisplatin-induced AKI is a single high dose of cisplatin (10-30 mg/kg), and animals are sacrificed 72h after injection. This model does not accurately represent the clinical dosing regimen, which involves repeated dosing of cisplatin.

Methods: In this study we compared the standard single dose model to a new multiple dose model where mice received lower doses of cisplatin once a week for 4 weeks. We measured and compared indicators of kidney function (KIM-1, NGAL, BUN, and Serum Creatinine) as well as inflammatory cytokines and mediators (i.e. TNF, IL-6, CXCL1, MCP-1). Indicators of apoptosis and cell death were measured as well as indicators of fibrosis (i.e. TGF-β, CTGF, BMP-7, and Sirius Red staining).

Results: In comparing the results of the single and multiple dose models, BUN values were similar, suggesting a comparable loss of kidney function. However, KIM-1 and NGAL were reduced by roughly 10-fold and 100-fold, respectively. Inflammation was also decreased in this model with TNFα, IL-6 and IL-1β reduced by 4, 10 and 5-fold, respectively. Fibrosis was nearly non-existent in the single dose model; however, the multiple dosing model showed a significant increase in fibrosis. Also, expression of PAI-1, a mediator of fibrosis was significantly increased in the multiple dosing model compared to the single dose model.

Conclusions: Taken together, we propose that the multiple dosing model is a more relevant model for the discovery of renoprotective agents in the prevention/treatment of cisplatin-induced AKI.

Genetic Knock Out of CHOP Protects against Ischemia-Mediated Acute Kidney Injury

Rachel Carlisle, Elise Brimble, Jeffrey G. Dickhout. Nephrology, St. Joseph’s Healthcare Hamilton and McMaster Univ, Hamilton, ON, Canada.

Background: Acute kidney injury (AKI), a major cause of morbidity and mortality in North America, is characterized by a sudden increase in serum creatinine. Renal ischemia, a common cause of AKI, induces endoplasmic reticulum (ER) stress and activates the unfolded protein response. This leads to a subsequent upregulation in the expression of the pro-apoptotic gene, CHOP. Transgenic knock out of CHOP inhibits ER stress-mediated acute tubular necrosis, implicating CHOP in the pathogenesis of AKI.

Methods: Bilateral renal ischemia/reperfusion (UR) was performed in mice, using atrumatic vessel clamps, and confirmed via color change (turn to dark purple) of the kidney. Surgeries were performed on C57BL/6 mice to determine the appropriate time point to cause significant renal damage. Various time points for renal ischemia were examined, between 25-55 mins, with 48-72 h of recovery. ER surgeries were subsequently performed on C57BL/6 and CHOP knock out mice. Ischemia was induced for 55 mins, and mice recovered for 48 h. Plasma creatinine was measured using an enzymatic assay, and kidneys were stained to analyze renal damage. Imaging of the kidneys was focused on the juxtamedullary region, as this area is the most vulnerable to ischemic damage.

Results: The results of creatinine levels increased significantly within 12 h of wild type and CHOP knock out mice; however, creatinine levels from CHOP knock out mice were significantly lower than from wild type mice. Stained kidney sections confirm renal protection in CHOP knock out mice, demonstrating reduced cellular damage and vaculization in kidneys from these animals.

Conclusions: These results suggest that CHOP plays a significant role in ischemia-mediated renal injury, and attenuating its expression may provide new therapeutic strategies to protect against AKI.

SA-PO270

The Protective Role of Doxycycline for Cisplatin-Induced AKI by Its Anti-Inflammatory and Anti-Oxidative Effects

Terumasa Nakagawa, Yutaka Kizako, Yoshikazu Miyasato, Teruhiko Mizamoto, Manabu Hayata, Yuichiro Izumi, Takashige Kuwabara, Taku Miyosi, Masataki Adachi, Kenichiro Kitamura, Masashi Mukoyama. 1 Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; 2 Internal Medicine III, Univ of Yamanashi Faculty of Medicine, Yamanashi, Japan.

Background: Cisplatin (CDDP) is a chemotherapeutic drug widely used for the treatment of solid tumors. However, its nephrotoxicity is the major dose-limiting factor.

Doxycycline (Dox) is a tetracycline antibiotic commonly used in a variety of infections, but several other properties have been suggested such as an antiinflammatory effect or the inhibition of matrix metalloproteinase (MMP). In this study, we investigated whether Dox exerts the protective effects on CDDP-induced acute kidney injury (AKI).

Methods: Ten-week-old male C57BL/6J mice were divided into following four groups: 1) Control, 2) Dox (2mg/ml in drinking water), 3) CDDP (25 mg/kg, intraperitoneally) and 4) CDDP+DOX. After 7 days pretreatment with Dox, CDDP was administrated, and animals were sacrificed 3 days later. BUN and serum creatinine (Cr) were measured and renal histological changes as well as, inflammation, and oxidative stress markers were evaluated.

MMP and serine protease activities in the kidney tissue were assessed with zymography.

Results: No apparent adverse effects were observed in Dox group. Dox did not affect mRNA expression of transporters for CDDP (OCT-1, OCT-2 and MATE1) in the renal tubules. CDDP caused severe tubular damages along with elevated BUN and Cr levels. It also increased mRNA expression of inflammatory and profibrotic molecules, together with enhanced oxidative stress in the kidney. Dox alleviated significantly those detrimental changes (Cr, Control, 0.13±0.01; Dox, 0.13±0.03; CDDP, 1.48±0.20 and CDDP+Dox, 0.30±0.12 mg/dL). Moreover, Dox suppressed the activities of MMP-2 and 9 as well as serine proteases, which were enhanced by CDDP in the kidney tissue.

Conclusions: Dox mitigated CDDP-induced AKI through its pleiotropic effects, i.e., antiinflammatory, anti-oxidative and anti-fibrotic. Our results suggest that Dox could become a new strategy for the prevention of CDDP-induced nephrotoxicity in humans.

Reperfusion Induced Renal Injury

Discoid Domain Receptor 1 Is a Key Mediator of the Ischemia-Reperfusion Injury

Hideyuki Saito.
Naoko Oyama,
Involvement of Indoxyl Sulfate in Exacerbated Susceptibility of

Background: In the rat kidney, the discoid domain receptor 1 (DDR1) is expressed by different cell types in the kidney, which displays tyrosine-kinase activity. DDR1 overexpression plays a deleterious role in inflammation and loss of renal function. DDR1 overexpression was observed in different models of chronic kidney disease. The aim of our study was to investigate whether DDR1 participates in the pathophysiological mechanisms of ischemia/reperfusion (I/R), a model of acute renal injury.

Methods: To this end, male mice subjected to I/R were injected either with scrambled sequences (SCR, n=7) or with scrambled sequences (SCR, n=7). Mice were sacrificed after 24h and parameters of renal function, structure and inflammation were measured.

Conclusions: DDR1 inhibition protects mice from the I/R-induced histological damage, increased cytokine and PAR-1 expression. We further investigated the importance of increased PAR-1 signaling and the strain background of the mice.

Methods: Mice WT or TFdelact/delact on MGB having simialr basal PAR-1 expression and much greater inducible PAR-1 expression( 5 fold compared to 2.8 fold for WT). TFdelact/delact mice on a mixed genetic background deficient (MGB) in the cytoplasmic domain of tissue factor (TF) mice developed severe renal injury. TFdelact/delact mice on MGB background had similar renal injury and PAR-1 expression to WT mice.

Conclusions: The cytoplasmic domain of TF may contribute to renal IR injury by regulating PAR-1 expression. The role of the TF cytoplasmic domain in regulating renal injury is genetic background dependent.

Methods: This study was aimed to determine if the two new endonuclease inhibitors recently identified by us, IG-17 (1,3-phenylene-bis-aminoguanidine hydrochloride) for DNase I and PNR-382 (5-((1-(2-naphthoyl)-5-methoxy-1H-indol-3-yl)methylene)-2-thioxodihydropyrimidine-4(1H,5H)-dione) for EndoG, could ameliorate cisplatin toxicity to kidney tubular epithelial cells in vitro and in vivo.

Results: In vitro experiments using NRK-52E cells showed that the compounds are able to suppress endonuclease activity inside the cells provide partial protection against cisplatin toxicity measured using LDH release assay and TUNEL, and are non-toxic at the used concentrations. The inhibitors were found to markedly suppress the total-body endonuclease activity in mice at the dose of 5 mg/kg administered subcutaneously, and were non-toxic up to 25 mg/kg as measured using 14 blood plasma markers of organ toxicities.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Importantly, cisplatin-induced kidney injury was functionally (creatinine) and structurally (acute tubular necrosis, TUNEL) reduced by the administration of the inhibitors (5 mg/kg) in mice suggesting their potential therapeutic value.

Effect of Oxygen and Hypothermic Therapy on the Prevention of Acute Kidney Injury

Sang H. Woo, 1 Cholawat Pacharinsak, 2 Medicine, Thomas Jefferson Univ, Philadelphia, Pa; 2Dept of Comparative Medicine, Stanford Univ.

Background: There is no effective therapy for acute kidney injury. The effect of oxygen, hypothermic therapy delivered through urinary tract on the treatment of acute kidney injury has not been known. This pilot study was performed as a proof of concept of a catheter-based oxygen and hypothermic oxygen therapy in preventing and treating acute kidney injury.

Methods: Rats (n=6) were used for the experiment. Three rats were used to compare oxygen therapy and control. The other three rats were used to compare hypothermic oxygen therapy and control. Oxygen was cooled for hypothersmic oxygen therapy before its delivery to the kidney. Right kidneys received treatment (oxygen or hypothersmic oxygen) and left kidneys were used for control. After a catheter was placed in a bladder, oxygen (or cooled oxygen) was delivered to the right kidney from the bladder through the catheter for five minutes for pretreatment before clamping. Both right and left renal arteries were clamped for 30-45 mins to induce acute kidney injury. Only right kidneys continued to receive oxygen or hypothersmic oxygen during and after the induction of acute kidney injury. The kidneys were extracted after the induction of acute kidney injury with the clamping. Gross examination of both kidneys during the clamping and after the extraction was performed.

Results: Gross examination of kidneys demonstrated less ischemic changes of kidneys treated with oxygen or hypothersmic oxygen during and after the induction of acute kidney injury. As shown in Figure 1, right kidneys that received oxygen therapy or hypothersmic oxygen showed less ischemic changes on gross examination during the clamping and after extraction.

Involvement of CYLD as a Regulatory Factor in Fribotic Response of Ischemic AKI Kidney and Hypoxic HK-2 Cells

Go Yoneda, 1 Naoki Suenaga, 2 Nozomi Yabuuchi, 3 Kazuhiro Nishii, 2 Hirofumi Jono, 2, 3 Hideyuki Saito, 1, 2, 3 Clinical Pharmaceutical Sciences, Kumamoto Univ Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; 2Hemodialysis and Apheresis, Kumamoto Univ Hospital, Kumamoto, Japan; 3Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.

Background: Cylindromatosis (CYLD), a tumor suppressor, regulates various signaling pathways by acting as a deubiquitinating enzyme. Recent studies have revealed that CYLD is associated with not only tumors, but also chronic inflammatory diseases, such as tissue fibrosis. It is well-documented that tissue fibrosis is common hallmark of chronic kidney disease (CKD), and CKD progresses toward end-stage renal disease through renal fibrosis. However, the molecular pathogenesis of renal fibrosis is not fully uncovered yet. In this study, we elucidated the roles of CYLD in renal fibrosis by using in vivo and in vitro models.

Methods: We generated model mice of ischemia/reperfusion (I/R)-induced acute kidney injury (AKI) and hypoxic human kidney (HK)-2 cells. CYLD expression in kidney tissue and HK-2 cells was determined by immunoblot analysis. Fibrosis gene expression of PAI-1, CTGF and COL1A1 were examined by RT-PCR.

Results: In I/R-induced AKI mice, serum creatinine (Scr) and BUN were elevated 2 days after I/R treatment, and renal fibrosis was induced 28 days after I/R treatment. In those kidney tissues of I/R-AKI mice, CYLD protein expression was markedly decreased (0.4-fold) in a time-dependent manner. Interestingly, fibrosis gene expression (PAI-1: 12-fold, CTGF: 2.5-fold, COL1A1: 4-fold) was significantly increased in response to the CYLD down-regulation. In HK-2 cells, siRNA knockdown of CYLD gene expression significantly increased the PAI-1 gene expression (12-fold). Moreover, CYLD mRNA expression was significantly suppressed (0.5-fold) under hypoxic condition, an important factor of CKD progression, whereas the PAI-1 gene expression (2-fold) was elevated in HK-2 cells.

Conclusions: In conclusion, CYLD may be a novel regulatory factor involved in renal fibrosis and its down-regulation may trigger fibrosis under ischemic and/or hypoxic condition.

Attenuation of Renal Fibrosis After Unilateral Ischemia Reperfusion May Require a Multi-Target Approach

Nathalie Leclef, 1 Bruce L. Riser, 2 Patrick C. D’Haese, 1 Benjamin Arthur Vervaet, 1 Laboratory of Pathophysiology, Univ of Antwerp, Wilrijk, Antwerpen, Belgium; 2B LR Bio LLC, WI.

Background: Acute kidney injury (AKI) is an important risk factor of chronic kidney disease (CKD). We optimized a mouse model of AKI to CKD by unilateral ischemia-reperfusion (UIRI) with development of renal fibrosis. To validate this model for use in therapeutic intervention studies, 3 experimental treatments were tested: administration of: 1) recombinant human CCN2/CTGF antagonist, 2) TGFβ neutralizing antibody (ID11) or 3) dexamethasone (corticosteroid).

Methods: Male C57Bl/6 mice underwent 21 min of unilateral ischemia-reperfusion (UIRI) at 36°C body temperature. 8 treatment groups (n=4/group, ip) were included: dexamethasone (10 mg/kg, daily), vehicle (PBS, daily), rCCN2 (5 µg/kg, daily), vehicle (PBS, daily), antibody to TGFβ (0.5 mg/kg, every other day), vehicle (PBS, every other day), an untreated URI control and a sham group. Three weeks after URI renal fibrotic outcome was determined by gene expression analysis (qPCR) of collagen I, TGFβ, CTGF, CCN3, PAI-1 and TNFα.

Results: URI induced a ~40% reduction in renal mass. Treatment with rCCN2, anti-TGFβ or dexamethasone did not attenuate this reduction. URI induced significant upregulation of the fibrosis-related genes. rCCN2 treatment had no effect on gene expression. Anti-TGFβ antibody treatment induced significantly less upregulation of TGFβ and CCN3 gene expression, however, vehicle also reduced TGFβ expression. Dexamethasome treatment induced significantly less upregulation of collagen I and CCN2/ CTGF gene expression and a trend towards higher CCN3 upregulation.

Conclusions: Despite the earlier proven benefits of TGFβ antagonism and CCN3 treatment in the development of fibrosis, neither treatment (at doses demonstrated to be effective in more mild injury models) showed effect in the URI model. Broad anti-inflammatory suppression by dexamethasone attenuated fibrotic gene expression. We speculate that the natural course of renal demise after URI is very robust and highly likely to require a multi-target approach. Whether some combination of the therapies tested here could have efficacy in this model remains to be determined.

MicroRNA-17 Is Induced via P53 to Protect against Renal Ischemia-Reperfusion Injury by Targeting Death Receptor 6

Jielu Hao, 1 Qingqing Wei, 1 Changlin Mei, 1 Zheng Dong, 1 Nephrology, Shanghai Changzheh Hospital, Shanghia, China; 2Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA.

Background: Ischemia-reperfusion injury is the critical cause of acute kidney injury (AKI) in clinical settings, which unavoidably develops into chronic kidney disease (CKD) due to lack of understanding of mechanism and effective therapies. In the present study, we investigated the role of microRNA-17 (miR-17) regulation in kidney damage in ischemia-reperfusion injury.

Methods: Renal ischemia-reperfusion was induced in C57 mice by bilateral clamping of renal arteries, followed by releasing of the clamps. BUN and serum creatinine were measured to indicate the loss of renal function. In vitro, rat kidney proximal tubular cells (RPTC) were treated with 1% oxygen. To test the effect of miR-17, anti-miR-17-LNA and miR-17 mimic were transfected before hypoxia. The change of p53 and DR6 were detected by Western blot. Pifithrin-α and dominant-negative p53 were used to determine the role of miR-17 in miR-17 expression.

Results: By real time PCR, we identified that miR-17 was significantly increased in kidney tissues after 30 minutes of bilateral renal ischemia and 12h-48h reperfusion. In the moderate injury model of 25 minutes of ischemia, miR-17 was induced at day 1 and the induction lasted for a week. In vitro, hypoxia also induced miR-17 in RPTC cells. Furthermore, miR-17 mimic reduced apoptosis and caspase activation, whereas anti-miR-17-LNA increased apoptosis during hypoxia, suggesting a cytoprotective role of miR-17. Blockade of p53 with pifithrin-α or a dominant-negative mutant p53 were used to determine the role of p53 in miR-17 expression.

Conclusions: We demonstrated that miR-17 is induced less ischemic changes of kidneys treated with oxygen or hypothermic oxygen during and after the induction of acute kidney injury. As shown in Figure 1, right kidneys that received oxygen therapy or hypothermic oxygen showed less ischemic changes on gross examination during the clamping and after extraction.

Proximal Tubule-Derived CSF-1 Mediates Expansion and Polarization of Renal Macrophages/Dendritic Cells and Recovery in Acute Kidney Injury

Yinquin Wang, Bing Yao, Raymond C. Harris, Ming-Zhi Zhang. Medicine, Vanderbilt Univ, Nashville, TN.

Background: Colony-stimulating factor-1 (CSF-1)-mediated renal macrophage expansion and polarization play an essential role in recovery from acute kidney injury in ischemia/reperfusion (I/R)-injury and selective apoptotic proximal tubule injury in transgenic mice expressing the human diphteria toxin receptor (DTR) and exposed to DT (DTR-AKI). In the kidney, a major site of CSF-1 production is in proximal tubular epithelial cells.

Methods: Male DTR mice with CSF-1^−/− (wild type) or with γ-GT-Cre:CSF-1^−/− (CSF-1 KO in renal proximal tubule) were used for DTR-AKI and for I/R injury (30 min of ischemia and contralateral nephrectomy).

Results: CSF-1 expression in the proximal tubule and its deletion in CSF-1^−/− KO mice were confirmed with immunostaining. Six days after DTR-AKI, activation of the CSF-1 receptor (p-c-fms) was markedly attenuated in both renal tubules and interstitial cells, including macrophages (F4/80 and p-c-fms dual positive cells). Flow cytometry and qPCR indicated fewer renal macrophages/dendritic cells and reduced mRNA levels of M2 phenotype markers (CD206, IL-4Rα, TGF-β and 15-LOX) in CSF-1^−/− KO mice 6 days after DT injection. Although selective proximal tubule CSF-1 deletion did not affect the severity of kidney injury, it delayed renal functional recovery, in association with increased oxidative stress, increased secondary necrosis (HMGB1 expression) and severe tubulointerstitial fibrosis, with increased Picro-sirius red staining of fibillary collagen and increased proinflamatory and fibrotic components (α-SMA, CTGF, Fibronectin, collagen I and IV). Selective proximal tubule CSF-1 deletion also delayed to functional recovery after I/R injury, with decreased mRNA levels of M2 phenotype markers in isolated renal macrophages/dendritic cells and more severe renal fibrosis. In both I/R injury and DTR-AKI, selective proximal tubule CSF-1 deletion had minimal effects on the expression of M1 phenotype markers.

Conclusions: These studies demonstrate that proximal tubule is a major source of CSF-1 that mediates the expansion and polarization of renal macrophages/dendritic cells that play an essential role in recovery following AKI.

Ablation of Myo-Inositol Oxidase Protects against Cisplatin-Induced Acute Kidney Injury by Inhibiting p53 Activation

Rajesh K. Dutta, Yashpal S. Kanwar. Dept of Pathology, Northwestern Univ, Chicago, IL.

Background: MIOX is a renal tubular enzyme. Its role in the pathogenesis of diabetic nephropathy is currently being investigated. Conceivably, it modulates redox imbalance and apoptosis in tubular cells in diabetes via modulation of glucuronate-xylulose (G-X) pathway. However, its role in acute kidney injury (AKI) is unknown.

Methods: In this study we used both MIOX-over-expressing transgenic and MIOX null mice to elucidate its role in a model of cisplatin induced AKI.

Results: We observed severe cisplatin-induced proximal tubular injury in MIOX transgenic and protection in null mice compared to wild type mice. In transgenic mice an increased serum creatinine and urea levels, caspase-3 activity and tubular apoptosis along with marked deterioration of tubular morphology was observed. Renal injury was remarkably less in null mice compared to wild type mice. Cisplatin treatment led to p53 activation in wild type and MIOX transgenic mice, whereas minimal p53 activation was observed in MIOX null mice. Likewise, we noted that cisplatin induces mTOR pathway in both wild type and MIOX transgenic mice while such an effect was not observed in MIOX null mice. Treatment with mTOR inhibitor, rapamycin, prevented cisplatin-induced MIOX expression, p53 activation and deterioration of tubular morphology in control mice. In vitro studies revealed significantly high levels of ROS generation, caspase-3 activity and apoptosis in MIOX over-expressing cells compared to control cells transfected with empty vector following cisplatin treatment.

Conceivably, this was attributed to the accentuated induction of GX-pathway and its associated myriad enzyme system.

Precision Medicine for AKI: Novel RNA Labeling Technique Demonstrates Unique Transcriptional and Cellular Responses in Different Injury Models

Background: The clarity brought to CKD patients by Precision Medicine has not been applied to AKI, which is currently defined by the rise of a single analyte, the Perentimine (Pcr).

Methods: To identify specific molecular responses we investigated 3 models: (i) ischemia (10min bilateral pedicle clamping), (ii) volume depletion (72 hr water deprivation which matched the Per of the ischemic model) and (iii) a model of cystitis (small volume UPEC inoculation). We generated a novel technique of cell and time-specific Cre mediated in-vivo RNA labeling to purify specific RNA species directly from the kidney.

Results: We analyzed RNA pools from the entire Collecting Duct (CD) and its subset Intercalated Cells (IC). We found a robust genetic response of CD to volume depletion (94.5% of the induced genes) but a limited genetic response to ischemia (3.2% of induced genes) with very little overlap (2.3%). In contrast, the IC subset demonstrated a greater response to ischemia (62% of the induced genes) compared to volume depletion (32% of induced genes) and only 6% of the genes were shared. Remarkably, the IC cell population demonstrated an overwhelming specific response to cystitis (95% of induced genes). Region-specific laser capture microdissection validated the cellular distinctions: ischemia and volume depletion induced different transcriptional changes in different cells with limited overlap. Moreover, functional analyses demonstrated activation of different molecular pathways, and different secreted proteins. Testing the urine of 100 Emergency Department patients revealed five new candidate biomarkers that distinguished ischemia and volume depletion.

Conclusions: We found that despite identical Per, ischemia and volume depletion targeted different regions, cell types and genes with limited overlapping genetic responses: the CD responded robustly to volume depletion while the IC were unique sensors of ischemia and infection. These data demonstrate that while Per cannot distinguish between models of injury, the specific responses of the nephron provide Precision AKI diagnoses.

Calcium Oxalate Crystal-Induced Acute Kidney Injury Involves Ripk3-Mild Mediated Tubular Cell Necroptosis

Hans J. Anders, Jyarsi Desai, Santosh Kumar, Jonathan Nicodemos Eberhard, Dana Thomasova, Simone Romoli, Andreas Linkermann, Shrikant R. Mulay. Ludwig Maximilians Univ, Munich, Germany; Christian-Albrechts-Univ, Kiel, Germany.

Background: Crystalline nephropathy (CN) & nephro-urolithiasis involves crystalline induced renal inflammation via NLRP3 inflammasome (Mulay et al, JCI 2013), but the mode of direct crystal cytotoxicity remains elusive. The aim of the study was to identify mechanisms of crystal cytotoxicity in kidney.

Methods: All in vivo experiments were approved by the local government authorities. Acute oxalate nephropathy (AON) was induced by i.p. injection of sodium oxalate (NaOx) (100mg/kg) and 3% NaOx in drinking water for 24hr. IHC, EM, RT-PCR, MTT assay, PI stain and multicolour FACS were used for data analysis.

Results: We found that crystals of calcium oxalate (CaOx), monosodium urate, calcium pyrophosphate dehydrate & cystine trigger casapse-independent necrosis of mouse tubular cells, human kidney cells & human renal progenitor cells. Pretreatment with Ripk3 inhibitor necrostatin-1 (Nec-1), MLKL inhibitor & RNA interference of Ripk3 or MLKL blocked crystal cytotoxicity. Consistently, deficiency of Ripk3 or MLKL protected mice from AON (e.g. plasma creatinine, BUN, renal tubular injury score, renal KIM-1 & α-GST mRNA expression, neutrophil count and TUNEL+ve cells) despite similar crystal deposition. I.p. injection of crystals induced neutrophil recruitment into periureal cavity, which was unaffected by Nec-1 as was crystal injection into air pouches at the back of mice. However, Nec-1 significantly reduced microvascular permeability & leukocyte extravasation from post-ischemic cremaster muscles. Thus Ripk3 signaling activates Ripk3-dependent necroptosis in this model. Finally, etanercept, TNFR inhibitor R-7050 & Nec-1 protected mice from AON.

Conclusions: Crystal-cytotoxicity involves TNFR1-Ripk3-Ripk3-MLKL pathway. All components of this pathway represent novel molecular targets for therapeutic interventions to limit CN.
SA-PO284
Allopurinol Protects against Rhabdomyolysis and Acute Kidney Injury Induced by a Membrane Protein (Lp25) from Pathogenic Leptospires Antonio C. Seguro,1 Daniele Canalé,1 Patricia A. Abreu,2 Denize Monaris,2 Tatiana B. Gótt,2 Larissara R. Matos,2 Thales de Brito,2 Pedro H. Gois,3 Antonio J. Magalhães.1 1Nephrology, Hospital das Clínicas FMUSP, São Paulo, Brazil; 2Lab. de Bacteriologia, Inst Butantan, São Paulo, Brazil.

Background: Acute kidney injury (AKI) in leptospirosis is frequently nonoliguric, hypoxic or normokalemic. Higher serum potassium levels, elevated creatine phosphokinase (CPK) and uric acid (UA) were reported, suggesting that AKI in leptospirosis could be caused by degradation of pS261-AQP2 in PCs through a LC3/Atg7-dependent autophagy process. We studied if Allopurinol (Allo) protects from exercise-induced rhabdomyolysis.

Methods: Three groups of guinea pigs were studied: 1) Sham (phosphate-buffered solution); 2) Lp25+; 3) Lp25+Allo. One mL of PBS and Lp25 (400µg of Lp25/mL) were intraperitoneally injected for 4 days. Lp25+ Allo received Allo (30mg/kg) in drinking water during this time. On the 5th day, animals were placed in metabolic cages for 12 hour urine collection. We measured urinary volume (Ur V/12h), creatinine clearance (ml/min/100gBW), serum potassium (mEq/L), CPK (U/L), uric acid (mg/dL), phosphate (mg/dL), and UA (mg/dL).

Results: Lp25 induced hyperkalemia, rhabdomyolysis (elevated CPK, uric acid, phosphate) and oliguria. Allo ameliorated CrCl, serum potassium, CPK and uric acid.

Conclusions: These data demonstrate that Allo attenuates rhabdomyolysis and AKI induced by Lp25 in guinea pigs. This may represent a new therapeutic approach for AKI in patients with leptospirosis. (CNPq, FAPESP).

SA-PO285
Conventional Autophagy Regulates the Degradation of AQP2 in Hypokalemia Wan-Young Kim1, Sun-ah Nam1, Yumi Kim1, Arum Choi2, Yong kyun Kim2, Jin Kim1. 1Anatomy and Cell Death Disease Research Center, The Catholic Univ of Korea, Seoul, Korea; 2Internal Medicine and Cell Death Disease Research Center, The Catholic Univ of Korea, Bucheon, Korea.

Background: Autophagy is a catabolic pathway utilized to maintain a balance among the synthesis, degradation, and recycling of cellular components, thereby playing a role in homeostasis. Abundance of AQP2 is regulated through balance between production by tranlation and removal by degradation. Although AQP2 degradation is supposed to be occurred via lysosomal or proteasomal degradation, the precise mechanisms still remain unknown. It has been known that prolonged hypokalemia causes vasopressin-resistant polyuria and induces autophagy especially in principal cells (PC) of collecting duct.

Methods: To investigate the role of autophagy in the degradation of AQP2, we generated AQP2-cre;Atg7-/- mice, in which Atg7, an essential gene for mammalian autophagy, was defficient. Immunofluorescence staining and western blotting were performed. The level of AQP2 was tested in AQP2-cre;Atg7-/- mice and the level of cleaved Caspase-3 were detected after the addition of compound C, which is an AMPK inhibitor.

Results: In control AQP2-cre;Atg7+/+ mice, there was a decrease of conversion of LC3-I to LC3-II and a marked accumulation of p62 selectively in PCs. Rab9 protein, an essential molecule for alternative autophagy pathway, and Rab9-positive vacuoles were markedly increased. Interestingly, pS261-AQP2 was distributed throughout the cytoplasm and not co-localized with Rab9 or LC3-positive vacuoles in the PCs of AQP2-cre;Atg7-/- mice. There was no difference in localization of pS256-AQP2 at the plasma membrane from each genotype.

Conclusions: These results suggest that down regulation of AQP2 in hypokalemia could in part be caused by degradation of pS261-AQP2 in PCs through a LC3/Atg7-dependent conventional autophagy pathway. Funding: Government Support - Non-U.S.

SA-PO286
Early Autophagy Precedes Angiotensin II-Induced Podocyte Apoptosis Tae-Sun Ha. Pediatrics, Chungbuk National Univ, Cheongiu, Chungbuk, Korea.

Background: Autophagy is a highly regulated catabolic process that is involved in the turnover of unwanted cellular materials, on the other hand, apoptosis removes damaged or unwanted cells. Therefore, autophagy and apoptosis constitute the two processes through which injured/aged cells or organelles are eliminated. Angiotensin II (Ang II) induces podocyte apoptosis in vitro and in vivo. It was reported that autophagy, which is the relationship between autophagy and apoptosis in Ang II-induced podocytes is not elucidated and the role of Ang II-induced autophagy in podocyte survival remains unclear. We investigated the sequential relationship between autophagy and apoptosis in Ang II-induced podocytes.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II at and different incubation times. The changes of podocyte autophagy and apoptosis were observed by electron microscopy, confocal imaging, Western blotting, and FACS assay according to the presence of Ang II. Results: Ang II-treated podocytes showed an increase in autophagosomes compared with control cells at early phase in a dose-dependent manner. This pro-autophagic effect of Ang II was inhibited by pretreatment with 3-methyladenine, an inhibitor of PI3-kinase class III. Ang II enhanced podocyte expression of autophagic proteins such as LC3-II and beclin-1. Atg5 siRNA further reduced the expression of LC3-II and cleaved caspase-3 suppressed by Ang II at 12 hrs. However, Atg5 siRNA did not affect the expression of Atg5, LC3-II, and cleaved caspase-3 in the presence of Ang II at 24 hrs. Thereafter, Ang II induced podocyte apoptosis significantly in concentration- and time-dependent manners in FACS assays. We conclude that Ang II-induced autophagy and apoptosis in podocytes is regulated by Ang II.

Funding: Government Support - Non-U.S.

SA-PO287
Emodin Ameliorates Cisplatin-Induced Renal Tubular Cell Apoptosis Through Activation of Autophagy Hong Liu1, Wei Sun2, Yiangan Wang2, Liuobao Gu1. 1Dept of Nephrology, Affiliated Hospital of Nanjing Univ of Chinese Medicine, Nanjing, China; 2Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China; 3Center for Diabetes Care, Education and Research, Jiangsu Province Inst of Geriatrics, Nanjing, China.

Background: Emodin plays a key role in regulating cell survival. Emodin can activate PI3K/Akt and p38 MAPK, then explored the effects and mechanisms of emodin on cisplatin-induced apoptosis in NRK-52E cells by activation of autophagy.

Methods: NRK-52E cells were treated with cisplatin with or without emodin, cell morphology and expressions of cleaved Caspase-3 and autophagy makers LC3I/II were detected. Red fluorescent protein-LC3 (RFP-LC3) plasmid was transiently transfected into NRK-52E cells, and changes of RFP-LC3 fluorescent particles were observed by fluorescence microscopy. The level of LC3 was tested after treated with Bafilomycin A1 and mTOR inhibitor rapamycin. Besides, morphological changes of apoptotic cells were evaluated and cell death was evaluated by FACS analysis. Finally, AMPK/mTOR signaling pathway related proteins were detected. Further, changes of cell morphology and the level of cleaved Caspase-3 were detected after the addition of compound C, which is an AMPK inhibitor.

Results: Emodin improved cisplatin-induced cell shape change, cell viability and caspase 3 cleavage. This protective effect of emodin was associated with increased LC3 conversion and occurrence of RFP-LC3 punctate structures. Further studies revealed that the suppressive effect of emodin on cisplatin-induced apoptosis could be abolished by suppression of autophagy with bafilomycin A1 and mimicked by activation of autophagy with rapamycin. Additionally, AMPK/mTOR signaling pathway was important for the induction of autophagy and inhibition of apoptosis.

Conclusions: Induction of autophagy could be an important mechanism by which emodin protected renal tubular cells against cisplatin-induced cell injury, and the potentially mechanism of emodin-induced autophagy may be attributed to the activation of AMPK and inhibiting mTOR signaling pathway. Emodin may have a therapeutic potential in the prevention of cisplatin-induced nephrotoxicity.

Funding: Government Support - Non-U.S.

SA-PO288
Autophagy in Renal Tubular Epithelial Cells Plays a Protective Role in Renal Fibrosis Yong Kyun Kim3, Sun-Ah Nam2, Wan-Young Kim2, Arum Choi2, Yumi Kim1, Ho Cheol Song1, Jin Kim2. 1Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; 2Dept of Anatomy and Cell Death Disease Research Center, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.

Background: Renal tubulointerstitial fibrosis (TIF) is the final common pathway of various renal injuries. Autophagy is a cellular process of degradation of damaged cytoplasmic components and regulates cell death or proliferation. Recent studies reported that autophagy has protective role in renal TIF. However, the mechanism of autophagy

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 692A
regulating fibrosis is not fully understood. In this study, we investigated the proposed mechanisms of autophagy in renal TIF induced by UUO by using conditional knockout mice in which Atg7 is genetically ablated specifically in tubular epithelial cell (TEC).

**Methods:** Atg7-floxed mice were crossed with Ksp-Cre mice to generate TEC-specific Atg7 deletion mice. In electron microscopy, TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increased expression and the expression of c-Myc as a regulator of cell apoptosis and proliferation.

**Results:** In vitro, TGF-β treatment induced autophagy. In vivo, TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increase expression and the expression of c-Myc as a regulator of cell apoptosis and proliferation. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as markers. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as markers.

**Conclusions:** Our data suggest that autophagy regulate expression of TGF-β, PAI-1 and p62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs through the expression of c-Myc during renal TIF. Autophagy could represent a therapeutic target for renal TIF.

Partial De-Differentiation of Parietal Epithelial Cells Caused by Reduced Expression of Sirt1 and Concomitant Increased Expression of p21 and CD133 in Diabetic Nephropathy

**Kazuhito Hasegawa,** Shu Wakino, Hiroshi Itoh. Keio Univ.

**Background:** We have previously reported the role of proximal tubal Sirt1 in diabetic nephropathy (DN). Parietal epithelial cells (PECs) and their cellular metabolism reportedly play a pivotal role in kidney. Sirt1 is a key energy sensor, whereas DNS disrupts energy metabolism.

**Methods:** Thus, we examined the effect of Sirt1 expression in PECs on DN.

**Results:** In two DN murine models including streptozotocin-treated and db/db mice, expression of Sirt1 in proximal tubules and PECs was decreased at 8 weeks after the onset of DN, corresponding to the early stage of DN. Sirt1 expression was also downregulated in podocytes at 24 weeks. We further investigated the changes in PECs at 8 weeks. No change was found in the number of PECs. The morphology of all PECs showed hypertrophy, and some PECs contained autophagic vesicles, especially in the periphery or the border of the plasma membrane at basolateral sides.

**Conclusions:** Sirt1 may be a promising target for protection against DN-induced de-differentiation of PECs, which would prevent not only hypertrophy of PECs but also the concomitant thickening of the basement membrane of Bowman’s capsule.

HG treatment of cultured PECs resulted in significant reductions in cell proliferation and migration, while increasing the production of extracellular and basement membrane components such as type IV collagen. We performed DNA microarray, confirmatory real-time PCR, and immunofluorescence, revealing that an increase in Glut1 (glucose transporter) expression promoted influx of high amounts of glucose into PECs, which led to a reduction in Sirt1 expression. HG treatment of cultured PECs resulted in significant reductions in cell proliferation and migration, while increasing the production of extracellular and basement membrane components such as type IV collagen. We performed DNA microarray, confirmatory real-time PCR, and immunofluorescence, revealing that an increase in Glut1 (glucose transporter) expression promoted influx of high amounts of glucose into PECs, which led to a reduction in Sirt1 expression.

**Conclusions:** Sirt1 may be a promising target for protection against DN-induced de-differentiation of PECs, which would prevent not only hypertrophy of PECs but also the concomitant thickening of the basement membrane of Bowman’s capsule.

APOL1 Variants are Critical to Induce Vitamin D Receptor (VDR) Down Regulation in Dedifferentiated Podocytes

**Shabirul Haque,** Xiqian Lan, Amrita Kaur Chawla, Ashwani Malhotra, Pravin C. Singhal. Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY. 1Medicine, Hofstrna North Shore LII Medical School, Great Neck, NY; 2Medicine, Rambam Health Care Campus, Haifa, Israel.

**Background:** Dysregulated growth and loss of podocytes are important features of HIV-associated nephropathy (HIVAN). In a recent report, HIV-induced programmed cell death in T cells has been implicated to pyroptosis as a consequence to inflammation formation. We hypothesized HIV would also be promoting podocyte loss through the induction of pyroptosis. We evaluated the role of HIV in podocyte NOD-like receptor family, pyrin domain containing (NLRP) 3 protein complexes (inflammasomes) formation both in vitro and in vivo.

**Methods:** Renal cortical sections of control and Tg26 (HIVAN) mice (n=4) were labeled with APOL1 mRNA decayed in an accelerated mode (more than 35%) during G2 expressing cells. Stability/decay kinetic assay revealed that variants (G1 and G2) of APOL1 when compared APOL1G0. 293 T cells also displayed lower expression of G1 and G2. However, there was no difference in mRNA expression in APOL1G0 and APOL1G1/G2 were probed for APOL1 and reprobed for actin. RNAs were extracted with HPs expressingVect, G0, G1 and G2 and NDNA were amplified with APOL1 specific primer. 293T cells were transfected with equal amount of plasmids (vector, G0, G1 and G2) for 48 hours. Protein blots were probed for APOL1 and reprobed for actin. To evaluate stability/decay rate of APOL1 mRNA, APOL1/APOL1 variants expressing HPs were pulsed with actinomycinD and RNAs were harvested at different time points (0.0, 0.5, 1.0, 3.0, 8.0, and 24 hours) by Trizol method.

**Results:** APOL1 variants (G1/G2) expressing HPs displayed lower expression of APOL1 when compared APOL1G0. 293T cells also displayed lower expression of G1 and G2. However, there was no difference in mRNA expression in APOL1G0 and APOL1G1/G2 expressing cells. Stability/decay kinetic assay revealed that variants (G1 and G2) of APOL1 mRNA decayed in an accelerated mode (more than 35%) during ¼ to 24 hours after actinomycin D exposure.

**Conclusions:** These findings suggest that APOL1 variants protein instability may be related to loss/decrease of variants APOL1 mRNA or to some extent defects in protein translation/stability.

Post-Transcriptional and Post-Translation Status of APOL1 (G0) and Its Variants (G1and G2) in Podocytes and 293T Cells

**Shahidur Haque,** Xiqian Lan, Amrita Kaur Chawla, Ashwani Malhotra, Pravin C. Singhal. Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 1Medicine, Rambam Health Care Campus, Haifa, Israel.

**Background:** APOL1 gene variants have been reported to contribute to higher prevalence of kidney diseases in African Americans. APOL1 gene is known to contribute to kidney cell injury but the mechanisms involved are not clear. Interestingly, renal biopsy specimens in kidney disease patients with APOL1 variants displayed lower podocyte expression of VDR. Down regulation of VDR has been reported to be activated rennin angiotensin system in kidney cells. HIV-induced low VDR status in kidney cells has been shown to contribute to the progression of HIVAN. We asked whether APOL1 variants would be contributing to accelerate podocyte injury in HIVAN and HIV infected non-HIV infected patients through down regulation of VDR. Down regulation of VDR has been reported to acti

**Methods:** RNAs were extracted from human podocytes (both DPs and DDPs) stably expressing vect, G0, G1 and G2. cDNAs were amplified with a specific VDR primer specific. Vector, G0, G1 and G2 expressing DPs and DDPs were infected with HIV followed by Western blotting and probing for SNAIL (a transter of VDR). Additionally, the effects of APOL1 variants were evaluated on glycosylation and methylation status of SNAIL. SNAIL proteins were probed for IMMs and actin. Glut1 (glucose transporter) expression promoted influx of high amounts of glucose into PECs, which led to a reduction in Sirt1 expression.

**Results:** In vitro, TGF-β treatment induced autophagy. In vivo, TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increase expression and the expression of c-Myc as a regulator of cell apoptosis and proliferation. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as markers. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as markers.

**Conclusions:** Our data suggest that autophagy regulate expression of TGF-β, PAI-1 and p62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs through the expression of c-Myc during renal TIF. Autophagy could represent a therapeutic target for renal TIF.

**HIV Promotes NLRP3 Inflammasome Complex Activation in HIVAN**

**Shabirul Haque,** Xiqian Lan, Amrita Kaur Chawla, Rivka Lederman, Rabani Bharara, Ramachandra prasanna Bongu, Ashwani Malhotra, Pravin C. Singhal. Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.

**Background:** APOL1 modulates VDR expression in DDPs only. We conclude that APOL1 modulates VDR expression in DDPs only. Since HIV occurs in APOL1 variants only, presence of APOL1 variants seems to be critical to sustain HIV-induced podocyte injury.

**Methods:** Renal cortical sections of control and Tg26 (HIV AN) mice (n=4) were labeled with APOL1 mRNA decayed in an accelerated mode (more than 35%) during G2 expressing cells. Stability/decay kinetic assay revealed that variants (G1 and G2) of APOL1 mRNA decayed in an accelerated mode (more than 35%) during ¼ to 24 hours after actinomycin D exposure.

**Conclusions:** These findings suggest that APOL1 variants protein instability may be related to loss/decrease of variants APOL1 mRNA or to some extent defects in protein translation/stability.

expressions as well as protein expressions of iNOS. Serum from Tg26 mice showed higher levels of IL-1β in the chronic kidney disease (CKD) group, suggesting a possible link between oxidative stress and the generation of reactive oxygen species and potassium efflux contributed to HK-2 cell apoptosis.

Conclusions: These findings indicate that generation of reactive oxygen species and potassium efflux contributed to HK-2 cell apoptosis.

SA-PO293
Urinary Cytochrome C (Cyto C) Detects Subliminal Injury and Correlates with Apoptosis in Acute (AKI) and Acute on Chronic Kidney Disease (A-CKD)
Lena Sencer,1 Philip Peake,1 Zoltan H. Endre.1 1Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia.

Background: Mitochondrial Cyto C is a potentially specific biomarker of apoptotic kidney injury in AKI. We investigated urinary Cyto C in detecting subliminal kidney injury (histological injury without an increase serum creatinine, sCr) in two models of A-CKD.

Methods: In male Sprague Dawley rats (i) adenine-CKD was induced by diet supplementation with 0.025% adenine, days (d) 0 to 28 and monitored until d56 (n=8). On d56, AKI was induced in rats by a subnephrotic (2mg/kg; n=8) or nephrotic (4mg/kg; n=8) cisplatin (Cis) dose and monitored until d98 (n=8 in matched controls); (ii) A250 cytochrome-oxidase negative (A-CKD) induced by AA-1 (10mg/kg) ip for five days and monitored to d21 (n=6) or d42 (n=6) then 2mg/kg (n=6) or 4mg/kg (n=6) Cis and monitored to d28 and d49 respectively. Cyto C was measured by ELISA. Tubulointerstitial damage (TID) and TUNEL staining were quantified on d63.

Results: Cyto C levels increased in subclinical AAN (d1 to d7) and adenine-CKD (d3 to 21) without change in sCr, but increased in both CKD groups after 2mg/kg and 4mg/kg Cis doses in controls. In AAN, Cyto C levels increased progressively (d22 to d28) after Cis exposure with increasing controls given 4mg/kg whereas Cyto C was lower after Cis on d42 to d49. Regardless of Cis dose, Cyto C increased in controls and adenine-CKD. A-CKD rats displayed diffuse medullary and cortical TID with positive TUNEL staining while injury in CKD alone was largely in outer medulla. In AAN peak Cyto C, 72 hours post Cis, correlated significantly with TUNEL staining (R=0.86* and cortical apoptosis (R=0.81*). In adenine fed rats, Cyto C Correlated only with medullary apoptosis (R=0.79*) sCr correlated only with severe diffuse cortical TID (R=0.94*) (*P<0.05).

Conclusions: Cyto C detected subliminal injury and correlated strongly with outer medullary apoptosis in A-CKD, which alone did not increase sCr. Cyto C is a useful biomarker for early detection of apoptotic kidney injury.

Assessment of Graphene Toxicity to Kidney Tubular Epithelial Cells and Cell Spheroids Using DNase Activity Probe
Tariq Fahmi,1 Zeid A. Nima,1 Julietta Sargsyan,1,2 Alexei G. Basnakian,1,3 Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR,1,2,3Univ of Arkansas at Little Rock, Center for Integrative Nanotechnology Sciences, Little Rock, AR.

Background: Recently invented nanomaterial, graphene, consists of monomolecular carbon sheets, which are extremely strong, light and flexible. It will be used widely because of its versatility. However, little is known about its potential for being a toxicant and even at low concentrations. Hence, study graphene toxicity is not established. Kidney is one of the primary organs for the assessment of nanomaterial toxicity. We hypothesized that graphene induces nephrotoxicity mainly through DNA damage, and measuring of DNase activity by using near infrared fluorescence (NIRF) DNase activity probe would be a reliable tool for assessing graphene cytotoxicity.

Methods: Non-modified graphene (50 µg/ml) exposed with cultured rat kidney tubular epithelial cell NRK-52E cells induced TUNEL-type DNA fragmentation usually associated with cytotoxicity. Raman spectroscopy showed the TUNEL-positive cells have significantly higher graphene content than TUNEL-negative cells. DNase activity was quantified in live cells using the oligonucleotide-based NIRF probe. Quantitative immunocytochemistry (qICC) was then used to measure apoptotic DNases such as caspase-activated DNase (CAD), endonuclease G (EndoG), and DNase I, and the marker of oxidative stress, heme oxygenase-1 (HO-1).

Results: The NIRF fluorescence and all of the above qICC markers were induced in NRK-52E cells by graphene exposure. In addition, a 50% colocalization of HO-1 with DNase activity was observed suggesting a possible link between oxidative stress and the DNases. Furthermore, we developed kidney spheroids (mini-kidneys) model by culturing NRK-52E cells using 3D hanging drop method, and tested the graphene toxicity in this model by measuring the DNase activity using the NIRF probe. The results showed a strong dose-dependent increase of DNase activity induced by graphene.

Conclusions: Measuring of DNase activity by using NIRF probe in combination with TUNEL assay and qICC are appropriate tools for assessment of graphene toxicity. Funding: NIDDK Support, Other U.S. Government Support, Veterans Administration Support

Identification of a Novel Bidirectional Regulatory Mechanism Involving AKT/B-Catenin and Anillin That Drives Podocyte Proliferation
Gentzon Hall,1,4 Jose A. Gomez,1 Brandon M. Lane,2 Guanghong Wu,1 Himani Vaidya,4 Robert F. Spurney,2 Rashied A. Gbadegesin.1,3,4 Internal Medicine, Duke Univ; 1Pediatrics, Duke Univ; 1Nephrology, Duke Univ; 1Duke Molecular Physiology Inst, Duke Univ.

Background: Mutations of the F-actin binding protein Anillin (ANLN) have been shown to cause familial FSGS. Although ANLN is a suspected modulation phosphoinositol-3 kinase (PI-3K) signaling, specific interactions with PI-3K pathway intermediates and the role of these interactions in the pathogenesis of FSGS remains unknown.

Methods: siRNA-mediated gene knockdown studies, immunoblot and proliferation assays were performed by co-immunoprecipitation methods in conditionally immortalized podocytes (CHIP). Furthermore, we investigated the effects of ANLN overexpression on PI-3K signaling in podocytes.

Results: We evaluated the effect of ANLN overexpression and targeted ANLN knockdown (KD) on AKT activation in podocytes. Additionally, we explored the effects of pharmacologic inhibition of AKT on ANLN expression in podocytes. Finally, we examined the role of AKT-mediated activation of B-Catenin via the direct phosphorylation of serine 552 in podocyte ANLN expression. We determined that ANLN overexpression significantly attenuated AKT activation. Conversely, ANLN KD significantly enhanced AKT activation and upregulated AKT-mediated phosphorylation/activation of β-Catenin at serine 552. Pharmacologic inhibition of AKT also inhibited basal podocyte proliferation. Finally, we determined that pharmacologic inhibition and targeted gene knock down of β-Catenin significantly attenuated podocyte ANLN expression.

Conclusions: These findings elucidate a novel mechanism of reciprocal regulation involving AKT/B-Catenin signaling and ANLN which may provide valuable insights into the role of ANLN in the pathogenesis of FSGS and other proliferative podopathies.

SA-PO296
Akt Mediates Cell Survival in Proteinuric States
Elif Erkan, Jian Gao, Sam Z. Coffey. Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: The degree of proteinuria correlates with progression in association with tubulointerstitial injury in glomerulonephritis. High concentrations of albumin in the glomerular filtrate results in apoptosis. Protein kinase B (Akt) is an serine/threonine kinase involved in multiple signaling events including cell survival. We hypothesized that down regulation of survival protein, protein kinase B (Akt) triggers tubular apoptosis in proteinuric states.

Methods: We utilized in vitro and in vivo model of albumin overload. Human kidney proximal tubule epithelial cells (HKC-8) are exposed to 10mg/ml albumin for 24-hours to induce apoptosis. C57BL/6C mice are housed in a conventional environment for 4 weeks to induce albuminuria. Fluorometric caspase-3 assay and TUNEL staining were utilized to assess apoptosis. Protein expression was assessed by Western blotting and immunofluorescence.

Results: In vivo and in vitro model of albumin overload. Human kidney proximal tubule epithelial cells (HKC-8) are exposed to 10mg/ml albumin for 24-hours to induce apoptosis. C57BL/6C mice are housed in a conventional environment for 4 weeks to induce albuminuria. Fluorometric caspase-3 assay and TUNEL staining were utilized to assess apoptosis. Protein expression was assessed by Western blotting and immunofluorescence.

Conclusions: Akt overexpression and targeted Akt inhibition and Akt knockdown (KD) in podocytes caused an increase expression of ANLN in podocytes. However, Akt knockdown (KD) in podocytes caused a decrease expression of ANLN in podocytes. Therefore, we determined that pharmacologic inhibition and targeted gene knock down of β-Catenin significantly attenuated podocyte ANLN expression.

Altered Protein Kinase Signalling Causes Major Phenotypical Changes in Renal Cells from Patients with Nephropathic Cystinosis
Ekaterina A. Ivanova,1 Fanny Oliveira Arcelino,1 Maria Pia Rastaldi,2 Lambertus P.W.J. Van den Heuvel,1 Elena N. Levtechken.1,2 Pediatric Nephrology, UZ Leuven, Leuven, Belgium; 1IRCCS Policlinico, Milano, Italy.

Background: Cystinosis is caused by mutations affecting the lysosomal cystine transporter cystinosin and results in lysosomal cystine accumulation. Cystinosis causes proximal tubular dysfunction, but also glomerular damage, which is present starting from early age. Current therapy of cystinosis is based on cystine-lowering cystine transporter, which greatly improves the prognosis, but does not cure the Fanconi syndrome and fails to prevent kidney damage in the majority of patients. It is therefore likely that, apart from the transporter function, cystinosis is implicated in other important cellular processes. We have investigated the mTORC-Akt signalling cascade in cystinosis-deficient renal cells. Akt kinase lies at the crossroads of cellular signalling regulating cytoskeleton, motility,
response to stress and survival, and is a target of mTORC2 and an upstream activator of mTORC1. mTORC1 is the master regulator of autophagy and metabolism. mTORC1 and 2 are also implicated in the regulation of cytoketone and cell motility.

Methods: Using conditionally immortalized proximal tubular epithelial cells (PTECs) and podocytes originating from cystinosin patients and healthy donors, we performed biochemical and microscopic analysis of phosphorylation and activation of protein kinases in response to various stimuli.

Results: Phosphorylation of Akt1 and 2 was increased in cystinosin podocytes and PTEC in response to nutrient/growth factor replenishment and wounding of cellular monolayer. In podocytes, such increased phosphorylation, was associated with altered cytoketone, disturbed focal adhesion sites and increased motility. Treatment with specific Akt inhibitor demonstrated a prominent decrease of motility and Akt phosphorylation. mTORC1 activation in response to nutrient replenishment was delayed in cystinosin PTECs accompanied with abnormal subcellular distribution of the kinase complex, as revealed by antibody staining of mTOR.

Conclusions: We demonstrate that cystinosin dysfunction is associated with disturbed signalling of protein kinases mTORC1 and Akt1 and 2.

Interstitial Pericytes Decrease in Aged Mouse Kneys

Anna Maria Stefanska,1 Diana G. Eng,1 Natalya V. Kaverina,1 Jeremy Stuart Duffield,2 Jeffrey W. Pippin,1 Stuart J. Shankland.1

1 Div of Nephrology, Dept of Medicine, Univ of Washington, Seattle, WA; 2 Biogen Idec, Cambridge, MA.

Background: With increasing age, the kidney undergoes characteristic changes in the glomerular and tubulo-interstitial compartments, which are ultimately accompanied by reduced kidney function. Studies have shown age-related loss of perivascular cells. Normal peripheral vessel tone, function and survival depend on neighboring pericytes. Pericyte detachment leads to vascular damage, which can be accompanied by their differentiation to fibroblasts and myofibroblasts, a state that favors matrix production.

Methods: To better understand the fate of pericytes in the aged kidney, 27-month-old mice were studied. Picrosirius red staining was performed to evaluate kidney fibrosis. Histological sections were stained against endothelial antigen CD31 together with pericyte markers PDGFRα and NG2. Additionally, immunoreactivity of myofibroblast marker aSMA was assessed together with pericytes.

Results: Compared to 3 month-old young adult mice, aged kidneys showed a substantial decrease in capillaries, identified by CD31 staining, in both cortex and medulla. This was accompanied by a marked decrease in surrounding NG2/PDGFRα pericytes. This decrease was more pronounced in the medulla. Capillaries devoid of pericytes were typically dilated in aged mice. Aged kidneys were also characterized by increased collagen-I (Col1α1) I. III staining. This was accompanied by an increase in the number of pericytes that acquired a pro-fibrotic phenotype, identified by increased PDGFRα/aSMA staining.

Conclusions: These findings are consistent with the decline in kidney interstitial pericytes as a critical step in the development of changes to the perivascular vasculature with aging, and accompanying fibrosis.

Interactions of Urotensin II and Mitophagy in Diabetic Nephropathy and Its Implications on Drug Design

Guan-Jong Chen, Fei Wu, Ai-hua Zhang, Dept of Nephrology, Peking Univ Third Hospital, Beijing, China.

Background: Urotensin II (UII), an important vasoactive neuropeptide, and the processes of mitophagy have been considered as possible therapeutic targets for treating diabetic nephropathy (DN). The present study is to define the interaction between UII and the process of mitophagy under the setting of DN.

Methods: Immunohistochemistry and western blot analysis were conducted on the protein extracts harvested from the kidney tissues of DN mice that were induced eighteen weeks after the injection of streptozotocin. In vitro cell experiment, HK-2 cells were cultured and treated with different concentrations of UII (10⁻⁹-10⁻⁹ mol/L) for 12 h and 3-MA treatment was used as a negative control. The cell protein extracts were then analyzed by western blot. For immunohistochemistry and western blot analysis, BNP3 was used as a marker for mitophagy.

Results: Immunohistochemistry and western blot analysis results of the animal renal tissue sections showed that the expressions of UII and BNP3, marker of mitophagy, are upregulated in the kidney sections of diabetic mice compared to that of controls. In vitro cell experiment results also demonstrate that UII can upregulate BNP3. The data indicates that UII expression is positively associated with the expression of BNP3.

Conclusions: Our results indicate that UII expression can upregulate mitophagy in DN. Past studies already demonstrate that mitophagy can have a therapeutic role in DN. Our study carries the implication that UII and its effect on the process of mitophagy presents potential as a novel target for DN.

Reduction in CTGF Leads to Increased Proliferation Through Influences on Claudin-1 and Extracellular Matrix Protein Spondin 2

Leighton R. James, Yongxin Gao. Medicine, Univ of Florida, Jacksonville, FL.

Background: Accumulation of extracellular matrix is a characteristic feature of diabetic kidney disease. We have recently demonstrated that connective tissue growth factor (CTGF) mediate increases in extracellular matrix production, proteinuria and scarring in mice. In addition to these properties, in specific human neoplasms (breast, colon), increased CTGF have been linked to reduced proliferation, improved response to therapy and prognosis but data is not consistent. On the other hand, metastatic melanoma progression correlates with CTGF levels and inhibition of CTGF reduces invasion and metastasis.

Methods: To define a possible role for CTGF in proliferation, embryonic fibroblasts (MEF) generated from wild-type and a previously reported CTGF knock mice line were studied. Expression array (Illumina) was used to identify changes in gene expression in MEF where CTGF expression was knocked down by Immunoblotting. Inhibition of MAPK (SP600125, SB203580 and U0126) were used to assess role of MAPK in glucose-mediated CTGF expression by cultured MEF.

Results: CTGF gene disruption lead to enhanced proliferation (3-fold) in CTGF knockout cells compared with wildtype cells. Reduced CTGF led to 50% decreased expression of the gene for the extracellular protein, procollagen 4 alpha 4 (Col4α4; confirmed at protein level)) in association with 2.8-fold increased expression of claudin-1, a member of the tight junction proteins. In addition, there was a 3.2-fold increased expression of spondin-2 and a 1.6-fold increased expression of Secreted protein, acidic and rich in cysteine-like 1 (SPARC1). Immunoblottning confirmed the observation for claudin-1. Glucose induced CTGF expression (2-3 fold) was attenuated by inhibitors of p38MAPK and JNK, but unaffected by inhibition of ERK (p42/44 MAPK).

Conclusions: In MEF, CTGF gene disruption lead to increased proliferation and altered matrix protein linked to increased expression of claudin 1 and other extracellular protein. Secondly, glucose-induced CTGF level is mediated by MAPK (p38 and JNK). Targeted alteration in CTGF along with one of more of these extracellular protein may offer new approaches to manage glomerulosclerosis.

miR21 Upregulates YY1 to Increase Renal Cell Apoptosis in Diabetes

Si Super Liang,1 Sammy L. Habib.1 1Geriatric Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX; 2Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.

Background: The regulation of miRNAs in response to hyperglycemia that contributes to the pathogenesis of kidney disease has been underscored.

Methods: In the current study, we investigated the role of miR21 in regulation of cells apoptosis in human renal proximal tubular cells (HK2) cells exposed to high glucose and in type II diabetes mouse model.

Results: Cells pretreated with either miR21 inhibitor or antisense before exposed to HG resulted in decrease YY1 expression and decrease cleavage of caspase 3. Nuclear extracts from HK2 cells exposed to high glucose for 48hrs showed increase in binding of YY1 to the YY1 promoter element by nuclear extracts of cells EMSA. On the other hand, pretreatment with miR21 inhibitor or antisense significantly decrease the binding of miR21 to YY1 in nuclear extracts of cells grown in NG or treated with HG. The DNA-protein complexes were significantly decreased in the presence of the YY1 antibody, indicating that YY1 is indeed a component of these complexes. Transfected the cells with promoter/reporter construct of miR21 showed significant increase in miR21 promoter activity in cells exposed to HG while cells pretreated with miR21 inhibitor reverse the effect of HG. In addition, significant increase in the percentage of TUNEL-positive tubular cells stained in the kidney sections of db/db mice compared to kidney sections of the wild type mice. Quantification of miR21 by real-time PCR showed significant increase miR21 levels in kidney of diabetic mice (db/db) compared to kidneys from wild type mice. Immunostaining analysis of miR21 showed that majority of miR21 staining within the tubular cells and glomerular compartments.

Conclusions: In summary, expose renal cells to HG and increase hyperglycemia in kidney of diabetic mice resulted in significant increase in miR21. Increase binding of YY1 to miR21 under HG condition suggesting the important role of miR21 in regulating YY1 to increase cell apoptosis. The data provide a novel role of miR21 as a target for controlling renal cell death that induced by hyperglycemia during diabetic nephropathy.

The Role of miR-302 and Let7 in Macrophage Polarization

Thomas K. Dodd, John Crean, Letizia De Chiara, Orina Belton. Diabetic Complications and Renal Disease, Univ College Dublin, Dublin, Ireland.

Background: Recent advances in the pathogenicity of renal injury highlighted the critical role of the immune system in the onset and resolution of disease. Monocytes canto differentiate along two pathways: pro-inflammatory (M1) due to the secretion of cytokines such as IL-6 and a pro-resolution attributable to the secretion of cytokines such as IL-10. Bane/Lu et al. have suggested that the ratio of M1 and M2 macrophages is controlled by

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
interplay between two micro RNAs, miR302 and Let7. We have recently shown that the silencing of DRD2 in THP-1 cells, the TGFβ receptor type II and type I receptors respectively and hypothese that this circuirty plays a critical role in macrophage differentiation.

Methods: The pro-resolving lipid mediator, conjugated linoleic acid (CLA), inhibits the acquisition of a pro-inflammatory macrophage phenotype by priming monocytes towards an anti-inflammatory phenotype. To identify pathways associated with this phenotype we performed proteomic analysis of THP-1 treated with CLA. Exosomes were isolated from urine samples taken from patients with renal injury and analyzed for miRNA expression.

Results: We found that caspase-3, caspase-7, Bax;Becl2 ratio, TGF-b1, Smad-2/3 and Smad-4 were activated in CsA group and that omega-3 FA prevented this activation related with apoptosis and fibrosis. The expression of Nrf-2 was decreased in CsA-treated rats but Nrf-2 was increased by omega-3 FA.

Conclusions: We suggest that Nrf-2 is one of potential mediator induced by omega-3 FA supplementation attenuating inflammatory pathway, fibrotic process and apoptosis. Further studies are necessary to elucidate cross-talks between Nrf2 expression and related signals of omega-3 FA.

SA-PO305
The Role of High Mobility Group Box 1 in Renal Epithelial Cell Survival During Hypertensive Stress Michael M. Yebboh,1 Marla A. Chesnik,1 Hayley Lund,2 Kevin R. Regner,1 David L. Mattson.2

1Div of Nephrology, Medical College of Wisconsin, Milwaukee, WI; 2Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: High mobility group box 1 (HMGB1) is a ubiquitous and evolutionarily conserved, DNA-binding protein and is characterized as an alarmin or damage associated molecular pattern because of the ability of extracellular HMGB1 to trigger an inflammatory response when it binds to its putative receptors, including RAGE, TLR2 and TLR4. New and emerging evidence suggest that intracellular HMGB1 is involved with numerous cell survival functions. The aim of this study was to examine the functional role of HMGB1 in tubular epithelial cells during hypertonic stress.

Results: In vivo, 2 groups of Dahl Salt sensitive rats were placed on high salt diet (4% NaCl, n=5/group) and were treated with either daily intraperitoneal injection of a HMGB1 inhibitor (glycyrrhetic acid) or a vehicle for 3 weeks while their blood pressure was monitored by telemetry. In vivo, NRC25E cells were incubated in control medium (332 mMol/kg) or hypertonic medium that contained NaCl (500 or 600 mMol/kg) for 6 hours in the presence or absence of the HMGB1 inhibitor. In other experiments, cells were transfected with scrambled siRNA or siRNA against HMGB1 and were exposed to control medium or hypertonic medium.

Results: Following exposure to a high salt diet, pharmacologic inhibition of HMGB1 resulted in more severe kidney damage as assessed by the percentage outer medullary area with tubular dilatation and protein casts, when compared with vehicle-treated rats. Inhibition of HMGB1 was associated with a significant increase in tubal cell apoptosis in comparison to vehicle treatment on TUNEL staining. Also, inhibition of HMGB1 led to significantly higher urinary albumin excretion and blood pressure at day 21 compared with vehicle treatment. Exposure of NRC25E cells to hypertonic medium resulted in increased expression and release of HMGB1 from the cells. Both pharmacologic inhibition and siRNA-mediated knock-down of HMGB1 led to reduced cell viability as determined by MTT assay.

Conclusions: HMGB1 plays an important role in renal tubular epithelial cell survival during hypertonic stress.

SA-PO306
KIM-1-Mediated Phagocytosis Defines a New Mechanistic Paradigm for Kidney Epithelial Cells, which Involves Autophagy and Anti-Inflammatory Antigen Presentation Craig R. Brooks, Melissa Y. Yeung, Takaharu Ichimura, Joseph V. Bonventre. Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background: The expression of kidney injury molecule-1 (KIM-1), the protein most upregulated in proximal tubules (PTCs), is associated with distal nephron injury. We previously showed that KIM-1 expression and release of HMGB1 from the cells. Both pharmacologic inhibition and siRNA-mediated knock-down of HMGB1 led to reduced cell viability as determined by MTT assay.

Conclusions: HMGB1 plays an important role in renal tubular epithelial cell survival during hypertonic stress.

Apoptotic Cells Activate AMPK and Inhibit Proximal Tubular Cell (PTC) Growth without Change in Intracellular Energy Stores

Philip Speigel,1 Snezana Vujicic,1 Lanfei Feng,1 Natalia O. Litbarg,1 Vimal Patel,1 Wilfred Lieberthal,2 Jerrold S. Levine.1 1Nephrology, Univ of Illinois at Chicago, Chicago, IL; 2Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.

Background: Apoptosis plays an indispensable role in the maintenance and development of tissues. We have shown that receptor-mediated recognition of apoptotic target cells by viable kidney PTCs inhibits the proliferation and survival of these viable PTCs. Here, we examined the effect of apoptotic target cells on PTC cell growth (cell size during G1 phase of cell cycle).

Methods: We used BU-MPT cells, a conditionally immortalized PTC line, as responder cells. BU-MPT cells, induced to undergo apoptosis in several ways, were used as apoptotic targets.

Results: Apoptotic cells potently activated AMP-activated protein kinase (AMPK), a highly sensitive sensor of intracellular energy stores. AMPK activation led to decreased activity of its downstream target, ribosomal protein p70 S6 kinase (p70S6K) and concomitant inhibition of cell growth. Importantly, these events occurred without detectable change in intracellular levels of AMP, ADP, or ATP. Inhibition of AMPK, either pharmacologically by compound C or molecularly by shRNA, diminished the effects of apoptotic targets, and largely restored p70S6K activity and cell size to normal levels.

Conclusion: Our results suggest that AMPK is a key signaling pathway that regulates apoptosis.

The Effect of Uremia on Cardiac Autophagy

William White, Steven Michael Harwood, Petros Andrikopoulos, Muhammad M. Yaqoob. William Harvey Research Inst, Barts & The London School of Medicine & Dentistry, Queen Mary Univ of London, London, United Kingdom.

Background: Autophagy is the process by which cells remove and recycle unwanted structures, contributing to intracellular homeostasis and energy production. Cardiac autophagy has a role in heart protection and ventricular remodeling, and decreasing autophagy is central to aging. Evidence suggests these processes are disordered in CKD. We hypothesize that uremia induces a decrease in autophagy.

Methods: In Vivo Rat cardiac myoblasts (H9C2) were cultured in the presence of indoxyl sulphate (IS) to simulate a uremic milieu, for 24 or 48 h, with or without 25 mM chloroquine (CQ, a late-stage autophagy inhibitor) for the last 6h. Cells were lysed and underwent immunoblotting for LC3B and p62.

Results: LC3 II/I ratio decreased in uremic cells (p=0.01, ȡ=0.4), CVD (p=0.0002), CAC score (p=0.008, ȡ=0.5) and diabetes mellitus (p=0.007, ȡ=0.05). The process of VC is complex, and has been linked to apoptosis. A potential contributor of VC is dysfunctional mitochondria. Dysfunctional Mitochondria Albumin Endocytosis in the Proximal Tubule Causes Accumulation of Dysfunctional Mitochondria

Angele Nolina, Ryan M. Mulhern, Ramon G. Bonegio, Zhiyong Wang, Steven C. Berkman, John H. Schwartz, Andrea Havasi. Renal, Boston Univ Medical Center, Boston, MA.

Background: Proteinuria is a major risk factor for chronic kidney disease progression. Furthermore, exposure of proximal tubular epithelial cells (PTECs) to excess albumin promotes tubular atrophy and fibrosis, key predictors of progressive organ dysfunction. The mechanism by which protein exposure causes tubular cell injury is unclear. We hypothesize that albumin endocytosis causes tubular cell injury by inhibiting autophagy, including macroautophagy, resulting in an accumulation of dysfunctional mitochondria leading to enhanced ROS production, mitochondrial and cellular injury.

Methods: The effect of proteinuria was examined both in vivo and in vitro experiments. Proteinuria was induced in mice by injection of a sheep nephrotic serum that causes acute immune-complex glomerulonephritis with massive proteinuria by 24-48 hrs. In Vitro, to mimic nephrotic glomerular filtrate, PTECs were exposed to albumin. Autophagy was assessed in tissue samples from mice and primary PTECs. Steady state LC3-II, an autophagy marker was quantified by immunoblot. Autophagosomes (APs) were visualized by cell culturing using fluorescent markers and in renal cortical tissue using immunohistochemistry. Mitochondrial respiration was measured in primary cells. Mitochondrial morphology and colocalization with autophagosomes were imaged using confocal microscopy. Reactive oxygen species production was measured using a 2',7'-dichlorodihydrofluorescein diacetate assay.

Results: Exposure to excess albumin induced defective autophagy and mitophagy in vitro. In renal cortices, proteinuria decreased both the number of LC3-II positive APs and the amount of LC3-II detected in cell lysates. Albumin-exposed cells accumulated damaged mitochondria with altered mitochondrial function and morphology. Albumin exposure caused mitochondrial dysfunction as evidenced by decreased oxygen consumption rate from coupled ATP production. Increasing albumin exposure time caused an increase in ROS production.

Conclusion: Dysfunctional autophagy caused by proteinuria likely contributes to tubular cell toxicity leading to renal progression.

Albumin Endocytosis in the Proximal Tubule Causes Accumulation of Dysfunctional Mitochondria

Philip Speigel,1 Snezana Vujicic,1 Lanfei Feng,1 Natalia O. Litbarg,1 Vimal Patel,1 Wilfred Lieberthal,2 Jerrold S. Levine.1 1Nephrology, Univ of Illinois at Chicago, Chicago, IL; 2Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.

Background: Changes in autophagy activity and senescence in uremic hearts may be due to increased p53 expression in uremia, suggesting an increase in senescence, which we are currently investigating. Interestingly p53 expression was increased in the uremic group.

Methods: We used BU-MPT cells, a conditionally immortalized PTC line, as responder cells. BU-MPT cells, induced to undergo apoptosis in several ways, were used as apoptotic targets.

Results: Changes in autophagy activity and senescence in uremic hearts may be due to increased p53 expression in uremia, suggesting an increase in senescence, which we are currently investigating. Interestingly p53 expression was increased in the uremic group.

Conclusion: These results suggest that TGF-β1 evokes an activation of mTORC1 signaling and the apoptosis caused by proteinuria in podocytes, whereas DCN downregulated TGF-β1 protein expression, and thus inactive mTORC1 signaling and induce autophagy on podocytes, inducing DCN may have a potential in alleviating TGF-β1 induced podocyte injury in MsPGN.

Funding: Government Support - Non-U.S.
Conclusions: These findings provide evidence that cell senescence and apoptosis are important in the development of FV and CVD in the uricemic milieu, and further strengthen the hypothesis that comorbidities present in CKD could be caused by a premature ageing process. Attempts to ameliorate any progeric process in this patient group is therefore of great interest.

Endothelial Autophagy Is Essential for Vascular Lipid Homeostasis

Kumiko Torisi,1 2 Subodh Verma,2 Takehiro Torisu,1 2 Krishna K. Singh,2 Toren Finkel.1 2 Center for Molecular Medicine, National Heart, Lung, and Blood Inst, NIH, Bethesda, MD; 3Div of Cardiac Surgery, St. Michael’s Hospital, Univ of Toronto, Toronto, ON, Canada; 4Graduate School of Medical Sciences, Kyushu Univ; Fukuoka, Japan.

Background: Cardiovascular disease is one of the common complications in chronic kidney diseases. It is known that autophagy plays a critical role in the course of kidney diseases. The resulting cardiovascular diseases are presumably regulated by autophagy. However the physiological role of autophagy in the vascular endothelial cells remains poorly understood.

Methods: Using human umbilical venous endothelial cells (HUVECs), induction of autophagy by ox-LDL, and uptaking or transcytosis of LDL are analyzed. To inhibit autophagy pharmacologically, chloroquine is used. The essential autophagy gene, Atg7 shRNA-mediated knockdown are performed to inhibit autophagy genetically. To assess an acute and chronic in vivo model of lipid exposure, we generated endoplasmic reticulum (ER)-associated protein reticulon-1, RTN1-A, and its role as a mediator of tubulointerstitial injury in diabetic nephropathy.

In vitro autophagy was studied using real-time PCR to determine the role of RTN1-A in HK2 cells treated with or without human serum albumin (HSA) or H2O2. Both proteasome inhibitors and autophagy inhibitors RA and 3-methyladenine (3-MA) were used to inhibit autophagy. Atg7 KO and Atg7+/− mice were generated to evaluate survival of MSCs in diabetic kidneys, which maintain tissue homeostasis by replacement of old or dying cells and repair of injured tissues.

In summary, our findings support a model in which autophagy regulates ER stress and apoptosis in the kidney tubules. The protective effect of RTN1-A knockdown in vivo is due to an increase in the expression of autophagy markers, and this is associated with an increase in cell survival in vitro. We propose that RTN1-A likely mediates proteinuria-induced tubular cell injury and progression of kidney disease through ER stress and apoptosis.

Targeted Mutations at the p66 Locus Antagonize Stem Cell Aging and Delay Expression of Senescent Phenotypes in Diabetic Kidneys

Background: Senescence has important implications for the biologic function of tissue stem cells, which maintain tissue homeostasis by replacement of old or dying cells and repair of injury. The p66 longevity gene plays a key role in the activation of gene programs that induce senescent and apoptotic phenotypes. We hypothesize gene base strategies targeting p66 will delay or prevent stem cell senescence and premature aging phenotypes in diabetic kidneys.

Methods: Mesenchymal stem cells (MSCs) were isolated from kidneys of p66 KO mice and p66 KO mice. Atg7 knockdown or pharmacological inhibition of autophagy resulted in higher accumulation of intracellular LDL, suggesting that in vascular endothelial cells, autophagy plays a critical role in regulating intracellular LDL accumulation within endothelial layer. Prevention of the decline in autophagy flux accompanied by kidney diseases pharmacologically might be beneficial to treat atherosclerotic diseases.

The Full Time Course and Localization of mTOR Activation in Compensatory Renal Hypertrophy

Jinxian Xu,1 Meiichu Cheng,1 Jianchun Yang, Jang-Kang Chen.1 Cellular-Biology & Anatomy and Medicine, George Regents Univ, Augusta, GA; 2Medicine, Vanderbilt Univ, Nashville, TN.

Background: Previous studies documented an essential role for mTOR activation in mediating compensatory renal hypertrophy induced by unilateral nephrectomy (UNX) but the time course and localization of the mTOR activation are unclear.

Methods: 8-week-old male FVB/NJ mice were subjected to right UNX or sham surgery, followed by sacrifice at different time points to collect left kidney and determine the time course and localization of mTOR activation by immunoblotting and immunofluorescence staining for phospho-S6K1 and phospho-p65, along with nephron segment-specific markers.
TGFβ does not regulate the expression of full length CCN3. However, it does reduce the expression of VEGF-A indicating that VEGF is an autocrine proximal tubular epithelial cell growth blocker indicating that EGF stimulates proximal tubular cell proliferation via the secretion of EGF-stimulated VEGF-A secretion indicating that mTOR and p42/44 MAPK proliferation. Although mTOR inhibition reduces HIF1-a, it upregulates MAPK with a very modest reduction of VEGF-A secretion indicating that the EGF effect is at least partly HIF1-a dependent. EGF increases HIF1-a expression, stimulates VEGF-A secretion and promotes proliferation of HK2 cells under normoxic conditions. HIF1-a knockdown decreases EGF-dependent VEGF-A secretion indicating that the EGF effect is at least partly HIF1-a dependent even in normoxia. EGF stimulates HIF1-a and VEGF-A via activation of the EGF receptor and upregulation of mTOR and p42/44 MAPK pathways. p42/44 MAPK inhibition significantly downregulates HIF1-a dependent VEGF-A secretion and cell proliferation. Although mTOR inhibition reduces HIF1-a, it upregulates MAPK with a very modest reduction of VEGF-A secretion indicating that mTOR and p44/42 MAPK may act via parallel pathways in VEGF-A regulation. Finally, we demonstrate that the EGF-stimulated proliferation of HK2 cells is reduced by VEGF Receptor 2 (VEGFR2) blocker indicating that EGF stimulates proximal tubular cell proliferation via the secretion of VEGF and the activation of the VEGFR2 receptor.

Conclusions: EGF stimulates VEGF-A secretion via activation of the EGF receptor, and stimulation of HIF1-a. EGF stimulates proliferation of HK2 cells via the secretion of VEGF-A indicating that VEGF is an autocrine proximal tubular epithelial cell growth blocker. The effects of EGF on HIF1-a, and VEGF-A in HK2 cells are modulated by complex crosstalk between p44/42 MAPK and mTOR pathways.

EGF Dependent Regulation of VEGF-A Secretion by Proximal Tubule Cells

Diana Zepeda-Orozco,1 Hisang M. Won,2 Nandita S. Raikwar,2 Chris P. Thomas.2 1Pediatrics, Univ of Iowa, Iowa City, IA; 2Internal Medicine, Univ of Iowa, Iowa City, IA.

Background: Vascular endothelial growth factor A (VEGF-A) plays a critical role in peritubular capillary development by promoting vasculogenesis and angiogenesis. It is now recognized that there is increased expression of VEGF-A by proximal tubular epithelial cells in ischemia reperfusion injury and in chronic tubulointerstitial injury. Although hypoxia is known to induce expression of VEGF-A in renal tubular epithelial cells in vitro and in vivo, the mechanisms regulating VEGF-A secretion by proximal tubule epithelial cells in normoxia has not been established.

Methods: We utilized HK2 cells, an immortalized human proximal tubule cell line, to characterize the epithelial growth factor (EGF)-dependent regulation of VEGF-A secretion by proximal tubular epithelial cells. Results: EGF increases HIF1-a expression, stimulates VEGF-A secretion and promotes proliferation of HK2 cells under normoxic conditions. HIF1-a knockdown decreases EGF-dependent VEGF-A secretion indicating that the EGF effect is at least partly HIF1-a dependent even in normoxia. EGF stimulates HIF1-a and VEGF-A via activation of the EGF receptor and upregulation of mTOR and p42/44 MAPK pathways. p42/44 MAPK inhibition significantly downregulates HIF1-a dependent VEGF-A secretion and cell proliferation. Although mTOR inhibition reduces HIF1-a, it upregulates MAPK with a very modest reduction of VEGF-A secretion indicating that mTOR and p44/42 MAPK may act via parallel pathways in VEGF-A regulation. Finally, we demonstrate that the EGF-stimulated proliferation of HK2 cells is reduced by VEGF Receptor 2 (VEGFR2) blocker indicating that EGF stimulates proximal tubular cell proliferation via the secretion of VEGF and the activation of the VEGFR2 receptor.

Conclusions: EGF stimulates VEGF-A secretion via activation of the EGF receptor, and stimulation of HIF1-a. EGF stimulates proliferation of HK2 cells via the secretion of VEGF-A indicating that VEGF is an autocrine proximal tubular epithelial cell growth blocker. The effects of EGF on HIF1-a, and VEGF-A in HK2 cells are modulated by complex crosstalk between p44/42 MAPK and mTOR pathways.

SA-PO318

Selective Regulation of a Novel Truncated CCN3 Protein by TGFβ1 in Human Tubule Epithelial Cells

Matthew Pottl,1 Bruce L. Risier,2 Mark E. Dockrell.1 1SJT Inst for Renal Research, London, United Kingdom; 2BLR Bio, WI.

Background: CCN3 is a member of the matricellular CCN family of proteins along with the structurally similar CCN2/CTGF, a powerful fibrotic agent, but recent work supports our hypothesis that CCN2 and 3 act in opposition to each other regulating fibrosis. In renal cell culture, the expression of CCN3 in HCCT1 cells in vitro has been shown to counter regulate the expression of CCN2 and CCN3 in the vertebral nucleus pulposus and in mesangial cells. We have previously characterised TGFβ1 induction of CCN2 in proximal tubule epithelial cells (PTEC); here we investigate the expression of CCN3 in human PTEC and its potential regulation by TGFβ1.

Methods: Primary human PTEC were cultured on collagen IV in supplemented medium. At 80% confluence cells were treated with TGFβ1 (0.25 - 2.5 ng/ml) for 24 & 48h, medium was collected and cells lysed. Equal amounts of lysate were subject to PAGE and Western blotting then probed with antibodies (Ab) to the C-terminal and N-terminal termini detected bands of approximately 23-28 KDa. The C-terminal Ab did not detect the 39 KDa band. The antibody to the N-terminal detected proteins of approximately 45 KDa as well as the 39 KDa form. Treatment with TGFβ2 for 24h had no effect on the 51 KDa protein but significantly inhibited the expression of the 39 KDa.

Conclusions: At a concentration that induces EGF (10 ng/ml) expression in PTEC, TGFβ1 does not regulate the expression of full length CCN3. However, it does reduce the expression of a truncated form apparently lacking the CT domain. The characteristics of this smaller protein are not consistent with any known splice variants and may represent an orphan splice form of CCN3. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

SA-PO319

Deletion of TGF-β1 Receptor in Proximal Tubule Cells Impairs HGF Signaling

Stellar Nlandu Khodo,2 Leslie S. Gwin,1,2 1Research, Tennessee Valley Veterans Affairs, Nashville, TN; 2Medicine, Div of Nephrology, Vanderbilt Univ, Nashville, TN.

Background: The growth factors TGF-β and HGF have antagonistic and synergistic interactions that govern renal development and response to injury. We previously showed that TGF-β worsens the epithelial response to acute renal injury, so we postulated that inactivating TGFβ-1 signaling may improve injury. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

Methods: To address how TGF-β1 signaling alters epithelial responsiveness to HGF, we generated proximal tubule (PT) cells with the TGF-β type 2 receptor, necessary for all signaling, either intact (TbRII wild type) or deleted in vitro with adenov-Cre (TbRII-/-). Responsiveness to HGF was assessed by receptor (cMet) phosphorylation, and the biological relevance of altered HGF signaling was determined by branching morphogenesis studies in 3D gels and migration assays.

Results: TbRII-/- PT cells had increased tubular branching and impaired migration compared to cells with the receptor intact. Unexpectedly, PT cells lacking TbRII had impaired response to HGF in both branching morphogenesis and migration assays compared to TbRII wild type cells. TbRII-/- PT cells had impaired cMet phosphorylation associated with reduced membrane expression of cMet and transcriptional downregulation of the HGF receptor. Notch signaling, a known inducer of cMet transcription, was increased in cells with TbRII intact, and Notch inhibition by gamma-secretase equalized the responses to HGF by PT cells with and without the receptor.

Conclusions: PT cells lacking TbRII have impaired responsiveness to HGF signaling, and this is due to reduced Notch-mediated cMet transcription. Thus, efforts to block TGF-β1 signaling may inadvertently inhibit signaling pathways of other growth factors such as HGF.

Enhancement of HGF-Induced Tubulogenesis by Endothelial Cell-Derived GDNF

Masano Nakatani, Akito Maeshima, Shunsuke Takahashi, Hidetsugu Ikeuchi, Toru Sakai, Tatsuo Hasegawa, Yoshibumi Nojima, Dept of Medicine and Clinical Science, Gunna Univ Graduate School of Medicine, Maebashi, Gunna, Japan.

Background: Renal proximal tubular epithelium can regenerate itself after a variety of insults. However, the microenvironment that regulates regeneration process of renal tubules after injury remains unclear. We previously established in an vitro 3D tubulogenesis assay which at least partly mimics in vivo regeneration processes of renal tubules after injury (Am J Physiol Renal Physiol: 301: F387-95, 2011). Utilizing this system, the endothelial cell-derived factors that regulate tubulogenesis was examined.

Methods: Human renal proximal tubular epithelial cells (RPTC) were cultured in gels (type I collagen/matrigel mixture) in the presence of HGF with or without human umbilical vein endothelial cells (HUVEC) using Transwell filter system. The signaling pathways activated by co-culture with HUVEC in tubular structures were examined using phospho-receptor tyrosine kinase (RTK) array.

Results: HGF, a potent renotrophic factor, induced aquaporin-1-positive tubular structures with microvilli, suggesting that these structures are morphologically equivalent to renal tubules in vivo. When co-cultured with HUVEC, HGF-induced tubular formation was significantly enhanced. Tubulogenic effect of HGF was also enhanced in the presence of HUVEC-conditioned media (HUVEC-CM), but not in the presence of VEGF, basic FGF or PDGF. Co-culture with HUVEC did not induce tubular structures in the absence of HGF. RTK array revealed that phosphorylation of RET (GDNF receptor) was markedly enhanced in tubular structures cultured with HUVEC-CM compared to those without HUVEC-CM. HUVEC produces GDNF and RTPEC expresses both RET and GFR alpha1 (co-receptor). HGF-induced tubulogenic formation was significantly enhanced by addition of GDNF.

Conclusions: HGF-stimulated tubulogenesis was significantly enhanced in 3D tubulogenesis cultures with HUVEC-CM. HGF in the absence of HUVEC-CM is not sufficient for tubulogenesis. Therefore, GDNF, the peptide growth factor that stimulates HGF signaling in tubular structures, is essential for tubulogenesis in 3D cultures. Further studies are required to determine the mechanism of GDNF to enhance HGF-stimulated tubulogenesis in 3D cultures.
SA-PO323
Cytokine Response of Primary Human Mesangial Cells Is LPS Strain Dependent
Margaret M. O’Neill, Carine Boustany, Steven S. Pullen.
CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma, Inc, Ridgefield, CT.

Background: LPS stimulation of Toll-like receptor 4 (TLR4) induces the release of proinflammatory cytokines which activate potent immune responses. LPS is an important structural component of the outer membrane of Gram-negative bacteria and consists of three parts: lipid A, core oligosaccharide, and an O side chain. It has been studied extensively in models of inflammation with E.coli 011:B4 most often referenced in the literature. The antigenicity of LPS varies from strain to strain depending on the composition of its O side chain. A comparative study was designed to identify the optimal strain to be used for LPS-stimulated release of proinflammatory mediators from primary human mesangial cells (HMC).

Methods: HMC were stimulated with 7 strains of LPS and 24 hour supernatants were analyzed for production of inflammatory mediators ([IL-1β, IL-6, IL-8, TNF-α and MCP-1]). Cultures were pre-treated with antioxidants and 4-Plex II and MCP-1. TLR4 antagonists EX00076824 and FHAN_2014062 were tested to evaluate inhibition of LPS activity in HMC using 3 LPS strains with most pronounced inflammatory effects.

Results: LPS induced strain-dependent increases in IL-6, IL-8, and MCP-1 in HMC, while there was no effect on IL-1β and TNF-α. When compared to controls, IL-6 production was significantly (p<0.05) increased. E.coli 011:B4 (25X), LPS-EB (10X), E.coli K12 (44X), E.coli O55:B5 (8X), S.Minnesota (99X), S.typhosa (18X) and P.gingivitis (6X). All strains induced IL-8 and MCP-1 except for E.coli O55:B5 (IL-8) or MCP-1. Both TLR4 antagonists blocked LPS induced production of IL-6, IL-8, and MCP-1 in a dose dependent manner. IC50 values for both inhibitors (EX00076824: 30-60nM; FHAN_2014062: 800-2700pg/ml) were consistent across LPS strains and analyte detected.

Conclusions: In this study we demonstrate that LPS-stimulated release of inflammatory mediators in HMC is strain dependent, and can be blocked using TLR4 antagonists. These data highlight the importance of identifying the most effective LPS strain in a cell type of interest, prior to initiating pharmacology studies.

SA-PO324
Effect of Angiotensin II Type 1 Receptor Blocker on 12-Lipoxygenase Activity and Slit Diaphragm Protein Nephrin and P-Cadherin Expression in Type 2 Diabetic Rat Glomeruli
Wan-min Wang, Yuan-yuan Zhang, Hong-zhao Xu, Fu-ze Ma, Tao Sun, Hang Yuan, Mindan Sun, Zhong-gao Xu. Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China.

Background: 12-lipoxygenase (12-LO) and Angiotensin II/Ang II interaction plays an important role in the development of diabetic nephropathy (DN), in which proteinuria was thought to be associated with decreased expression of glomerular slit diaphragm protein nephrin and P-cadherin. However, it is unclear whether Ang II type 1 receptor blocker (ARB) regulates 12-LO activity and slit diaphragm protein expression in type 2 diabetic rat glomeruli and hence was investigated in this study.

Methods: Podocytes and glomeruli isolated from rats were used in this study. The 12-LO products 12(S)-HETE and Ang II were infused into rats by osmotic mini-pump. Rats fed high fat diet received low dose streptozotocin to make type 2 diabetes. Glomeruli were isolated with sieving method and classified into small glomeruli (SG, on the 75mm sieve) and large glomeruli (LG, on the 125mm sieve). ELISA, RT-PCR and Western blot for related targets were performed respectively.

Results: Ang II increased 12(S)-HETE levels in podocytes and glomeruli. Direct infusion of rats with 12(S)-HETE and Ang II significantly decreased LG nephrin, but increased SG nephrin expression compared to control. The glomerular P-cadherin expression was reduced after Ang II and 12(S)-HETE treatment and there was no difference between LG and SG. ARB did not affect blood glucose levels but completely attenuated increases in 12(S)-HETE content, AT1 expression and proteinuria induced by diabetes. Nephrin protein expression was significantly reduced in diabetic LG but increased in diabetic SG compared to control. P-cadherin expression was decreased in both diabetic LG and SG. These abnormalities were partially but significantly prevented by ARB treatment.

Conclusions: ARB could ameliorate the progression of DN via upregulation of glomerular nephrin and P-cadherin expression through inhibition of 12-LO activation in type 2 diabetic rat glomeruli.

APOL1 Risk Variants and HIV Stimulate Induction of PDGF-β Receptor in Podocytes
Naqian Lan, Hongxu Wen, Ashwani Malhotra, Karl Leon Shu, Pravin C. Sinha, 1 Alan Arkin, 1 Shengli Yu, 1 John M. Flatmark, 2 Larry Frank, 2 Xiqian Lan, 1 Medicine, Rambam Health Care Campus, Haifa, Israel.

Background: Clinical reports demonstrated that two coding sequence variants (G1 and G2) in the APOL1 gene were associated with the highest percentage of kidney disease in African Americans. This disparity between patients with APOL1 variants versus wild type APOL1 increases by 10 fold for the development of HIVAN in patients of HIV infection who are not on antiviral therapy. Podocytes do not express platelet-derived growth factor (PDGF) receptors constitutively nonetheless, in experimental animal models, podocyte

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
700A
upregulated expression of PDGFs manifested as progressive glomerulonephritis. We hypothesized that APOL1 risk variants and HIV carry potential for the induction of the activation of the PDGF pathway in podocytes.

**Methods:** To determine the effect of APOL1 and APOL1 variants expression, stably expressing Vector, APOL1G0, APOL1G1, or APOL1G2 human podocyte (HP) cell lines were developed. To compare PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGF-E expression, pseudo type HIV (NL4-3) or empty vector (control) virus was transduced into APOL1G0/HPs, APOL1G1/HPs and APOL1G2/HPs. After 48 h, RNAs were extracted. CDNAs were amplified with specific primers for PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGF-E.

**Results:** Consistently increased expression of PDGF–A, PDGF-B, PDGF-C, PDGF-D, and PDGF-FR β in podocytes/G0/HPs, G1/HPs, and G2/HPs with or without HIV transduction did not display any change in the expression of PDGF–B, PDGF-C, or PDGF-D, when compared with vector; whereas, G2/HPs in HIV milieu displayed enhanced expression of PDGF–A. Interestingly, both G1/HPs and G2/HPs displayed 10 fold increase in PDGFFR expression when compared to vector/HPs or G0/HPs.

**Conclusions:** These findings indicate that PDGFs and their receptor PDGFR can be induced by HIV and APOL1 risk variants. The present variant could lead to new therapeutic targets for HIVAN.

**Assessment of Urinary Liver Type Fatty Acid Binding Protein in Patients of Type 2 Diabetes Mellitus with Early Chronic Kidney Disease**

**Om Prakash Kalra.** 1 Mohit Garg, 1 Ashok Kumar Tripathi, 1 Samir Agarwal. 1 Medicine, UCMS & GTB Hospital, Delhi, India; 2 Biochemistry, UCMS & GTB Hospital, Delhi, India.

**Background:** Diabetes mellitus is the most common cause of chronic kidney disease (CKD) worldwide. Various markers are being indentified which can detect nephropathy at an earlier stage. Both glomerular and tubular injury play an important role in etiopathogenesis of diabetic nephropathy (DN) and tubular damage precedes glomerular damage. Tubular markers could be used as a surrogate marker for the early stage of DN.

**Methods:** Serum liver-type fatty acid binding protein (L-FABP) was measured in 58 subjects with normoalbuminuria suggesting early tubular injury in these patients. This suggests that urinary L-FABP may be a promising early marker for detection of diabetic nephropathy.

**Results:** There was a significant positive correlation found in subjects of group II and III when compared with group I. Values of L-FABP were also found to be relatively intact in group III compared to group II. There was a significant positive correlation found between urinary L-FABP and eGFR.

**Conclusions:** These findings indicate that urinary L-FABP could be a promising early marker for detection of diabetic nephropathy.

**Neuropilin Regulates Pericyte Behavior in Postnatal Kidney**

**Monika Lucyna Wnuk, Regula Buergy, Werner A. Graber, Valentin Djonov.** 1 Inst of Anatomy, Univ of Bern, Bern, Switzerland.

**Background:** Neuropilin 1 (Nrp1) is a transmembrane co-receptor implicated in the regulation of endothelial cell migration during angiogenesis. In the adult kidney, Nrp1 is however expressed not only by endothelium but also by pericytes including peritubular pericytes and mesangial cells.

**Methods:** In order to precisely address the role of Nrp1 in postnatal kidney, two complementary mouse models were used; in the first one, Nrp1 was deleted specifically in pericytes with tamoxifen-inducible NG2Cre line and in the second approach, Nrp1 was blocked with an antibody (Genentech). In both models, tamoxifen/antibody treatment started at P21.

**Results:** Mutant mice showed mild proteinuria and/or hematuria at 3 months of age with Nrp1 excision efficiency being around 30% based on colocalization level between Nrp1 and PDGFR β. Kidney pathology revealed that it was primarily glomerular basement membrane (GBM) that was affected; mutant mice presented thickened, folded GBM with relatively intact podocyte foot process and endothelial fenestrations. The expression of genes encoding GBM proteins was examined and the deregulation of nidogen1 could be confirmed on protein level. Mutant mice showed additional dilated tubules with increased glomerular capillary surface area. Interestingly, these mice also had a tendency for fewer renal stained glomeruli as compared to Ctrl- controls. Furthermore, mutants had more BrdU-positive interstitial cells. Consistently, mice treated with anti-Nrp1 neutralizing antibody showed no difference in GBM abnormal reorganization and showed abnormal deregulation. Interestingly, in both models, male but not female mice were primarily affected. In vitro experiments with primary mesangial human and mouse cell lines showed increased cell proliferation, abnormal spreading and actin reorganization in Nrp1 knock down cells.

**Conclusions:** This study shows a novel role of Nrp1 in adult kidney pericytes. Future experiments with kidney cholesterol models and measurement of blood pressure will further clarify these interesting findings.

**Development of a Spontaneous, Reproducible and Treatable Kidney Fibrosis Model**

**Jessica Marie Overstreet, Ming-Zhi Zhang, Raymond C. Harris.** Medicine, Vanderbilt Univ, Nashville, TN.

**Background:** Kidney fibrosis in chronic kidney diseases causes gradual loss of kidney functionality. Currently, only a few kidney fibrotic models are available. New kidney fibrotic models are needed. Since our previous studies indicated that activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, we have developed a model with selective overexpression of human EGFR ligand, human heparin-binding EGF (hHB-EGF) in renal proximal tubule.

**Methods:** BD2 transgenic mice with selective overexpression of an EGFR ligand, human heparin-binding EGF (hHB-EGF) in renal proximal tubule, were generated. Male C57/BL6 homozygous Hbb-EGF mice received vehicle (water) or erlotinib (80 mg/kg/ day) by daily gastric gavage & 10 of 10 mice.

**Results:** Kidney cortical hHB-EGF mRNA and protein levels were dramatically higher in homozygous hHB-EGF mice than in heterozygous mice. Profound renal interstitial fibrosis was found in both BD2 and C57/BL6 homozygous hHB-EGF mice, but not in heterozygous mice, as indicated by histology and increased levels of the pro-fibrotic and fibrotic components (CTGF, α-SMA, collagen 1 and IV). Homozygous HBB-EGF mouse kidneys also exhibited increased oxidative stress and infiltration of both macrophages and T-lymphocytes. Interstitial fibrosis appeared as early as 4 weeks old. Homozygous hHB-EGF mice with increased kidney EGFR activation (increased phosphorylation of EGFR) and activation of downstream signaling, p-ERK and p-AKT. In addition, there was markedly increased p-Smad 2/3, p-EGFR, p-ERK, and p-Smad 2/3 were all primarily localized to proximal epithelial cells, indicating that hHB-EGF-mediated EGFR activation in proximal epithelial cells is the primary event in the development of interstitial fibrosis. Treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, inhibited EGFR signaling pathways and attenuated the development of renal interstitial fibrosis.

**Conclusions:** These studies suggest that ligand-mediated EGFR activation in renal proximal tubules of epithelial cells leads to spontaneous, reproducible, and treatable renal interstitial fibrosis. Therefore, homozygous HBB-EGF mice may be a useful renal fibrosis model to test the effectiveness of anti-fibrotic agents.

**TWEAK/Fn14 Signaling Promotes Kidney Disease by Driving Myofibroblast Activation, Inflammation and Vascular Instability**

**Ivan G. Gomez, 1 Allie M. Roach, 1 Gamze Karaca, 1 Linda Burkly, 1 Jeremy Stuart Duffield.** 1 Research & Development, Biogen, Cambridge, MA; 2 Medicine, Univ of Washington, Seattle, WA.

**Background:** We identified Fibroblast growth factor-inducible 14 (Fn14) as a receptor on pericytes, which is strongly upregulated as they differentiate into myofibroblasts in vivo in kidney disease. TNF-related weak inducer of apoptosis (TWEAK), a TNF-family member that binds the TNF receptor superfamily member 14 (TNFRSF14) expressed on pericytes, and stimulates myofibroblast differentiation in vitro, is induced in renal disease.

**Methods:** The kidneys of C57BL/6J mice were harvested, and proteins were extracted. Proteins were resolved in 10% Tris-HCl gels and transferred to nitrocellulose membranes. Membranes were blocked in 5% nonfat dry milk in Tris-buffered saline (TBS) and then incubated with primary antibodies recognizing Fn14, TNFRSF14, and fibroblasts with enzymes, including those that are known to be elevated in renal disease, were used to detect upregulated expression of Fn14 and TNFRSF14 in renal disease.

**Results:** Consistently, mice treated with anti-Nrp1 neutralizing antibody showed no difference in GBM abnormal reorganization and showed abnormal deregulation. Interestingly, in both models, male but not female mice were primarily affected. In vitro experiments with primary mesangial human and mouse cell lines showed increased cell proliferation, abnormal spreading and actin reorganization in Nrp1 knock down cells.

**Funding:** Government Support - Non-U.S.
cytokine produced predominantly by myeloid leukocytes has been reported to activate NFκB and induce TNF-α. We hypothesized that NFκB and TNF-α signaling was activated in myofibroblasts in vivo and the activation of TAZ/FK506 binding protein 14 (FKe14) in HK-2 cells suggested that these cytokines likely disable core Hippo signaling. TAZ overexpression promoted the nuclear entry of TAZ and pSMAD3 in HK-2 cells upon Angiotensin II stimulation, supporting a role for TAZ in the canonical NFκB pathway in chronic kidney disease. Future studies are needed to delineate the role of TAZ in the non-canonical NFκB signaling.

Results: FN14 deficiency ameliorates myofibroblast appearance, fibrosis and myofibroblast-driven nephrotic phenotype. FN14 overexpression in HK-2 cells promotes the activation of core fibrotic pathways, including fibronectin and PAI-1, suggesting that these cytokines likely disable core Hippo signaling. TAZ overexpression further activates established pathological myofibroblast cultures. Transcriptional profiling of these activated myofibroblasts supports its multifaceted role and identifies TAZ-responsive genes, including inflammatory, matrix and vascular destabilizing pathways. TWEAK stimulates non-canonical NFκB pathway, an interferon response, as well as ERK signaling in myofibroblasts. Non-canonical NFκB downstream signaling plays a vital role in myofibroblast responses to TWEAK. The importance of TWEAK signaling in disease progression was evaluated in the mouse Alport model of chronic kidney disease. Anti-TWEAK antibodies preserve organ function and significantly attenuate disease progression.

Conclusions: These findings suggest that targeting the TNF superfamily TWEAK gene may be an approach to modulate myofibroblast activation and a novel way to block both inflammatory and fibrotic aspects of chronic kidney disease.

Center for Cell Biology and Cancer Research, Albany Medical Center, Albany, NY; Dept of Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands.

Background: Hippo pathway is the principal regulator of organ size. Transcriptional co-activator with PDZ-binding motif (TAZ), a nuclear transducer of Hippo pathway, is activated by loss of cellular polarity, tensional forces and soluble factors. TAZ has been implicated in the progression of lung fibrosis and cancer. However, role of Hippo-TAZ pathway in chronic kidney disease (CKD) is unknown.

Methods: We utilized three mouse models of renal injury [ureteral ligation (ULO), aristolochic acid nephropathy (AAN), streptozotocin (STZ)-driven diabetic nephropathy] and TAZ genetic manipulation in HK-2 tubular epithelial cells and NRK-49F renal fibroblasts to investigate role of TAZ in renal fibrosis.

Results: TAZ is activated [as evident by increased nuclear accumulation (4-fold) and expression (2.5-fold) at both in the tubular and interstitial cells and decreased TAZ phospho-serine] in the UO kidney compared to controlateral controls. TAZ expression is also upregulated in AAN and STZ-induced renal diabetic injury models. TAZ activation correlated with increased pSMAD3 in the fibrotic kidney. TGF-beta1 and Angiostatin II stimulation, moreover, promoted TAZ and pSMAD3 nuclear entry in HK-2 cells suggesting that these cytokines likely disable core Hippo signaling. TAZ stable gene expression (2.5-fold) at both in the tubular and interstitial cells and decreased TAZ phospho-serine

Conclusions: Activated during renal injury, TAZ is a novel profibrotic effector of TGF-beta1 and Angiostatin II induced profibrotic responses. TAZ nuclear accumulation in response to TGF-beta1 and Angiostatin II is suggestive of cross-talk among Hippo pathway and these cytokines.

Design and Characterisation of Novel BMP Agonists and Antagonists Daniel Crean, Satnam Surat, Finian Martin, Catherine Godson. UCD; UCD; UCD.

Background: We have previously reported a role for the Bone Morphogenetic Protein [BMP] antagonist Gremlin in a driver of diabetic nephrinopathy and fibrosis in both kidney and lung. Bone Morphogenetic Proteins are integral regulators of bone and organ development. BMPs are secreted proteins and signal by associating with membrane bound receptors. The activity of BMP agonists is modulated by a family of secreted protein antagonists, including Noggin, Crossveinless-2 and Gremlin that limit BMP-receptor association by binding to the BMP ligand and thereby inhibiting receptor binding.

Methods: We have analysed BMP-receptor and BMP-antagonist interactions using a newly designed automated pipeline, Protein Complex Tool (PCT). Co-crystal structures of the BMP-BMP receptor and the BMP-antagonist complexes were submitted to PCT and in silico alanine substitution scans were performed to calculate the free energy contribution of each BMP-2, or BMP-7, residue to the stability of the complexes with receptors, BMPRIa (BMP-2 only) and AcRIa, and antagonists, Crossveinless-2 (BMP-2 only) and Noggin (BMP-7 only).

Results: The free energy calculations identified the key contributions of BMP residues to both binding events and suggested mutations that might generate super-agonist and dominant negative mutants.

Conclusions: We conclude that BMP antagonists are likely to be able to block both BMP-receptor and the BMP-antagonist binding to BMP receptors, and that co-treatment of BMP agonist and antagonist will be required to achieve therapeutic benefit. The complexity of BMP antagonist pharmacology and the potential for generating super-agonists and dominant negatives, bind antagonist but not receptor.

Engienged Growth Factors to Treat Acute Kidney Injury Shawdeeb Fahahi, Kerstin Kleinbecker, Tim Stowe, Matt Ousman. Silver Creek Pharmaceuticals, San Francisco, CA.

Background: Acute kidney injury remains a major unmet medical need and economic burden. There are no therapies that act directly on damaged kidney cells to promote survival. At Silver Creek Pharmaceuticals, we are engineering a new class of therapeutics called Smart Growth Factors that act selectively on damaged kidney cells to safely deliver pro-survival signals and restore kidney function.

Methods: We harness the power of survival and mitogenic signaling of growth factors and engineer more desirable drug-like properties, including extended half-life and cell type-specific targeting. Our first SGF, designed to reduce cardiomyocyte death following acute myocardial infarction, has shown positive pre-clinical efficacy and is being prepared for an Investigational New Drug application. We are now designing an SGF to treat acute kidney injury, where apoptosis of proximal tubule cells is a leading mechanism of pathology. We developed an in vitro model of tubule cell apoptosis using hypoxia to screen wild type growth factors for the ability to restore cell viability and promote proliferation. We then used computational models to design SGFs that could maximize pro-survival signaling and targeting in damaged kidney tubule cells.

Results: SGF variants were built, expressed and purified in-house, and screened for their ability to activate prosurvival and proliferative signals selectively in damaged cells using the in vitro hypoxia model. SGFs with favorable rescue ability, selectivity and pharmacokinetics will be tested in a rodent AKI model using bilateral ischemia.

Conclusions: Smart growth factors have the potential to transform the treatment of acute kidney injury, but safely delivering potent pro-survival and mitogenic signals specifically to damaged cells, hopefully leading to better outcomes for this patient population.

SA-PO334

Loss of the Podocyte Glucocorticoid Receptor Exacerbates Proteinuria Julie Goodwin, Xuwei Tian, Shuta Ishibe, Pediatrics, Yale Univ School of Medicine, New Haven, CT; Internal Medicine, Yale Univ School of Medicine, New Haven, CT.

Background: Nephrotic syndrome is one of the most common renal diseases in children and podocyte foot process effacement is its histologic hallmark. Glucocorticoids (GC) are the mainstay of treatment. Podocytes express the glucocorticoid receptor (GR) and new evidence suggests that podocyte-specific GC effects may be central to controlling proteinuria.

Methods: Mice with knockout of GR in podocytes were generated by crossing GR flox mice with podcrein Cre mice. Proteinuria was induced using both a systemic stimulus (LPS) and a renal-specific insult (nephrotic serum (NRS)). Urine protein/creatinine ratios, serum albumin and GMB morphology were assessed in both controls and knockout animals. In vitro, wound healing assays and analysis of stress fiber formation after stimulation with LPS in the presence or absence of dexamethasone (DEX) were performed in primary podocytes isolated from animals of both genotypes.

Results: Podocyte GR knockout mice did not have a phenotype at baseline. Their weight, serum creatinine, serum albumin, urine protein/creatinine ratios and foot process diameter were similar to controls. When challenged with low-dose LPS (12.5 mg/kg, IP), knockout mice developed significantly more proteinuria (2.11 ± 0.77 vs. 0.60 ± 0.21, p<0.05, n=5/group) compared to controls. When treated with NTS, similar results were noted. In vitro, GR knockout podocytes showed fewer and more disorganized stress fiber formation and impaired wound healing after LPS treatment compared to control podocytes. Administration of DEX could rescue the in vitro phenotype in control, but not GR knockout, podocytes.

Conclusions: These results demonstrate that (1) loss of podocyte GR exacerbates proteinuria in two different models in vivo, (2) podocytes lacking GR are more intolerant to injury, and (3) DEX administration ameliorates cellular injury in control, but not GR-negative podocytes. We conclude the podocyte GR plays a key role in maintaining the integrity of the slit diaphragm after injury.

Deletion of Inositol-Requiring Enzyme-1a in Podocytes Disrupts Glomerular Capillary Integrity and Autophagy Daniel Robert Kaufman, Joan Papillon, Takao Iwawaki, Andrey V. Cybulsky. Physiology, McGill Univ, Montreal, QC, Canada; Medicine, McGill Univ, Montreal, QC, Canada; Medicine, Gunma Univ, Maebashi, Japan.

Background: Inositol-requiring enzyme-1a (IRE1a) is an endoplasmic reticulum (ER)-transmembrane endoribonuclease-kinase, which plays an essential function in response to stress and injury during normal development, and is activated during ER stress. IRE1a may be involved in upregulating genes associated with the unfolded protein response and

Conclusions: Data will be presented from our investigations of these molecules as potential therapeutic leads for treating foot process effacement.

Funding: Pharmaceutical Company Support - ROCHE
ER-associated degradation, as well as in the activation of c-Jun N-terminal kinase (JNK)-1, and induction of apoptosis and autophagy. In this study, we address the functional role of IRE1α in podocytes.

Methods: Podocyte-specific IRE1α knockout (KO) mice were produced by breeding mice with loxP sites surrounding exons 20-21 with podocin (NH2P2)-Cre mice. LoxP-mediated excision in podocytes was confirmed by Southern blotting.

Results: In male mice, deletion of IRE1α in podocytes resulted in albuminuria beginning at 5 months of age, and worsening with time. Electron microscopy revealed focal podocyte foot process effacement in 9 month old male KO mice, as well as microvillous transformation of podocyte membranes and cytotoxic vacuolation. By light microscopy, glomerular cross-sectional area (an indicator of hypertrophy) was greater in KO mice, compared with control, and capillary lumens occupied a higher fractional area of KO glomeruli, suggesting formation of aneurysms. By immunofluorescence microscopy, WT-1-positive cells per glomerulus were comparable in KO and control males. Immunoblotting showed reduced LC3B-II expression and JNK-1 phosphorylation in KO glomeruli, in keeping with reduced autophagy. There was also a reduction in neprilysin maturation in KO glomeruli, suggesting impaired ER function. Finally, expression of IRE1α or IRE1α K599A (dominant inhibitor) in cultured CO3-1 kidney cells did not affect ERAD, as monitored by the downregulation of the CD3A ERAD reporter.

Conclusions: Podocyte-specific deletion of IRE1α leads to albuminuria and morphologic evidence of podocyte injury. Thus, IRE1α is essential to the maintenance of podocyte integrity as well as its ER function. The mechanism may, at least in part, relate to disruption of autophagy.

Funding: Government Support - Non-U.S.

SA-PO336
Consistent Downregulation of Autophagy Gene Atg12 Through MicroRNA-192 in Diabetic Nephropathy Supriya Deshpande, Mitsuo Kato, Mei Wang, Rama Natarajan. 1 City of Hope; 2City of Hope; 3City of Hope.

Background: Autophagy (Atg) plays a key role in the pathogenesis of kidney diseases, however its role in Diabetic Nephropathy (DN), and particularly in mesangial cells (MC) is not clear. TGF-b1, a key player in the pathogenesis of DN, regulates expression of various microRNAs (miRs) including miR-192. Also, several miRs regulate expression of various Atg genes. We hypothesized that miR-192 plays an important role in Atg regulation in DN.

Methods: Atg gene expression was analyzed in type-2 diabetic (db/db) and in STZ-injected type-1 diabetic mice. To analyze the role of miR-192 in Atg regulation, STZ-injected mice were treated with control locked-nucleic acid (LNA) oligonucleotides (oligos) or LNA oligos targeting miR-192 (anti-miR-192-LNA), and Atg gene expression was analyzed in kidneys. Atg gene analysis was also conducted in WT and STZ-injected miR-192 knockout (KO) mice. The effect of TGF-b1 on Atg gene expression and GFP-RFP-LC3 puncta formation was analyzed using mouse MC (MMC).

Results: Expression of several Atg genes was decreased in kidneys of type-1 and type-2 diabetic mice compared to controls. Treatment with LNA-anti-miR-192 reversed the effect of diabetes on some of the Atg genes. Further, Atg gene expression was not affected in kidneys of diabetic miR-192-KO mice compared to controls. In vitro studies using MMC treated with TGF-b1 also showed a decrease in Atg gene expression compared to control. Transfection of MMC with miR-192 mimics oligo decreased expression of certain Atg genes. In addition, transfection of MMC with a GFP-RFP-LC3 plasmid decreased the average number of RFP-LC3 puncta/cell following TGF-b1 treatment, and this effect was reversed in MMC from miR-192-KO mice. Of all Atg genes analyzed, Atg12 expression was consistently decreased in these mouse models, and its decrease was reversed by anti-miR-192 LNA oligos as well as in miR-192-KO mice.

Conclusions: These results demonstrate that consistent downregulation of Atg12 through miR-192 contributes to an overall decrease in autophagy and subsequent increase in cellular hypertrophy in response to TGF-b1 in MC and in glomeruli of diabetic cells leading to DN.

SA-PO337
mTOR Dependent Regulation of the Podocyte Metabolic Profile Tillmann Bork, Wei Liang, Tobias B. Huber. Renal Div, Univ Hospital Freiburg, Freiburg, Baden-Wuerttemberg, Germany.

Background: Podocytes play a critical role in the formation and maintenance of the kidney filtration barrier. Previously we have highlighted the role of mTOR signaling as a regulator of podocyte adaption, differentiation and size-control. However, the eventual link between podocyte size control and the regulation of podocyte metabolism by mTOR remains elusive.

Methods: Mice models of mTOR hyperactivation (Tsc1 PckKO) and mTOR loss of function (Raptor PckKO) were crossed to a Tomato/eGFP reporter line to efficiently isolate podocytes for primary cell culture studies. Mitochondrial respiration and ATP synthesis were assessed using Seahorse bioanalyzer with specific inhibitors of glycolysis and β-oxidation.

Results: Lipids are the main source for ATP synthesis due to oxidative phosphorylation in podocytes. Anerobic transformation of lipids and anerobic glycolysis is the dominating pathway to use glucose. Active mTOR signaling pathway massively enhances basal metabolic activity and the capacity for oxidative phosphorylation, β-oxidation and anerobic glycolysis.

Conclusions: Podocyte metabolism relies on β-oxidation of lipids and anerobic glycolysis. mTOR signaling regulates metabolic activity without affecting the preferences for the used metabolic pathways. Targeting the predominant metabolic pathways of podocytes might help to ameliorate diabetic nephropathy or podocyte ageing.

Funding: Government Support - Non-U.S.

SA-PO338
Derlin-2 Knockout Mice Unravel an Essential Role for Protein Dislocation in Podocytes Guihui Ren, Kwi Hye Koh, Jing Li, Changli Wei, Mehmet M. Altintas, Jochen Reiser. Dept of Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Protein quality control represents a balance between chaperone-assisted removal and folding of misfolded proteins from the endoplasmic reticulum (ER). Disturbed balance results in ER stress in podocytes that is associated with cellular injury. Derlin-2, a component that mediates cellular dislocation machinery, has been identified as an important element in skeletal and matrix producing cells.

Methods: Western blot and immunofluorescence staining were used for detection of protein expression. Derlin-2 knockdown or overexpression in podocytes was achieved with transfection of lenti viruses containing shRNA or CDNA. Podocyte-specific Derlin-2 knockout mice were generated by crossing Derlin-2-floxed mice with podocin-Cre mice. Autophagy was detected with the conversion of LC3-I to LC3-II. Activation of caspase-12 was measured by cleavage of procaspase-12.

Results: Derlin-2 was expressed in both mouse and human podocytes. Derlin-2 deficiency in podocytes could be compensated for by inositol-requiring enzyme 1 (IRE1) induced autophagy at basal conditions. However, in situations with induced ER stress owed to adriamycin (ADR) or other compounds, the compensatory response of autophagy was overwhelmed. Meanwhile, caspase-12 mediated apoptosis pathway was activated, and severe cellular injury ensued, leading to heavy proteinuria in podocyte-specific Derlin-2 knockout mice, as compared with wild type C57BL/6d control mice. In contrast, Derlin-2 overexpression in vitro attenuated podocyte injury. Derlin-2 expression was induced in patients during focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN) as well as in ADR nephropathy in BALB/cJ mice, streptozotocin (STZ)-induced diabetic mice and BTBR ob/ob DN mice.

Conclusions: Podocytes like osteocytes and chondrocytes emerge from mesenchyme and belong to a group of cells that employ Derlin-2 to guarantee protein quality and minimize ER stress for cellular homeostasis. Overexpression of Derlin-2 may be a mechanism to rescue damaged podocytes. Induction of Derlin-2 expression in vivo may have applications for prevention and therapy of glomerular diseases.

SA-PO339
Protein O-GlcNAcylation Is Essential for Normal Podocyte Structure and Function Shinya Ono, 1 Makyo Yasuda, 1 Shinji Kume, 1 Osamu Sekine, 1 Jun Nakazawa, 1 Hiszumi Araki, 1 Masami Kanakasi, 1 Shin-ichi Araki, 1 Daisuke Koya, 1 Masakazu Haneda, 1 Takashi Uzu, 1 Hiroshi Maegawa. 1 Dept of Medicine, 2 Dept of Medical Science, 3 Dept of Cell Biology, 4 Dept of Medical Biology & Endocrinology, Kanazawa Medical Univ, Kakohu-Gun, Ishikawa, Japan; 1 Div of Metabolism and Biosystemic Science, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.

Background: Post-translational modification is essential for normal cell function. The O-linked β-N-acetylglucosamine (O-GlcNAcylation) of proteins is a form of post-translational modification and serves as a nutrient/stress sensor for modulating cell functions. However, little is known about the role of O-GlcNAcylation in podocyte function. Podocytes contain a high level of O-GlcNAc (O-GlcNAc) and O-GlcNAc transferase (Ogt) is a critical enzyme for O-GlcNAcylation in mammals, and resides on the X chromosome. To examine the physiological role of O-GlcNAcylation in podocytes, we analyzed the renal phenotype of male podocyte-specific Ogt-knockout (Podo-OGTKO) mice, which were generated by crossing Ogt-floxed mice with podocyte-specific Cre mice.

Results: O-GlcNAcylation was immunohistochemically observed in the nuclei of podocytes in wild-type mice, but was completely absent in Podo-OGTKO mice. Podo-OGTKO mice showed normal birth rate and growth up to 32 weeks of age. Proteinuria was first apparent at 8 weeks of age and increased with age up to 32 weeks. Scanning transmission electron microscopy showed disruption of podocyte foot processes in Podo-OGTKO mice after 8 weeks of age. Immunofluorescence showed podocin to have a punctate distribution in Podo-OGTKO podocytes and to be at a reduced level compared with wild-type mice. Furthermore, the numbers of podocytes in 16-week-old Podo-OGTKO mice were significantly decreased compared with wild-type mice. Finally, severe glomerular sclerosis with tubulointerstitial damage was observed in Podo-OGTKO mice at 32 weeks of age.

Conclusions: O-GlcNAcylation of intracellular proteins by OGT is necessary to maintain podocyte numbers and normal foot process structure. Our results provide new insight into podocyte biology.

SA-PO340
Identification of Novel Gene Products That Regulate Podocyte Function Davide Pietro Cina, 1,2 Chengjin Li, 1 Jason Moffatt, 1 Susan E. Quaggin, 1,2 Div of Nephrology, Northwestern Univ, Chicago, IL; 1 Feinberg Cardiovascular Research Ins, Northwestern Univ, Chicago, IL; 1 Tennenbaum-Lunenfeld Research Ins, Mount Sinai Hospital, Toronto, ON, Canada; 1 Donnelly Centre and Banting and Best Dept of Medical Research, Univ of Toronto, Toronto, ON, Canada.

Background: Podocyte function is linked to the organization of its cytoskeleton and adhesion to the glomerular basement membrane. To identify genes that regulate podocyte function, we designed an in vivo genome-wide screen for factors involved in podocyte adhesion to fibronectin, an integrin mediated pathway, or sLFTI/Fc, a heparin sensitive pathway, using a pooled 9000 shRNA library.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

703A
Methods: A pool of knockdown podocytes was generated using this library and plated on both substrates followed by separation of the adherent and floating fractions and deconvolution by illumina sequencing. We developed a stringent method for statistical analysis and ‘hit’ determination and performed a small-scale validation of this method by interrogating top candidate genes individually. We also performed a larger scale validation using a secondary, focused pool Cas9 mediated knockdown screen.

Results: We identified 121 genes that increased adhesion to fibronectin and 45 genes that increased adhesion to sFLT1/FC. We also identified 66 genes that decreased adhesion to fibronectin and 106 genes that decreased adhesion to sFLT1/FC. DPH1, DPH2, DPH3 and DPH5 were among the top ten hits for increased adhesion to both fibronectin and sFLT1/FC. Stable podocyte knockdown lines for these genes displayed increased adhesion to both substrates. We also generated Cas9 mediated podocyte knockdown lines for DPH1, DPH2 and DPH5, which displayed increased adhesion and a spreading defect.

Conclusions: We have developed a novel method for identifying genes that regulate podocyte function. Future work will investigate how DPH1, DPH2 and DPH5 regulate podocyte adhesion, and select novel candidate genes that decrease podocyte adhesion. This unbiased approach will yield a list of genes that broaden our understanding of podocyte physiology and the disease states that perturb this system resulting in kidney disease. Targeted Deletion of Drp1 in Podocytes Mitigates Mitochondrial Remodeling and Progression of Diabetic Nephropathy
Bernard A. Ayanz, Yin Wang, Shawn S. Badal, Farhad R. Daneshvar, Department of Pathology, University of Texas MD Anderson Cancer Center, Houston, TX; ‘Division of Nephrology, Baylor College of Medicine, Houston, TX; ‘Department of Pharmacology, Baylor College of Medicine, Houston, TX.

Background: Diabetic nephropathy (DN) is the most common cause of end-stage kidney disease in the United States. Recent evidence, from our lab and others, suggests that mitochondrial fission may be linked to the pathogenesis of DN and little is known on how mitochondrial fission could contribute to the development of diabetic nephropathy. Mitochondrial fission is regulated by at least three dynamin-related GTPases, including Opa1, mitofusin, and Drp1. Drp1 is an evolutionary conserved protein whose loss results in elongated mitochondria. We have previously reported that Rock1-mediated Drp1 activation leads to increased mitochondrial fragmentation and podocyte apoptosis. We hypothesized that attenuation of Drp1 expression and activity in podocytes may ameliorate features of DN.

Methods: To investigate the role of Drp1 in podocytes, we deployed a genetic and pharmacological approach using a model of Type 2 diabetes (Lepr-null). First, we crossed conditional Drp1 (db/db;Drp1f/f) mice with a Podocyte-specific tamoxifen, inducible Cre recombinase line. Second, we employed the Drp1 GTPase activity inhibitor, Mdivi-1, to pharmacologically assess the therapeutic potential of targeting Drp1 in diabetic mice.

Results: Both Drp1-specific, Drp1+/− and pharmacological inhibition of Drp1 by Mdivi-1 in diabetic mice exhibited significantly attenuated albuminuria, mesangial matrix expansion, increased podocyte numbers, reduced podocyte foot process effacement and attenuated glomerular basement membrane thickening. Ultrastructural analysis revealed significantly elongated mitochondria in Drp1−/− diabetic mice compared to non-induced diabetic controls. Progression of mitochondrial abnormalities was reversed by treatment with Mdivi-1 in diabetic mice. High glucose induced mitochondrial fission, apoptosis and mitochondrial ROS production in podocytes.

Conclusions: Our Data Suggest that Drp1 as a key regulator of mitochondrial dynamics in podocytes, and point to Drp1 as a potential therapeutic target in DN. Funding: NIDDK Support

A Lack of eNOS Leads to Mitochondrial Injury in the Podocytes
Shuko Ueda,1,2 Shota Ozawa,1,3 Kiyoshi Moriz,1 Katsuhiko Asanuma,1 Motoko Yanagita,1,4 Shunya Uchida,2 Takahiko Nakagawa,1 ‘TMK Project, Medical Innovation Center, Kyoto Univ Graduates School of Medicine, Kyoto, Japan; ‘Teikyo Univ School of Medicine, Tokyo, Japan; ‘Pharmacology Research Laboratories II, Mitsubishi Tanabe Pharma Corporation, Saitama, Japan; ‘Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

Background: Endothelial nitric oxide synthase deficiency was shown to accelerate the progression of glomerular injury in several types of renal disease, but the role of eNOS to podocyte integrity remains unclear.

Methods: In order to examine the role of eNOS in the podocytes, cell morphology and mitochondria were examined by using adult male eNOS knockout mice.

Results: A lack of eNOS caused the glomerular hypertrophy in occasionally accompanied with mesangiolysis and glomerular sclerosis. Urinary albumin excretion was also significantly increased in the eNOS knockout mice compared to the wild type mice. Ultrastructural analysis showed that the injured podocytes exhibited the enlarged lysosomes, microvillus formation, pseudocysts and foot process effacement. An increase in oxidative stress was also associated with podocyte injury. With respect to mitochondria, its number was elevated while its size was reduced, suggesting that mitochondrial fragmentation was induced in the podocytes due to eNOS deficiency. While the expressions of several mitochondrial proteins were not altered, the D-17 mutation in mitochondrial DNA was significantly induced in the kidney of eNOSKO mice. Mitochondrial function was also likely impaired by eNOS deficiency as ATP level was significantly reduced in renal cortex of eNOSKO mice. Furthermore, the primary podocytes from eNOSKO mice exhibited the impairment of mitochondrial respiration. Consistently, conditioned medium derived from cultured glomerular endothelial cells lacking NO caused a greater degree of mitochondrial fragmentation and reduced mitochondrial oxidative stress in the cultured podocytes while such alterations was reversed by an NO donor.

Conclusions: These data suggest that eNOS may be necessary to maintain podocyte integrity, especially mitochondrial function.

Cytosolic Phospholipase A2 Alpha Regulates G1 Progression Through Modulating Forkhead Box Protein 1 Activity
Mehrdad Nami,1 Said Movahedi,2,3 Gabriel Choukroun,2 Dirk M. Hentschel,1 Joseph V. Bonventre,1 ‘Brigham and Women Hospital, Renal Division, Boston, MA; ‘Amiens Southern Hospital, Renal Division, Amiens, Picardie, France.

Background: Mesangial cell (MC) proliferation is characteristic of a number of chronic progressive glomerular diseases. cPLA2α is expressed in MCs and plays a role in cellular proliferation, however the mechanisms involved remain unclear. Here, we show for the first time a novel regulatory role for cPLA2α in the regulation of G1 phase of the cell cycle that is conserved in zebras and mammals.

Methods: Mouse embryonic fibroblasts (MEFs) and MCs were derived from cpla2+/− mice. cPLA2α was knocked down in zebras using morpholinos (MOs). Cell cycle progression was assessed by flow cytometry in zebras larvae and in Gs, synchronized cells after stimulation with PDGF. S phase population was assessed in zebras and MEFs by BrdU pulse studies. Analysis of the phosphorylation of proteins was carried out by western blot assays using phosphospecific antibodies.

Results: We identified two zebras cpla2α genes, termed cpla3αa and cpla3ab, with conserved phosphospecific activity. In zebras and MC cPLA2α promotes G1 progression via its phosphospecific activity and through PGE, production. PGE, through the PI3′-AKT pathway, promotes FOXO1 phosphorylation and FOXO1 nuclear export. This, in turn, inactivates FOXO1 resulting in upregulation of cyclin D1 and downregulation of p27(kip1), thus promoting G1 progression. These data indicate an evolutionary conserved mechanism between lower vertebrates and mammals. Further, using pharmacological inhibitors, we show that C216RAF/MAPK signaling pathways cooperatively regulate G1 progression in response to mitogenic stimulation.

Conclusions: cPLA2α is a critical effector of the G1 phase of the cell cycle through its phosphospecific activity. Pharmacological targeting of this enzyme may have important therapeutic benefits in disease mechanisms that involve excessive cell proliferation including progressive acute and chronic glomerulonephritis.

Podocyte Specific Glycogen Synthase Kinase 3 Is Critical for Neonatal Survival and for Renal Function in Maturity
Jenny Hurcombe,1 Abigail Charlotte Lay,1 Gavin Iain Welsh,1 Peter Mathieson,1 Satish Patel,1 Susan E. Quagg,1 James R. Woodgett,1 Richard Coward,1 ‘Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; ‘Samuel Lunenfeld Research Inst, Univ of Toronto, Toronto, ON, Canada; ‘Feinburg School of Medicine, North Western Univ, Chicago, IL.

Background: GSK3 is a multi-functional serine/threonine kinase existing as two distinct isoforms, termed GSK3α (41KDa) and GSK3β (45KDa). Knockout mouse models suggest that the GSK3 isoforms have different and cell type specific functions. This study aims to examine the importance of GSK3 in the podocyte.

Methods: We have used Cre/LoxP technology to generate mice with podocyte-specific ablation of GSK3α and/or GSK3β. Conditional Gsk3β knockout in development (using the podocin cre driver) and in maturation (using the doxycycline inducible podocin RtTA – tet-o-cre driver). In maturation (using the doxycycline inducible podocin RtTA – tet-o-cre driver).

Results: Mice developmentally lacking either GSK3α or GSK3β specifically in the podocyte were viable with normal life span (up to 2 years) and normal renal histology. In contrast, mice null for both GSK3α isoforms, born at normal Mendelian frequency, die at 10-16 days with massive albuminuria and acidosis. These mice have vacuolated glomeruli and glomerulosclerosis. Knockout of GSK3β and β after full glomerular development, at 4 weeks of age, also results in significant renal disease which develops within 2 weeks of knockdown. It consists of significant albuminuria with renal failure in some mice. Furthermore, there is evidence of a crescentic proliferative glomerulopathy, together with massive fibrosis and glomerulosclerosis. Mechanistically the wt signalling pathway is up-regulated and β-catenin activated throughout the kidney. Contemporaneous knockout of β-catenin in the developmental model dramatically improves albuminuria and renal histology but not acidosis or survival indicating the involvement of other pathways. These are currently being investigated through a glomerular transcriptomic approach.

Conclusions: Podocyte specific GSK3 is critical for glomerular and renal function in development and full maturity. Loss of single isoforms can be compensated throughout life but loss of both is catastrophic.

Podocyte Oxidative Stress Coupled with Ubiquitin C-Terminal Hydroxylase Deletion Exacerbates Renal Damage

Background: Ubiquitin C-terminal hydroxylase 1 (UCHL1) may promote antioxidant by hydrolyzing ubiquitin-thioester bonds on glutathione (GSH) thereby protecting GSH from deactivation. Podocyte UCHL1 is upregulated in diseased glomeruli where it may maintain redox balance. UCHL1-deleted mice overexpressing podocyte-specific NOX should exhibit exacerbated glomerular damage due to unregulated oxidative stress.

Methods: UCHL1 protein increased 1.9-fold in COS7 cells infected with AdNOX vs. AdGFP-infected controls. Similarly, glomeruli from 12-week-old NOX5+/− mice showed limited UCHL1 mRNA induction (1.5-fold). ACR increased in NOX5+/−/UCHL1−/− mice at 12 weeks (40 μg/mg) but not in nonTG, UCHL1−/− and NOX5+/−/UCHL1−/− mice (24, 28 and 25 μg/mg). Renal mass was reduced by 10% in both UCHL1−/− and NOX5+/−/UCHL1−/− mice as compared to nonTG mice. Interestingly, GFR was elevated in NOX5+/−/UCHL1−/− mice (121 μl/min/kg) in its UCHL1−/−/− mice, but was not different from NOX5+/−/− mice (127 μl/min/kg) at 12 weeks.

Conclusions: UCHL1-null mice have altered renal function and mass. When intercrossed with NOX5+/− mice, UCHL1 deletion combined with unchecked oxidative stress promotes filtration barrier damage.

Insulin Receptor Isoform A Is Implicated in Podocyte Injury in Diabetic Kidney Disease

Background: Disruption of physiological insulin signaling occurs in podocytes in experimental diabetic kidney disease (DKD). Two isoforms of insulin receptor (IR) have been described that either lack (IRB) or contain (IRB) the 12 amino acids encoded by exon 11. IRA signals primarily through p70S6 kinase and IRB signals primarily through KRAB and S6K.

Methods: Podocytes were treated with insulin (0.1 or 1 nM, 30 min) and samples were used for Western blot analysis. Co-immunoprecipitation experiments (Co-IP) were performed in HEK cells, transfected with 1ug of GFP- or FLAG-SMPDL3b, FLAG-IR, FLAG-IRB, GFP-Cav1 plasmids. Flow cytometric analysis was measured using BD FACS Calibur and CellQuest 3.0 Fluorometric Assay kit. Cell surface area was measured by confocal microscopy (OPERA XL).

Results: Podocytes overexpressing SMPDL3b (OE) showed significant increase of IRB/IRa mRNA expression ratio compared to control podocytes (CT) (1.00±0.00 and 0.74±0.05, p<0.05). Co-IP demonstrated that both IRA and IRB interact with Cav1. SMPDL3b overexpression augmented IRA/Cav1 interaction and suppressed IRB/Cav1 interaction. OE podocytes showed bigger cell surface area compared to CT (2778±0.00 and 2171.0±1.57, p<0.05). Insulin stimulation had no effect on the caspase-3 activity in CT podocytes while it induced apoptosis in OE cells (1.19±0.08 and 2.14±0.32, p<0.05).

Conclusions: Our data suggest SMPDL3b overexpression suppresses IRB signaling and facilitates IRA signaling leading to podocyte hypertrophy and apoptosis.

SMPD3 Counteracts Disturbed Apoptotic Pathways in Podocytes of Diabetic Patients

Background: SMPD3 expression is increased in glomeruli of patients with FSGS and TNFα expression is increased in podocytes of patients with FSGS. TNFα treatment of human podocytes causes NFAT activation leading to reduced ABCA1 expression and cholesterol accumulation in association with podocyte apoptosis. Our data suggest that treatments targeting the TNFα-NFAT-ABCA1 cholesterol axis may prevent podocyte injury in FSGS.

Podocytes Mediate Cholesterol Efflux in Human Diabetic Nephropathy

Background: Podocytes are among the first cells of the kidney to be affected in experimental and clinical diabetes. Podocytes overexpressing SMPDL3b (OE) showed significant increase of IRB/IRα mRNA expression ratio compared to control podocytes (CT) (1.00±0.00 and 0.74±0.05, p<0.05). Co-IP demonstrated that both IRA and IRB interact with Cav1. SMPDL3b overexpression augmented IRA/Cav1 interaction and suppressed IRB/Cav1 interaction. OE podocytes showed bigger cell surface area compared to CT (2778±0.00 and 2171.0±1.57, p<0.05). Insulin stimulation had no effect on the caspase-3 activity in CT podocytes while it induced apoptosis in OE cells (1.19±0.08 and 2.14±0.32, p<0.05).

Conclusions: Our data suggest SMPDL3b overexpression in human podocytes impairs IRB signaling leading to increased apoptosis and augments IRA signaling resulting in cell hypertrophy.

TNFa Mediated NFAT Activation Causes Podocyte Cholesterol Accumulation in FSGS

Background: In vitro studies demonstrate the role of TNFα in podocyte cholesterol accumulation. TNFα overexpression increases cholesterol uptake in podocytes, while TNFα depletion decreases cholesterol uptake. We hypothesized that TNFα causes NFAT mediated lipoprotein podocyte apoB56 expression in FSGS.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
ORO staining and prevented the development of mesangial expansion in KO+CD group compared to KO+Vehicle. A significant reduction in ACR, renal function or mesangial expansion in WT mice.

Conclusions: Based on these results, we conclude that CD improves renal function in a mouse model for AS and could be a new therapeutic strategy for the treatment of AS patients.

The Glomerular Matrisome in Alport Syndrome Is Altered prior to the Onset of Albuminuria

Michael J. Randles,1,2 Sophie C. Collinson,1 Jeffrey H. Miner,1,3 Rachel Lennon,1,2 Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester, Manchester, United Kingdom; 1,3 Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester, Manchester, United Kingdom; 1 Renal Div, Washiv Univ School of Medicine, St. Louis, MO.

Background: Alport Syndrome is caused by genetic defects in COL4A3, COL4A4 or COL4A5, but despite this knowledge there are currently no targeted therapies. We aimed to build our basic understanding about the glomerular extracellular matrix (ECM) in Alport syndrome and performed global analysis of composition and ultrastructural imaging in the COL4A3/−/− mouse.

Methods: Cellular and extracellular matrix (ECM) fractions from wild type and COL4A3/−/− mice at 6 and 16 weeks of age were analysed by mass spectrometry (MS) and imaged using serial block face-scanning electron microscopy (SBF-SEM).

Results: MS analysis revealed moderate changes in the composition of glomerular ECM at 6 weeks, even prior to the onset of barrier dysfunction. These included complete absence of type IV collagen α1, α4, α5 and upregulation of type IV collagen α3, α6 and type V collagen. At 16 weeks more dramatic changes were detected including elevated type IV collagen α1, α2, fibronectin, type 1 collagen, laminin α2 and fibrinogen chains. Global and pathway analysis of cellular fractions indicated changes in actin regulating proteins at 6 weeks and mitochondrial dysfunction at 16 weeks. SBFSEM demonstrated thickened and irregular glomerular basement membranes with evidence of podocyte protrusions into this ECM.

Conclusions: Our data demonstrate that Alport syndrome progresses with distinct early changes in ECM followed by more profound ECM accumulation, disruption and mitochondrial dysfunction. Enhanced understanding about the pathways that control podocyte-matrix adhesion may ultimately inform therapeutic strategies to correct or repair glomerular barrier function in Alport syndrome.

Creation and Analysis of Mouse Models of Human Nephrotic Syndrome Caused by the Laminin b2 (LAMB2) S80R Mutation

Steven Daniel Funk, Jeffrey H. Miner. Renal Div, Washiv Univ School of Medicine, St. Louis, MO.

Background: Most cases of congenital nephrotic syndrome in the first year of life are caused by mutations in 4 genes expressed in podocytes: NPHS1, NPHS2, WT1, and LAMB2. LAMB2 encodes laminin b2, a glomerular basement membrane component critical for glomerular filtration. We previously created transgenic mice using the lamin b2 promoter to study missense mutations discovered in patients with congenital nephrotic syndrome, including R246Q and C321R, which inhibit laminin-521 secretion and/or assembly.

Methods: In our first approach the S80R mutation was engineered into the rat lamin b2 cDNA and placed under the control of the promoter, this construct was used to make transgenic mice expressing LAMB2-S80R in podocytes on the LAMB2−/− background. In a second approach, we utilized CRISPR/Cas9 and homologous recombination to “knock-in” the S80R point mutation into the endogenous LAMB2 gene.

Results: Several transgenic mouse lines were characterized as very high, high, and low/mosaic LAMB2-S80R-expressing mouse lines. Surprisingly, high S80R expressing mice did not exhibit albuminuria up to 1 year of age. The low/mosaic expressers exhibited persistent, low level albuminuria that never progressed into the nephrotic range or overt kidney disease. These observations suggested to us that unregulated transgene expression may compensate for what could be only a mildly pathogenic mechanism. We then used CRISPR/Cas9 technology in zygotes to generate LAMB2-S80R knock-in mice that will better mimic the endogenous expression of the mutant protein, as in the patient. These are currently being bred for analysis.

Conclusions: The LAMB2-S80R mutation seems to be mild vs. other LAMB2 mutations. S80R is in the laminin N-terminal (LN) domain important for laminin polymer formation. High transgene expression may compensate for S80R-induced polymerization defects, which will be avoided with CRISPR/Cas9-induced, S80R knock-in mutants.

Diff erential Roles of Cell Surface Proteoglycans in Podocyte-Glomerular Basement Membrane Adherence

Angela C. DiPoto-Brahmbhatt, Deborah J. McCarthy, Kevin J. McCarthy. Pathology and Translational Pathobiology, LSU Health Sciences Center-Shreveport, Shreveport, LA.

Background: Cell surface proteoglycans (PG), via their heparan sulfate (HS) chains, work in a cooperative fashion alongside integrins to mediate podocyte (POD)-glomerular basement membrane (GBM) interactions. Results of our previous studies have shown that complete loss of HS at the POD cell surface leads to the development of foot process effacement. Since POD have at least two cell surface HS PG’s that are capable of mediating such interactions, the purpose of this study was to determine the effects of selective deletion of the cell surface PG, syndecan-1 (Sdc1) or syndecan-4 (Sdc4) on POD in vivo.

Methods: Frozen tissue sections from POD KO mice and mice expressing Sdc1 or Sdc4 knockout (KO) were immunostained with antibodies against the core proteins of Sdc1 and Sdc4, HS (antibody HS43C), syndapton (SYN), nephin, and α-actinin-4. To determine the potential for loss of anionic charge associated with HS, 500nm sections of unfixed kidneys from wild type, Sdc1KO or Sdc1KO mice were immunostained with antibodies against HS, polyethyleneimine (PEI) followed by fixation and processing for transmission electron microscopy.

Results: TEM studies showed that the GBMs of both Sdc1 and 4 KO mice had GBM irregularities, the POD in Sdc4KO mice showing moderate foot process effacement. Immunostaining for HS did not show differences in staining intensity for HS between Sdc1 and Sdc4KO mice. However, PEI labeling showed that the GBMs in Sdc4 KO mice had larger aggregates of PEI than those found in the GBM of Sdc1 KO mice. Immunostaining showed that a compensatory increase in Sdc4 expression in Sdc1KO glomeruli or Sdc1 expression in Sdc4KO glomeruli did not occur. The glomeruli of Sdc1 KO mice showed disruption of nephrin organization compared to Sdc4 and WT mice. Immunostaining for α-actinin-4 in both Sdc1KO and Sdc4KO glomeruli was also disrupted compared to control.

Conclusions: The data show that disruption of either Sdc1 or Sdc4 interactions with the GBM, Sdc4 expression is required to maintain normal morphology.

ERMA Protein Activation by CLIC4 in Glomerular Endothelial Cells

Abass Almomany, Nahtab Tavasoli,1 Laji Li,1 John C. Edwards, Barbara J. Ballermann,1 Medicine, Univ of Alberta, Edmonton, AB, Canada; 1Internal Medicine, St. Louis Univ, St. Louis, MO.

Background: We reported (J. Cell Sci. 2014, 127:5164) that the podocyte-predominant CLIC5A stimulates PI(4,5)P2 production and consequent ERM (ezrin, radixin, moesin) protein phosphorylation (pERM). Activated ERMs link membrane-spanning proteins to cortical actin, and inactive ERMs are unstable. CLIC4, homologous to CLIC5A, is expressed at high levels in glomerular and peritubular capillary endothelial cells (EC), and in proximal tubule brush border and basolateral membranes. CLIC4 deficient mice (CLIC4−/−) have fewer glomeruli and a lower peritubular capillary density than wild-type mice (BMC Nephrology 2014, 15:54). Here, we explored whether CLIC4 regulates ERMA protein activation, similar to CLIC5A.

Methods: Confocal immunofluorescence (cIF) microscopy was used to visualize CLIC4 and pERM in kidney sections. Western blot analysis (WB) was used to study total and cytoskeletal fractions from isolated mouse glomeruli and cultured human glomerular EC cells. In cultured human glomerular EC, CLIC4 was silenced with CLIC4-specific siRNA or CLIC4 cDNA rescue.

Results: By cIF CLIC4 co-localized exclusively with moesin in mouse glomerular EC. WB showed that CLIC4 is absent from CLIC4−/−glomerular lysates, and that the ratio of pERM : tubulin is lower in CLIC4−/− than in CLIC4+/+ glomeruli (1.28 ± 0.11 vs. 2.26 ± 0.30, respectively, p < 0.01, mean ± SD, n=3). Total ERM protein was also reduced, and much less ERM protein was observed in the cytoskeletal fraction of CLIC4−/− compared to CLIC4+/+ glomeruli. In cultured human glomerular EC, CLIC4 siRNA reduced CLIC4 protein by >90% and resulted in ERM protein dephosphorylation and dissociation from the cytoskeleton, all rescued by over-expression of CLIC4. CLIC4-induced ERM phosphorylation was abolished by PLC activation with m-MTFPS, indicating that PI(4,5) P2 dependence.

Conclusions: Hence, CLIC4 co-localizes with moesin in glomerular EC in vivo. Like CLIC5A, CLIC4 promotes ERMA phosphorylation in a PI(4,5)P2-dependent fashion. We speculate that defective ERM phosphorylation may be responsible, in part, for the morphological and physiological abnormalities in CLIC4−/− mice.

Vascular Glycocalyx Syndecan (SDC) 4 Loss Coincides with Albuminuria in Diabetic Nephropathy (DN)

Raina D. Ramsay, Amy Russell, Rebecca R. Foster, Gavin Iain Welsh, Andy Salman, Simon C. Mearns,1 Renal Unit, Univ of Bristol, Bristol, United Kingdom.

Background: The endothelial glycocalyx is a critical determinant of vascular health and a key regulator of vascular permeability. Increasing evidence points to disruption of the endothelial glycocalyx as a contributor to development of albuminuria (albumin in the urine) and eventually DN. TNFα which is important in the development of microvascular disease in diabetes caused a disruption of the glomerular endothelial cells (GEC)
glycocalyx through shedding of SDC4 and heparan sulfate (HS). We seek to investigate the role of vascular endothelial glycocalyx in DN and determine the mechanisms involved in its disruption in DN.

Methods: DN was induced in DBA2 mice by giving daily intraperitoneal injection of streptozotocin (STZ) at 50mg/kg for 5 days. The mice became hyperglycemic at 2 weeks and significantly albuminuria in glomeruli in DN, suggesting that STZ injection.

Results: In DN, SDC4 protein expression was significantly decreased in isolated glomeruli. This was accompanied by a corresponding increase in SDC4 in the circulation and in the urine, suggesting shedding of vascular glycocalyx SDC4. An increase in SDC4 shedding was a downstream mechanism resulting in an increase in SDC4 mRNA and in the urine, suggesting shedding of vascular glycocalyx SDC4. An increase in SDC4glomeruli. This was accompanied by a corresponding increase in SDC4 in the circulation and in the urine, suggesting shedding of vascular glycocalyx SDC4.

Conclusions: MMP2, 9-mediated shedding of SDC4 is likely to contribute to vascular endothelial glycocalyx dysregulation and albuminuria observed in DN. Potential therapies targeted at glycocalyx protection will be of benefit not only in DN but also in ameliorating systemic vascular disease in diabetes.

Blood Cell Velocities in Glomerular Capillaries Measured by 2-Photon In Vivo Microscopy

Giovambattista Capasso,
Eugenio Gutierrez,
Sara Damiano,
Francesco Trepiccione,
Giovanni Musco,
Capodiferro D, Sepe F, Stoppa A, Sebastian Frisch.

Methods: Male Munich-Wistar rats were intubated, anesthetized with isoflurane, and ventilated. Blood pressure and heart-rate were monitored. The left kidney was exteriorized and the rat placed in the 2-photon microscope. The vessel was visualized using a 70 µm-diameter probe. Longitudinal lines in the lumen of glomerular capillaries in superficial glomeruli were scanned at a frequency of >700 Hz. The axial movement of single blood cells was measured. 308 different capillaries were analyzed in 17 glomeruli from 5 different rats.

Results: Blood cell velocity was 2.99 µm/s ± 0.54. A Gaussian distribution and a Gamma-distribution were fitted to data from 13 glomeruli in which >12 capillaries were studied. C-tests (n = 0.05) showed 5 of 13 datasets not to follow a Gaussian distribution and 1 of 13 not to follow a Gamma-distribution. The data of all 308 capillaries normalized to the mean of the respective glomeruli did not follow a Gaussian distribution (P < 0.05). The Gamma-distribution allows an asymmetrical distribution around the mean and provided the best description.

Conclusions: This study provides experimental evidence of heterogeneity and an asymmetrical distribution of blood cell velocity in glomerular capillaries. The new experimental evidence calls for refinement of current models of glomerular blood flow heterogeneity and invokes the possibility to investigate the potential regulatory control of the ultrafiltration coefficient by regulation of capillary flow heterogeneity, e.g. by the activity of mesangial cells.

SA-PO356
Assessment of Exosomes Derived from Mesangial Cells Stimulated with High Glucose

Antonio S. Novoa,
Fernanda Teixeira Borges,
Marcos Dias,
Mirian A. Boim.

Methods: Exosomes and microvesicles (MV) are extracellular vesicles (EV) that are released by cells and are involved in the transfer of biochemical and genetic information. Exosomes are small (~100-150 nm) membrane-bound vesicles that are released by cells and play a role in the intercellular communication. They are formed by the inward budding of the cell membrane and are involved in the transfer of biochemical and genetic information.

Results: In the presence of high glucose, the expression of fibronectin in target control HMC stimulated with HG was higher in control HMC treated with HG-Ex compared with those treated with C-Ex, indicating that HG-Ex can modify the function of normal HMC.

Conclusions: In conclusion, the exosomes derived from HG stimulated HMC were able to induce fibronectin production in target control cells, and suggest that the intercellular communication through the exosomes may have pathophysiological implications in the diabetic kidney.

Axl Receptor Tyrosine Kinase Is Involved in Proliferation of Human Mesangial Cells Activated by PDGF

Stacy D. Hall,
Kerstin Eberfors,
Jennie C. Nystrom,
Stacy D. Hall,
Kerstin Eberfors,
Jennie C. Nystrom,
Stacy D. Hall,
Kerstin Eberfors,
Jennie C. Nystrom,
Stacy D. Hall,
Kerstin Eberfors,
Jennie C. Nystrom.

Methods: PDGF-BB was obtained from a commercial source or isolated from biopsy specimens of patients with IgA or other glomerular diseases. Quiescent human primary MC were stimulated by PDGF-AB in the presence or absence of different inhibitors. MC lysates were used to evaluate whether they are able to modify the function of target control HMC. PDGF-BB induced fibronectin production in target control cells, and suggest that the intercellular communication through the exosomes may have pathophysiological implications in the diabetic kidney.

Results: PDGF-induced proliferation of cultured MC through multiple signaling pathways. Targeting Axl may provide a new therapeutic strategy for IgAN.

Conclusions: Axl is involved in PDGF-induced proliferation of cultured MC through multiple signaling pathways. Targeting Axl may provide a new therapeutic strategy for IgAN.

Different Effects and Mechanisms of Prostaglandin E2 Receptor Subtypes EP2 and EP4 in TGF-β1-Induced Mesangial Cell Injury

Chen Xiao Lan,
Yuan Li.

Methods: To study effects of prostaglandin E2 receptor subtype 2 and 4 (EP2 and EP4) in mesangial cell injury by transforming growth factor -β1 (TGF-β1) and relevant signal pathways.

Results: 1. The primary cultures of EP2 gene knockout (EP2−/−), EP4 gene knockout (EP4−/−), and wild type (WT) mice mesangial cells were established; 2. grouping: A: WT; B: EP2−/−, C: EP2−/− + TGF-β1; D: EP4−/−, E: EP4−/− + TGF-β1; F: EP2−/− + TGF-β1 and EP4−/− + TGF-β1; G: EP2−/− + TGF-β1 and EP4−/− + TGF-β1 as control; 3. the level of PGE2, cAMP, the PKA activity of mesangial cell was tested; 4. phosphatase and PGE2, PKA activity increased; 5. ERK inhibitor blocks the function caused by agonist EP4; while EP2 upregulated the activity of PKA and reduced the occurrence of injury and fibrosis of mesangial cell; while EP4 may coordinate the promotional effect of mesangial cell injury induced by TGF-β1 by activating the phosphorylation ERK pathway, resulting in regulating effects different from that of EP4.

Conclusions: EP2 and EP4 have different regulating effects on injury and renal fibrosis of mesangial cells: EP2 receptor mediated PGE2 induced up-regulation of the level of cAMP and PKA activity, so as to inhibit transduction effects of TGF-β1/Smad3 pathway and reduced the occurrence of injury and fibrosis of mesangial cell; while EP4 may coordinate the promotional effect of mesangial cell injury induced by TGF-β1 by activating the phosphorylation ERK pathway, resulting in regulating effects different from that of EP4.

Mesenchymal Stem Cells in the Repair of the Damaged Mesangium: A Step by Step Ultrastructural Account of the Events Taking Place
Jiamin Teng, Pathology and Transitional Pathobiology, Louisiana State Univ Health Science Center, Shreveport, LA.

**Background:** Not much is known about repairing the damaged mesangium. The use of mesenchymal stem cells (MSCs) to repair the injured mesangium is a rather novel concept. The present study aimed at analyzing the entire process using transmission electron microscopy in an effort to better understand the various steps involved.

**Methods:** Mesangial cells (MCs) cultured single layer in dish (2D) and on Matrigel (3D), MCs were first cultured to confluent and quiescent for 48 hours. Then they were incubated with glomerular epithelial light chains (GLCs)(10µg/ml) purified from the urine of patients with type 1 diabetic nephropathy with light/proliferative glomerulopathy (AL-Am) (n=3) and light chain deposition disease (LCDD) (n=3) for 4 days and subsequently labeled MSCs were added. Samples were collected 10 days after the introduction of the MSCs (day 14) and processed for light and transmission electron microscopy.

**Results:** MSCs revealed evidence of direct damage by the GLCs including apoptosis with apoptotic bodies released. MSCs identified and migrate to areas where cellular damage was present. When MSCs became activated they acquired a “macrophage” phenotype. They then become active in phagocytosing cell debris, apoptotic bodies damaged extracellular matrix and non-extracellular matrix material. Their process of cleaning the damaged mesangium resulted in MSCs full of cellular debris and eventually disposing of the internalized material.

**Conclusions:** After performing this function, they proceeded to differentiate into mature MCs.

SA-PO360
Characterization of Circulating APOL1 Complexes and Their Kidney Distribution in African Americans

**Background:** The apolipoprotein L1 gene (APOL1) G1 and G2 renal-risk variants associate with non-diabetic nephropathy and cardiovascular disease in African Americans (AAs). Although substantial APOL1 protein is present in the circulation, with enrichment in podocytes compared to other renal cells, little is known about circulating APOL1 protein.

**Methods:** Total renal APOL1 levels were examined by Western blot in a cohort of healthy AAs who had a 1° degree relative with kidney disease. APOL1 protein complexes were isolated from fast protein liquid chromatography (FPLC) peak fractions and characterized by proteomic analyses. Results were subsequently confirmed by co-immunoprecipitation and Western blot.

**Results:** No significant differences were detected in serum APOL1 protein concentration based on APOL1 genotypes. However, serum APOL1 protein binds to other protein complexes. Non-denaturing gel electrophoresis and FPLC demonstrated that serum APOL1 protein existed in two non-overlapping peaks (12.2nm and 20.0nm in diameter, respectively). The smaller complex was labeled complex A and the larger complex B. Density gradient ultracentrifugation and agarose gel electrophoresis confirmed that neither APOL1 protein complex was associated with HDL or LDL cholesterol.

**Conclusions:** Results provide unique insights on the composition of circulating APOL1 protein complexes. The role of circulating APOL1 in kidney and cardiovascular disease in AAs requires further investigation.

Deep Mapping of the Native Mouse Podocyte Proteome
Markus M. Rinschen,1 Florian Grahhammer,2 Tobias B. Huber,3 Thomas Benzing.1 Internal Medicine, Univ Hospital Cologne, Cologne, Germany;1 Internal Medicine, Univ Hospital Freiburg, Freiburg, Germany.

**Background:** The entity of proteins expressed within a podocyte is still not known.

**Methods:** We performed mass spectrometry based absolute and relative quantification of the proteome of FACS-sorted native mouse podocytes.

**Results:** We resolved the podocyte proteome at a near-comprehensive resolution (more than 8000 identified proteins). Absolute copy numbers of proteins correlated with copy numbers obtained from deep-sequence transcriptomic analysis. The dataset indicates agreement between transcriptome and proteome regarding expression of proteins which are mutated in hereditary forms of proteinuria and FSGS in humans. 541 proteins were enriched within podocytes at very high ratios and significance. This study suggests that the podocyte is not only target to inflammatory stimuli such as TNFalpha and IFNGamma, but also an unanticipated other stimuli. In addition, this study delineates podocyte enriched tyrosine kinases, a few of these are druggable. Protein domains significantly enriched in podocyte proteins comprise not only PDZ and Fn3 domains, but also i-set domain, an adhesion domain. The majority of podocyte specific proteins also stain positive for glomerulus in human samples, with a weak correlation between staining intensity and absolute protein abundance measured by MS/MS.

**Conclusions:** This initial, near comprehensive draft of the podocyte proteome reveals untapped molecules and mechanisms. This dataset will be of benefit to understand podocyte physiology, pathobiology and develop potential therapeutics strategies.

A Longitudinal Study on Kidney Function, Pathology, and Multiple Urinary Biomarkers in ZSF1 Rat Model of Type II Diabetic Nephropathy
Zhi Su, Deborah Widomski, Marian T. Namovic, Diana L. Donnelly-Roberts, Laura Leys, Katherine Salte, Arthur L.nikkel, Lauren Olson, Jia Ma, Timothy A. Esbenshade, Steve McGaraughty. Renal Discovery, Abbie, N Yemen, Chicago, IL.

Background: Obese ZSF1 rats display many clinical features of human type II diabetic nephropathy (DN). To further understand this model and to identify relevant biomarkers of disease progression, we followed the development of DN by measuring glomerular filtration rate (mGFR), histopathology, and a variety of urine and tissue biomarkers over 24 weeks after uninephrectomy (Unx). Correlations between mGFR and individual urinary biomarkers were assessed.

Methods: Male rats (9-week old) underwent either a sham or Unx (right kidney) surgery and were fed a high carbohydrate diet. GFR was measured by transradial clearance of FITC-sinistrin. Urine samples were collected once every 2-4 weeks for biomarker analysis, and renal tissue was examined for collagen deposition as well as for the levels of key inflammatory and fibrotic genes.

Results: Kidney hyperfiltration was observed (2-3 fold increase in mGFR) in obese rats 2-week after surgery lasting until week 4. The mGFR subsequently declined over time in these rats and was 2-fold lower than control rats by end of study. Compared to lean rats, obese rats also demonstrated time-dependent increases in urinary excretion of protein, KIM-1, L-FABP, NGAL, Cystatin C, Clusterin, Beta2-microglobulin, alkal-1 acid glycoprotein, VEGF, MCP-1, TIMP-1, Collagen IV, TGF-b1, and TGF-b2. A significant correlation was found between mGFR and a number of urinary biomarkers (L-FABP, KIM-1, TIMP-1, Cystatin C, and TGF-b2). Kidney fibrosis was significantly elevated by week 12 post surgery and continued to expand in the following weeks. Unx increased the weight and glomerulosclerosis of the remaining kidney and accelerated the decline of mGFR in obese rats during late weeks of observation.

Conclusions: ZSF1 rats showed a progressive increase of fibrosis and loss of GFR over the 24-week study. A number of urinary biomarkers demonstrated a strong inverse correlation with the time-dependent changes in mGFR. Additionally, Unx significantly increased glomerulosclerosis and loss of GFR in obese rats.

Haptoglobin 2-2 Genotype Is Associated with Decreased Levels of Vitamin D Receptor (VDR), Klotho and Accelerated Renal Apoptosis in Mice and Humans Diabetic Nephropathy
Farid M. Nakhoui1, Farber Evgeny2, Nadia Thawho1, Andy Levy1, Inbal Dahm1. 1Diabetic Nephrology Lab, Baruch-Padheh Poriyu M. Center, Lower Galilee, Israel; 2Nephrology, Faculty of Medicine In Galilee Bar Ilan Univ, Israel; 1Vascular Medicine, Technion, Haifa.

Background: Haptoglobin (Hp) is an antioxidant protein by its ability to bind free hemoglobin (Hb) and prevents heme-iron mediated oxidation. Diabetic mice & humans with different Hp genotype (1-1, 2-2) have a different susceptibility to develop Diabetic Nephropathy (DN) due to impaired Hb clearance and increased iron deposits in the lysosomes of the kidney proximal tubules (PCT). This leading to increased renal oxidative stress and cell damage. Our study proposed a molecular mechanism explaining the influence of Hp genotype, klotho expression on the pathogenesis of DN in VDR and PPAR-γ in DN patients.

Methods: Slides from kidney biopsies of DN patients and mice with different Hp genotype (1-1, 2-2) were subjected to Immunohistochemistry staining of iron modified with D/VDR in DN patients.

Results: Reduced levels of the anti oxidant klotho and VDR in the kidney 2-2 mice compared to 1-1 and 1-2 mice. The kidney from 2-2 animals showed a significant increase expression of active caspase-3 staining that was accompanied with decrease renal expressions of VDR, 1α hydroxylase and klotho levels.

Conclusions: Hp 2-2 genotype associated with increased iron deposits and high levels of PCT apoptosis Decreased levels of the anti oxidant klotho and VDR in the renal PCT. We propose a molecular mechanism explaining the influence of klotho and klotho expression on renal PCT apoptosis in DN patients. These results provide new insights into the role of Klotho and VDR expression on the pathogenesis of DN in patients with Hp2-2 genotype.

Resistance Exercise Training Prevents Kidney Hypertrophy and Increases the Biogenesis Mitochondrial in Diabetic Rats
Luziana Jorge1, Kleiton Augusto Santos Silva2, Rafael Luiz2, Rodolfo Rosseto Rampaso1, Janaina Paulini Aguiar2, Nestor Schor1, 1Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil; 1Molecular Biology, Univ of Utah, Salt Lake City, UT.

Background: Diabetic nephropathy(DN) is a progressive complication arising from diabetes. Kidney cell response to injury includes cell division, cell hypertrophy and apoptosis. Increasing evidence indicates that the disruption of mitochondrial bioenergetics and structural change in the kidney may be important in the development and progression of DN. Therefore, it is fundamental the understand of non pharmacological intervention as exercise training to prevent those complications. We investigated the effect of resistance training(RT) on the DN pathogenesis.

Methods: Male Wistar rats were divided into control(C), control trained(Ct), diabetic(D) and diabetic trained (DT). DM was induced by STZ. Trained groups were submitted to a resistance exercise training on Ladder climb (8wk). Urinary volume and proteinuria were evaluated. Tissue weight/tibial length ratio was used as kidney hypertrophic index. Expression of P-Akt, P-Mtor,P-AMPK and MF2N protein was evaluated by western blotting.

Results: RT improved renal parameters in DT group show a decreased urinary volume (C=160; DT=120; C=13; CT=14ml), proteinuria(D=45; DT=32; C=18; CT=7 mg/24h) (p<0.05). Diabetes resulted in increased hypertrophic index (50%)and RT prevented it. Renal expression of PAMPK and MF2N was reduced in D group and RT normalized this expression(p<0.05). Moreover, the renal expression of PAKT and PmTOR were increased in the DM and the RT influence on it(p<0.05). Histological analysis showed glomerular hypertrophy in D and RT prevent this complication.

Conclusions: RT attenuated progression of diabetic nephropathy; Those improvements could be a result of increased AMPK/MF2N pathway, an important pathway to biogenesis mitochondrial; and inhibition of AKT/mTOR pathway, responsible for hypertrophic response, demonstrating that those complications were prevented by exercise training. Ours findings demonstrated that RT is an important approach to avoid, both molecular and functional complications in diabetic kidney. Funds from FAPESP, CNPq and CAPES.

SA-PO367

Aerobic Exercise Training Improves Proteinuria and Renal Inflammatory Factors in Rats with Diabetic Nephropathy
Rodolfo Rosseto Rampaso1, Rafael Luiz2, Kleiton Augusto Santos Silva1, Luziana Jorge1, Edison Andrade Pessoa1, Mario Luis Ribeiro Cesaretti1, Nestor Schor1, 1Nephrology, UNIFESP, SP, Brazil.

Background: The objective of this study was to evaluate the effects of aerobic exercise training in controlling the progression of diabetic nephropathy, inflammatory factors, and its possible renoprotective effects.

Methods: Adult male Wistar rats/4 groups, n=8/group: Sedentary controls (C-SED), Diabetes+ Sedentary (DM-SED), Diabetes+Exercise (DM-EXE) and control exercise (CEX). Diabetes was induced with STZ, 50 mg/kg bw. The exercise training were conducted on a treadmill 60min/day, 5 days/week/8 weeks. Weekly certain, maximal exercise test(set MEtest) was used. Dietary and physical activity were controlled. Glycemia after post 24 education(24 glycemiapt), MEtest, creatinine clearance(BW), proteinuria(uProt) were evaluated. Tissue weight/tibial length ratio was used as kidney hypertrophic index.

Results: DM-EXE improved renal parameters show a decreased urinary volume (C=517±88*#&; CT=462±05*#&; DM-EXE=18±72) and uProt ( mg/24h) (C=387±64*#&; CT=324±34*#&; DM-EXE=218±34*#&). Moreover, the renal expression of IL-6, IL-10 and TNF-α were measured. Data as mean ± SD.

Conclusions: Reductions in blood glucose and AP – 11% comparing DM-EXE vs DM-SED. The DM-EXE controlled weight loss ~40% compared to DM-SED, but did not prevent change in CrCl/BW with this protocol. However, the effect was surprisingly observed EXE reduction in both excretion through uProt ~60% and ~25% in MD-EXE. Furthermore, preliminary data suggests that aerobic exercise can reduce proteinuria and inflammatory factors in diabetic animals and hence reduce the potential effects caused by diabetic nephropathy and could reduce the progression of renal failure.
SA-PO368
Inhibition of miR-25 Processing Mediated by Mecp2 Phosphorylated by HIPK2 Can Upreregulate NOX4 in Early Diabetic Nephropathy
Hyung Jooh Oh, Mitsuo Kato, Supriya Deshpande, Mei Wang, Linda L. Lanting, Rama Narasaran. Diabetes and Metabolism, Beckham Research Inst of City of Hope, Duarte, CA.

Background: Altered microRNA (miR) levels play key roles in the pathogenesis of diabetic nephropathy (DN), but it is unclear if miR processing is involved. Phosphorylated mediator of epigenetic protein 2 (p-MeCP2), known to act as a transcriptional repressor, was recently reported to suppress the processing of several miRs. Homeo-domain interacting protein kinase2 (HIPK2) can bind to and phosphorylate MeCP2. However, it is not known if MeCP2 and HIPK2 are involved in processing and expression of candidate miRs in DN.

Methods: p-MeCP2 and HIPK2 staining in kidney sections from 4-week streptozotocin (STZ) injected diabetic and control mice, was studied by immunohistochemistry. Protein, miRNA and miR levels were examined by Western blotting (WB) or RT-qPCRs in TGF-b1- or high glucose (HG)-treated mouse mesangial cells (MMCs).

Results: p-MeCP2 and HIPK2 immunostaining, and their protein levels were significantly higher in renal glomeruli (but not cortex) of STZ mice than control. Moreover, Seven in Absentia Homolog 1 (SIAH1), which mediates proteosomal degradation of HIPK2, was decreased in STZ mice compared with control. Among several regulated miRs, miR-25 and -93 levels were significantly decreased in STZ mice relative to control. The precursors of miR-25 and -93 were also significantly decreased in STZ mice, while conversely, NADPH oxidase4 (NOX4), a target of miR-25 that is associated with renal fibrosis and DN, was significantly increased in STZ mice. Protein levels of p-MeCP2 and HIPK2 were also increased in vitro in TGF-b1- or HG-treated MMCs compared to control. Moreover, mRNA levels of the genes mentioned above in vivo were similarly regulated in MMCs in vitro.

Conclusions: Bioinformatic analysis and in vivo expression data of genes regulated by HIPK2 and MeCP2 in MMCs suggest that genes regulated by HIPK2 and MeCP2 may play roles in the development of DN.

SA-PO369
Ursolic Acid Attenuated High Glucose Induced Podocyte Injury by Increasing Autophagy Level via Inhibition of miR-21 Expression and PTEN/Akt/mTOR Pathway
Qinglu Fan. Nephrology, The First Hospital of China Medical Univ, Shenyang, Liaoning, China.

Background: Autophagy played an important role in maintaining podocyte homeostasis. The defective autophagy might contribute to podocyte dysfunction under high glucose condition. Moreover, we investigated the effect of Ursolic acid (UA) on autophagy and injury of podocyte cultured with high glucose condition.

Methods: Conditionally immortalized murine podocyte were cultured in high glucose, the effect of PI3K inhibitor LY294002 and ursolic acid treatment would be observed. The autophagic inhibitor 3-MA was used to assess the effect of ursolic acid on autophagy in podocyte. The miR-21 expression was detected using RT-qPCR. The activation of PTEN-PI3K/Akt/mTOR pathway, expression of autophagy-associated protein and podocyte associated protein were determined by western blot. Immunofluorescence staining showed the expression of podocyte associated protein and endogenous accumulation of LC3. Autophagosomes were observed using electron microscopy.

Results: In the high glucose condition, high basal level of autophagy in podocyte became defective and defective autophagy facilitated the podocyte injury. miR-21 expression was upregulated, PTEN level was downregulated, PI3K/Akt/mTOR pathway was activated in podocyte cultured with high glucose. Ursolic acid and LY294002 could reduce podocyte injury by increasing autophagy level via inhibition of PI3K/Akt/mTOR pathway. However, LY294002 did not affect the expression of miR-21 and PTEN. Ursolic acid inhibited miR-21 expression and upregulated PTEN level. Downregulation of autophagy with 3-MA significantly suppressed the protective effect of ursolic acid on podocyte.

Conclusions: These data suggested that podocyte injury is associated with defective autophagy under high glucose condition. Ursolic acid could reduce podocyte injury by increasing autophagy level via inhibition of miR-21 expression and PTEN/Akt/mTOR pathway.

SA-PO370
Hyperglycemic Memory in DN: Effects of Epigenetic Changes of SHP-1 in Podocytes
Farah Lizotte, Benoit Denhez, Andreanne Guay, Pedro Miguel Geraldines. Medicine, Univ ok Sherbrooke, Sherbrooke, QC, Canada.

Background: Previous animal and clinical observation suggested that disruption of normal insulins is a part of the etiology of diabetic nephropathy (DN). Although, intensive blood glucose control reduced the development of DN, the EDC study showed that, if not started early, it is not sufficient to prevent DN progression. This hyperglycemic memory phenomenon can be explained by epigenetic changes. Our previous studies demonstrated that SHP-1, a protein tyrosine phosphatase, is elevated in renal cortex of type 1 diabetic mice (Akita) causing insulin unresponsiveness and DN. We hypothesize that epigenetics changes lead to persistent increase of SHP-1 expression despite systemic glucose normalization with insulin implants. SHP-1 expression was increased by 2 fold in renal cortex of DM and DM mice treated with insulin implants. Elevated expression of SHP-1 mRNA, protein and phosphatase activity in HG conditions remained increased in hyperglycemic memory group and associated with insulin actions inhibitions. Evaluation of histone modifications showed that monomethylation of the H3K4 (me1), which is associated with enhanced gene activity, in the promoter region of SHP-1 was increased in HG and remained elevated after returning to NG concentration.

Conclusions: In conclusion, hyperglycemia induces epigenetic changes on SHP-1 promoter causing persistent expression and elevated activity of SHP-1 leading to podocyte unresponsiveness to insulin and DN.

SA-PO371
Targeting the Polycystic Repressive Complex Chromatin Remodeling Machinery for Therapeutic Benefit in Diabetic Nephropathy
Lettizia De Chiara, Hayley Beaton, Catherine Godson, John Crean. UCD School of Biomolecular and Biomedical Science, Diabetes Complications Research Centre, Univ College Dublin, Dublin, Ireland.

Background: Diabetic Nephropathy (DN) manifests as renal microvascular abnormalities, mesangial sclerosis and tubulointerstitial fibrosis as a result of longstanding hyperglycemia. Emerging evidence indicates that multiple factors involved in the etiology of diabetes can alter epigenetic mechanisms and regulate susceptibility to microvascular complications.

Methods: Immunoprecipitation, ChIP, Western Blot, miR302 overexpression, luciferase assay.

Results: We have previously identified SMAD3 and EZH2 as part of a context dependent switch enhancing complex that regulates cell fate during fibrotic processes. Here we describe the further characterisation of this interaction and delineate its potential pathogenic significance. Comparative analysis of gene expression data from patients, animals and cell models of diabetic kidney disease revealed a subset of genes that are potentially regulated by the interaction between Smad3 and EZH2, including critical regulators of epithelial fate such as E-Cadherin. Endogenous immunoprecipitation and luciferase performed in renal epithelial cells demonstrated that EZH2 and recruits EZH2 to the E-Cadherin promoter causing its down-regulation during Epithelial to Mesenchymal Transition. We further demonstrated that this interaction is disrupted by mutating SMAD3 protein sequence. Perturbation of the interaction between SMAD3 and EZH2 was facilitated by viralt overexpression of miR302. Human renal mesangial cells transduced with miR302 underwent profound changes in gene expression exhibiting de novo expression of SNAIL and EZH2 and start to express de novo E-Cadherin.

Conclusions: Our results suggest that SMAD3 and EZH2 control the repression of E-Cadherin during DN, opening the possibility for therapeutic manipulation of this nexus during the progression of renal disease. Understanding the processes through which dynamic epigenetic silencing is controlled in adults will allow us to address the epigenetic state of acquired disease and whether original states, regenerative in nature, can be restored with therapy.

Funding: Government Support - Non-U.S.

Effects of DPPIV Inhibitor versus Combined Treatment with DPPIV Inhibitor and ARB on Renal Function in Type 2 Diabetic Mice
Hyve Sook Min,1 Jin Jooh Cha,1 Sung Jin Kim,2 Kitae Kim,1 Jung Eun Kim,1 Jungyoo Ghee,1 Ji Eun Lee,2 Hyunwook Kim,1 Jee Young Han,1 Young Sun Kang,3 Dae R. Cha.1 1Internal Medicine, Korea Univ Ansan Hospital; 2Nephrology, Sam Hospital, Anyang; 3Internal Medicine, Wonkwang Univ Sanbon Hospital; 1Pathology, Inha Univ, Incheon, Republic of Korea.

Background: Recent evidence has shown that DPPIV is involved in all steps leading to renal function, such as inflammatory response, cell apoptosis and fibrosis. The aim of our study was to investigate the mechanisms and effects of DPPIV inhibitor (DA1229) alone and combined treatment with DPPIV inhibitor and ARB (LC158809) on renal injury in db/db mice.

Methods: The mice were divided into five groups as follows: non-diabetic db/m mice (control), untreated db/db mice, db/db mice treated with DA1229 (300mg/kg/d), db/db mice treated with LC158809 (1.5mg/kg/d) and db/db mice combined treatment with DA1229 and LC158809 for 12 weeks.

Results: 1week HbA1c level was significantly decreased in combined treatment group. Oxidative stress markers were not different from each other. Activity of serum DPPIV significantly was reduced with DA1229. 24h albuminuria significantly decreased with LC158809 treatment at 8 weeks and with DA1229 at 12 weeks in diabetic mice. However, no additive effect on albuminuria was observed with combined treatment. Administration of DA1229 or LC158809 significantly decreased accumulation of ECM protein, TL4 and NOX4 expression in glomeruli. Moreover, these effects were observed in both genotypes directly engaged in the treatment group. Urinary excretion of nephrin was increased in diabetic mice and was decreased in combined treatment with DA1229 and LC158809. In vitro, DPPIV was expressed on the
podocyte membrane and its expression was activated by angiotensin-II. Nephrin expression in cultured podocyte was attenuated by high glucose and angiotensin-II. This attenuation was recovered with DA1229 treatment, but not with other DPPIV inhibitors.

**Conclusions:** Our data suggest that renoprotective effects of DA1229 in experimental diabetic mice might be associated with protective effect of podocyte injury. DA1229 might be a potential therapeutic agent to slow the progression of diabetic nephropathy.

**SA-PO373**

**PBI-4425, a Novel Anti-Inflammatory/Fibrotic Compound, Improves Kidney Function and Structure in the Diabetic db/db Mouse Model**

**Background:** Kidney disease associated with diabetes mellitus is a major health problem worldwide. Glomerular injury plays a pivotal role in the development of diabetic nephropathy. PBI-4425 possesses a pleiotropic mechanism of action with anti-inflammatory, antioxidant and anti-fibrotic properties. The aim of this study was to investigate the protective effect of PBI-4425 on kidney function and structure in uninephrectomized (NX) diabetic (db/db) mice.

**Methods:** Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4425 (100 mg/kg, oral once a day) from day 1 through 105. Kidney function (GFR), kidney mesangial lesions, modulation of gene expression, and serum cytokines were investigated.

**Results:** GFR assessed by inulin clearance was significantly reduced in NX-db/db mice compared to NX-C57BL/6 negative control mice, and PBI-4425 treatment significantly improved GFR. As shown by PAS staining, NX-db/db mice had larger glomeruli with increased glomerular mesangial lesions scores were significantly reduced by PBI-4425 treatment. Gene expression of inflammation, fibrosis, oxidative stress, and extracellular matrix remodeling markers were assessed. Kidney MCP-1, IL-6, Collagen I, NOS, MMP2, and Timp1 mRNA expression were markedly increased in NX-db/db mice, and PBI-4425 treatment induced a significant decrease of these markers. Glomerular response to injury was accompanied by activation of kidney development-related genes, such as glomerular epithelial protein 1 (GLEPP1); expression of GLEPP1 was significantly increased in NX-db/db mice, and restored to the negative control level following treatment with PBI-4425. Moreover, PBI-4425 significantly reduced serum pro-inflammatory cytokines IL-6, IL-12p70, and TGF-β.

**Conclusions:** These results suggest that PBI-4425 offers the potential as a novel therapy for diabetic nephropathy by improving kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

**SA-PO374**

**The Effect of Nox Inhibitor APX-15 on Diabetic Kidney Disease**

Jim Jun Cha,1 Hye Sook Kim,2 Kicat Kim,3 Jung Eun Kim,1 Jungyeon Ghee,1 Hyunwook Kim,1 Ji Eun Lee,2 Ji Young Han,2 Young Sun Kang,1 Dae R. Chung.1 1Internal Medicine, Korea Univ Medical College Ansan Hospital, Ansan, Republic of Korea; 2Internal Medicine, Wonkwang Univ Medical College Sanbon Hospital, Gunsan, Republic of Korea; 3Pathology, Inha Univ College of Medicine, Incheon, Republic of Korea.

**Background:** Excess reactive oxygen species generated by NADPH oxidases (Nox) have been implicated in the inflammatory and fibrotic processes of chronic kidney disease. Recent studies have suggested the importance of renal Nox in the progression of diabetic nephropathy. Therefore, we investigated the effect of a novel NOX-inhibitor APX-15 on diabetic nephropathy in an experimental model of type 2 diabetic mice.

**Methods:** 8 to 10 week old db/m and db/db mice were treated with APX-15 for 12 weeks. APX-15 was administered by oral gavage at a dose of 60mg/kg/day. To compare the effects of APX-15 with a selective Nox inhibitor, db/db mice were treated with GKT136901 according to same protocol.

**Results:** APX-15 significantly improved insulin resistance in diabetic mice similar to GKT136901. Oxidative stress measured by plasma S-isoprostane level was decreased in APX-15 group compared to diabetic control. All lipid profiles, both in plasma and tissues (kidney, fat, liver) improved with Nox inhibition. Nox mRNA expressions in adipose tissue (Nox1, Nox2) and in kidney tissue (Nox4) were downregulated and Nox protein expressions were decreased with APX-15. 24 hour urinary albumin excretion was reduced and creatinine clearance was preserved with APX-15. In diabetic kidney, structural changes were notably attenuated with APX-15. Importantly, mesangial expansion was significantly improved with APX-15, but not with GSK 136901. Kidney PaI-1 and TGF-β expressions were decreased and nephrin expression increased in both APX-15 and GKT136901 groups compared to diabetic control. Additionally, F4/80 infiltrations in the adipose tissue and the kidney were decreased with APX-15.

**Conclusions:** Our findings suggest that APX-15 may have a better renoprotective effect compared to selective inhibitor GKT136901 in experimental animal model of diabetic nephropathy. Broad Nox inhibition with APX-15 might be a promising therapy for diabetic nephropathy.
**Methods:** Male db/db mice at 8 weeks of age were fed resveratrol (20 mg/kg/day) via gavage for 3 weeks. Serum, urine, and renal tissue were obtained for analysis in changes in metabolic parameters, molecular levels and renal structure.

**Results:** Resveratrol treatment showed favorable effects on albuminuria, glomerular matrix expansion and inflammatory cell infiltration. Increased expressions of AdipoR1 and AdipoR2 were observed with increases in phospho-AMP and PPAR-a level. It also ameliorated free fatty acid and triacylglycerol accumulation in the kidney which was related to increases in the phosphorylation of AMPK and the activation of SIRT1-PGC-1a signaling and of the key downstream effectors, the PPARα-Forkhead box O (FoxO1)/ FoxO3a anti-fibrotic and anti-inflammatory proteins. Related AMPK and PPAR-a activity induced oxidative stress and apoptosis in cultured human glomerular endothelial cells (HGECs) through activation of both AdipoR which prevent lipotoxicity related apoptosis and oxidative stress in the kidney.

**Conclusions:** In conclusion, our results suggest that resveratrol exerts its renoprotective effects through activation of both AdipoR which prevent lipotoxicity related apoptosis and oxidative stress in the kidney.

Oral Treatment with PBI-4547, a Novel Anti-Diabetic and Anti-Fibrotic Compound, Ameliorates Kidney Function and Glomerular Integrity in the Diabetic db/db Mouse Model 

**Background:** Diabetic nephropathy is the most common complication of longstanding diabetes affecting up to 30% of all diabetic patients, and is the cause of end-stage kidney disease. This study examined the long-term nephroprotective effects of PBI-4547 in uninephrectomized (NX) diabetic (db/db) mice, a model of type 2 diabetes.

**Methods:** Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4547 (10 and 50 mg/kg, oral once a day) from day 1 through 105. Kidney function (GFR and structure (mesangium lesions, glomerular integrity), regulation of pro-inflammatory/fibrotic gene expression in the kidney, as well as serum pro-inflammatory cytokine levels were examined.

**Results:** Kidney function assessed by GFR was significantly reduced in NX-db/db mice compared to NX-C57BL/6 negative control animals, and PBI-4547 treatment significantly improved GFR in NX-db/db mice. As shown by PAS staining, mesangial matrix accumulation/expansion was prominent in NX-db/db mice compared to the negative control, but was significantly suppressed in PBI-4547 treated NX-db/db mice. Moreover, qPCR analysis of the expression of MCP-1, IL-6, Collagen I, MMP2, TIMP1, and JUN showed that PBI-4547 downregulated diabetic-induced inflammation, fibrosis, oxidative stress, and extracellular matrix remodeling in the kidney. Expression of GLEPP1 was significantly increased in NX-db/db mice, and restored to the negative control level following treatment with PBI-4547. Serum levels of cytokines were measured (multiplex panel). Early/intermediate TNP-α, IL-1β, and IL-6 cytokines were markedly reduced by PBI-4547, as well as TH1-induced oxidative stress and apoptosis in cultured human glomerular endothelial cells (HGECs) through activation of both AdipoR which prevent lipotoxicity related apoptosis and oxidative stress in the kidney.

**Conclusions:** These results suggest that PBI-4547 is a potential novel therapy for diabetic nephropathy by blocking kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

**SA-PO379**

Prostaglandin E2 Receptor 3 (EP3) Inhibits Vasopressin-Stimulated Water Reabsorption and Contributes to Diabetic Renal Dysfunction in Mice 

Rami Hazouneh, Rania Nasrallah, Joe A. Zimpelmann, Kevin D. Burns, Richard L. Hébert. Kidney Research Centre, Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, ON, Canada.

**Background:** The early renal manifestations of diabetes are polyuria and reduced urine osmolality (Uosm), and when sustained long-term lead to nephropathy. We propose that these processes are mediated through the interaction of prostaglandin E2 (PGE2) acting via EP3 and the anti-diuretic hormone, vasopressin (VP).

**Methods:** Global EP3-/- and wild-type (WT) 8wk male C57BL6 mice were injected with vehicle or streptozotocin (STZ) and analyzed after 12wks. Prostaglandin filtration rate (GFR) was measured by inulin clearance. Aquaporin (AQ) 1/2 and cyclooxygenase-2 (COX-2) were assessed by Western blotting. PAS stain was done to assess renal injury or protein excretion. 24hr urinary VP excretion rate was quantified. Cortical collecting ducts (CCD) were sectioned. These results suggest that PBI-4547 is a potential novel therapy for diabetic nephropathy by blocking kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

**Conclusions:** These results suggest that PBI-4547 is a potential novel therapy for diabetic nephropathy by blocking kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

Effects of Diuretics on SGLT2 Inhibitor-Induced Changes in Blood Pressure and Natriuresis in Obese Rats Suffering from the Metabolic Syndrome 

Akira Nishiyama, Daisuke Nakano, Wararat Kittikulth. Dept of Pharmacology, Kagawa Univ Medical School, Kagawa, Japan.

**Background:** Experiments were carried out to investigate whether diuretics (hydrochlorothiazide + furosemide) impact on the effects of a sodium-dependent glucose co-transporter 2  (SGLT2) inhibitor on glucose metabolism, blood pressure and rate of urinary excretion of sodium in metabolic syndrome SHR/Ndmc-cp(+/-) rats (SHRcp).

**Methods:** Male 13-week-old SHRcp were treated with: (i) vehicle; (ii) the SGLT2 inhibitor luseogliflozin (10 mg/kg/day, p.o.); (iii) diuretics (hydrochlorothiazide; 10 mg/kg/day + furosemide; 5 mg/kg/day, p.o.); or (iv) luseogliflozin + diuretics for 5 weeks (n = 8–10 for each group). Blood pressure and glucose metabolism were evaluated by a telemetry system and oral glucose tolerance test, respectively.

**Results:** Vehicle-treated SHRcp developed non-dipper type hypertension (dark-light period mean arterial pressure (MAP) 148±1.7mmHg; 148±0.7 mmHg at day 5, respectively, P<0.05). Treatment with luseogliflozin- treated rats showed an approximately 4000-fold increase in urinary excretion of glucose and improved glucose metabolism. Luseogliflozin also significantly decreased blood pressure and converted the circadian rhythm of blood pressure from a non-dipper to dipper pattern (dark-light period MAP: 138±0.16 and 132±0.13 mmHg, respectively, P=0.01), which were associated with a significant increase in urinary excretion of sodium. Addition diuretics did not influence luseogliflozin-induced improvement of glucose metabolism and circadian rhythm of blood pressure in SHRecp.

**Conclusions:** These data suggest that a SGLT2 inhibitor elicits its beneficial effects on glucose metabolism and hypertension in subjects with metabolic syndrome undergoing treatment with diuretics.

SGLT2 Inhibition Slows the Progression of Diabetic Nephropathy in the db/db Mice 

Li Tang, Yuanyuan Wu, Yufeng Huang. Fibrosis Research Laboratory, Div of Nephropathy, Univ of Utah, Salt Lake City, UT.

**Background:** It has been shown that SGLT2 inhibitor not only enhanced renal glucose excretion and lowered blood glucose (BG) but also reduced albuminuria in patients with Type 2 diabetes (T2DM). However, the renoprotective effect of SGLT2 inhibition in diabetes has not fully established.

**Methods:** This study sought to determine whether dapagliflozin, a selective SGLT2 inhibitor, could slow the progression of glomerulosclerosis in the uninephrectomized db/db mouse, a model of T2DM.

**Results:** Untreated uninephrectomized db/db mice developed progressive albuminuria and glomerulosclerosis between wks 18 and 22, associated with increased renal expression of TGFβ1, PAI-1, type IV collagen and fibronectin. Treatment with dapagliflozin (1mg/kg/d) via gel diet from wks 18 to 22 did not affect body weight but reduced BG from 573.3±21.73 to 371.1±55.02 mg/dL, P<0.05 and HbA1c levels. Of note, treatment with dapagliflozin dose not affected the increase in body weight, albuminuria and markers of glomerulosclerosis seen in db/db mice between wks 18 to 22. Renal expressions of NF-kBp67, MCP-1, Nox4, Nox2, and p47phox and urine TBARS levels, the markers of renal inflammation and oxidative stress, were increased during disease progression in db/db mice. Treatment with dapagliflozin reduced these markers. In addition, db/db mice had markedly increased daily water intake, urinary output, urinary sodium and potassium excretion but decreased urinary osmolality. Dapagliflozin had no effects on these measurements. Interestingly, dapagliflozin

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PB - Publication Only; Underline represents presenting author.
ameliorated diabetes-induced glomerular hyperfiltration determined by elevated creatinine clearance rates (2.44±0.55 ml/min in treated db/db vs. 1.72±0.63 ml/min in db/db) and caused a significant reduction in renal RAS activity determined by urinary aldosterone levels (45.5±4.93 vs. 60.9±4.01, μg/24h, P<0.05).

**Conclusions:** These results suggest that SGLT2 inhibitor not only reduces albuminuria but also retards the progression of diabetic nephropathy arising from T2DM by improving hyperglycemia and renal inflammation and oxidative stress. Decreasing glomerular hyperfiltration and negatively regulating renal RAS activity by SGLT2 inhibitor may be also renoprotective.

**Effect of SGLT2 Inhibitor Ipragliflozin on Urinary Na Excretion and Body Fluid Volume**

Takahiro Fu, Yuko Watanabe, Minami Watanabe, Keiko Fukuda, Akira Onishi, Hermann Koespel, Volkner Vollan, Daisuke Nagata, Eric W. Mayoux, Falk Bernhard Batz.

**Background:** Sodium-glucose cotransporter (SGLT) 2 inhibitors are new antidiabetic drugs that increase urinary glucose excretion (UGE) by inhibiting renal SGLT2. SGLT2 inhibitors may induce body fluid reduction due to the increase in urine volume and Na excretion, but the details remain unclear.

**Methods:** Spontaneously Diabetic Torii (DM) rat, a non-obese type 2 diabetic model was used in this study. At the onset of diabetes (blood glucose ≥250 mg/dl), DM rats and age-matched Sprague-Dawley (non-DM) rats were separated to vehicle (Veh) and 0.01% (in diet) Ipragliflozin (Iprga) group, respectively. After 8 weeks, biopsied impedance spectroscopy (ImpediVet) for the assessment of total body water, urine collection and blood tests were performed.

**Results:** Renal membrane protein expression of SGLT2 was significantly higher in DM rats compared with non-DM rats. Iprga enhanced the expression of SGLT2 in non-DM rats, but not in DM rats. Iprga induced similar blood (33.6±0.6 vs. 32.1±0.9 g/dl) and blood glucose (105.6±5 vs. 116.1±10 mg/dl), and GFR (329.3±36 vs. 370.2±20 ml/min) in DM rats, but not in non-DM rats (Veh 172±11 vs. Iprga 158.5±8 mg/dl, P<0.12), but significantly decreased in DM rats (681±21 vs. 361±22 mg/dl; *P*<0.05). Iprga increased fractional glacial fraction in non-DM rats (0.3±0.2 vs 31.3±2.1 %) and DM rats (31.5±1.7 vs. 52.9±3.2 %). In non-DM rats, Iprga increased urine volume (363.7±7 vs. 61.5±6 ml/day*), UGE (0.4±0.1 vs. 4.8±0.2 g/day*), urinary Na excretion (3.0±0.4 vs. 4.2±0.3 ml/day*), food intake (31.1±1 vs. 34.1±1 g/day*) and fluid intake (61.9±5 vs. 87.8±5 ml/day*). These parameters were higher in DM rats than in non-DM rats, but Iprga did not significantly change these parameters. Total body water (related to body weight) and fluid balance (fluid intake-urine volume) were similar among the 4 groups. Iprga increased body weight changes in body fluid volume (3.0±0.3 ml/day*), food intake (31.3±0.6 vs. 32.1±0.9 g/day*), and body weight (33.6±0.6 vs. 32.1±0.9 g/day*).

**Conclusions:** These results suggest that SGLT2 inhibitors not only reduce albuminuria but also reduce body fluid volume. The SGLT2 inhibitor Ipragliflozin might maintain fluid balance in response to the osmotic diuresis whereas the natriuresis is likely due to greater food intake.

**Up-Regulated SGLT2 Reduces Proximal Tubular Sirt1 and Augments Renal Glucoseogenesis in Early Stage Diabetic Nephropathy**

Hiroki Umino, Kazuhiro Hasegawa, Shu Wakinou, Hiroki Itoh. Keio Univ.

**Background:** We previously reported that high glucose (HG) decreases proximal tubule SGLT2 (Sglt2) expression in S1-2/2/- mice prior to decreasing glomerular Sirt1, which leads to a disruption of tubule-podocyte communication in diabetic nephropathy (DNP) (Nat Med 2013). Protein expression levels of Sglt2 are elevated to compensate for the increased demand for glucose uptake in DN, which causes a rise in intracellular HG in PT. Here, we investigated whether Sglt2-mediated HG down-regulates PT Sirt1.

**Methods:** Cultured Pts (HK2) were cultivated on a two-chamber-system consisting of an upper chamber equivalent to the ureteral lumen on the apical side of PTs and a lower chamber corresponding to the vascular lumen on the basolateral side of PTs. Pts were cultured with combinations of normal glucose (NG) or HG in each chamber to determine the polarity of HG that affects Sglt2 and Sirt1 expression. We also administered a Sglt2 inhibitor (canagliflozin) to 8-week-old db/db mice and analyzed the Sglt2 and Sirt1 expression. **Results:** HG in the lower chamber increased Sglt2 and decreased Sirt1 expression, but HG in the upper chamber had no effect. Thus, high blood sugar (BS), but not glucosuria regulates Sglt2 and Sirt1. Furthermore, in db/db mice, high BS also elevated Sglt2 and lowered Sirt1 expression in PTs, as confirmed by immunofluorescence and immunoelectron microscopy, and reduced deacetylation of Foxa2, a Sirt1 target. Decreased Sirt1 expression led to an increase in Foxa2 acetylation, which induces activation of DNA microarrays and confirmatory real-time PCR using laser-microdissected db/db PTs showed an increase in Pck1 and G6pase in concert with Sglt2 upregulation and Sirt1 downregulation. However, Sglt2 inhibitors blocked these changes.

**Conclusions:** Increased Sglt2 expression, already seen in the early stage of DN, forms a vicious cycle whereby both exogenous HG, mediated by a Sglt2-induced influx of BS, and endogenous HG, generated by Sglt2-induced renal glucoseogenesis, reduce PT Sirt1 levels. Decreased Sirt1 acetylates and activates Foxa2, further promoting renal glucoseogenesis, which accelerates this cycle. However, Sglt2 inhibitors can block the HG-induced reduction in Sirt1 levels and prevent DN progression.
Results: Inhibiting SGLT2 shifts Na+ transport to downstream nephron segments, possibly increasing their Qm. In particular concerns are the S3 segment and medullary thick ascending limb (mTAL), which are at risk for hypoxic injury. Dual SGLT1–SGLT2 inhibition protects the S3 segment, but could further reduce mTAL oxygenation. Model simulations suggest that SGLT2 inhibition substantially increases S3 Qm. Together with elevated renal NaCl cotransporter (NKCC2), SGLT2 inhibition also increases mTAL Qm. Additionally, we used the model to determine the optimal combination of SGLT1 and SGLT2 inhibition, in terms of suppressing tubular glucose uptake and maintaining sufficiently low S3 and mTAL Qm.

Conclusions: In conclusion, SGLT2 inhibition significantly increases oxygen consumption of the mTAL. This research was supported in part by NIH grant DK-89066. Funding: NIDDK Support

SGLT2 Expression Is Increased in Human Diabetic Nephropathy:

SGLT2 Inhibition Decreases Renal Lipid Metabolism, Inflammation, and the Development of Nephropathy in Diabetic Mice

Xiaoxin Wang,1 Jonathan Levi,2 Yuhuan Luo,1 Evgenia Dobrinskikh,3 Almen Gnutz,4 Michal Herman-Edestein,5 Uzi Gafter,6 Avry Chagnac,7 Hermann Koeppel,8 Jeffrey B. Kopp,9 A. Rosenberg,9 Moshe Levi,9 1Univ of Colorado Denver; 2NIDDK; 3Rabin Medical Center; 4Univ of Wurzburg.

Background: The renal sodium gradient dependent glucose transport protein SGLT2 expression is increased in renal biopsies from human subjects with diabetic nephropathy. Methods: To determine the potential mechanisms of beneficial effects of SGLT2 inhibition in progression of diabetic renal disease we treated db/db mice with a selective SGLT2 inhibitor.

Results: We found that SGLT2 inhibition caused marked decreases in systolic blood pressure, kidney weight/body weight ratio, urinary albumin (745±36 mg/d in db/db vs. 207±5 mg/g in treated db/db, p<0.001) and urinary thromboxane B2-acid-reacting substances (TBARS). SGLT2 inhibition also a) prevented renal lipid accumulation via inhibition of LPL, SC-1 and DGAT1, key enzymes that mediate fatty acid and triglyceride synthesis; b) decreased inflammation via inhibition of CD28 macrophage accumulation, and expression of p65, TL4, MRP 1 and OPN, and c) increased CD73 and decreased adenosine A receptors (Adora1, Adora2a, and Adora2b mRNA). These effects were associated with prevention of mesangial expansion, accumulation of extracellular matrix proteins fibronectin and type IV collagen, as well as loss of podocyte markers WT1 and synaptopodin, as determined by quantitative immunofluorescence microscopy.

Conclusions: In summary, our study showed that SGLT2 inhibition modulates renal lipid metabolism and inflammation and prevents the development of nephropathy in db/db mice. Funding: Pharmaceutical Company Support - J&J

Loss of Angiotensin-Converting Enzyme 2 Alters Glomerular Structure in Non Obese Diabetic Mice

Heleca Rosa-Ho,1 Marta Riera,1 Marta Rebull,2 Javier Gimeno,2 Julio Pascual,3 Maria Jose Soler. 1Nephrology, Hospital del Mar-Inst Hospital del Mar d’Investigacions Mèdiques, Barcelona, Spain; 2Pathology, Hospital del Mar, Barcelona.

Background: ACE2 has been shown to play an important role in diabetic nephropathy (DN). We studied renal morphology and kidney function in non-obese diabetic (NOD) female mice (with spontaneous autoimmune diabetes) carrying a deletion on ace2 gene (NOD.ACE2-/-) and NOD.ACE2+/+ female mice has not been previously studied.

Methods: To evaluate the potential mechanisms of beneficial effects of SGLT2 inhibition in progression of diabetic renal disease we treated db/db mice with a selective SGLT2 inhibitor.

Results: We found that SGLT2 inhibition caused marked decreases in systolic blood pressure, kidney weight/body weight ratio, urinary albumin (745±36 mg/d in db/db vs. 207±5 mg/g in treated db/db, p<0.001) and urinary thromboxane B2-acid-reacting substances (TBARS). SGLT2 inhibition also a) prevented renal lipid accumulation via inhibition of LPL, SC-1 and DGAT1, key enzymes that mediate fatty acid and triglyceride synthesis; b) decreased inflammation via inhibition of CD28 macrophage accumulation, and expression of p65, TL4, MRP 1 and OPN, and c) increased CD73 and decreased adenosine A receptors (Adora1, Adora2a, and Adora2b mRNA). These effects were associated with prevention of mesangial expansion, accumulation of extracellular matrix proteins fibronectin and type IV collagen, as well as loss of podocyte markers WT1 and synaptopodin, as determined by quantitative immunofluorescence microscopy.

Conclusions: In summary, our study showed that SGLT2 inhibition modulates renal lipid metabolism and inflammation and prevents the development of nephropathy in db/db mice. Funding: Pharmaceutical Company Support - J&J

Ace2 Deficiency Accentuates AngII-Induced Hypertension and Albuminuria in Diabetic Mice

Serger Clozet-Freixas, Maria Jose Soler, Marta Rebull, Julio Pascual, Marta Riera. Nephrology, Hospital del Mar-Inst Hospital del Mar d’Investigacions Mèdiques, Barcelona, Spain.

Background: Angiotensin II (Ang II) is a powerful vasoconstrictor that can promote several cardiovascular and renal disease manifestations. Inhibition of the renin-angiotensin system (RAS) reduces these effects and improves renal function. However, the role of Mas-related G protein-coupled receptor (MasR) in cardiovascular and vascular disease remains uncertain. In contrast to MasR, the ACE2 receptor cleaves Ang II into angiotensin-(1-7) and generates bradykinin and other vasodilators. We compared hypertension and albuminuria in Ang II-infused normoglycemic (WT) and ACE2 deficient (ACE2-/-) diabetic BKS.CRI-STZ/db/db mice to evaluate the potential effects of ACE2 deficiency in a diabetic setting.

Methods: We evaluated the effect of AngII infusion in age matched C57BL/6 wild-type (WT) and ACE2KO streptozotocin(STZ)-induced diabetic mice and their respective non-diabetic controls. At week 8 of follow-up, mice were anesthetized and micropumps for AngII infusion (ANGII) were surgically implanted. Sham-operated (SHAM) mice were used as control groups. Study groups: WT-Control(CONT) + SHAM, WT-CONT + ANGII, WT-Diabetic(DB) + SHAM, WT-DB + ANGII, ACE2KO-CONT + SHAM, ACE2KO-CONT + ANGII, ACE2KO-DB + SHAM, ACE2KO-DB + ANGII. Blood glucose, body weight, kidney weight/body weight (KW/BW), heart weight/body weight (HW/BW), systolic blood pressure (SBP) and urinary albumin excretion (UAE) were studied.

Results: Hyperglycemia and reduced BW were observed in all groups given STZ. ACE2 deletion and AngII infusion supposed a modest decrease in body weight in control and diabetic female mice. Both, SHAM and AngII-infused ACE2KO diabetic mice showed higher KW/BW compared to WT. AngII infusion significantly augmented HW/BW and SBP in control and diabetic ACE2KO mice as compared to non-infused mice. Diabetes and AngII infusion were accompanied by increased UAE in all groups. This increase was more pronounced in ACE2KO groups. ACE2KO-CONT + ANGII and ACE2KO-DB + ANGII showed significantly higher HW/KW, SBP and UAE than WT-CONT + ANGII and WT-DB+ANGII.

Conclusions: Loss of ACE2 accentuated renal hypertrophy and AngII-induced hypertension, albuminuria and cardiac hypertrophy in diabetic female mice.

Funding: Government Support - Non-U.S.
Conclusions: Genetic ACE2 ablation worsens glomerular hypercellularity in diabetic mice whereas GFR and ACR are not significantly altered and other markers of glomerular pathology are minimally affected.

Funding: NIDDK Support, Private Foundation Support

Blood Pressure-Independent Amelioration of Glomerulosclerosis in Diabetic Rats Treated with Dual AT1,Receptor-Nephrilysin Inhibition versus AT1-Receptor Blockade Alone
Lodzi C.W. Roskoene,1 Richard Van Veghel,1 Marian Claesen - van Groningen,2 René De Vries,3 Ingrid M. Garrelsd, Usha M. Bhaagg, Jeanette M. Van Gool,3 Edith C.H. Friesema,1 Frank P.J. Leijten,1 Ewout J. Hoorn,1 Alexander H. Danser,1 Wendy W. Batenburg.1
Division of Pharmacology and Vascular Medicine; Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 2Dept Pathology, Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 3Dept Pathology, Erasmus MC, Rotterdam, Netherlands.

Background: Dual AT1, receptor-nephrilysin inhibition (ARNI) has recently been shown to exert beneficial effects on blood pressure (BP), NT-proBNP, and estimated GFR in heart failure patients, compared with AT1 receptor blockade (ARB) alone. Nephrilysin is upregulated in epineurial arterioles of diabetic rats. We hypothesized that ARNI improves cardiac and kidney parameters in diabetic TGR(mREN2)27 rats, a model displaying angiotensin II-mediated hypertension.

Methods: Rats were made diabetic with streptozotocin, for 5 or 12 weeks. In the final 3 weeks, rats were treated with vehicle, the ARB irbesartan (15mg/kg/day) or irbesartan (15mg/kg/day)+ the nephrilysin inhibitor thiopran (0.1mg/kg/day; ARNI). BP was measured by telemetry in the 5-week group only.

Results: Baseline mean arterial BP (MAP) was 157±5mmHg. ARNI lowered MAP identically over the 3-week period, reaching a maximum reduction of ~50mmHg around day 7. Heart weight/tibia length ratio in 12-week diabetic rats was 17%-lower after ARNI treatment vs. ARB treatment (P<0.05). Proteinuria and albuminuria were observed from 8 weeks of diabetes onwards. ARNI reduced proteinuria more strongly than ARB (-78% vs. -49%, P<0.05), and a similar trend was seen for albuminuria. Kidney of ARNI-treated rats showed less focal segmental glomerulosclerosis than those of ARB-treated rats. At the end of the study, no differences between ARNI- and ARB-treated rats were found regarding diuresis, natriuresis, plasma endothelin-1, vascular reactivity (acetylcholine and endothelin-1 responses), or kidney sodium transporters.

Conclusions: ARNI reduces proteinuria, focal segmental glomerulosclerosis, and cardiac hypertrophy in diabetic TGR(mREN2)27 rats more strongly than ARB, and this occurs in a blood pressure-independent manner.

SA-PO392
Collateral Effects of Atrasentan on Renin-Angiotensin System
Lidia A. de Jonge,1 Marja Gerards,1 Floris van Dijk,2 Coen Koning,2 Richard Van Veghel,2
1Dept Pathology, Erasmus MC, Rotterdam, Netherlands; 2Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands.

Background: Endothelin-1 is a vasoconstrictor peptide that has been shown to be upregulated in type 1 and type 2 diabetes. The mechanism of this upregulation is incompletely understood. In this study we investigated the accumulation of macrophages in glomeruli and interstitium of humans with various stages of DN.

Methods: Renal autopsy samples of 5 non-diabetic and 18 diabetic kidney samples obtained at autopsy of type 2 diabetes patients (N=88) were used in this study. The rats were fed a high-fat diet and given low-dose streptozotocin to induce type 2 diabetes. The 12 Lo-produced 12(S)-hydroxyeicosatetraenoic acid (12[S]-HETE) was infused through an osmotic minipump. Enzyme-linked immunosorbent assay, Western blot, and morphometric analyses were performed.

Results: High glucose (HG) increased p16INK4a protein expression in MCs, but this increase was prevented by the 12-Lo inhibitor cinamanyl-3,4-dihydroxy-o-cynacnonominate (CYN). The levels of p-p38MAPK and p16INK4a in MCs were significantly elevated after 12(S)-HETE treatment, whereas the p38MAPK inhibitor SB203580 prevented these increments. Compared with levels in control MCs, marked increases in p38MAPK activation and p16INK4a expression were observed in MCs plated on collagen IV, while CDC-40 treatment prevented these changes. Subcutaneous injection of CDC did not affect glucose levels but completely attenuated the diabetes-related increases in 12(S)-HETE content, p16INK4a expression, p-p38MAPK levels, glomerular volume, and kidney/body weight ratio.

Conclusions: 12-Lo-p38MAPK mediates the upregulation of p16INK4a in HG-stimulated MCs and type 2 diabetic glomeruli, and new therapies aimed at 12-Lo inhibition might be beneficial in ameliorating diabetes-induced glomerular hypertrophy.

patients without DN were used. Macrophages in 50 glomeruli per sample were counted. Intestinal and interstitial macrophages were counted semi-quantitatively. Glomerular and interstitial macrophages were correlated to histological and clinical parameters.

Results: Glomerular CD68+ and CD163+ cells were present in all stages of DN according to the histopathological class and did not differ between classes, but the accumulation varied widely. The mean influx of glomerular CD68+ cells over the classes was 4.2 (range 0-19) and the mean influx of glomerular CD163+ cells was 2.1 (range 0.1-14.74). The mean ratio of CD163+ cells amounted 0.5. Glomerular macrophages were also present in the control groups. Renal function was associated with the number of CD163+ cells in all clinical groups and cells were significantly correlated with histological lesions. Intestinal macrophages significantly correlated with clinical parameters like eGFR stage and albuminuria.

Conclusions: We showed that macrophages (including anti inflammatory CD163+ macrophages) are present in all stages of DN both in the glomerulus and interstitium. Correlation between clinical data and intestinal macrophages indicates that intestinal inflammation probably influences the progression of DN. In addition, presence of glomerular macrophages in early diabetic nephropathy suggests that they influence the glomerular diabetic damage as well. Therefore, therapies targeting macrophages might be a useful novel therapy in DN.

SA-PO396
Activation of CXCL16/CXCR6 Pathway by Inflammation Accelerates the Progression of Diabetic Nephropathy Zehu Wu, Kun Ling Ma, Yang Zhang, Wen Yu, Bi-Cheng Liu, Inst of Nephrology, Southeast Univ, Nanjing City, Jiang Su Province, China.

Background: Diabetic nephropathy(DN)was considered as a chronic inflammatory disease. Inflammation plays critical roles in the progression of DN. This study investigated the role of CXC chemokine ligand 16 (CXCL16)/CXCL6 pathway in inflammatory stress and its possible mechanisms mediated by purinergic receptor P2X ligand-gated ion channel 7 (P2X7R).

Results: Diabetic nephropathy was randomly divided into two groups: db/db, and db/db+casein for eight weeks. Casein was subcutaneously injected to induce chronic inflammation. The morphological change of renal pathology and ultra-structure were checked by pathological staining and electron microscopy. Lipid accumulation in kidneys was observed by Filipping staining and quantitative assay of intracellular free cholesterol. The expression of CXCL16/CXCR6 pathway, inflammatory cytokine, and fibrin index related molecules were detected by immunohistochemistry, immunofluorescent staining, and Western Blot.

Results: The 24-hour urinary protein, tubulointerstitial injury, inflammatory cell infiltration, and the expression of monocyte chemotactic protein (MCP-1), tumor necrosis factor a (TNFa), CD68, A-Smooth muscle actin (a-SMA), and fibronectin (FN) in kidneys of db/db+casein mice were significantly increased compared with the db/db mice. Furthermore, there was significant lipid accumulation, increased protein expression of CXCL16 and CXCR6 and decreased disintegrin and metalloproteinase-10(ADAM10) expression in kidneys of db/db+casein mice compared with db/db mice, accompanied with increased P2X7R expression. Further analysis demonstrated that there was a positive correlation between P2X7R and CXCL16/CXCR6 expression.

Conclusions: Inflammation accelerates tubulointerstitial injury in DN partly through the activation of CXCL16/CXCR6 pathway, which may facilitate inflammation induction and lipid accumulation in cells. The P2X7R pathway may be involved in the activation of CXCL16/CXCR6 pathway.

Albumin Glycation Induces Structural Changes That Reduce Proximal Tubule FcRn-Absorption Binding and Reclamation Mark C. Wagner, Jerald Mylinski, Shiv Pratap Singh Yadav, George Rhodes, Ruben M. Sandoval, Sudhanshu Kumar, Sarah E. Wean, Fnu Ashish, Bruce A. Moltitorris.

1Nephrology Div, Dept of Medicine, Indiana Univ School of Medicine, Indianapolis, IN; 2Cellular & Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; 3CSIR-Inst of Microbial Technology, Chandigarh, India.

Background: Diabetic nephropathy remains the leading cause of chronic kidney disease (CKD) and ESRD. It results in increased albumin glycation and this is believed to be involved in proximal tubule cell injury and the pathophysiology of interstitial fibrosis and CKD progression.

Methods: To understand the mechanisms we have addressed specific in vitro albumin modifications and their impact on albumin-FcRn binding since proximal tubule FcRn is necessary for transcytosis and reclamation of filtered albumin.

Results: These studies showed markedly reduced binding to FcRn when albumin was glycosylated proportional to the level of glycation. To address the mechanism for reduced binding we used SAXS analysis and molecular modeling to determine structural changes. SAXS analysis revealed significant shape changes occur to albumin upon glycation which affected its binding affinity to FcRn. Our prediction would be that albumins with weaker FcRn binding would have more rapid serum clearance implying increased PT catabolism via lysosomal degradation. Prior to evaluating modified albumin, control albumin was labeled with multiple fluorophores to determine conjugation ratios and dyes that retained normal pH dependent FcRn binding and would thus permit accurate serum clearance to be evaluated. The results agreed with our prediction and we are presently evaluating the serum clearance for the glycosylated albumins that have been conjugated to a fluorescent probe.

Conclusions: The data indicate modifications to albumin lead to structural alterations resulting in reduced PT pH dependent FcRn binding, which alters lysosomal catabolism leading to transcytosis and reclamation resulting in a shorter serum half life and may mediate the enhanced interstitial inflammation and fibrosis in diabetic nephropathy.

SA-PO398
The Effects of Glucagon-Like-Peptide-1 and Vitamin D on Inflammatory and Histological Changes of Diabetic Nephropathy in db/db Mice Yael Einbinder,1,2 Sydney Bencherit,1 Tali Zisman-Gal,1 Ren Physiology Laboratory, Dept of Nephrology and Hypertension, Meir Medical Center, Kfar Saba, Israel; 2Sackler Faculty of Medicine, Tel Aviv Univ, Tel Aviv, Israel.

Background: Glucagon-like-peptide-1 is a gut incretin hormone that stimulates insulin secretion and may affect the inflammatory pathways involved in type 2 diabetes mellitus (T2DM). Calcitriol plays an important role in renal, endothelial, and cardiovascular protection.

We evaluated the anti-inflammatory and histological effects of GLP-1 and calcitriol in a db/db mice diabetic model.

Methods: C57BL/6 (WT) and BKS.Cg-Dock7m+ / + Lepr db/db (db/db) mice were randomized to: a) WT mice; b) db/db mice (diabetic control group); c) db/db mice+GLP-1 analog (100 nmol/kg); and d) db/db mice+GLP-1 analog + calcitriol (250 ng/kg). Blood glucose levels and weight were evaluated weekly. At the end of the 14-week treatment, kidneys were perfused and removed for protein analysis and histology.

Results: Blood glucose levels and weight were significantly higher in db/db mice compared to control WT mice. Blood glucose level was non-significantly lower in the db/db GLP-1 group compared to untreated db/db mice (460.5±38.2 mg/dl vs 526.3±33.3 mg/dl). GLP-1 treatment significantly up-regulated eNOS protein expression and significantly down-regulated p65 protein expression compared to the db/db control group. Vitamin D did not improve the beneficial effect observed on protein expression. Kidney VDN protein expression increased only in the vitamin D group compared to the db/db control group. Kidney histology demonstrated beneficial effect of GLP-1 treatment on glomerular morphology in db/db mice at 26 weeks of age but had no significant effect on the severity of mesangial expansion.

Conclusions: In the experimental model of diabetic nephropathy (db/db mice), GLP-1 analog treatment improved the protein expression involved in the inflammatory response and significantly ameliorated the glomerular hyper trophy seen in the diabetic control group.

Mineral Metabolism and Interleukin-6: Predictive Risk Factors for Left Ventricular Hypertrophy in Patients with Diabetic Nephropathy Teresa M. Jerojsonim,1 André Fragoso,2 Filipa Brito Mendes,1 Ana Paula Silva,1 Ana Pocinho Pimentel,1 Nelson Tavares,2 Pedro L. Neves,1,2 Nephrology, Centro Hospitalar do Algarve, Faro, Portugal; 2Dept of Biomedical Sciences and Medicine, Univ of Algarve, Faro, Portugal; 3Cardiology, Centro Hospitalar do Algarve, Faro, Portugal.

Background: Left ventricular hypertrophy (LVH) is an important risk factor for cardiovascular disease in patients with diabetic nephropathy (DN) and is an independent predictor of mortality in patients with chronic kidney disease (CKD). The aim of this study was to evaluate the predictive risk factors of LVH in a population of patients with DN.

Methods: The authors analysed the relationship of LVH with gender, body mass index (BMI), systolic blood pressure (SBP), estimated glomerular filtration rate (eGFR), albumin, cholesterol, hemoglobin, calcium, phosphorus, parathyroid hormone (PTH), urine albumin-to-creatinine ratio (UACR), interleukin-6 (IL-6), hemoglobin A1c (HbA1c) and insulin resistance (HOMA-IR). Descriptive statistics, Student’s t-test and logistic regression model were used.

Results: In a cross-sectional study were included 119 type 2 diabetic patients with CKD stages 3 and 4. Patients with LVH had significant lower values of eGFR and albumin, higher levels of UACR, HOMA-IR and IL-6. Phosphorus (odd ratio (OR) = 0.602 (1.075-4.414), p = 0.038), PTH (OR = 1.009 (1.098-3.000), p = 0.004) and IL-6 (OR = 1.264 (1.863-6.719), p = 0.0001) were independently related with LVH.

Far-Infrared Retraffects Pancreatic Beta Cell Function and Survival in a Streptozotocin-Nicotinamide-Induced Type 2 Diabetic Mouse Model

Yung-Ho Hsu, 1 Tso Hsiao Chen, 2 Cheng-Hsien Chen. 1,2 1 Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, Taipei, Taiwan; 2Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.

Background: In diabetes, the apoptotic cell death of insulin-producing beta cells leads to insulin deficiency. Recently, we found low-temperature far-infrared (FIR) irradiation increased proliferation and survival of human umbilical vein endothelial cells via prolymphocytic leukaemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

Methods: In this study, we investigate the protective effects of FIR on pancreatic beta cell function and survival in the nicotinamide (NA) and streptozotocin (STZ)-induced type II diabetic mouse model. eLS via prolymphocytic leukaemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

Results: The present study showed that FIR therapy decreased non-fasting blood glucose levels and increase blood insulin levels in diabetic mice in a dose-dependent manner. Immunohistochemistry staining revealed that FIR therapy retrieved insulin production of pancreatic beta cells in diabetic mice. But the influence of FIR on blood glucose and insulin levels was not found in NA/STZ-treated KPI3F-knockout mice. We also used the insulin-secreting beta cell line RIN-m5f to investigate the protective effects of FIR in vitro. FIR irradiation promoted cell proliferation and inhibited STZ-induced apoptosis in RIN-m5f cells. FIR also induced PLZF nuclear translocation and increased PI3K expression and Akt phosphorylation in RIN-m5f cells. PLZF siRNA transfection inhibited the influence of FIR on RIN-m5f cells.

Conclusions: Our data suggest that FIR therapy retrieves pancreatic beta cell function and survival in diabetic mice via a PLZF-mediated pathway.

Transgenic Mice Overexpressing Human CD39 (ENTPD1) Are Protected from High-Fat Diet-Induced Obesity and Insulin Resistance

Anna U. Brandes, Yue Zhang, Kristina M. Heiney, Simon C. Robson, Bellamkonda K. Kishore. 1 Internal Medicine, Univ of Utah & V4 Med Ctr; Salt Lake City, UT; 2Internal Medicine, BIDMC, Harvard Univ, Boston, MA.

Background: CD39 is a vascular ecto-nucleotidase that sequentially hydrolyzes extracellular ATP to ADP, and AMP; thus terminating P2 receptor signaling. Previously we reported that deletion of Cd39 results in hepatic insulin resistance (IR). We also found that intraperitoneal (IP) or oral administration of CD39 expression plasmid significantly reduced IR.

Methods: Here, we hypothesized that global overexpression of human CD39 (hCD39), which decreases the availability of extracellular nucleotides should attenuate development of HFD-induced obesity and IR. Groups of age-matched adult wild type C57/B6 (WT) and syngeneic transgenic (TG) mice globally overexpressing hCD39 were fed regular diet (10% calories from fat; n=5) or HFD (60% calories from fat; n=7) with free access to food and water for 10 weeks. Body weights (BW), food and water consumption and urine output were monitored periodically. Glucose tolerance (GT) and insulin sensitivity (IST) tests were conducted between 8 to 10 weeks.

Results: In response to HFD feeding, both genotypes showed significant increases in BW over the experimental period as compared to their counter parts fed regular diet. However, the gain in BW was significantly less in TG vs. WT mice (mean 21.5 ± 0.3 vs. 15.3 ± 2.0 g, n = 7, p = 0.005). There were no significant differences between the genotypes in the amount of food consumed, nor was there evidence of steatorrhea indicating malabsorption. Fasting blood glucose levels in HFD fed TG mice were 2-fold higher vs. WT mice (p<0.05). Glucose tolerance test (GTT) at 12 vs. 88 ± 5 mg/dL (n = 7, p = 0.001). When fed HFD, both genotypes exhibited glucose intolerance, but this was less severe in TG mice. In parallel, insulin sensitivity was significantly better in HFD-fed TG vs. WT mice.

Conclusions: Our results demonstrate that overexpression of hCD39 confers significant protection against the development of HFD-induced obesity and IR, and thus validating the proposition that dominantly deleterious roles are played by extracellular nucleotides in metabolic homeostasis.

SA-PO402

Mass Spectrometry Imaging Reveals a Role for Glomerular Sphinogomyelin in Suppressing AMPK Activity by Stimulating ATP Production in Mesangial Cells

Satoshi Miyamoto, 1,2 Cheng-Chih Hsu, 1 Gregory Hamm, Manjula Darshi, 1,2 Jonathan Staubner, Pieter Dorrestein, 1,2 ImaBiotech, MS Imaging Dept, Lille, France.

Background: We have recently shown that the ATP/AMP ratio is increased in the glomeruli in a mouse model of type 1 diabetes by matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) and may be the basis for reduced AMP-activated protein kinase (AMPK) activation in diabetic glomeruli. Here, we applied MALDI-MSI to identify a key matrix that regulates levels of glycolytic enzymes.

Methods: For MALDI-MSI, 23 weeks-aged male diabetic Akita (C57BL/6J-Inj(Ins2–205f)) (A), and normal AKITA mice (W) and control mice (H) were used. For cell culture study, murine mesangial cells (MMCs) were treated with sphingomyelin(di4:1/1:6:0) (SM)-containing liposomes (SL), control liposomes (CL) and vehicle. For ATP measurements, MMCs were transfected with sphingomyelin synthase (SMS1); 2, or control siRNA before treatment with liposomes.

Results: By MALDI-MSI, we found that SM(di4:1/1:6:0) was preferentially distributed in the glomeruli in W and H. Importantly, we found that SM is more abundant in glomeruli of A compared with W, and associated with increased SMS1 and 2 in the glomeruli (p<0.05). We also found stimulation of AMPK activity in MMCs complex with CL (p<0.01) and was inhibited by siRNA based inhibition of SMS1. AMPK activity and PGC1α protein expression were significantly reduced by SL (p<0.05). In addition, SL increased glucose consumption and lactate production in high glucose conditions (p<0.05) suggesting a role for AMPK in glucose metabolism.

Conclusions: We demonstrate using MALDI-MSI that the accumulation of glomerular SM in type 1 diabetic mice is associated with increased ATP in glomeruli and may contribute to reduced AMPK activity in diabetes. These findings suggest that reduction of SM may lead to novel therapeutic targets for the treatment of diabetic kidney diseases.

Chronic Hyperglycemia Activates Autophagy Through an Increased Lysine-63 Linked Ubiquitination: A Candidate Mechanism in the Progression of Tubular Damage in Diabetic Nephropathy

Paola Pontrelli, Annarita Oranger, Mariagrazia Barozzino, Francesca Conserva, Massimo Papale, Matteo Accetturo, Maria Teresa Rocchetti, Giuseppe Castellano, Loretto Gesualdo. Dept of Emergency and Organ Transplant, Nephrology Unit, Univ of Bari, Italy.

Background: Chronic hyperglycemia, a key pathogenic factor of diabetic nephropathy (DN), can alter autophagy whose role in tubular cells under hyperglycemic conditions (HG) remains unclear. We reported that lysine63-ubiquitination (K63-Ub) plays a key role in the progression of tubular damage in DN; moreover K63-Ub promotes protein autophasic clearance. Aim of our study was to: evaluate the HG effect in modulating autophagy in tubular cells (HK2); evaluate in vivo the autophagy state in patients with diabetes without renal damage and in different DN classes; investigate the K63-Ub role in the modulation of tubular cells autophagy.

Methods: K63-Ub was inhibited in HK2 under HG (10mM) by UBE2vl silencing, E2 enzyme involved in K63-Ub, or by NSC697923 inhibitor. The expression of the autophagic marker LC3 was significantly increased by western blot and immuno-fluorescence microscopy. Immunohistochemistry (IHC) and immunofluorescence (IF) were performed on kidney biopsies of 3 control patients, 3 diabetic, 9 DN (classes IIb, III and IV).

Results: HK2 showed a significant increase in LC3 protein after 24h of HG. UBE2vl silencing completely abolished LC3 induced protein expression after 24h of HG. Confocal microscopy showed the reduction of autophagic vesicles induced by HG in the presence of the K63-Ub inhibitor (NSC697923). IHC on kidney biopsies revealed an increased tubular expression of LC3 in diabetic patients vs controls, that persists in all DN classes and class IV patients showed cytoplasmic accumulation of fused-vesicles. The same tubules with activated autophagy, expressed K63-Ub proteins both in diabetic and in DN patients (IF).

Conclusions: In conclusion, our data demonstrate that chronic hyperglycemia induces an increase in autophagy, linked to the accumulation of K63 ubiquitinated proteins. However, uncontrolled autophagy levels could lead to tubular damage through the generation of intracellular vesicles, bringing to the progression of renal damage in DN patients.

Complexome Profiling of Mitochondrial Respiratory Chain Proteins from Podocytes of Diabetic Mice

Zhenchu Yu, Shawn S. Badal, Daniel L. Galvan, Jianyin Long, Farhad R. Danesh. Div of Nephrology, Dept of Internal Medicine, BIDMC, Harvard Univ, Boston, MA.

Background: Mitochondria play essential roles in many aspects of biology, and their dysfunction has been linked to diverse diseases, including diabetic nephropathy (DN). Central to proper mitochondrial function is oxidative phosphorylation (OXPHOS), coordinated by respiratory chain complexes encoded by both nuclear and mitochondrial genomes. Whether alterations in specific OXPHOS complex protein expression/activity contribute to mitochondrial dysfunction in DN remain largely unknown.

Methods: To assess complexome profiles, mitochondria were isolated from podocytes of db/db-old diabetic (db/db) and nondiabetic (db/m) mice. Blue Native Gel Electrophoresis (BNE) was coupled with quantitative mass spectrometry (nano HPLC/ESI/MS/MS) to identify known and unknown macromolecular protein complexes.

Results: We identified a total of 1216 mitochondrial proteins. Complexome profilingrevealed mitochondrial complex I and III to be markedly reduced in podocytes compared to controls. Consistent with MS results, Complex I activity was significantly reduced in podocytes of db/db mice compared to controls. Importantly, we found that the protein expression levels of Ndufb2, Ndufb3 and Ndufb8, all components of complex I, were significantly reduced in podocytes of db/db mice. We further validated

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
our initial results and found that the podocyte-derived mitochondria from diabetic db/db mice showed a highly reduced mass and protein expression levels of Ndufb8. These changes are coincident with significantly decreased Complex I activity from analogously isolated and processed mitochondria derived from db/db mice.

Conclusions: Our study uncovers a previously unrecognized role of complex I in the pathogenesis of DN. We propose that deficiencies in components of complex I may disrupt complex I assembly, eventually reducing mitochondrial oxidative metabolism of podocytes in diabetic kidney disease. Further genetic studies are currently underway in our laboratory to establish the value and limitations of using Ndufb8 transgenic mice in experimental models of diabetes as a model for targeting mitochondrial dysfunction in DN.

Hyperglycemia and Hyperinsulinemia Increased Cell Proliferation and Regulated DNA Damage/Repair Pathways in Type II Diabetic (db/db) Mice

Mouse Samy L. Habib,1,2 Shaili Liang,1,2 Geriatric Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX;1 Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.

Background: The mechanisms by which hyperglycemia and/or hyperinsulinemia activate cell proliferation to regulate the DNA damage/repair pathways and increase renal cell damage in diabetes remain unclear.

Methods: In the current study, we investigated the role of hyperglycemia and hyperinsulinemia in regulating cell survival and cell proliferation to regulate the DNA damage/repair pathways in the type II diabetic (db/db) mouse.

Results: Significant increase in proteinuria, albuminuria, creatinine in 24h urine as well as hypoaerobic tumor formation was detected in db/db mice compared to wild type mice. Cell proliferation was measured by Ki67 staining and PCNA expression in kidney sections of diabetic and wild type mice. Data showed significant increase of Ki67 staining and protein expression of PCNA in kidney of diabetic mice compared to wild type mice. The activity of hypoaerobic kinase Akt (measured by phospho-Akt at Ser473) was significantly increased and associated with increased activation of mTORC1 (measured by phospho-p70S6K at Thr389) in kidney cortex of db/db mice compared to wild type mice by Western blot analysis. DNA repair OGG1 and the transcription factor regulates OGG1 (Nrf2) were significantly decreased with an immunoreceptor tyrosine-based activation motif (ITAM-FcgRs) in the kidney of diabetic CRP-Tg mouse induced by streptozotocin (STZ).

Conclusions: Over a third of the adults in the United States are obese. Obesity predisposes individuals to other health risks, including CKD, diabetes, stroke, and cardiovascular disease. Our studies provide a novel mouse model for obesity.

Spleen Tyrosine Kinase Activation Promotes the Progression of Diabetic Nephropathy in the Early Stage

Fei Liu,1,2 Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Background: Inflammation triggered by metabolic disorder has played an important role in the pathogenesis of diabetic nephropathy (DN) in the early stage. The inflammatory cytokines binding to immunoglobulin G Fc receptors (FcgRs) in the surface of cell contribute to the progression of inflammation. It was found in our previous study that there was an increased expression of FcgRs with an immunoreceptor tyrosine-based activation motif (ITAM-FcgRs) in the kidney of diabetic CRP-Tg mouse induced by streptozotocin (STZ). It was also observed that ITAM-FcgRs were increased and spleen tyrosine kinase (SYK) were activated in rat glomerular mesangial cells (GMC) cultured with high glucose. SYK is a cytoplasmic nonreceptor tyrosine kinase and plays critical role in intercellular signal transduction of ITAM-FcgRs. It has been established that activated SYK signal cascade leads to the pro-inflammatory cytokines production in antibody-dependent kidney disease. However, the role of SYK in the progression of DN remains unclear. The present study investigates the potential role of SYK activation in the early stage of DN.

Methods: Diabetes was induced by STZ in Sprague Dawley (SD) rats for assessment of kidney injury at 2, 4, 6 and 8 weeks by real-time PCR, immunohistochemistry and western blot analysis. In vitro, the pathogenic effect of SYK was observed. SYK inhibitors treatment, urine albumin excretion significantly increased in diabetic SD rats at 2, 4 and 8 weeks after STZ injection. Renal inflammation has been developed with enhanced infiltration of macrophages and T cells, and upregulation of pro-inflammatory cytokines (IL-1β, TNFα) in diabetic rats. Enhanced renal inflammation in diabetes is caused by the increase of SYK phosphorylation and the over-activation of nuclear factor xB (NF-κB) signaling pathway. In vitro, high glucose significantly upregulated pro-inflammatory cytokines (IL-1β, TNFα) via SYK cascade, which further promoted high glucose-mediated renal inflammation.

Conclusions: These findings suggested that SYK may be as "signal switch" to activate NF-κB signaling pathway and promote the progression of renal injury in the early stage of DN.

Smooth Muscle Specific Heavy Chain Ferritin Knockout Mice as a Model of Obesity

Vyvyca Walker, Bo Chen, Reny Joseph, Anupam Agarwal. Nephropathy Research and Training Center, Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

Background: Ferritin, consisting of heavy (H) and light (L) chain subunits, is a highly conserved abqusibob protein that safely sequesters iron in a non-toxic form. During the course of our studies to evaluate the role of heavy chain ferritin (FH) in a model of vascular calcification in TUD, we generated a transgenic mouse using the cre-lox system with smooth muscle cell-specific deletion of FH (FH−/−). Serendipitously, we discovered the FH−/− mice gained more weight compared to control “floxed” FH mice and exhibited features resembling metabolic syndrome.

Methods: To characterize FH−/− mice as a model of obesity, male FH−/− mice and FH+/− control mice were individually housed from 6-28 weeks of age to monitor weight, food intake, body composition utilizing quantitative magnetic resonance (QMR) imaging. Protein analysis was performed on skeletal muscle and fat to determine expression levels of inflammatory signaling molecules and iron regulators. RNA analysis of inflammatory markers expressed in white fat was also performed.

Results: At 28 weeks old, FH−/− mice gained more weight (30.5g vs 27.72g ± 1.06 controls) during the observation period and consumed significantly more food starting at 20 weeks of age than the controls. QMR studies revealed that FH−/− mice had slightly more fat, lean and water mass compared to controls. Protein analyses of skeletal muscle and white fat revealed a loss of GLUT4 expression and iron trafficking proteins, respectively, in transgenic mice. Moreover, there was an increase in tissue iron concentration and gene expression of TNFa in the fat tissue of FH−/− mice compared to controls. Interestingly, review of publically available microarray data sets (NCBI, GEO data set GDS3876) derived from human samples suggest a significant (~1.5 fold) increase in FH gene expression in obese individuals compared to lean controls.

Conclusions: Over a third of the adults in the United States are obese. Obesity predisposes individuals to other health risks, including CKD, diabetes, stroke, and cardiovascular disease. Our studies provide a novel mouse model for obesity.

The Induction and Role of p53 in Tubular Cell Apoptosis During High Glucose Treatment and Diabetes

Lin Li,1,2 Zhengwei Ma,1,2 Changlin Mei,1,2 Zheng Dong.1,2 Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA;1 Dept of Nephrology, Shanghai Changcheng Hospital, 2nd Military Medical University of PLA, Shanghai, China.

Background: p53, known as a tumor suppressor, plays a crucial role in the cellular response to various stresses. P53 has been implicated in diabetic kidney disease but its role remains unclear and controversial.

Methods: Kidneys from Akita mice and STZ-treated diabetic mice were collected for in vivo studies. In vitro, renal proximal tubular cells (RPTC) with or without p53 dominant negative (p53-DN) were cultured in medium containing 5.5 mM or 30 mM glucose. Apoptosis was detected by morphologic observation, TUNEL, and flow cytometric analysis. The cells were also fractionated to investigate the subcellular redistributions of Bax and cytochrome c. The expression of p53, phosphorylated-p53 and apoptosis-related proteins were examined by western blot, immunohistochemistry/immunocytochemistry and immunofluorescence.

Results: Apoptosis was detected in renal tubules within a few weeks of diabetes, which was accompanied by p53/p-p53 expression. In cultured RPTC cells, high glucose induced apoptosis and p53. In these cells, there were Bax translocation to the mitochondria and cytochrome c release. Interestingly, these changes and apoptosis were attenuate in p53-DN cells. Consistently, they were also suppressed by pithrin-a, a pharmacological inhibitor of p53.

Conclusions: These results suggest that p53 may be an upstream mediator of tubular cell apoptosis during high glucose treatment and in diabetic kidneys. P53 is induced under these conditions and may activate the mitochondrial pathway of apoptosis.

Mechano-Growth Factor Regulates mTOR and Other Growth Factor Expression in Mouse Mesangial Cells, Enhancing Cell Proliferation and Extracellular Matrix Production: Implications for Diabetic Glomerulosclerosis

Yongxin Liu,1,2 Leighton R. James,1,2 Charles W. Heilig. Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.

Background: MGF-S mesangial cells (MC) overexpress Mechano-Growth Factor (mGF) protein and, with increased mGF, exhibit persistent proliferation, transforming growth factor (TGF)-mediated matrix formation (ECM). Here we examined mTOR expression and downstream S6 kinase activation, VEGF and TGF beta1 in our MGF-S exhibited persistent stimulation of VEGF expression 1.6-fold the MGF-EV control. mTOR expression increased 7.7-fold vs MGF-EV, leading to activation
of S6 kinase (phospho-S6 kinase) protein 8.7-fold. This increase in mTOR and active S6 kinase correlated with increased proliferation rate of MGF-S vs. MGF-AS. MGF-S vs. MGF-AS had suppressed mTOR by 69%, but suppressed active S6 kinase by an insignificant amount. VEGF expression was suppressed 60% in MGF-AS vs. MGF-EV. TGF beta 1 protein was increased 1.8-fold in MGF-S, and reduced 46% in MGF-AS. GLUT1 protein in MGF-S was increased 4.2-fold. H2-Dog uptake was suppressed 85% in MGF-AS vs. MGF-EV. In MGF-S, Type IV collagen (Col-IV) was increased 4.2-fold.

Conclusions: MGF-S MC demonstrate increased mTOR with S6 kinase activation, compared with their enhanced proliferation rate, while the increased VEGF and TGF beta 1 promote Col-IV protein expression. Overexpression of MGF in MC to mimic events in diabetic glomeruliter recreates many features of high glucose-exposed MC. MGF-AS MC demonstrate a role for MGF in basal VEGF and TGF beta 1 expression.

High Fat and High Sucrose Diet Induce Steatohepatitis That Is Dependent on Fructokinase

Takui Ishimoto,1 Miguel A. Lanaspa,1 Shoichi Maruyama,1 Richard J. Johnson.2 1Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; 2Renal Diseases and Hypertension, Univ of Denver, Aurora, CO.

Background: High fructose intake from added sugars, which are high in Western diet, correlates with the epidemic rise in obesity, metabolic syndrome, nonalcoholic fatty liver disease, and chronic kidney disease. However, the interaction of fructose with high fat intake, which is also rich in Western diet, remains unclear. Here we tested the interaction between fructose and fat, and determined whether this was dependent on a primary enzyme in fructose metabolism, fructokinase.

Methods: Wild type mice and fructokinase knockout mice (C57BL6J background, male) were assigned to one of three groups (n = 8–9) respectively, matching mean body weight among the groups. Mice had free access to tap water, and a low fat (11%, LFD), high fat (36%, HFD) or high fat (36%) and high sucrose (30%) diet (HFHSF) for 15 weeks. Urine samples were collected at 13 weeks using metabolic cages. At 15 weeks, blood was withdrawn, and tissues including kidney and liver were taken after 6 h fasting.

Results: Both wild type mice fed HFD and fructokinase knockout mice fed HFD developed dietary hypertrophic steatosis without hepatic inflammation compared to mice fed LFD. In contrast, wild type mice fed HFHSF developed more severe hepatic steatosis and low grade inflammation and fibrosis in pathological analysis, but not in fructokinase knockout mice. Increased CD68, TFF-alpha, MCP-1, alpha-smooth muscle actin, and collagen I and TIMP1 expression were found in wild type mice fed HFHSF. These changes were prevented in the fructokinase knockout mice. Meanwhile, there was no significant change of urinary protein and urinary NGAL, and no apparent renal pathological change among groups.

Conclusions: This study demonstrated an additive effect of high fat and high sucrose diet on the development of hepatic fat accumulation. Furthermore, the combination of sucrose with high fat diet may induce steatohepatitis. These results indicate the important role of fructose in the development of fatty liver and nonalcoholic steatohepatitis.

The Sustentaculum R1 Contributes to Obesity-Induced Type II Diabetes and Chronic Kidney Disease

Peter M.T. Deen,1 Claudia Carmone,1 Janna A. Van diepen,1 Joris Hubertus Robben,1 Ana Carolina Ariza,1 Olivier Devuyst,1 Richard J. Johnson,2 M.T. Deen,1 Radboud Univ Medical Center, Nijmegen, Netherlands; 2Physiology, Univ of Zürich, Zürich, Switzerland; 1Internal Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: Cell stress-induced release of mitochondrial succinate and activation of its SUCNR1 receptor in the macula densa is essential for type 1 diabetes mellitus (T1DM)-related renin release and hypertension. Obesity-induced T2DM and Chronic Kidney Disease (CKD) are aggravated by hypertension and go with cell stress in adipose/kidney tissue and macrophages, which express SUCNR1. Here we tested the role of SUCNR1 in obesity-induced T2DM and CKD.

Methods: Wild-type (wt) and SUCNR1−/− mice were fed a low fat diet (LFD; 10%) or high (H) FD (60%). At different weeks, mice were weighed, and subjected to metabolic cages (electrolyte measurements), glucose tolerance tests (GTT). Mice were sacrificed and blood and tissues collected.

Results: Blood succinate was increased in diabetic patients versus healthy controls. Isolated adipose tissue of wt and SUCNR1−/− mice revealed increased succinate release with hypoxia or high glucose. 16 weeks LFD/HFD showed similar body, adipose tissue and kidneys weight gain for both HFD groups, but liver and heart weight gain was reduced in HFD SUCNR1−/− versus wt mice. Starving glucose levels were similarly increased in both HFD groups, but SUCNR1−/− mice had a better GTT response. Inflammatory signals and macrophage infiltration was higher in adipose tissue of wt than SUCNR1−/− mice. Bone marrow derived cells of SUCNR1−/− mice migrated less efficient towards chemotactic signals from diabetic/hypoxic 3T3 cells. Blood sodium and urine volumes were similarly decreased and eGFR increased in both HFD groups versus LFD controls. However, only wt SUCNR1−/− mice showed albuminuria, elevated collagen IV expression, and some increase in inflammatory gene expression in the kidney.

Conclusions: SUCNR1-mediated chemotaxis of macrophages to affected adipose tissue may contribute to obesity-induced hypertension, contributes to obesity-induced T2DM and CKD development. If similar in humans, SUCNR1 may form a novel therapeutic target for T2DM and CKD.

Fluoxetine Disrupts E-Cadherin-Mediated Cell Adhesion and Calcium Homeostasis in Pancreatic β Cells

Yun-wen Chen,1 Huang-Yu Chang.1 1Pharmacology, National Cheng Kung Univ, Tainan, Taiwan; 2Pharmacology, National Cheng Kung Univ, Tainan, Taiwan.

Background: Major depressive disorder (MDD) is a common psychiatric illness and it affects as many as 840 million people.MDD and Type 2 diabetes (T2D) are disorders with common risk factors, and identified in prevalence study reports. Antidepressant treatment could be another critical factor affecting the bidirectional associations between MDD and T2D. Long-term use of selective serotonin reuptake inhibitors (SSRIs), the most commonly prescribed class of antidepressants, is associated with an increased risk of developing T2D. E-cadherin mediated cell-cell adhesion has been linked to diseases such as cancer and diabetes. Loss of cell-cell adhesion in beta cells decreases insulin secretion.

Methods: Here we examine the effects of the SSRI fluoxetine (Prozac®) on beta cell function employing MIN6 cells, a mouse beta cell line, to elucidate the underlying molecular mechanisms.

Results: We showed that fluoxetine treatment significantly reduced glucose stimulated insulin secretion (GSIS). We found that fluoxetine has no effect on the total expression of E-cadherin, but decreased the surface of E-cadherin. Moreover, fluoxetine triggered E-cadherin redistribution in cultured cell, mainly localized in Golgi, not in endoplasmic reticulum (ER). Our immunohistochemistry showed that reduction cell surface E-cadherin is due to increased endocytosis. Moreover, ER calcium release and the activation of store-operated calcium entry (SOCE) were suppressed by fluoxetine.

Conclusions: Taken together, the results suggested that the impairment of E-cadherin and calcium homeostasis may be underlying mechanisms by which fluoxetine caused the reduction of GSIS in pancreatic beta cells.

Involvement of Ischemic Condition in the Pathophysiology of Renal Damages in Obesity-Induced Kidney Injury

Koji Futatsugi,1 Hirobumi Tokuyama,1 Makiko Naitoh,1 Shu Wakino,1 Hiroshi Itoh.1 1Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.

Background: We have reported hypertrophic proximal tubules in obese mice which implies an inefficient oxygen supply in this area (Obesity Int, 2012). We examined whether hypoxic condition in proximal tubules is involved in the pathogenesis of obesity-induced renal injury. We also test the hypothesis that this injury can be ameliorated by molecular intervention of prolyl hydroxylase domains (PHDs), sensors for tissue oxygen levels that is a crucial molecule for tissue response to hypoxia.

Methods: Tissue hypoxic conditions were assessed by pimonidase immunostaining. Peritubular capillaries (PTC) were counted using a counting CD34 stained vessels. Tamoxifen (Tam)-inducible proximal tubules-specific PHD2 deficient mice were created by crossing PHD2−/− mice and Tam-inducible N-myc down-regulated gene-I-Cre mice on C57BL6J background. These inducible conditional knock out (KO) mice mired their wild type littermates (WT) were fed a high fat diet (HFD) or a low fat diet (LFD) for 12 weeks. The expressions of PHD2 and VEGF were measured by real-time PCR and immunohistochemistry.

Results: The WT mice on HFD manifested renal histological changes, including cellular enlargement of proximal tubules and a rarefaction of PTCs, which were consistent with more hypoxic area in proximal tubules than in WT mice on LFD. Urinary albumin and NGAL excretion were higher in HFD-fed mice, indicating ischemic tissue damage in proximal tubular area. However, expression of either PHD2 or VEGF was unchanged in HFD-fed WT mice, suggesting the lack of hypoxic tissue response in HFD-fed WT. Injection of Tam to HFD-fed KO mice downregulated PHD2 in proximal tubules, increased VEGF expression, increased the number of PTCs, decreased hypoxic area, and attenuated proximal tubular damages and albuminuria.

Conclusions: Hypoxic condition due to enlarged cell with vascular rarefaction is evident in the proximal tubular area of obese mice whereas tissue reaction to hypoxic damages failed to properly compensate. The early reduction of PHD2 specifically in the proximal area may constitute a novel strategy against the progression process from an early stage of obesity-induced kidney injury.

Herbal Mixture of Radix Puerariae and Fructus Crataegi Prevents Renal Injury in Type 2 Diabetes via Inhibition of AKT/P38 kinase

Chen Yingjie,1 Yu Wei,1 Guo Xiujuan,1 Chen Zhengyue1 1Herbal Mixture of Radix Puerariae and Fructus Crataegi Prevents Renal Damages in Obesity-Induced Kidney Injury, School of Medicine, Ningbo Univ, Ningbo, China; 2Division of Nephrology, Ningbo Urology and Nephrology Hospital, School of Medicine, Ningbo Univ, Ningbo, China.

Background: It has been reported recently that radix puerariae (RP) is one of the best herbal medicines for metabolic diseases, as it has pronounced anti-oxidative effects and helps improving insulin resistance and lowering blood sugar and lipid levels. Fructus crataegi
(FC) also possesses strong antioxidant activity in vitro. The present study was designed to investigate whether RF and FC together (RF/FC) can prevent renal injury through a diabetic rat model generated by a high-fat diet and a low-dose streptozotocin (STZ).

**Methods:** A Type 2 diabetic model was generated by feeding rats with high-fat diet followed by injecting a low dose of STZ. Rats were randomly divided into five groups: normal diet, high-fat diet, high-fat diet plus RF/FC prevention, diabetes mellitus plus RF/FC prevention. RF/FC was given to rats daily by intragastric gavage for 3 weeks. The rats were monitored for body weight, blood glucose, oral glucose tolerance, blood insulin and lipids, serum creatinine and urea nitrogen, urinary protein. Renal pathological changes were examined with hematoxylin and eosin staining, periodic acid Schiff staining, and Masson trichrome staining. The mRNA and protein levels of α-smooth muscle actin (α-SMA) and collagen IV in the kidney were detected by RT-PCR, Western blot and immunohistochemical staining. The levels of PI3K and AKT were determined by Western blot.

**Results:** Rats treated with RF/FC showed reduced 24 h proteinuria and decreased blood glucose level compared with corresponding vehicle treated rats, but RF/FC prevention did not affect blood lipids. Glomerular mesangial matrix expansion, renal capsule constriction, and renal tubular epithelial cell edema were less severe following RF/FC prevention. Moreover, RF/FC prevention markedly reduced protein levels of PI3K, AKT, α-SMA and collagen IV in the kidney of diabetic rats.

**Conclusions:** Combined prevention with RF/FC may inhibit the PI3K/AKT pathway in the kidney, thereby preventing renal injury in diabetic rats.

**High Protein Diet Markedly Accelerates Diabetic Nephropathy While Nephrectomy Has Minor Effects in the BTBR ob/ob Mouse Model**

**Background:** Recent studies have shown that diet can markedly alter the progression of diabetic nephropathy (DN). The obese diabetic BTBR ob/ob mouse was recently shown to mimic key features of human DN including progressive proteinuria and glomerular lesions.

**Methods:** In an attempt to enhance the progression of renal disease further we challenged the model through unilateral nephrectomy (performed at 7 weeks of age) or nephrectomy performed at 18 weeks of age high protein treated BTBR ob/ob also had lower creatinine (median 3.2 mg/dl) indicative of hyperfiltration. Morphological assessment of glomeruli demonstrated decreased the number of podocyte slits per mm GBM.

**Results:** BTBR ob/ob mice exhibited hyperuricemia and hyperglycemia with elevated HbA1c. The urinary albumin excretion rate (AER) was increased 33-fold in intact and 2-fold in nephrectomized BTBR ob/ob at 20 weeks age whereas high protein diet increased AER 332-fold in BTBR ob/ob at 18 weeks age compared with lean controls. Plasma creatinine level was lower in intact (median 3.2 mg/dl) and nephrectomized (median 2.9 mg/dl) BTBR ob/ob compared with lean controls (median 7.2 mg/dl ) at 20 weeks. At 18 weeks age high protein treated BTBR ob/ob also had lower creatinine (median 3.2 mg/dl) indicative of hyperfiltration. Morphological assessment of glomeruli demonstrated notable mesangial matrix expansion in BTBR ob/ob mice at 20 weeks, which was slightly increased by nephrectomy. High protein diet (up to 24 weeks of age) resulted in a significant aggravation of renal pathology, with increased mesangial expansion as well as subcapsular and interstitial fibrosis. Moreover, the high protein diet increased GBM thickness and decreased the number of podocyte slits per mm GBM.

**Conclusions:** In conclusion, the BTBR ob/ob mouse demonstrated renal injury with marked renal interstitial fibrosis and glomerulosclerosis. Disease progression was not significantly advanced by nephrectomy and maintained an intact capacity of filtration comparable to lean mice. Using high protein content diet appears to be a straightforward method to aggravate BTBR ob/ob pathology, which enables new end points for efficacy studies and shortens cycle times.

**Insulin Stimulates Renal Proximal Tubule Sodium Transport in Overt Type 2 Diabetic Nephropathy**

**Background:** The 1.6 vs 3.3) and overt proteinuria (1.5 vs 34 mg/mg Creat). NBCe1 activity was also determined in a T2D patient with renal carcinoma who had decreased cGFR (39.2 ml/min/1.73m²), massive proteinuria (2.5 g/g Creat), and histological changes compatible with overt diabetic nephropathy.

**Results:** The basal NBCe1 activities of OLETF rats and the patient were comparable to those of respective non-diabetic control rats and humans. Furthermore, 10⁻⁸ M insulin markedly stimulated the NBCe1 activity by 65% and 104% in OLETF rats and the patient, respectively. While the expression of insulin receptor was moderately reduced by 15%, the expression of IRS2 was completely preserved in kidney cortex of OLETF rats.

**Conclusions:** Previous reports demonstrated that high blood insulin and lipids, serum creatinine and urea nitrogen, urinary protein. Renal pathological changes were examined with hematoxylin and eosin staining, periodic acid Schiff staining, and Masson trichrome staining. The mRNA and protein levels of α-smooth muscle actin (α-SMA) and collagen IV in the kidney were detected by RT-PCR, Western blot and immunohistochemical staining. The levels of PI3K and AKT were determined by Western blot.

**Results:** Rats treated with RF/FC showed reduced 24 h proteinuria and decreased blood glucose level compared with corresponding vehicle treated rats, but RF/FC prevention did not affect blood lipids. Glomerular mesangial matrix expansion, renal capsule constriction, and renal tubular epithelial cell edema were less severe following RF/FC prevention. Moreover, RF/FC prevention markedly reduced protein levels of PI3K, AKT, α-SMA and collagen IV in the kidney of diabetic rats.

**Conclusions:** Combined prevention with RF/FC may inhibit the PI3K/AKT pathway in the kidney, thereby preventing renal injury in diabetic rats.

**Modulation of Akt/AS160 Phosphorylation Mediates Insulin Resistance in a Rat Model of Metabolic Syndrome**

**Background:** We have previously shown that the insulin receptor substrate (IRS) localization and function is decreased in obesity mediated diabetes, several intermediary steps in insulin signaling are unaltered. However, the most consistent finding was reduced phospho Akt/AS160, which could be a major determinant of insulin resistance in obesity.

**Murine Recombinant ACE2 Reduces Renal Fibrosis in Experimental Alport Syndrome (AS)**

**Background:** ACE2 is a monocarboxylpeptidase in the renin angiotensin systemethat catalyzes the breakdown of angiotensin II (AngII) to angiotensin (1-7) (Ang-7). We have reported that ACE2 expression and activity in kidney are reduced in experimental Alport Syndrome (AS) but the impact of this finding on disease progression has not been studied.

**Methods:** Accordingly, we evaluated the effects of murine recombinant ACE2 (mACE2) in Col4α3/- mice, a model of AS characterized by proteinuria and progressive renal injury. mACE2 (0.5 mg/kg/day) was administered from 4-7 weeks of age via osmotic mini-pump.

**Results:** Treatment with mACE2 led to an increased urinary ACE2 excretion, reduced renal AngII level and a corresponding reduced Ang1-7 level in 7-week-old Col4α3/- mice. Pathological structural changes and albuminuria in the mutant mice were both attenuated by mACE2 administration. mACE2 ameliorated kidney fibrosis in Col4α3/- mice as shown by decreased expression of profibrotic genes, less accumulation of extracellular matrix proteins and inhibition of the TGF-β signaling activation. Further, the increases in proinflammatory cytokine expression, macrophage infiltration, inflammatory signaling pathway activation and heme oxygenase-1 (HO-1) level in Col4α3/- mice were also reduced by mACE2 treatment. Lastly, mACE2 influenced the turnover of renal ACE2, as it suppressed the expression of TNF-α converting enzyme (TACE), a negative regulator of ACE2.

**Conclusions:** In summary, treatment with mACE2 alters angiotensin peptide metabolism in the kidneys of Col4α3/- mice and attenuates the progression of AS nephropathy.

Blockade of CDK9 and Smad3/4 Signaling Reduces Renal Fibrosis in Mice with Unilateral Ureteral Obstruction

Jinhu Li, Xinli Qu, Xiaoyuan Jiang, John F. Bertram, David J. Nikolic-Paterson. 1 Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Vic, Australia; 2 Dept of Pediatrics, The First Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China; 3 Dept of Medicine, Monash Medical Centre, Monash Univ, Clayton, Vic, Australia.

Background: TGF-b1/Smad signaling plays a central role in the pathogenesis of renal fibrosis. Smad3 and Smad4 are pro-fibrotic, while Smad2 is anti-fibrotic. However, these Smads form heterogeneous complexes the functions of which are poorly understood. This study investigated Smad complexes in renal fibrosis in mouse unilateral ureteric obstruction (UUO).

Methods: UUO was established in wild type mice, mice heterozygous or homozygous for Smad3 and/or Smad4 (Smad3^-/-, Smad3^-/-^/+, Smad4^-/-, Smad4^-/-^/+) . siRNA was used to knock down CDK9. CDK9 activity and Smad3 c-terminal phosphorylation was inhibited by a specific CDK9 inhibitor or a Smad3 inhibitor in cultured mouse renal fibroblasts and in UUO.

Results: Smad3/4^-/- mice exhibited substantial protection from renal fibrosis on day 7 UUO, whereas Smad2/3^-/- or Smad2/4^-/- mice showed only modest protection. Formation of Smad3/Smad4/CDK9 complexes was an early event following UUO in wild type mice, which involved nuclear phosphorylation of the linker regions of Smad3. Smad3 or Smad4 deficiency significantly decreased the formation of Smad4/CDK9 or Smad3/CDK9 complex, Smad3 linker phosphorylation as well as fibrosis but at different degrees. In vitro, TGF-b1 stimulation of collagen I promoter activity involved formation of Smad3/Smad4/CDK9 complexes, and over-expression of each component gave additive increases in collagen promoter activity. CDK9 inhibitor or CDK9 siRNA significantly reduced TGF-b1-induced interaction between Smad3 and Smad4, Smad3 linker phosphorylation and fibrotic response in mouse renal fibroblasts. Co-administration of the CDK9 inhibitor and the specific Smad3 inhibitor achieved better protection from TGF-b1-induced fibrotic response in vitro and renal interstitial fibrosis in UUO.

Conclusions: Our studies suggest that the formation of Smad3/Smad4/CDK9 complex drive renal fibrosis in the UUO model. Formation of this complex represents a novel target for anti-fibrotic therapies.

Genetic Activation of Nrf2 Signaling Protects against Chronic Kidney Disease

Roderick J. Tin, 1 Dionysios V. Chartourmpeski, 1 Dong Zhou, 1 Brittany M. Simon, 1 Matthew P. Burger, 1 Youhua Liu, 1 Medicine, Univ of Pittsburgh, Pittsburgh, PA; 2 Pathology, Univ of Pittsburgh, Pittsburgh, PA; 3 Pharmacology, Univ of Pittsburgh, Pittsburgh, PA.

Background: The Keap1/Nrf2 pathway is upregulated in kidney injury, leading to the expression of an array of cytoprotective genes with antioxidant, anti-inflammatory, and detoxifying roles. Keap1 inhibits Nrf2 by sequestering it in the cytoplasm. During oxidative/electrophilic stress, Keap1 undergoes conformational changes that render it inactive and free to translocate to the nucleus to upregulate target genes. Pharmacologic inducers of this pathway have shown some promise in chronic kidney disease (CKD).

Methods: We hypothesized that genetic activation of the Keap1/Nrf2 pathway has therapeutic potential in chronic kidney disease (CKD). Mice that express a hyper-physiological level of Nrf2 (Keap1^-/- or lower) show lower Keap1 expression and increased Nrf2 activity. We subjected HM and wild-type (WT) mice to two models of CKD: unilateral ischemia followed by 10 days of reperfusion (IR); and unilateral ureteral obstruction (UUO). Kidney injury was assessed with serum creatinine, histology, western blotting and quantitative real-time PCR (qPCR) for injury markers.

Results: Compared to WT, HM mice had increased expression of numerous Nrf2-regulated genes after injury. In IR injury, HM mice were significantly protected from developing CKD, demonstrating decreased serum creatinine and renal fibrotic lesions compared to WT mice. Furthermore, HM mice had lower levels of fibronectin, n-smooth muscle actin, and TGF-b. In HM mice, as was pathologic b-catenin signaling, which is known to play a role in CKD progression. Similar results were obtained in the UUO model.

Conclusions: Most studies on the Keap1/Nrf2 pathway examine acute kidney injury or utilize pharmacologic agents with off-target effects. We demonstrate here that genetic enhancement of the Nrf2 pathway is protective in two models of CKD in mice, due to increased expression of cytoprotective genes as well as downregulation of b-catenin signaling. These studies suggest that the Keap1/Nrf2 pathway should remain a promising target in CKD treatment.

Early and Late Treatment with PBI-4050, an Orally Active Anti-Fibrotic Agent, Reduces Fibrosis and Increases Survival of 5/6-Nephrectomized Rats

Background: PBI-4050, a first-in-class orally active compound which is currently in clinical phase Ib/II in CKD patients, displays anti-fibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase 1, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effect. The aim of this study was to investigate the effect of early (Day 21) and late (Day 84) treatment of PBI-4050 on 5/6-nephrectomized rats.

Methods: Sprague-Dawley rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Oral treatment with PBI-4050 (200 mg/ kg, once a day) was initiated at day 21 or at day 84, following randomization based on their glomerular filtration rate (GFR) results. GFR was measured at day 21 or day 84 and assessed every 3 weeks up to day 190 (early) or day 128 (late).

Results: Early treatment with PBI-4050 resulted in a significant improvement (up to 20% relative to control) in early markers significantly reduced proteinuria. Histological lesion scores of kidney were also significantly (p<0.05) decreased in PBI-4050-treated rats (2.7±1.5) compared to control (3.9±1.4), as determined by H&E, PAS and Masson's trichrome staining. Early treatment with PBI-4050 induced a significant reduction of urine N-Acetylglucosaminidase (NAG) level. Furthermore, early treatment with PBI-4050 reduced the overexpression of fibrogenic (TGF-b1, collagen I and -alpha-2, pro-fibrotic cytokines (IL-23p19 and IL-6), remodeling (MMP2, SPARC and fibronectin), and oxidative stress (INOS) markers. Late treatment with PBI-4050 resulted in mild improvement of GFR and serum creatinine level (reduction of 50 mmol/L) but most importantly in an increase in survival (55% non-treated versus 80% with late treatment) at day 128.

Conclusions: These results suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and may potentially improve residual kidney function in patients with end-stage renal failure.

Targeting Cardiorenal Connectors Reduces Renal and Cardiac Fibrosis in Experimental Chronic Renocardiac Failure

Nynke R. Oosterhuis,1 Lennart G. Borgartz,1 Branko Braam,1 Marianne C. Verhaar,1 Roel Goldschmeding,1 Carlo A. Guillard,2 Jaap A. Joles.1 1 UMC Utrecht, Netherlands; 2 Univ of Alberta, Edmonton, Canada.

Background: Cardiorenal connectors (CRC) play a major role in progression of organ dysfunction in heart failure (substantial nephrectomy (SNX)) followed by coronary ligation (CL). We hypothesized that simultaneous inhibition of all CRC would be most effective in reducing cardiorenal fibrosis and functional decline. Methods: In rats subtotal nephrectomy was followed by coronary ligation (wk 8) [Borgartz, AJP, 2012]. In wk 11 we administered losartan (RAS), or PDTC, tempol and moldisomine (Inflammation-NO/ROS) or all of these plus metoprolol (all-CRC) until wk 16.

Results: Tubulo-interstitial (TI) fibrosis decreased in all treated groups (fig 1A). However, renal function was not significantly affected by any treatment. Systolic dysfunction stabilized in all treated groups, but declined further in vehicle-treated rats (fig 1B). Cardiac fibrosis improved in all treated groups without significant additive effect of targeting all CRC (fig 1C). TI and cardiac fibrosis correlated (fig 1D). Only all-CRC reduced MAP. Diastolic hemodynamics and ventricular and cardiomyocyte size were not affected by any treatment. Reducing TI injury and renal and cardiac CTGF mRNA expression was most effective by targeting all CRC.

Conclusions: Pharmacological targeting of cardiorenal connectors in this model of chronic renocardiac syndrome ameliorated the severity of cardiac and renal fibrosis and prevented further decline in systolic dysfunction.

SA-PO424

Fibroblast Growth Factor 23 Is Synthesised Locally by Renal Proximal Tubular Cells and May Be Pro-Fibrotic

Edward Robert Smith, Sven-Jan Tan,1,2 Stephen G. Holt,1,2 Tim Hewitson.1 1 Dept of Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; 2 Dept of Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.

Background: Physiologically, FGF23 synthesis occurs predominantly in bone and regulates mineral handling in the kidney. In Chronic Kidney Disease, circulating levels become markedly elevated and its strong predictive of disease progression, yet changes in FGFR3 are not explained by increased osteocytic synthesis. Since extra-ossseous FGF23
production is observed in diseased heart and vascular tissue, and is associated with the activation of pro-fibrotic cascades, the involvement of renal FGF23 synthesis and potential fibrogenic effects warranted investigation.

**Methods:** Kidneys were harvested from FVB mice at day 0 or after 3 or 9 days post-unilateral ureteric obstruction (UO) (n=6). Paraffin-embedded sections were stained for FGF23 and with lectins to identify specific nephron segments. Total RNA was extracted from whole kidney tissue and laser-capture microdissected glomerular and tubular regions, and analysed by qPCR. Rat renal fibroblasts were cultured with exogenous recombinant human FGF23 and stained for α-smooth muscle actin (αSMA) to assess myofibroblast differentiation.

**Results:** Generalised-low level FGF23 protein staining was observed in proximal tubules at day 0, with more intense focal staining at days 3 and 9 post-UO. Local FGF23 synthesis was confirmed by qPCR of whole kidney extracts, and specifically, in tubules at day 0, with more intense focal staining at days 3 and 9 post-UO. Normalised FGF23 expression increased 11-fold in day 3 UO relative to day 0 (both p<0.01). Treatment of rat UO fibroblasts with 10ng/mL FGF23 resulted in 4-fold increase in αSMA staining over 72h, equivalent to the effect of 1ng/ml transforming growth-factor-β (both p<0.01).

**Conclusions:** Local renal FGF23 synthesis in proximal tubular cells is enhanced by tubulointerstitial injury and may augment myofibroblast differentiation.

**Quantitating Intracellular Oxygen Tension in Kidney by Phosphorescence Lifetime Measurement**

**Yoosuke Hirakawa,1 Imari Minura,1 Toshitada Yoshithara,2 Mako Kiamiya,3 Yasuteru Urano,4,5 Seiji Tobita,2 Masaoi Nangaku,1 1Graduate School of Medicine, The Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan; 2Dept of Chemistry and Chemical Biology, Gunma Univ, 1-5-1 Tenjino-cho, Kita-ku, Gunma, Japan; 3PRESTO, Japan Science and Technology Agency, 4-1-8 Honcho, Kagawa-ku, Saitama, Japan; 4Graduate School of Pharmaceutical Sciences, The Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan; 5CREST, Japan Science and Technology Agency, 4-1-8 Honcho, Kagawa-ku, Saitama, Japan.

**Background:** Hypoxia plays critical roles in the progression of chronic kidney disease, since intracellular reactions to hypoxia depend on intracellular oxygen (O2) tension. However, existing techniques to detect intracellular hypoxia cannot quantify O2 tension.

**Methods:** Phosphorescence lifetime (PL) measurement is reported to be useful to quantitate O2 tension in vivo, however, most phosphorescent probes distribute extracellularly. Here we used BTDP1M, a lipophilic phosphorescent probe, to probe intracellular hypoxia in the kidney. We measured PL in Human Kidney 2 (HK-2) cells and murine kidney after BTDP1M administration.

**Results:** We first made a calibration curve between PL and partial pressure of O2 (pO2) in HK-2 cells. Then we confirmed that BTDP1M distributed in tubular cells in vivo. Next we measured PL of the murine kidney in normal condition, renal ischemia, hypoxemia and anemia. PL were calculated to be 1.8±0.2µs, 4.0±0.3µs, 2.8±0±2µs, 2.2±0.2µs, respectively. We also investigated chronic kidney damaged model mice of 7 days after 30 minutes unilateral ischemia-reperfusion (UIR) injury of kidney. PL of I/R injured kidney was longer than contralateral kidney (2.2±0.2µs vs 1.8±0±1µs). We also found an increase in pimonidazole adduct protein and a decrease in peritubular capillary density in I/R injured kidneys. We quantitated in vivo intracellular pO2 by extrapolating the calibration curve in HK-2 cells. The intracellular pO2 of normal kidney tubule was estimated to be 50mmHg, which was compatible with published value obtained by needle O2 electrode.

**Conclusions:** Our novel technique allowed accurate estimation of intracellular O2 tension of the normal and diseased kidney in vivo for the first time.

SA-P0426

**Rersveratrol Increases Expression of Heme Oxygenase-1 via Nrf2 Signaling to Ameliorate Renal Damage by Anti-Complement, Anti-Oxidative, and Anti-Apoptotic Effect in a Murine Model of Membranous Nephropathy**

**Chia-su Wu,1 Kuo-cheng Lu,1 1Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; 2Dept and Graduate Inst of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan; 3Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.

**Background:** Idiopathic membranous nephropathy (MN) is an autoimmune-mediated glomerulonephritis and a common cause of nephrotic syndrome in adults. There are limited available treatments for MN. We assessed the efficacy of resveratrol (RSV) therapy for treatment of MN in a model of this disease.

**Methods:** Murine MN was experimentally induced by cationic bovine serum albumin, in addition to an injection of Ang II. The control group was injected with a vehicle. Sodium-glucose linked cotransporter-2 (SGLT2) is expressed in the apical side of the proximal tubules and can transport not only glucose but also sodium. Because salt is an aggravated factor for the salt sensitive hypertensive renal injury model, SGLT2 expression may be related to the progression of renal injury due to salt sensitive hypertension. The aim of this study is to reveal the role of SGLT2 inhibitor in angiotensin II (AII) induced renal injury.

**Methods:** Male C57BL6 wild-type mice were divided into three groups: The Ang II group was systemically infused with Ang II for 16 days. The SGLT2 inhibitor (SGLT2-I) group was given an oral dose of the dapaglifozin SGLT2 inhibitor of 1mg/kg/daily in addition to an injection of Ang II. The control group was injected with a vehicle.

**Results:** In both the Ang II and the SGLT2-I groups, the degree of hyperension, the glycemic levels in blood and the body weight were similar. Renal gene expressions of apoptosis marker and SGLT2 significantly increased in both the Ang II and the SGLT2-I groups than the control group. Renal gene expression of the angiotensinogen in the SGLT2 inhibitor group tended to be lower than that in the Ang II group. The degree of macrophage infiltration and urinary albumin levels tended to be lower in the SGLT2-I group than in the Ang II group. These results suggested that SGLT2 inhibitor may attenuate the renal damage due to salt sensitive hypertension via inhibiting the activation of renal renin angiotensin system.

**Conclusions:** In conclusion, SGLT2 inhibitor may be a useful treatment of hypertensive renal disease.
The Renoprotective Effect of Nuclear 1 Factor Related Factor 2 (Nr2f2) Activator, Bardoxolone Methyl, in Aldosterone and High Salt-Induced Renal Injury Mikako Hisamichi,1 Atsuko Ikemori,1,2 Takeshi Sugaya,1 Kenjiro Kimura,1,2 Yugo Shibaigaki,1 1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Activation of nuclear 1 factor related factor 2 (Nr2f2) is reported to have anti-oxidant and anti-inflammatory effects. In the aldosterone (Ald) and high salt-induced renal injury model using mice, we previously reported that severe tubulointerstitial damage was provoked by oxidative stress. The aim of this study is to reveal the renoprotective effect of the Nr2f2 activator in this model.

Methods: To evaluate the degree of tubulointerstitial damage using the urinary liver type fatty acid binding protein (L-FABP) known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP+) male. Male Tg mice (n=24) were fed a 0.2% w/w adenosine-containing diet. Two weeks later from the start of the diet, renal dysfunction of these mice were confirmed and were divided into the four groups: the adenine group was given only the diet containing each Feb (3mg/kg), Top-H (3mg/kg), Top-L (1mg/kg) in addition to adenine for another 2 weeks. Thereafter, adenosine-containing diet was stopped, only each medication was continued for additional 2 weeks and the kidneys in each group were removed.

Results: Renal dysfunction, the degree of macrophage infiltration, tubulointerstitial damage and renal fibrosis were significantly attenuated in the kidneys of the Feb, the Top-L and the Top-H groups compared to those in the adenine group. Serum uric acid levels and renal xanthine oxidoreductase activity in the Feb, the Top-L and the Top-H groups were significantly lower than those in the adenine group. Those levels in the Top-H group were significantly lower than those in the Feb group. Urinary excretion levels of L-FABP in both the Top-H and Top-L groups were significantly lower than those in both the adenine and Feb groups.

Conclusions: In conclusion, Topiroxostat attenuated the renal damage induced by hyperuricemia and may be a useful treatment for hyperuricemic renal damage. Funding: Private Foundation Support

Detection of Mesangial Tissue Transglutaminase Activity in Human Kidney Biopsy Specimens Kazuo Takahashi,1,2 Takeru Mizuno,1,2 Takakori Onouchi,1 Shin’ichi Akiyama,1,2 Hideki Tatsukawa,1 Mamoru Kasaka,1 Tadasu Nagamatsu,1 Yutaka Tsutsumi,1 Shoichi Maruyama,1 Hiroshi Kitamura,1 Jan Novak,2 Kyotaka Hitomi,1 Yukio Yuzawa,1 1Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan; 2Graduate School of Pharmaceutical Sciences, Nagoya, Aichi, Japan.

Methods: Monoclonal antibodies specifically reacting with human tissue TG2 were raised. These were used to detect mesangial TG2 activity in renal biopsy samples from patients with lupus nephritis, membranous nephropathy, membranoproliferative glomerulonephritis, IgA nephropathy, and polycystic kidney disease. Detection of TG2 activity was performed by indirect immunofluorescence microscopy with FITC-labeled highly reactive TG2 substrate peptides.

Results: The presence of mesangial TG2 activity was observed in 67% of the patients with lupus nephritis, in 14% of the patients with membranous nephropathy, in 21% of the patients with membranoproliferative glomerulonephritis, in 67.5% of the patients with IgA nephropathy, and in 3% of the patients with polycystic kidney disease.

Conclusions: The role of TG2 in human biopsy samples.

Accumulation of Indoxyl Sulfate in Renal Tubular Cells Aggravates Kidney Injury in Rats with 5/6 Nephrectomy Avano Konagai, Kaori Kikuchi, Ayako Fujieda, Sumie Goto, Hiroko Iijima, Yoshiharu Itoh. Pharmaceuticals Division, Kureha Corporation, Tokyo, Japan.

Methods: Indoxyl sulfate (IS), a representative uremic toxin, is detected in renal tubular cells of CKD patients and 5/6 nephrectomized rats administrated with IS. It has been suggested that the retention of IS is induced through organic anion transporters in the basolateral membrane of renal tubular epithelial cells and this retention leads to nephrotoxicity. However, the mechanism for IS accumulation in renal tubules remains unclear. To reveal the correlation between IS accumulation and renal dysfunction in 5/6 nephrectomized rats, we investigated the expression of transporters in the apical or basolateral membrane and of markers for renal injury such as IS antigen.

Results: Serum IS levels were found to be increased in the 5/6 nephrectomized rats compared to the normal rats by the newly ELISA. The new system could sensitively detect the low concentration of IS. The value determined by ELISA is in a good correlation with HPLC. Immunohistochemistry showed a significant IS staining in renal sections of the 5/6 nephrectomized rats. The values of renal IS accumulation and renal dysfunction were significantly lower than those in the 5/6 nephrectomized rats in both the Top-H and Top-L groups.

Conclusions: IS accumulation aggravates renal injury. In conclusion, Topiroxostat attenuated the renal damage induced by hyperuricemia and may be a useful treatment for hyperuricemic renal damage. Funding: Private Foundation Support

IL-15 as a Potential New Therapeutic Treatment for Renal Fibrosis L. Lecuru,1 A. Devocelle,1 V. Le coz,1 C. Gallenne,1 S. Ferlicot,1 A. Durrbach,2 P. Eid,1 B. Azzaroni,2 H. Francois,1 J. Girondichel.1 1UMR Inserm 1197, Villejuif, France; 2Bicetre Hospital, Kremlin-Bicetre, France.

Background: The human epithelial cells of various tissues produce interleukin-15 (IL-15), which acts not only on immune cells, but also on epithelial cells, mainly via its anti-apoptotic action. Thus, human and mouse renal tubular epithelial cells (RPTEC) constitutively secrete IL-15. Our group recently reported that IL-15 preserves epithelial phenotype in human kidney tubular cells since IL-15 is sufficient to induce the WT commitment of RPTEC. Therefore, the goal of our study is to explore the renoprotective potential of IL-15 in vitro and in vivo in renal fibrosis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: Our study sought to examine if IL-15 could inhibit EMT in tubular epithelial cells because of upregulation of tubulointerstitial fibrosis using the unilateral ureteral obstruction model (UUO) in mice. We also analyzed IL-15 expression in various human nephropathies.

Results: IL-15 expression decreased in human renal disease and in mice during UUO (p<0.05, n=19). IL-15 treatment coupled with its soluble receptor (IL-15Rα-Fc) prevents interstitial fibrosis during UUO (10.7 ± 1.1% in control group, vs 8.2 ± 0.7% in IL-15 treated mice and 6.4 ± 0.6% in IL-15/IL-15Rα treated mice, p<0.01, n=7 mice/group). qPCR analysis of treated IL-15 mice revealed decreased expressions of MCP1 in expression of IL-15 and IL-15/IL-15Rα treated mice (p<0.05, n=7 mice/group). IL-15 also reduced TGFβ1-induced EMT in vitro on RPTEC and tubular cell line (HK2) (p<0.05). This protective effect of IL-15 acted through Snail inhibition and C-Jun activation (p<0.05). Furthermore, we found a direct inhibition of IL-15 on collagen synthesis, in both HK2 (collagen IV) and myofibroblasts (collagen I and III).

Conclusions: In conclusion, IL-15 can attenuate TGFβ1-induced EMT by acting directly through a reduction of collagen synthesis, both on myofibroblast, the main effector of fibrosis, and tubular cell. IL-15 also modulates macrophages infiltration in vivo in UUO. Therefore IL-15 could be a novel therapeutic player in renal diseases.

SA-PO434 Loss of the Vascular Class 3 Semaphorin, Semaphorin 3G, Leads to Attenuated Fibrosis and Reduced Tubular Injury by Unilateral Urinary Obstruction in Mice

Methods: 6-8-week old male C57BL/6 mice were treated intraperitoneally daily either with PBS (control) or 10 mg/kg IL-15 (IL-15). Total RNA was extracted, and RTqPCR performed for IL-6, IL-1β, NLRP3, and GAPDH. Results were normalized by protein content. Exact stratified Wilcoxon test was used for statistical analyses.

Results: Histologically, UUO kidneys does not show obvious difference between controls and IL-15 treated mice, although mRNA expression of Tgfb and Snail, a key regulator of TGFβ-induced fibrosis, increases by IL-15 in controls, these increases are attenuated in Sema3G KO UUO kidneys (for Tgfβ, 55% suppression compared to controls, P<0.03 at day3,95% suppression, P<0.01 at day7), suggesting that Sema3G KO mice are protected against interstitial fibrosis.

Conclusions: Together, these data demonstrate that endothelial Sema3G acts on adjacent tubular/interstitial cells and promotes fibrosis by UUO. Identification of the mechanism of this interaction would provide new therapeutic targets for CKD and renal fibrosis.

SA-PO435 Leukemia Inhibitory Factor Attenuates Tubulointerstitial Fibrosis in Unilateral Ureteral Obstruction

Methods: The experiments were carried out in vivo on RPTEC and tubular cell line (HK2) using both in vivo and in vitro approaches. RPTEC and HK2 were treated with LPS and TLR4 agonists to mimic the renal injury. IL-15 was added to the cultures to assess its effect on pro-inflammatory pathways and T-cell infiltration indicating a possible future treatment option.

SA-PO436 Dendritic Cell-Specific Sph-1-Knockout Mice Spontaneously Develop Unique Glomerulo- and Tubulointerstitial Nephritis Miltshahiya Watanabe,1 2 3 Keiji Hiromura,1 Yoriaki Kaneko,1 Masato Kinoshita,1 Yuki Ohashi,1 Toru Sakairi,1 Hidekazu Ikuchi,1 Akito Maeshima,2 Hiroshi Ohnishi,1 Takashi Matozaki,1 Yoshihisa Nojima,1 2 3 1 Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Japan; 2 Dept of Laboratory Sciences, Gunma Univ Graduate School of Health Sciences, Japan; 3 Div of Molecular and Cellular Signaling, Dept of Biochemistry and Molecular, Kobe Univ Graduate School of Medicine, Japan.

Background: Sphingosine-1-phosphate-1 (Sph-1) is a guanine nucleotide exchange factor (Geff) protein that regulates cell proliferation, survival and migration.

Methods: Mice were generated with Sph-1 deletion specifically in dendritic cells (DC) via conditional knockout (Mice were identified by FACS analysis).

Results: Compared to control mice, Sph-1 KO mice showed significantly higher serum creatinine at 40 wks or later. Anti-dsDNA antibody was detected at low levels at 8 wks and markedly elevated at 20 and 40 wks. At 40 wks, Sph-1 KO mice showed severe proliferative glomerulonephritis and tubulointerstitial nephritis by light microscopy with mesangial IgG and C3 depositions by IF staining. Electron microscopy revealed electron dense depositions in mesangial area, but few in subendothelial or subepithelial area. Immunohistochemical staining showed marked accumulation of DCs (CD11c+), macrophages (F4/80+) and helper T cells (CD4+) at periglomerular and tubulointerstitial area. Infiltration of numerous DCs and macrophages was consistent with a specific pattern, suggesting a possible involvement of DCs and macrophages in the pathogenesis of nephritis.

Conclusions: The DC-specific ablation of Sph-1 in mice resulted in development of unique autoimmune glomerulo- and tubulointerstitial nephritis, which is distinct from typical lupus nephritis characterized by wire-loop lesions and heavy proteinuria.

SA-PO437 TLR4 Mutant Mice Are Protected from Renal Fibrosis Following Folic Acid Injection

Methods: Primary cultures of RECs isolated from WT or TLR4 mutant mice were incubated with 20nM with increasing doses of LPS. Supernatant IL-6 was measured by ELISA. Total RNA was extracted, and RTqPCR performed for IL-6, IL-1β, NLRP3, and GAPDH. Results were normalized by protein content. Exact stratified Wilcoxon test was used for differences.

Results: LPS dose-dependently increased IL-6 secretion in WT TLR4 RECs, but TLR4 mutant RECs secreted very low levels of IL-6, and IL-6 mRNA expression was 7-fold lower than WT TLR4 RECs. After adjustment for day2 log BUN, TLR4 mutant mice were protected from IF at day 14 (p<0.01).

Conclusions: In vivo, TLR4 signaling can stimulate inflammatory processes and induction of pro-inflammatory cytokines.

SA-P0438

A New Mouse Model of Glomerular Foam Cell Accumulation in Disease

Minsceob Eom, Kelly L. Hudkins, Anna Batorsky, Charles E. Alpers. Dept of Pathology, Univ of Washington School of Medicine, Seattle, WA.

Background: Foam cells are lipid-laden cells of monocyte/macrophage origin which have a key role in the development of atherosclerosis. Similar foam cells are found in human kidney biopsies in various diseases (e.g. tip and cellular variants of FSGS, diabetic nephropathy, and the interstitium in nephrotic states). The pathophysiologic significance of foam cells in the kidney is poorly understood, in part due to lack of good animal models. We sought to develop a robust animal model for foam cell accumulation in the kidney to test their pathogenic significance.

Methods: Six-week old apolipoprotein E (Apo E)-null C57BL/6 mice were divided into two groups. Group 1: Mice were gavaged daily with 1% hydropropyl methylcellulose with 0.1% tween 80 (HPMC-Tween) (10ml/kg) for 30 days. Group 2: Untreated age-matched controls. Each organ including kidney was harvested for histologic evaluation.

Results: Immunohistochemical stains (IHC) for Mac2 were performed to quantify the state of monocyte/macrophage infiltration and uranil was calculated to conduct the urine albumin-creatinine ratio (ACR) and total albumin excretion. Results: IHC for Mac2 revealed that 83.76% of glomeruli were infiltrated by foam cells in the HPMC-Tween treated group. Most showed several foam cells in each glomerulus. Neither FSGS nor mesangiolysis nor interstitial foam cell accumulation developed in the treated mice despite the prominent glomerular foam cells. Additionally, there was no significant difference in ACR between treated group and control group, although the treated mice revealed a trend of higher urine ACR, compared with pre-treatment urine.

Conclusions: Treated mice developed widespread glomerular foam cells, FSGS, mesangiolysis, or interstitial changes that are features of human renal cell injury did not develop within the limited 30 day observation period during which foam cells accumulated. We speculate affected mice may not have had sufficient time to develop sclerosis. Apo E null mice treated with HPMC-Tween has potential to be a good animal model for the study of the tip and cellular variants of FSGS, for which no good mouse models currently exist.

Aberrant Methylated DNA Regions Lead to Low Activation of CD4+ T Cells with a Consequent Imbalance of the Th1/Th2 Polarization in IgA Nephropathy Patients

Fabio Salustio,1,2,3 Grazia Serino,1 Alessandra Dalla Gassa,3 Claudia Curi,1 Giuseppe De Palma,4 Barbara Banelli,1 Gianluigi Zaza,4 Massimo Romani,2 Francesco Paolo Schena,1 Sharon N. Cox,1 DETO, Univ of Bath, Bath, England; 2Univ del Salento, Lecce, Italy; 3Consorzio Carsia, Valenzano, Italy; 4Dept of Medicine, Univ of Verona, Verona, Italy; 5IST, IRCCS San Martino, Genova, Italy.

Background: The immunoglobin A nephropathy (IgAN) pathogenesis has a strong genetic component. In this setting, also the DNA methylation could be an important factor influencing the pathology. Aim of our study was the identification of abnormally methylated regions in CD4+ T cells of IgAN patients.

Methods: A genome-wide screening of the DNA methylation CD4+ T cells from 6 IgAN patients and 6 healthy subjects (HS) was performed. Differentially methylated regions have been validated on 40 samples of IgAN and HS by pyrosequencing and functional studies by 5-aza-2'-deoxycytidine and MSP-RT-PCR. The gene expression was verified by RTPCR. Activation of CD4+ T cells was studied by BrdU proliferation assays and IL2 and IL4 ELISA.

Results: We found 161 tiling regions, 12 promoters, 12 genes and 5 CpG islands underlined that represent the presenting author.

Conclusions: The identified DNA regions were in different immunological processes and may contribute to the development of IgAN.

Funding: San Martino, Genova, Italy.

5-Aza-2'-Deoxycytidine Reduces Nephrotoxic Nephritis and DNA Cytosine Methylation in Nephritic Glomeruli and Macrophages In Vitro

Thomas Oates,1 Stephen Paul McAdoo,2 Charles D. Pusey,3 H. Terence Cook,1 Enrico Pettetto.1 1Imperial NHS Trust, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3MRC Clinical Sciences Centre, London, United Kingdom.

Background: Nephrotoxic nephritis (NTN) is a macrophage dependent rat model of crescentic glomerulonephritis (CRGN). We investigated whether DNA cytosine methylation could determine dysregulation of macrophage activity and contribute to CRGN susceptibility, by examining the effect of 5-aza-2'-deoxycytidine (DAC), an inhibitor of DNA methylation, on NTN phenotypes and DNA methylation in both nephritic glomeruli and bone marrow derived macrophages.

Methods: NTN was induced in male WKY rats. 6 rats were treated with intra peritoneal DAC and 6 controls with vehicle only. Treatment was given every three days prior to sacrifice at 10 days and then NTN phenotypes assayed. The effect of DAC on DNA methylation was examined by multiplexed PCR sequencing of bisulfite converted DNA in both nephritic glomeruli from NTN animals, and in WKY bone marrow derived macrophages treated in vitro with DAC.

Results: DAC treated animals had fewer glomerular crescents, less proteinuria and less glomerular macrophage infiltration (ED1 staining).

DNA methylation in nephritic glomeruli was decreased across 200 cytosine bases in DAC treated samples compared to controls (P = 0.049, Wilcoxon rank sum test). This decrease was driven by 39 cytosines that showed demethylation in DAC treated animals. In vitro sequencing in macrophages showed diverse methylation changes after DAC treatment depending on length of exposure and dose.

Conclusions: These experiments show that DAC treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

Macrophages Present an Essential Source of Anti-Inflammatory Annexin A1 Signals During the Course of Acute Anti-Thy-1.1 Nephritis

Robert Labes,1 Philipp Dittert,2 Sebastian Bachmann,3 Alexander Paliege.2 1Dept of Anatomy, Charité - Universitätsmedizin Berlin, Berlin, Germany; 2Dept of Nephrology, Charité - Universitätsmedizin Berlin, Berlin, Germany.

Background: Macrophage subpopulations exert distinctive effects during inflammatory kidney disease and may either aggravate kidney damage or foster renal repair. The anti-inflammatory protein annexin A1 (AnxA1) has been shown to shift macrophage polarization towards the anti-inflammatory M2 phenotype. Cellular sources and regulation of intrinsic AnxA1 signals during renal inflammation remain to be elucidated.

Methods: Adult Wistar rats were injected with anti-Thy-1.1 antibody to induce mesangio proliferative glomerulonephritis and examined after 24h (initiation phase), 5d (proliferation phase), and 15d (resolution phase). Regulation of AnxA1 was studied by qPCR and immunohistochemistry. AnxA1+ cells were characterized by triple labelling immunofluorescence using antibodies against CD68 for monocytes and macrophages, and CD206 and CD163 for macrophages with M2 polarization. Quantification of immunoreactive cells was performed by cell counting on confocal micrographs.

Results: Induction of anti-Thy-1.1 nephritis caused a rapid increase of renal AnxA1 mRNA levels (24h: +92±16%; 5d: +128±19%; 15d: +78±33%; relative to controls; p<0.05). Quantitative image analysis revealed a pronounced interstitial accumulation of total, and CD206 + M2 macrophages at d5 (+150±40%; and +260±29%; p<0.05) and d15 (+378±43%; and +600±100%; p<0.05) as compared to controls. Triple labelling studies revealed elevated numbers of CD68+/CD206+/AnxA1+ interstitial M2 macrophages at d5 and d15 as compared to controls (+24±30%; and +450±38%; p<0.05). CD68+/CD206-/AnxA1+ macrophages were increased to a lesser extent (d5: +270±47% relative to controls; p<0.05).

Conclusions: In conclusion, we have shown that AnxA1 expression and protein abundance are significantly increased during the course of anti-Thy-1.1 nephritis. Accumulation of CD206+/AnxA1+ and CD206-/AnxA1+ macrophages at d15 suggests that these cells present a relevant source for anti-inflammatory AnxA1 signals during the resolution phase of renal inflammation. Further studies are needed to establish the characteristics of these cells.

Reduced Mitochondrial Energy Production in the Kidney Induces Focal Segmental Glomerulosclerosis in Low-Birth-Weight Rats at Adulthood
Toshiyuki Imasawa, Kidney Center, National Hospital Organization Chiba-East Hospital, Chiba-City, Chiba, Japan.

Background: Intraglomerular hypertension has been linked with the pathogenesis of focal segmental glomerulosclerosis (FSGS) lesions in low-birth-weight (LBW)-related nephropathy, which is associated with a decreased number of nephrons. However, other mechanisms may participate in the pathogenesis of LBW-related nephropathy. Here, we investigated innate factors that could induce LBW-related nephropathy at adulthood.

Methods: LBW rats (N = 7) were obtained by intraperitoneally injecting pregnant rats with dexamethasone. Normal-birth-weight (NBW) rats (N = 7) were obtained by saline injection. At 4 weeks of age, the left kidney was removed and used for histological analysis and quantitative proteomics (label-free LC-MS/MS). At 9 weeks of age, the right kidney was histologically analyzed.

Results: At 4 weeks of age, glomerular numbers in LBW rats were significantly lower than NBW rats (p < 0.01). However, there were no sclerotic lesions, and neither group showed any other pathological changes at this age. At 9 weeks of age, FSGS lesions were observed in 7.4% of glomeruli in LBW rats, but only 0.5% of glomeruli had lesions in NBW rats. The pathological changes in LBW rats at 9 weeks of age resembled that of human LBW-related nephropathy. Quantitative proteomics using the renal cortex from 4-week-old rats revealed that 685 proteins decreased in LBW rats compared with NBW rats, and among them, 97 proteins (14.2%) were mitochondrial proteins. In such reduced mitochondria, 12 subunits of OXPHOS, especially complex III and V, and 15 enzymes of TCA cycle were significantly decreased in LBW rat cortexes (p < 0.05). Western blotting revealed the reduced expression of α-AMPK, NRF-1, and TFAM, which are master regulators of mitochondrial biogenesis, in LBW rats at 4 weeks of age.

Conclusions: This is the first report to investigate the innate suppression of mitochondrial energy production in LBW animals. We have shown that in addition to intraglomerular hypertension, innate defects to mitochondrial energy production should induce the formation of FSGS lesions in LBW-related nephropathy at adulthood.

SA-PO443

Background: Tissue hypoxia (Hyp) is thought to influence the pathogenesis of chronic kidney disease (CKD), but direct evidence that prolonged exposure to tissue Hyp initiates the renal content of IL-1β or TLR-4 in S. Unexpectedly, Hyp attenuated IL-1β, TLR-4, and the effect of Hyp would involve activation of innate immunity.

Methods: Five-week-old rats were exposed to normoxic (N=19) or 1.6±0.3 to 1.6±0.3 in the renal cortex (N=19). Seven S (S 1.6±0.3 to 1.6±0.3, interstitial macrophages, cells/mm²; renal IL-1β, pg/g); and TLR-4 (2 1.6±0.3 to 1.6±0.3, normoxic or acute to chronic renal failure, and associated with decreased expression of hypoxia-inducible factor 2 (HIF-2) but decrease such a function upon their transition to myofibroblasts in fibrosing kidney disease. Hyppermethylation of erythropoietin 5’-untranslated region is demonstrated and associated with decreased expression of erythropoietin in kidney myofibroblasts. Demethylase with 5-azacytidine or knockdown of upregulated DNA methyltransferase 1 in kidney myofibroblasts is found to increase expression of erythropoietin in fibrosing kidney disease.

Conclusions: These studies demonstrate that epigenetic modifications may provide a molecular basis for decreased response of renal erythropoietin-producing cells to anemic stimulation in fibrosing kidney disease.

SA-PO445

Multiparametric Magnetic Resonance Imaging for Assessing Renal Histopathology in a Mouse Model of CKD Gunther Schlegl,1 Jutta Janko,2 Kai-Uwe Eckardt,3 Tobias Bäuerle,1 Carsten William.1 1Nephropathy and Histopathology, Univ of Erlangen-Nuremberg, Erlangen, Germany; 2Radioiology, Univ of Erlangen-Nuremberg, Erlangen, Germany.

Background: Multiparametric magnetic resonance imaging (MRI) allows non-invasive assessment of renal pathologies, especially in patients with chronic kidney disease (CKD) as it does not require contrast agent administration. We aimed to establish an imaging protocol for multiparametric MRI in an experimental CKD mouse model and correlate radiologic and histopathological parameters.

Methods: CKD was induced in male C57BL/6 mice (n=8) by feeding an ademin-supplemented diet for 3 weeks resulting in deposition of dihydroxyadenine crystals, tubular dilation, capillary loss, tubulointerstitial inflammation and fibrosis. Untreated animals (n=8) served as controls. Kidneys were fixed in paraformaldehyde and subjected to MRI in a 7-Tesla scanner ex vivo. Volumetry of renal cortex and medulla was performed on T2 weighted sequences. MRI parameters (apparent diffusion coefficient (ADC), fractional anisotropy (FA), T1, T2, T2* relaxation times) were determined for 3 regions of interest in a 7-Tesla scanner ex vivo. Volumetry of renal cortex and medulla was performed on T2 weighted sequences. MRI parameters (apparent diffusion coefficient (ADC), fractional anisotropy (FA), T1, T2, T2* relaxation times) were determined for 3 regions of interest placed manually in the cortex and outer medulla, compared between CKD and controls kidneys and correlated with (immuno-)histological analyses for crystal density, tissue cellularity, tubular dilation, inflammatory infiltration, fibrosis, and vascularization.

Results: CKD resulted in significant volumetric augmentation of the medulla. T1 times decreased in the control and diseased kidneys, T2 and T2* times were significantly increased in both cortex and medulla, whereas ADC was reduced in only some of the diseased kidneys in comparison to controls. In contrast, FA was significantly reduced in diseased cortex and medulla. T2* time correlated with the relative area of fibrosis (Spearman’s rho 0.71 or cortex, 0.79 or medulla), its (hyper)chromatinization (0.56, 0.81), and tubular lumen (0.74).

Conclusions: Multiparametric MRI enabled characterization and diagnosis of chronic changes in the presented CKD model and showed correlation of T2 times with fibrosis, inflammatory infiltration, and tubular dilation. These results may help to broaden our understanding of MRI findings in CKD patients.

SA-PO446

Nuclear Magnetic Resonance Based Metabonomic Profiles Produced by Aristolochic Acids: Comparison with Well-Known Tubulotoxic Agents Marlene Espagne,2 Aurielina Rozier,1,2,4 Eric De prez,5 Jean-Marie Coiret,1 Joelle L. Nortier.1,2 1Lab Experimental Nephrology, ULB; 2Lab Histology, UMONS.

Background: Aristolochic acids (AA) are powerful nephrotoxic and carcinogenetic products derived from Aristolochiaceae responsible for acute to chronic renal failure and urothelial cancer complications in countries using traditional herbal medicine. Early detection of renal tubular injury could be useful in individuals at risk of exposure to AA. Methods: The Consortium of Metabonomic in Toxicology (COMET) (http://www.cee.ucl.ac.be) has developed predictive models of renal toxicity based on the NMR-based metabonomic evaluation of urine and serum samples collected from rats acutely exposed to various well characterized nephrotoxins. Using this COMET protocol, we studied the metabonomic urine profile of rats injected with aristolochic acid 1 (AA1) or AA2 at different dosages (75, 100mg/kg). We then compared it to those obtained with 3 molecules known for their toxicity on the proximal tubule, i.e ifosfamide (If: 70, 70mg/kg), gentamicin (Gent: 40, 400mg/kg) and cisplatin (Cis: 0.5, 5mg/kg), respectively.

Mean ± SE, p <0.05 vs. respective S, p >0.05 vs respective Nor. Exposure to Hyp increased Hb in both S and N, but led to no injury or elevation of the renal content of IL-1β or TLR-4 in S. Unexpectedly, Hyp attenuated IL-1β, TLR-4, Mφ, GSI and %INT in N.

Conclusions: We found no evidence that chronic Hyp initiates or worsens CKD. Chronic Hyp may be even reprotective by unclear mechanisms, perhaps involving adaptive molecules. FAPESP/CNPq.

Funding: Government Support - Non-U.S.
Results: Metabolomic results obtained in AA rats demonstrated a urinary increase in metabolites involved in urea cycle (urate, betaine, glycine), cell death (lactate) and in reabsorptive capacity of the tubular epithelium (glucose), and a significant reduction of Krebs’s cycle components (alpha-ketoglutarate, succinate, citrate), suggesting a mitochondrial injury. The comparison of these AA profiles with those obtained with Ito, Genko, and Cu rats revealed similarities in 2D plots. However, the 3D modelization approach showed very close score plots shared by AA, Ito and Cu and a different behaviour exhibited by Genta samples. Conclusions: This metabolomic study confirms the mode of action of AA towards the proximal tubule and provides an original signature of induced mitochondrial insult. This approach could bring new insight in understanding the toxicity pathways of AA within the kidney. Moreover, it could be a useful tool of noninvasive screening in populations at risk of AA intoxication.

SA-PO447 Establishment of a 3-Step Method to Obtain the Absolute Number of Neprhrons in Mice Xiaogang Chu, Jian-Kang Chen. Deps of Cellular Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA.

Background: Low nephron number is implicated in hypertension and kidney disease. Existing methods to determine nephron number have various limitations. While using the Cre reporter mice expressing membrane-Tomato/membrane-Green fluorescent protein (mT/mG) for other studies, we fortuitously noticed that the Tomato fluorescence remarkably visualized all glomeruli in the kidneys, which prompted us to establish a 3-step (Separate-Press-Count) method to obtain the exact nephron number in mice.

Methods: One homozygous mTmG mouse (S232, available from the Jackson Laboratory, Stock Number: 007576) was bred with FVB/NJ mice. This produced ~11 heterogeneous pups per litter. After the pups reached 6 weeks of age, they were weighed and euthanized. Each kidney was decapsulated, weighed, and bluntly separated into 35-45 pieces (1-2 mm³) each using forceps with non-serrated but blunted tips. Each piece was pressed between a microscope slide with grids and a coverslip, followed by counting of every single glomerulus under a fluorescence microscope.

Results: The nephron number in male mice ranged from 10421 to 15577 (mean = 12718 ± 2136) for left kidney and 10374 to 15691 (mean = 12371 ± 2411) for right kidney (n=6) while that of female mice ranged from 13890 to 16277 (mean = 15184 ± 1443). This is still true when expressed as mean nephron number per gram of body weight

Conclusions: We have established a new simple method to count the absolute nephron number and are using it to define the minimum nephrons per gram of body weight that can maintain the normal blood pressure and kidney function in mice.

Funding: NIDDK Support

Background: One of the many unresolved questions regarding the permeability of the glomerular filtration barrier is the reason for the difference in permeability between albumin and polysaccharide probe molecules such as Ficol. The difference in sieving coefficients between albumin and a Ficol molecule of the same molecular size (~36 kDa) is ~2-3 orders of magnitude. Although this large difference in permeability has been attributed mainly to charge effects, we have previously shown that this would require a supraphysiological amount of charge on the filtration barrier, being about ~10 times more charge than the charge on the albumin molecule (~0.02 e/μm²).

Methods: The classic hetrotoperous model by Deen, Bridges, Brenner and Myers (Deen et al. JAP Renal Physiology, 1985) was extended by introducing size distributions on the solute molecules, making them flexible in their conformation. Experimental sieving data for Ficol, both from the rat glomerulus and from precision-made nanopore membranes, were analyzed using the model. The variation in solute size was quantified in terms of the geometric standard deviation gSD of the solute size distribution. (The mode/solute radius was assumed to be equal to the SE-radius and the pore size distribution gSD was set to unity. Results: For the glomerulus (n=7), a GSD for the Ficol size-distribution of 1.16 ± 0.01 was obtained, along with a small pore radius of 36.1 Å (± 0.5 Å) and a large pore radius of 152 Å (± 7 Å). This was compared to the sieving coefficient for GSD of 1.24 ± 0.01.

Conclusions: In the current study, we show, for the first time, that a variation of only ~15-17% in the size of the molecule is sufficient to explain the difference in permeability between albumin and Ficol. In addition, we show that the effects of applying a size-distribution on the solute molecule are only evident when the molecular size is close to the size of the selective elements of the barrier. This is well in line with experimental data, both from the GFB and from synthetic membranes.

SA-PO449 Rapid MicroRNA Isothermal Amplification and Detection in Ureteric Tissue for Nephrotic Syndrome and Other Renal Disease Biomarker Discovery Kathrin Gassei, Chandramohan Ishwad, Jacqueline Ho, Abhay N. Vats. Pediatrics, Childrens Hospital of Pittsburgh, Pittsburgh, PA.

Background: MicroRNAs play an important role in renal development and are being explored as biomarkers for several renal diseases including nephrotic syndrome (NS). However, miRNA detection assays can be expensive, laborious, and time consuming. Here we are developing a fast and reliable assay for miRNAs in urine and report a novel isothermal amplification method. We tested this method [ called cross hybridization amplification (CHAMP)] for detection of miR-30a-5p in urine of patients with NS and controls.

Methods: We designed two 20-25 nt primers and a probe specific for miR-30a-5p. Primers were labeled with either Biotin or Digoxigenin on the 3'-end. Synthetic miR targets were developed for miR-30a, miR30b and Let7 microRNAs. Amplification required, Bst DNA polymerase enzyme, and incubation at 65°C for 30-60 min. Assay optimization was performed on urine samples spiked with synthetic miR constructs. Amplification and detection was performed with real-time PCR; gel electrophoresis and later flow devices. Results: CHAMP was able to amplify and detect miR30a-5p in 60 minutes or less. The primers/probe were specific for miR30a and did not amplify miR30b or let7 microRNA.

Conclusions: A novel isothermal amplification method (CHAMP) can be used for rapid microRNA detection in human urine. It allowed a rapid, sensitive, and highly specific amplification and detection of miR-30a-5p in urine samples. The cost effective than qPCR or microarray. CHAMP could detect miR-30a-5p, with sensitivity similar to qPCR, without the need for RNA isolation and could be used for biomarker discovery based on microRNA studies for NS and other renal diseases.

SA-PO450 Dominant Negative Etv4 Expression in Metanephric Mesenchyme Reduces Nephron Endowment: A Model of Low Nephron Number CKD Susanne V. Fleig, Flavia G. Machado, Benjamin D. Humphreys. Brigham and Women's Hospital, Boston.

Background: The role of etv4 expression in the ureteric bud during kidney development has been established; however the role of etv4 in the metanephric mesenchyme was unknown. We asked what role Etv4 plays during nephrogenesis.

Methods: To inhibit etv4 function in the metanephric mesenchyme, we crossed mice with a loxP-flanked dominant-negative etv4 (R26-LoxP-DN-Etv4) with a metanephric mesenchyme-specific sux2-cre mice (Sux2-TGC 0.01); cre-negative littermates served as controls.

Results: Six2cre-DN-Etv4 mice express DN-etv4 in the nephron progenitor population starting dpc10.5. Cre-positive mice have lower body weight and fail to thrive. At four weeks, they display decreased nephron number (4,422 ± 840 vs. 86,8 ± 69 for control, P<0.01). They develop kidney failure (at 4 weeks: BUN 103.8±17.8mg/dl vs. 14.1±1.8mg/dl, P<0.001) and proteinuria (21.29±7.23 Albumin/g Creatinine vs. 0.14±0.03g Albumin/g Creatinine in urine, P<0.05). Their kidneys show all features of chronic kidney failure proteinuria, glomerulosclerosis, (fibrosis) and they die at 3-5 weeks of kidney failure.

Conclusions: Etv4 expression in the metanephric mesenchyme is required for normal kidney development, and expression of DN-Etv4 in the sux2+ population leads to defective kidney development with reduced nephron number and progressive chronic kidney failure at 3-5 weeks of age. Titration of DN-Etv4 expression in metanephric mesenchyme may provide a novel genetic model for low nephron endowment and progressive CKD.

SA-PO451 NO Depletion by L-NMMA Causes Increases in Rat Glomerular Permeability In Vivo – Reversal with Tempol and L-Arginine, but Not with the Potent NO-Donor DEA-NONOate Bengt Rippe, Julia Dolinina, Kristinn Sverrisson, Anna Rippe. Dept of Nephrology, Lund Univ, Lund, Sweden.

Background: There is increasing evidence that the permeability of the glomerular filtration barrier (GFB) is regulated by a balance between the bioavailability of nitric oxide (NO) and the presence of reactive oxygen species (ROS). It has been postulated that normal or moderately elevated NO levels protect the GFB from permeability increases, while ROS, through reducing the bioavailability of NO, have the opposite effect.

Methods: In anesthetized Wistar rats, the left ureter was cannulated for urine collection, while simultaneously blood access was achieved. To test the tentative antagonism between NO and ROS, rats were systematically infused with either L-NAME (6 mg/kg/min), or L-NAMe together with the superoxide scavenger tempol (1 mg/kg/min), or L-NAMe together with L-arginine (290 mg/kg/min). Furthermore, we tested whether the potent NO donor, DEA-NONOate, could reverse the permeability effects of L-NAMe. To measure glomerular sieving coefficients (θ) to Ficol, rats were infused with fluorescein

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underlines represents presenting author.
isothiocyanate (FTC)-Ficoll 70/400 (mol:radius 10-80A). Plasma and urine samples were analyzed by high performance size exclusion chromatography (HPSEC) for determination of 0 for Ficoll repeatedly during up to 2 hours.

Results: L-NNAME increased 8 for Ficoll,0 from 2.27 (± 1.30) x 10^-5 to 8.59 (±2.06) x 10^-5 (n=6; p<0.05) in 15 min. Tempol (n=6) completely abrogated these increases in glomerular permeability, the 0 Ficoll,0 being 7.0 (± 2.1) x 10^-5 at 15 min, which was also seen with L-arginine. However, DEA-NONOate did not reverse the permeability effects following L-NNAME.

Conclusions: NO depletion in vivo by L-NNAME caused increases in glomerular permeability, which could be reversed by either the ROS antagonist, tempol, or by L-arginine. By contrast, the potent NO-donor, DEA-NONOate, did not ameliorate the permeability effects of L-NNAME. It is concluded that moderate levels of elevated NO production act to protect the permeability of the GFB, whereas very high levels of NO, as provided following systemic DEA-NONOate infusion, may actually be detrimental to the GFB.

Down-Regulation Of Renal Tubular Wnt/beta-Catenin Signaling Induces Tubular Cell Death in Proteinuric Nephropathy

Background: A reduction of aortic Wnt/beta-catenin expression reduces cardiovascular remodeling in experimental hypertension.

Methods: Aortic expression of a dominant-negative beta-catenin was evaluated in male and female C57BL/6 mice.

Conclusions: Reduction of aortic Wnt/beta-catenin expression may contribute to the pathogenesis of proteinuric nephropathy.

SA-PO454

Endothelin-1 Increases Glomerular Permeability in Sickle Cell Mice Malgorzata Kaztn, Chao-Wang Sun, David M. Pollock.

Cardio-Renal Physiology & Medicine, Univ of Alabama at Birmingham, Birmingham, AL; Biochemistry & Molecular Biology, Univ of Alabama at Birmingham, Birmingham, AL.

Background: Sickle cell disease (SCD) leads to nephropathy manifested by increased glomerular permeability (P_g) and albuminuria/proteinuria. The endothelin-derivated peptide, endothelin-1 (ET-1), with its powerful vasoconstrictor and pro-inflammatory effects mediated primarily through ET, receptors, is elevated in SCD patients and may contribute to the development of sickle cell glomerulopathy. Therefore, the aim of the study was to determine whether ET-1 contributes to increased glomerular permeability to albumin in SCD and if ET, receptors blockers prevent ET, induced glomerulosclerosis in sickle cell mice. Furthermore, because our preliminary studies showed sex differences in the vasoconstrictor response to ET-1 in sickle cell mice the study was designed to determine if sex differences exist in this response.

Methods: Experiments utilized 12 week old humanized sickle cell mice (HbSS) and non-genetically modified (HBA) mice recently developed by the Tooney’s lab. Ambigrams (ETa antagonist), A-182086 (ETb antagonist) or vehicle was administered via drinking water (10mg/kg/day) for 2 weeks. Glomeruli were isolated for direct permeability measurements as a volume response of glomerular capillaries to an onecessory medium generated by defined concentrations of albumin.

Results: P_g was significantly higher in glomeruli from sickle mice (both in males and females) than control mice (0.50±0.07 and 0.47±0.06 vs. 0.13±0.02 and 0.10±0.02, respectively). Ambigrams treatment significantly reduced the elevated P_g in glomeruli from male (0.24±0.05 vs. 0.50±0.07) and female (0.20±0.03 vs. 0.47±0.06) HbSS mice. ET, receptors antagonism with A-182086 also significantly decreased the P_g in glomeruli from male (0.28±0.06 vs. 0.50±0.07) and female (0.24±0.03 vs. 0.47±0.06) HbSS mice. Treatment with both antagonists did not alter P_g in HBA mice.

Conclusions: These data suggest that endothelin-1 mediated permeability to ET-1 may play an important role in the development of sickle cell nephropathy and support the use of chronic ET, antagonism as a prospective treatment for sickle cell nephropathy.

SA-PO455

Longitudinal Transcutaneous Glomerular Filtration Rate (GFR) After Uninephrectomy (UNx) in Mice Hiroshi Kojima, Jonathan Street, Ana C. Souza, Peter S.T. Yuen, Robert A. Star.

Renal Diagnostics and Therapeutics Unit, NIDDK, NIH, Bethesda, MD.

Background: Glomerular filtration rate is a universally accepted measure of global kidney function. Serum filtration markers such as serum creatinine, BUN, or cystatin C have been used in confirming a renal insult, and measuring clearance of “inert” markers requires blood and urine collection, which can be cumbersome in unstable, oliguric patients, and small animals. A non-invasive method using fluorescently-labeled Sinistrin and a miniaturized fluorescence detector may non-invasively detect plasma disappearance in conscious mice. To determine if the assumptions for plasma disappearance are met, we tested the method in a classic mouse uninephrectomy model with a predictable change (50%) then slow recovery.

Methods: Young male CD-1 mice underwent left UNx at Day 0. Transcutaneous measurement of GFR was performed every 3-4 days until Day 18. Under isoflurane anesthesia, a depilatory was applied to the back, and a miniaturized fluorescence detector (NIC-Kidney; Mannheim Pharma & Diagnostics GmbH, Mannheim, Germany) was fixed on the exposed skin using a double-sided adhesive patch. After background signal was obtained, FITC-Sinistrin was injected intravenously. Data acquisition lasted 60 min. Data analysis consisted of tracking the fluorescence signal during the time of measurement.

Results: All fluorescence measurements decayed as a single exponential, consistent with a single, stable component model and a stable GFR during the time of measurement.

Conclusions: FITC-Sinistrin plasma disappearance follows single component kinetics at baseline and after UNx, allowing calculation of GFR by single pool kinetics. This technique can easily detect renal hyperfiltration early after UNx.

SA-PO456

CHOP Deficiency Impedes Progressive CKD by Inhibiting Proteinuria Zahna Mohammed-Ali, Chao La, Jeffrey G. Dickhout.

Health Care Unit; McMaster University, Hamilton, Ontario, Canada; St. Joseph's Healthcare Hamilton, Hamilton, Ontario, Canada.

Background: Endoplasmic reticulum (ER) stress occurs due to the accumulation of misfolded proteins in the ER and is associated with proteinuria in chronic kidney disease (CKD). CHOP (GADD153/DDIT3) is a pro-apoptotic transcription factor that is upregulated during ER stress. Increased expression of CHOP has been shown in biopsies of patients with membranous nephropathy and membranoproliferative glomerulonephritis. CHOP deficiency protects against oxidative stress, albuminuria and inflammation in mouse models of acute kidney injury and diabetic nephropathy. Therefore, we hypothesized that CHOP deficiency would influence the development of CKD.

Methods: Our model of CKD combines a uninephrectomy and subcutaneous implantation of a slow-release doxycycline sponge (DOCA) pellet and genetic deficiency of CHOP (Ang II osmotic infusion pump in C57BL/6 male mice. Mice were also given 1% sodium

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

728A
choline in their drinking water. Mice with total CHOP knockdown were used to test the role of CHOP in exacerbation of LD, measured by in-situ analysis. We sought to demonstrate an improvement in anemia and renal fibrosis using our PHD2 ASO. We developed an adenine-induced mouse model of CKD that demonstrates severe anemia and interstitial fibrosis. After simultaneous administration of EPO mRNA expression in the kidney interstitial fibroblasts by RT-PCR (~550-fold) and by in-situ analysis. We sought to demonstrate an improvement in anemia and renal fibrosis using our PHD2 ASO. We developed an adenine-induced mouse model of CKD that demonstrates severe anemia and interstitial fibrosis. After simultaneous administration of PHD2 ASO group. Histological analysis showed improved fibrosis based on reduced Sirius Red staining. There were also improvements in anemia based on whole blood analysis of hemoglobin and hematocrit levels.

Conclusions: These data indicate that reducing PHD2 with ASOs may be a viable option for treating CKD patients with severe anemia and renal fibrosis.

SA-PO461 Fibronectin Assembly Mediates KIM-1-Induced TFGB-dependent Kidney Fibrosis Venkata Sabbisetty, Cuiyun Xin, Sandhya Padmanabhan, Bhargavi Chandrasekar, Akinwande A. Akinfolarin, Joseph V. Bonventre.

Background: Cell-extracellular matrix interactions play a crucial role in kidney fibrosis. Localized activation of TFGB is critical for excretion of its cellular effects. Kidney Injury Molecule-1 (KIM-1) is upregulated in degenerated proximal tubular cells (PTECs) following kidney injury and has been shown to induce kidney fibrosis in vivo. Here, we report that KIM-1 mediates fibrosis by up-regulating the critical components of the TFGB activation pathway including fibronectin and corresponding integrin receptors in vivo. In support of this conclusion, blocking fibronectin assembly reduces kidney fibrosis.

Methods: Full-length KIM-1 or the KIM-1 mutant was overexpressed in LLC-PK1 and HEK cell lines and fibronectin and integrin levels were evaluated. Active TGFβ was measured using a bioassay. Mice were subjected to ischemia-reperfusion injury (IR) or

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underlines represents presenting author.

729A
unilateral ureteral obstruction (UUO). In the UUO model, mice were treated with fibronectin blocking peptide or control peptide to evaluate the effects of inhibition of fibronectin assembly on fibrosis.

Results: KIM-1 expressing PTECs produced significantly increased levels of fibronectin and fibronectin receptors. These increases were abrogated when phosphotyrosine-350 of KIM-1 was mutated or KIM-1 was deleted. KIM-1 expressing cells displayed higher levels of total and activated TGFβ as compared to control cells. In vivo, KIM-1 expressing tubular epithelial cells were characterized by high fibronectin staining after ischemia/reperfusion injury or UUO. Blocking fibronectin assembly with a blocking peptide decreased fibrosis in the UUO model.

Conclusions: KIM-1 induced localized activation of TGFβ through up-regulation of TGFβ, fibronectin and integrin receptors. Blocking fibronectin assembly reduced fibrosis in response to UUO in vivo. This mechanism can contribute to the fibrosis associated with chronic expression of KIM-1 and may be a common feature of chronic kidney disease. Blocking fibronectin assembly may be therapeutically beneficial to prevent or reduce kidney fibrosis.

Complement Modulation by C1-Inhibitor Hampered Pericyte (PC) to Myofibroblasts Trans-Differentiation (TDF) and Vascular Rarefaction in Ischemia/Reperfusion Injury (I/R) and Chronic Kidney Disease. Giuseppe Castellano, Rossana Franzin, Chiara Divella, Alessandra Stasi, Angelica Intini, Margherita Gigante, Marco Fiorentino, G. Lucarelli, M. Battaglia, Giuseppe Grandalino, Loreto Gesualdo, Nephrology and Urology Unit, Univ of Bari; Dept Medical and Surgical Science, Univ of Foggia, Italy.

Background: Preservation of endothelial–Pericyte (PC) interaction is critical to counteract renal fibrosis during chronic kidney disease; no data are available on PC involvement in AKI. We investigated whether Complement might modulate PC activation in I/R.

Methods: Ten pigs underwent to 30 min of renal warm ischemia followed by 24h of R. Five pigs were treated with C1-Inhibitor (C1-Inh). Biopsies were analyzed by IHC and IF for PDGFRβ, Caspase3 and aSMA. FACS, AnnV-IP and IF were performed on human kidneys trans-planted with normal or ischemic injury organs.

Results: I/R injury induced PC to myofibroblasts TDF by reducing PDGFRβ without PC apoptosis (PDGFRβ/Caspase3) in vivo. TDF was accompanied by a significant decrease in capillary lumen area (%T0:11.3 ± 2.1; T24:3.9 ± 2.3; p=0.05) and aSMA up regulation (%Bas: 15.2 ± 3.6; C5a:3.6 ± 2.3; TGFβ2:08.1 ± 4.0 p=0.05) and remodeling of aSMA-stress fibers, with contractile phenotype. Finally, C5a significantly up-regulated Id2 factor in PC, which is pivotal for cellular de-differentiation.

Conclusions: Complement might contribute to PC to Myofibroblasts TDF in I/R injury, leading to vascular rarefaction and renal fibrosis. C1-Inh may be an effective strategy to prevent kidney development in transplanted kidney.

Establishment of a Novel Mouse Strain to Trace Erythropoietin Producing Cells at Desired Time Points. Keiichi Kaneko, Motoko Yanagita. Nephrology, Kyoto Univ, Kyoto, Japan.

Background: We previously reported that resident fibroblasts including Erythropoietin (Epo) producing cells were increased with myelin protein zero-Cre and transdifferentiated into myofibroblasts during fibrosis with concomitant loss of Epo production. However, the previous method could not distinguish between Epo-producing cells and other resident fibroblasts and the behavior of Epo-producing cells remains unclear. Recently, Epo-Cre mice were generated which enabled the lineage tracing of Epo-producing cells with the history of Epo production. Using the mouse strain, the transdifferentiation of Epo-Cre labeled cells into myofibroblasts during fibrosis has been demonstrated. Because Epo-Cre labeled cells matched the cells with the history of Epo production from fetal period to adult life, we tried to narrow down the period of labeling and to trace the certain cell population with the current Epo-producing ability at desired time points.

Methods: We generated a novel mouse strain in which inducible form of Cre is knocked-in at the locus of Epo gene (Epo-CreERT2) mice. Epo-CreERT2 mice were crossed with R26tdTomato mice. Tamoxifen was administered to activate inducible form of Cre, Epo-CreERT2.

Results: Epo-CreERT2 labeled cells were located in the interstitium of the cortical and corticomedullary region of the kidney, and the numbers were increased with the induction of anemia. Epo-CreERT2 labeled cells expressed PDGFRβ and CD73, suggesting that Epo-CreERT2 labeled cells are resident fibroblasts and are likely to be Epo-producing cells. After unilateral ureteral obstruction (UUO), Epo-CreERT2 labeled cells transdifferentiated into myofibroblasts. The ratio of Epo-CreERT2 labeled cells transdifferentiated into myofibroblasts was 68 % at day 3 and 86 % at day 5 of UUO. The numbers of Epo-CreERT2 labeled cells were increased 1.9-fold at day 3 and 2.1-fold at day 5 of UUO.

Conclusions: We generated a novel mouse strain and succeeded in labeling Epo-producing cells at desired time points. We demonstrated that Epo-producing cells transdifferentiated into myofibroblasts and were increased in fibrotic kidney. We aim to elucidate the mechanism of injury and repair of Epo-producing cells with this strain, Epo-CreERT2 mice.

SA-PO464

Role of PI3 Kinase γ in Recruitment of Bone Marrow-Derived Fibroblasts and Development of Renal Fibrosis. Yunguo Wu, Hua Liang, William E. Mitch, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a prominent pathological feature of chronic kidney disease contributing to progressive loss of renal function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis remains debatable. Recent studies have shown bone marrow-derived fibroblasts contributed significantly to the pathogenesis of renal fibrosis. We have previously shown that CNXCL16 plays a critical role in recruiting bone marrow-derived fibroblasts into kidney. However, the signaling mechanisms are not known. In the present study, we examined the role of PI3 kinase γ (PI3Kγ) in the recruitment of bone marrow-derived fibroblasts and development of renal fibrosis.

Methods: We examined the role of PI3Kγ in the recruitment of bone marrow-derived fibroblasts and the development of fibrosis using a mouse model of folic acid-induced nephropathy in wild-type (WT) and PI3Kγ-KO mice in vivo and migration of cultured bone marrow monocytes treated with CNXCL16 in vitro.

Results: Compared with WT mice, PI3K-KO mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and displayed significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFRβ in the kidney 2 weeks after folic acid treatment. Furthermore, PI3K-KO mice exhibited fewer α-smooth muscle actin (α-SMA) positive myofibroblasts and expressed less α-SMA protein in the kidney following folic acid treatment. Consistent with these findings, PI3Kγ-deficiency significantly reduced total collagen deposition and suppressed expression of extracellular matrix proteins (collagen I and fibronectin). In cultured mouse monocytes, CNXCL16 activated PI3Kγ and induced the chemotactic migration, which was abolished in the absence of PI3Kγ.

Conclusions: These data indicate that PI3Kγ plays a pivotal role in recruiting bone marrow-derived fibroblasts into the kidney and developing renal fibrosis. Inhibition of PI3Kγ signaling may represent a novel therapeutic strategy for chronic kidney disease.

SA-PO465

Inhibition of K-Ras prior to Induction of Acute Kidney Reduces Long-Term Progression to Chronic Kidney Disease in a Murine Model of Aristotle Acid Nephropathy. Sujit Kumar Saha, Bruce M. Hendry, Claire C. Sharpe. Dept of Renal Sciences, King’s College London, London, United Kingdom.

Background: Acute kidney injury (AKI) is recognised to be an early harbinger of chronic kidney disease (CKD). We have previously shown that K-Ras expression and activation are up-regulated in renal fibrosis and reducing K-Ras expression can prevent scarring. In this study our aim was to test whether transiently reducing K-Ras expression in the peri-AKI period can reduce progression to CKD.

Methods: CD1 mice received i.p. injections of either 3.5 mg/kg Aristotle Acid (AA) or normal saline on Day 1 and on Day 5. A treatment group were also given a single

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

730A
subcutaneous injection of 100mg of mouse K-Ras antisense oligonucleotide (ASO) 2 days prior to the first AA injection. A vehicle group was given a subcutaneous injection of saline 2 days prior to the first AA injection. Renal function at multiple time points was assessed through a blood urea nitrogen (BUN) assay. The degree of fibrosis was ascertained through Picrosirius Red (PSR) and Masson Trichrome (MT) staining to quantify collagen deposition. The expression of K-Ras was determined by Q-PCR.

Results: CD1 mice given AA suffered an AKI with a 4.6 fold rise in BUN at Day 12 that returned to baseline by Day 30. However by Day 80, the AA mice had a 57% higher BUN than control mice, demonstrating later onset CKD. AA mice treated with mouse K-Ras ASO pre-AKI suffered a similar AKI but BUN at Day 80 was 48% lower than untreated AA mice and was comparable with healthy controls. PSR and MT staining demonstrated a 5 fold increase in collagen deposition by Day 80 in AA mice which was reduced by 30% in ASO-treated animals. K-Ras expression was consistently unregulated in the untreated AA mice throughout the chronic phase but the transient treatment with ASO prior to the acute injury resulted in normalisation of K-Ras mRNA by Day 80.

Conclusions: Transiently reducing K-Ras expression in the peri-AKI period in a murine model of aristolochic acid nephropathy reduces downstream fibrosis and prevents the decline in renal excretory function. Targeting K-Ras may provide a future therapeutic option for preventing renal fibrosis and CKD following AKI.

SA-PO466

Non-Osmotic Sodium Storage Affects Glomerular Endothelial Cell Permeability

Rik Hj Olde Engebrink,1 Peter Ochodnicky,2 Simon C. Satchell,3 Ed van Bavel,4 Liffert Vogt,4 Nephrology, AMC, Amsterdam, Netherlands; 1Pathology, AMC, Amsterdam, Netherlands; 2Renal Unit, Univ of Bristol, Bristol, United Kingdom; 3Biomedical Engineering and Physics, AMC, Amsterdam, Netherlands.

Background: High dietary NaCl intake may affect glomerular permeability via pressure effects or via direct effects. In this respect, the Na+ buffering capacity of heparan sulfate glycosaminoglycans (HS-GAGs) in the endothelial surface layer (ESL) is of interest. The objective of this study is to investigate the interplay between Na+ and HS-GAGs and their effects on glomerular permeability.

Methods: Human glomerular endothelial cell (GeCel) permeability to macromolecules was tested by measuring FITC-labeled albumin passage. Electrical resistance of a GeCel monolayer, reflecting ESL Na+ content, was assessed with the ECIS® system at 4000 Hz. We studied the expression of gene coding enzymes involved in heparan sulfate (EXT-1, EXT-2) and chondroitin sulfate (CHSY) synthesis using real-time qPCR. Measurements were performed at different NaCl concentrations (125/150/175 mM ± HS degradation enzyme heparinase, 0.7 U/mL). We added mannitol to keep osmolality constant.

Results: Relative to 125 mM, EXT-1 and EXT-2 expression was higher after stimulation with 150 mM NaCl while CHSY expression remained unchanged (Fig A). Albumin permeability decreased after 2 and 5-d stimulation with 150 and 175 mM NaCl (Fig B). ECIS experiments showed that NaCl addition led to a concentration-dependent decrease in resistance (Fig C). NaCl did not alter resistance in the absence of cells. Heparinase increased resistance when added to 125 and 150 mM NaCl (Fig D). Mannitol did not alter permeability or resistance.

Conclusions: High NaCl stimulates HS-GAG synthesis of the glomerular endothelium, which may facilitate more Na+ binding. Subsequent higher ESL Na+ content may seal the glomerular barrier as suggested by both lower permeability and lower resistance.

Funding: Netherlands Organization for Scientific Research, Koningin Wilhelmina’s Stichting, Flemish government.

SA-PO467

Precision-Cut Human Kidney Slices as a Model to Elucidate the Pathogenesis of Renal Fibrosis

Elisabeth G.D. Stribos,1,2 Therut Luangmongkon,2 Annemarie Leilved,4 Igle J. de Jong,4 Willem Van Son,3 Jan-luik Hillebrands,3 Marc Maj Seelen,2 Harry Van Goor,2 Peter Olinga,4 Henricus A.M. Mutua,3 1Dept of Internal Medicine, Div of Nephrology, Univ of Groningen, Groningen, Netherlands; 2Dept of Pharmaceutical Technology and Biopharmacy, Univ of Groningen, Groningen, Netherlands; 3Dept of Pathology and Medical Biology, Div of Pathology, Univ of Groningen, Univ Medical Center Groningen, Groningen, Netherlands; 4Dept of Urology, Univ Medical Center Groningen, Groningen, Netherlands.

Background: Renal fibrosis is a major problem in chronic kidney disease and chronic transplant failure. Unraveling the mechanisms underlying the initiation and progression of renal fibrosis is of key importance to identify new therapeutic targets. However, suitable human in vitro models for renal fibrosis are lacking. Here, we explored precision-cut human kidney slices (PCKS) as a model for human renal disease.

Methods: PCKS were prepared from human cortical kidney tissue obtained from tumor-nephrectomies and cultured up to 96th. Morphology, cell viability (ATP levels, LDH leakage) and metabolic functionality (UDP-galactose transferase and transporter activity) were determined to assess PCKS integrity. Furthermore, inflammation- and fibrosis-related gene expression was characterized. To validate the model, renal fibrogenesis was induced using transforming-growth factor b1 (TGF-b1).

Results: Preparation of PCKS induced an inflammatory tissue response, while long-term incubation (96h) induced fibrogenesis as seen by increased expression of collagen type 1a1 (COL1A1) and fibroactin (FN1). Importantly, PCKS remained functional for more than 48h as evidenced by active glucuronidation and phenolsulphonphthalein uptake. Moreover, treatment with TGF-b1 augmented fibrosis, as illustrated by at least 1.8-fold increase of multiple fibrosis markers including COL1A1, FN1, plasmagmin activator inhibitor-1 and a-smooth muscle actin.

Conclusions: Regardless of extended characterization, PCKS appear to be an excellent model to investigate renal pathology e.g. renal fibrosis. Moreover, the human origin of PCKS makes this ex vivo model very suitable for translational research.

SA-PO468

Centrality of Bone Marrow-Derived Fibroblasts in Magnetic Resonance Imaging Contrast-Induced Systemic Fibrosis

Viktor Dreul,1 Catherine Do,2 Chunyan Tan,3 Brent Wagner,4 1South Texas Veterans Health Care System, San Antonio, TX; 2Dept of Medicine, Univ of Texas Health Science Center at San Antonio, San Antonio, TX.

Background: So-called “nephrogenic” systemic fibrosis is a ghastly sclerotic condition that occurs only in conditions of low renal function (acute kidney injury or severe chronic kidney disease) and gadolinium-based contrast exposure. Nothing is known about the pathobiology of this disease.

Methods: Experiments were designed to test if bone marrow from magnetic resonance imaging contrast–treated donors is stimulated to induce fibrosis, and to what degree these cells can be primed to home to affected organs. Male Fisher 344 rats that express human placential alkaline phosphatase (hPLAP) were divided into two groups, one served as control, the other treated with the chemotherapeutic-grade gadodiamide (Omniscan, General Electric) 2.5 mol/kg IP daily, aiming for 20 doses over 4 weeks or evidence of systemic fibrosis. These recipients were divided into control and contrast–treated groups.

Results: Regardless of bone marrow source, contrast–treated recipients demonstrated severe skin fibrosis. Fibrocentin was similarly increased by immunofluorescence and immunoblot, but a synergistic effect evident in recipients of contrast–treated animals. The fibroblast precursor (“fibrocyte”) markers, CD45RO and procollagen I, were increased in the contrast–treated recipients. Recipients of marrow from contrast–treated donors demonstrated greater dermal CD34 without histologic evidence of fibrosis.

Conclusions: Bone marrow from contrast–treated donors did not induce systemic fibrosis, therefore target organs (such as the skin) appear central to the process. However, given the synergistic effect, “primed” fibroblast precursors do have an increased affinity for diseased lesions. Clinically, this may explain why repeat administrations of gadolinium–based contrast correlate with chronicity.

SA-PO469

SOSC2 Plays No Major Role in the Mouse Renmant Kidney Model of Fibrosis

Yael Segev,1 Muhamed Assadi,2 Ralph Rabkin,2 Daniel Landau,1 Microbiology and Immunology, Ben Gurion Univ, Beer Sheva, Israel; 1Research Inst, Veterans Administration Hospital, Palo Alto, CA; 2Medicine, Stanford Univ, CA; 1Pediatrics B, Schneider Children’s Medical Center, Petchach Tkva, Israel.

Background: SOSC2, a key negative regulator of GH stimulated JAK/STAT5 signaling, is overexpressed in muscle, bone and liver of uremic rats and is presumably a cause of uremic GH resistance and growth retardation. SOSC2 deficient mice are GH sensitive, exhibit gigantism and accumulate collagen in skin, trachea and lungs (Reiser K et al, AJP Renal 2004). Since GH overexpression in mice causes renal fibrosis, we tested whether SOSC2 deletion, by decreasing GH sensitivity, accelerates renal kidney fibrosis.

Conclusions: Mice deficient in SOSC2 did not exhibit any overt phenotype relative to wild-type controls. Collectively, these data suggest that SOSC2 plays a minor role in renal fibrosis in the mouse.

Funding: [Grant Number]
Methods: Four-week-old SOCS2 deficient mice (high growth - HG strain) and normal wild-type mice (N) underwent 5/6 nephrectomy (CRF) or sham operation (SO), forming 4 groups: SO-N, SO-HG, CRF-N, CRF-HG. Mice were sacrificed after 3 weeks. IP bovine GH was given within 30 min before sacrifice.

Results: Weight gain was reduced significantly in CRF-N versus SO-N. In contrast, growth was accelerated significantly versus both CRF-N and SO-N. Kidney SOCS2 mRNA, absent in HG mice, was significantly increased in CRF-N versus SO-N. The degree of renal insufficiency was similar in CRF-N and CRF-HG mice. TGF-β and type IV collagen mRNA levels were increased to the same extent in SO-HG, CRF-HG and CRF-N Vs SO-N. Renal GH receptor mRNA levels were decreased in both CRF groups. GH stimulated STAT5 phosphorylation increased in SO-HG Vs SO-N, decreased in CRF-N Vs SO-N and increased in CRF-HG Vs CRF-N. IL6, SOCS3 mRNA and phospho-STAT3 levels increased similarly in both CRF groups Vs SO controls.

Conclusions: STAT5 signaling is depressed in remnant kidneys of CRF-N mice but is increased in non-uremic and uremic SOCS2 deficient mutants. Levels of fibrosis-related genes rose similarly in CRF-HG and CRF-N, despite absence of SOCS2 expression in CRF-HG mice. This suggests that SOCS2 does not play a central role in Remnant kidney fibrosis. On the other hand, IL6 and its mediators phospho-STAT3 and SOCS3, were elevated in CRF-N and CRF-HG mice suggesting that inflammation may play a role in remnant kidney fibrosis.

Funding: Veterans Administration Support, Government Support - Non-U.S.

SA-PO470
β-arrestin2, Downstream of Angiotensin II Type I Receptor Biased Signaling Pathway, Plays an Important Role in Renal Fibrosis

Yan-Dao Wang, Chen Yu. Dep't of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.

Background: Expect G protein signaling pathway, it is now considered that there is also a β-arrestin pathway in the downstream of G protein-coupled receptors (GPCRs); angiotensin II type 1 receptor (AT1R) belongs to GPCRs and angiotensin II (AngII) is a bimodal stimulus with G protein pathway and β-arrestin pathway; it is important to known which downstream pathway involving in AngII-AT1R induced renal fibrosis. In this study, we used β-arrestin biased agonist SII ([1-sar, 4, 8 iel]-angiotensin II) to study β-arrestin pathway in renal fibrosis.

Methods: The model of unilateral ureteral obstruction (UUO) was used in vivo, and rat kidney fibroblast cell line (NRK-49F) was treated with SII in vitro. Results: 1) SII induced the binding of β-arrestin2 with AT1R, not β-arrestin1. 2) SII increased the synthesis of collagen I and fibronectin in NRK-49F in NRK-49F. Transfection of β-arrestin2 siRNA abolished the effect of SII on the accumulation of ECM. Overexpression of β-arrestin2 increased SII-induced ERK1/2 phosphorylation. 5) The mRNA and protein levels of β-arrestin2 were significantly upregulated in the UUO model.

Conclusions: Our results suggested that AT1R downstream β-arrestin2 pathway, not β-arrestin1, might play a key role in renal fibrosis by forming complexes of β-arrestin2 and AT1R, inducing ERK1/2 phosphorylation and increasing ECM accumulation.

Deletion of ATR, a Master Molecule of DNA Damage Response, in the Proximal Tubule Exacerbates Kidney Injury and Increases Fibrosis

Sciji Kishi,1,2 Takaharu Ichimura,1,2 Ryutir Morizane,1,2 Joseph V. Bonventre,1,2,3
1Renal Div, Dept of Medicine, Brigham and Women’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Harvard Stem Cell Inst, Cambridge, MA.

Background: Impaired response of cells to DNA damage can cause cellular senescence. We have previously implicated the DNA damage response of renal proximal tubule cell (RPTC) in progressive kidney injury and fibrosis. The purpose of this study was to investigate the role of ATRaxia telangiectasia and Rad3-related (ATR), a master controller of the DNA damage checkpoint, in kidney injury and fibrosis.

Methods: RPTC-specific conditional ATR knockout (ATR−/−) mice were generated by crossing ATRfloxed (ATRflx) mice , ATR−/− mice and tamoxifen-inducible (SCL34a1-CreERT2) mice. We evaluated the role of ATR in susceptibility to cisplatin nephrotoxicity, unilateral ureteral obstruction (UUO) and renal ischemia/reperfusion injury (IRI).

Results: Four days after cisplatin injection, ATR−/− mice had increased kidney histological damage, increased Kidney Injury Molecule-1 (KIM-1) expression and decreased renal function compared with wild-type mice. Within the first 5 days, 34% of ATR−/− mice died, while no WT mice died. Increased DNA damage and the number of apoptotic cells were also found in ATR−/− mice. At 7 days after UUO, when compared with wild-type mice, ATR−/− mice exhibited increased kidney histological damage, KIM-1 expression, DNA damage, and number of apoptotic cells. They also exhibited increased expression of fibrosis-related genes and increased kidney fibrosis. After IRI there was worse kidney function on day 3 and day 7 in ATR−/− mice and increased interstitial fibrosis 4 weeks after IRI. Expression of p21, a marker of senescence, was significantly increased in ATR−/− mice in each of the three models of injury.

Conclusions: ATR activation in the RPTC represents a protective response in acute and chronic kidney disease of various etiologies.

Role of Heparanase in Renal Epithelial-Mesenchymal Transition Induced by Ischemia/Reperfusion

Valentina Masola,1 Gianluigi Zaza,1 Giovanni Gambero,2 Maurizio Onisto,3 Gloria Bellin,1,2 Gisella Vischini,2 Iyad Khamaysi,4 Antonio Lupo,1 Israel Vlodavsky,2 Zaid Abassi.1 Renal Unit, Dept of Medicine, Verona, Italy; 2Columbia-Gemelli Hospital Catholic Univ, Roma, Italy; 3University of Padova, Padova, Italy; 4Rambam Medical Center, Israel; 5Technion, Israel.

Background: Ischemia/reperfusion (IR) activates epithelial-mesenchymal transition (EMT) of tubular cells, thus leading to organ fibrosis. Heparanase (HPSE) controls the EMT induced by FGFR2 and TGF-β. The aim of this study was to evaluate whether HPSE modulates the EMT induced by I/R.

Methods: Tubular cells (HK-2) were established and silence HPSE were subjected to 24h of hypoxia and 24h of reoxygenation. The cells were also treated with SST0001 (Sigma-Tau Research Switzerland SA), an inhibitor of HPSE. The I/R injury has been reproduced in vivo by clamping the renal arteries for 30 min in transgenic mice over-expressing HPSE (HPSE-tg) and their wt mice. Mice were sacrificed after 48 and 72 h. Gene and protein immunoreactivity of EMT markers (α-SMA, VIM, FN and TGF-β) were evaluated by real-time PCR, WB and IF; histology was assessed by PAS staining.

Results: In vitro, I/R increased the expression of EMT-markers in wt tubular cells but not in HPSE-silenced cells. Similarly, the inhibition of HPSE with SST0001 (Sigma-Tau Research Switzerland SA) in wt cells prevented the development of I/R induced EMT. In vivo, FR induced acute tubular necrosis, which was more profound in HPSE-tg than their wt animals. In wt mice I/R-injury increased glomerular and tubular HPSE expression, but did not induce the EMT-markers. In contrast, in FR HPSE-tg mice remarkably induced the expression of EMT-markers already after 72h.

Conclusions: HPSE is a crucial factor for the development of EMT induced by I/R. HPSE inhibition therefore constitute a possible therapeutic approach for the prevention of fibrosis in organ transplantation.

Hydrogen Sulfide Deficiency in the Kidney and Brain in Aging Mice

Hak Joo Lee,1,2 Kavitha lakshmi Satara natarajan,4 Meenalakshmi M. Mariappan,1 Denis Feliers,1 Jeffrey L. Barnes,1,2 Goutam Ghosh-Choudhury,1 Christopher G. Kevil,1 Balakumantal S. Kasiyath.1,2 Medicine, MC7882, Univ of Texas Health Science Center, San Antonio, TX; 1Medicine, San Antonio VA Health Care System, San Antonio, TX; 2Pathology, Louisiana State Univ, Shreveport, LA; 3Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background: Hydrogen sulfide (H2S) is constitutively synthesized by cystathionine 7-lyase (CSE) and cystathionine β synthase (CBS). It regulates GFR and tubular transport in the kidney and NMDA receptors in the brain. H2S activates AMPK to inhibit mTORC1 and aborte matrix protein increment in high glucose treated renal cells (Lee, JBC, 2012). Since mTORC1 is implicated in aging, we surveyed the status of H2S relative to mTORC1 in the organs of aging mice.

Methods: C57B6 mice, immunoblotting, H2S generation and content assays, histopathology, cell culture.

Results: The renal and cerebral CSE and CBS expression, H2S content and generation were reduced in old mice (26-32 mos old, n=6 mice) compared to young mice (4-6 mos old, n=8 mice); such changes were not seen in the heart or the skeletal muscle. Old mice showed increase in renal collagen I, III, fibronectin, parenchymal fibrosis, albuminuria, and rise in serum cystatin C. Signaling analysis showed that aging was associated with renal and cerebral activation of Akt, reduced phosphorylation of AMPK, and activation of mTORC1 manifest as increase in the phosphorylation of p70S6 kinase and 4E-BP1. Since insulin has been implicated in the aging process, we examined insulin regulation of CSE and CBS in renal proximal tubular epithelial (MCT) cells; insulin rapidly reduced CSE and CBS expression and decreased H2S generation. Insulin also promoted the synthesis of fibronecrin matrix protein in MCT cells.

Conclusions: Our data show for the first time that the aging kidney and cerebrum share similar changes in H2S metabolism associated with reduced AMPK activity leading
to mTORC1 activation; these pathways could be related to age related changes including fibrosis. Insulin may mediate reduction in CBS, CSE and H2S and contribute to matrix accumulation in the aging kidney.

The Role of Ergothioneine/OCTN1 in CKD

Yusukazu Shinozaki, Kengo Furuchi, Shinji Kitajima, Akinori Haru, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. 1 Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; 2 Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Ishikawa, Japan.

Background: Chronic kidney disease (CKD) is a strong risk factor for end stage kidney disease, and closely complicates with other organ damages. Organic cation transporter 1 (OCTN1) is known as a specific transporter for ergothioneine (ERGO). ERGO is reported to have a strong antioxidant effect. We hypothesized that OCTN1 function and the reduction of ERGO were closely related to the progression of CKD.

Methods: To evaluate the effects of OCTN1 function in CKD, everted sac method was used in CKD model or control mice. Furthermore, the pathological changes and oxidative stress in the kidney of OCTN1-/- or OCTN1+/- were evaluated in the CKD model mice. Moreover, the amount of ERGO in red blood cells was of measured in CKD patients.

Results: The uptake of ERGO in everted sac significantly decreased in CKD mice as compared with control mice. Interstitial fibrosis, that evaluated by azan stain, Sirius red stain, and the content of hydroxyproline of injured kidney, was significantly advanced in OCTN1-/- mice compared with OCTN1+/- mice. Moreover, oxidative stress, that assessed by the number of 4-HNE positive stain cell, was exaggerated in OCTN1-/- CKD mice. Also, oxidative stress, that assessed by the number of 4-HNE positive stain cell, was exaggerated in OCTN1-/- CKD mice. The concentration of ERGO in red blood cells decreased accompanied with CKD stage.

Conclusions: The uptake of ERGO through OCTN1 decreased in CKD. The reduction of ERGO in CKD may participate in oxidative stress and progression of kidney injury.

SIRT2 − MDM2 Signaling Attributes to Fibrobasts Activation but Not Tubular Epithelial-Mesenchymal Transition During Tubulointerstitial Fibrosis

Chun Zhang, Renny You, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Renal resident fibroblasts and tubular epithelial cells are the main sources for extracellular matrix producing fibroblasts during tubulointerstitial fibrosis (TIF). Histone deacetylases (HDAC) inhibitors are shown to have an antimicrobial effect in skin, liver and lung. Sirtuin 2 (SIRT2), belonging to class III HDAC, mediates p53 deacetylation and subsequently sensitizes the sequestration of p53 by MDM2, thereby resulting in a p53 reduction and cell cycle progression. Up to now it is unclear the role of SIRT2 and its downstream targets in renal fibrosis.

Methods: In this study, we used renal fibrosis mouse model induced by unilateral ureteral obstruction (UUO). To investigate the role of SIRT2 and its downstream targets in renal fibrosis, we determined the expression levels of SIRT2 and MDM2, MDM2-Related genes, and inflammatory cytokines in the kidney of control mice and UUO mice model.

Results: Compared with WT, cPLA2 KO animals had a 1.5-2.0 fold increase in mRNA for matrix proteins such as collagen and fibronectin, pro-fibrotic chemokines such as fractalkine, and inflammatory markers such as MCP-1 after UUO as compared with WT animals at 7 days. By flow cytometry, cPLA2 KO animals had significantly more infiltration of CD45+ CD11b positive-Ly6C- negative cells than WT animals after UUO. Additionally, ameliorating the narrow transplant from cPLA2 KO mice into WT mice yielded worsening of histologic fibrosis after UUO as compared with transplants derived from WT animals.

Conclusions: Depletion of cPLA2 and/or its products, predominantly from circulating myeloid cells, contribute to the development of experimental fibrosis using a UUO model in mice.

Delayed Administration of Suramin Attenuates Peritubular Fibrosis in Rats

Na Liu, 1 Shining Zhang, 1, 2 Div of Medicine, Rhode Island Hospital and Alpert Medical School, Providence, RI; 1 Div of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China.

Background: Peritubular fibrosis is one of the most serious complications in patients with peritoneal dialysis (PD) and lacks effective treatments. Our recent study showed that treatment with suramin, a compound that inhibits the interaction of multiple cytokines and growth factors with their receptors, attenuated the development of peritubular fibrosis in a model of peritoneal fibrosis induced by chlorhexidine gluconate (CG). In the current study, we further assessed the therapeutic effect of suramin on the progression of peritubular fibrosis in this model.

Methods: Rats were given a daily intraperitoneal injection of chlorhexidine gluconate (CG) for 3 weeks to induce peritubular fibrosis followed by weekly administration of suramin at 20 mg/kg for an additional one or two weeks before kidneys were harvested.

Results: Delayed administration of suramin attenuated peritoneal membrane thickening and collagen fibril deposition occurred after CG exposure. Suramin was also effective in reducing CG-induced expression of a-smooth muscle actin, fibronectin and collagen I. However, in peritoneal mesothelium, suramin increased phosphorylation of Smad-3, a prominent mediator in transforming growth factor –β signaling, and epidermal growth factor receptor (EGFR), a key tyrosine kinase receptor associated with peritubular fibrosis; suramin treatment blocked their phosphorylation. Similarly, suramin reduced CG-induced phosphorylation of transducer and activator of transcription-3 (STAT3) and extracellular signal-regulated kinase 1 and 2 (ERK1/2), two molecules that mediate profibrotic signal transduction. Moreover, delayed application of suramin suppressed CG-induced expression of several inflammatory cytokines in fibrotic peritoneum.

Conclusions: Our results indicate that suramin treatment inhibits the progression of peritubular fibrosis via a mechanism involved in suppression of TGF-β1 and EGFR signaling pathways, and suggest that suramin holds a therapeutic potential for treatment of peritubular fibrosis.

MDM2 Mediates Tubulointerstitial Fibrosis and Fibroblasts Activation via p53-Independent Pathway

Hua Su, Chen Ye, Chun Zhang. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: MDM2 is an E3 ubiquitin ligase which plays essential roles in regulating cell cycle and mediating inflammatory process. MDM2 exerts its pathophysiological effects via p53 dependent or independent pathway. However whether MDM2 is implicated in tubulointerstitial fibrosis (TIF) and fibroblasts activation is still unknown.

Methods: Patients with TIF (secondary glomerulonephritis and interstitial nephritis were excluded) were enrolled in this study and Unilateral Ureteral Obstruction (UUO) animal model was constructed on B57CL/6 mice. In vitro study cultured tubular epithelial cell line NKR-52E (TEC) and renal fibroblast cell line NKR-49F were employed. The expression of SIRT2 and MDM2 was regulated by either shRNA transfection or transfection with SIRT2 regulating MDM2 plasmid. Moreover, genetic deletion of MDM2 by B6D2F1/J mice.

Results: Underline represents presenting author.

Conclusions: Our current study suggests that besides p53, SIRT2 also could modulate MDM2 during fibroblasts activation and targeting SIRT2-MDM2 signaling may be a potential strategy for the treatment of renal fibrosis.

The Role of ePLA2 in Experimental Renal Fibrosis

John Ross Monford, Allison M.B. Leman, Raphael A. Nennenof, Seth B. Furgerson. Div of Renal Disease and Hypertension, UC School of Medicine, Aurora, CO.

Background: Chronic kidney disease (CKD) is characterized by progressive renal fibrosis involving poorly defined signaling events between renal epithelial cells, fibroblasts, and inflammatory cells. Cytosolic phospholipase A2 (cPLA2) is abundant in renal epithelium and inflammatory cells and serves as the rate-limiting enzyme in eicosanoid production. Since eicosanoids regulate many biological processes important in renal injury, we aimed to investigate the role of cPLA2 in the progression of renal fibrosis in a mouse model.

Methods: Wild type (WT) and cPLA2 globally deficient (KO) C57BL/6 mice were subjected to unilateral ureteral obstruction (UUO). In separate experiments WT mice were lethally irradiated and transplanted with either WT bone marrow or cPLA2-deficient bone marrow. We then performed UUO 5-6 weeks after bone marrow transplantation. After UUO, we collected unfractioned and injured kidneys for RNA, protein, flow cytometry, and histologic analysis, and preparation of single cell suspensions for flow cytometry.

Results: Compared with WT, cPLA2 KO animals had a 1.5-2.0 fold increase in histologic fibrosis at 14 days after UUO. In addition, the KO animals had elevated levels of multiple peritubular fibrosis proteins such as collagen and fibrinectin, pro-fibrotic chemokines such as fractalkine, and inflammatory markers such as MCP-1 after UUO as compared with WT animals at 7 days. By flow cytometry, cPLA2 KO animals had significantly more infiltration of CD45+ CD11b positive-Ly6C- negative cells than WT animals after UUO. Additionally, ameliorating the narrow transplant from cPLA2 KO mice into WT mice yielded worsening of histologic fibrosis after UUO as compared with transplants derived from WT animals.

Conclusions: Depletion of cPLA2 and/or its products, predominantly from circulating myeloid cells, contribute to the development of experimental fibrosis using a UUO model in mice.

Biomarkers of Collagen Type III and V Turnover Can Predict Poor Recovery of Kidney Function in Kidney Transplant Recipients Daniel Guldgude Kringle Rasmussen,1,2 Signe Holm Nielsen,1 Federica Genovese,1 Morten Asser Karsdal,1 Shengqiang Xia,1 Martin Tepel,1 1Nordic Bioscience, Denmark; 2Univ of Southern Denmark, Denmark.

Background: Allograft dysfunction is a common complication after renal transplantation (Tx). The turnover of extracellular matrix proteins, collagen type III and type V, contributes to renal repair mechanisms which accompany allograft dysfunction. Distorted turnover may lead to progressive fibrosis and to loss of renal function. The objective of our study was to evaluate the role of specific collagen type III and type V cleavage fragments for early allograft dysfunction after kidney Tx.

Methods: 171 incident patients, receiving a kidney allograft were enrolled at Odense University Hospital. Plasma and urine samples were collected at the first postoperative days. CVM and Pro-C6 were measured in samples using novel ELISAs. Early allograft dysfunction was defined as eGFR less than 30 ml per minute per 1.73²m² 29 days after Tx. The change of plasma creatinine (RCPC) is the difference between plasma creatinine (pCrea) on the preoperative and first postoperative day divided by preoperative pCrea. Follow-up data on pCrea from a subset of patients was available at 6- and 12 months.

Results: Plasma Pro-C6 (pPro-C6) levels were significantly different in patients who received a deceased donor (DD), living donor (LD) and AB0 incompatible (AB0) donor kidney (p<0.001). pPro-C6 had a negative correlation with eGFR 29 days post-Tx (p<0.0001, r=-0.35) and a positive correlation with plasma CRP (p<0.0001, r=-0.35) and a positive correlation with pCrea at 6- (p=0.0001, r=0.31) and 12 months post-Tx (p<0.0001, r=-0.35). Plasma C3M was associated with plasma CRP (p<0.0001, r=-0.35) and a positive correlation with pCrea at 6- (p=0.0001, r=0.31) and 12 months post-Tx (p<0.0001, r=-0.35).

Conclusions: The study indicates that specific collagen type III and type V cleavage fragments, i.e. CVM and Pro-C6, are both markers for early and late allograft dysfunction after kidney Tx, and reflect the underlying pathophysiology.

Inhibitory Effect of Proximal Tubular Cells-Derived Neuropilin-1 in TGF Beta Signaling Pathway Rui Chen, Xinhe Lin, Symon Ma, Jian-xing Ma, Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma CIty, OK.

Background: Neuropilin-1 (NP-1) is a co-receptor for multiple growth factors including class 3 semaphorins, VEGF, PDGF and TGF-beta, and promotes signaling pathway involved in tumor growth, axonal chemorepellers, angiogenesis and liver fibrosis. In contrast, its function in the renal fibrosis has not been defined.

Methods: Primary renal proximal tubular cells (MRPTCs) were cultured from Npr-1-/- mice. After infection of Npr-1-/-MRPTC cells with adenovirus expressing Cre resulted in NRP1 knockout (Npr-1-/-) in the primary cells. Human proximal tubular cell line HKC-8, MEF cells and ST3-L1 cells were used in this study. TGF-beta-driven promoter transcriptional activity was measured by luciferase assay.

Results: NRP1 was down-regulated by TGF-beta in HKC8 and up-regulated in MEF cells and ST3-L1 cells, suggesting the different regulation mechanisms and functions of NRP-1 between proximal tubular cells and fibroblasts. Over-expression of TGF-beta suppressed TGF-beta-induced phosphorylation of Smad2/3 and expression levels of fibronectin. HKC-8 cells expressing NRP1 showed significantly decreased levels of both TGF-beta receptor I and receptor II. The Nrp-1 cells showed higher TGF-beta-induced Smad2/3 transcriptional activities and expression of fibronectin in Npr-1-/-MRPTCs, compared with control adenovirus-infected Npr-1+/+ MRPTCs.

Conclusions: Proximal tubular cells-derived NRP1 inhibits the TGF beta signaling pathway. NRP1 functions are cell type-specific in the kidney.

The cAMP-epac Pathway Regulates Renal Fibrosis by Promoting Mitochondrial Biogenesis of Tubular Epithelial Cell Lei Jiang, Junwei Yang, Xing Ma, Chunfang Wang, Junwei Yang, Lei Jiang, Junwei Yang, Xing Ma.

Background: Mitochondrial dysfunction is an early event in renal fibrosis, but how it leads to kidney fibrosis and how it is regulated is unclear. In this paper, we investigated the role of cAMP-epac pathway in mitochondrial biogenesis and renal fibrosis.

Methods: Animal models of renal fibrosis were induced by unilateral ureteral obstruction (UUO), chronic Ang II infusion and adriamycin administration. cAMP was given to CD1 mice under UUO by tail vein injection. Rolipram was injected intraperitoneally in CD1 mice under UUO. A primary tubular epithelial cell (PTC) culture from normal CD1 mice renal cortex was used. Rolipram, PKA activator, epac activator, PDE4b siRNA, epac siRNA and epac activator were added to PTCs. ATP kit and NADH kit were used to evaluate the mitochondrial function. Real-time PCR was used to detect mitochondrial DNA (mtDNA) expression. The morphology of mitochondria was observed by electron microscope.

Results: The level of cAMP was decreased in the fibrotic kidney; 2 PDE4b were upregulated obviously in the kidney under UUO, and the epac not PKA were response to fibrosis; 3. Upregulation CAMP by giving PDE inhibitor (rolipram) or CAMP could ameliorate the fibrotic kidney and protect mitochondrial structure; 4. Rolipram could stabilize the mitochondrial function and block the mitochondrial dysfunction induced by UUO; 5.TGF-b1 could induced the downregulation of cAMP in PTC. Increasing the level of cAMP in PTC by rolipram, PDE 4b siRNA, epac activator or epac siRNA could reduce the damage of PTC under TGF-b1 stimulation; 6: Rolipram could restore PGC-1a expression, reduce the mtDNA damage and protect the mitochondrial function and structure of PTC under TGF-b1 stimulation.

Conclusions: cAMP-epac pathway is involved in renal fibrosis. Increased CAMP level blocks the progress of renal fibrosis. CAMP promotes mitochondrial biogenesis and restores mitochondrial structure and function of tubular epithelial cell.
Angiopoietin-1 Deficiency Increases Tubulointerstitial Fibrosis
Krishnapriya Logathan,1 Susan E. Quaggin,2 Marie Jeansson.1 1Dept of Immunology, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden; 2Feinberg School of Medicine, Northwestern Univ, Chicago, IL.

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in aSGMs, fibroblasts, myofibroblasts that produce collagen. Identification of factors that regulate fibroblast proliferation and profibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to fibrosis in wound healing and diabetic nephropathy. Angpt1 acts through the Tie2 tyrosine kinase receptor expressed on endothelial cells and a subset of myofibroblasts. Here, we test the hypothesis that loss of Angpt1-Tie2 signaling destabilizes endothelial cells and results in an increased fibrotic response.

Methods: To investigate the role of Angpt1 in renal fibrosis we utilized Angpt1 conditional knockout mice in experimental models of renal fibrosis, including unilateral ureteral obstruction (UUO) and ischemia/reperfusion injury. Gene and protein regulation of fibrotic markers were evaluated at different time points. We also performed lineage tagging experiments using Tie2-Cre and Lyn-M-Cre to better understand the contribution of Tie2+ cells and macrophages to the myofibroblast population in UUO.

Results: Angpt1 deficient mice showed a significant (~0.1%) increase in fibrotic area 3 days after UUO, 9.7±0.45%, compared to controls, 7.9±0.24%. At the same time point, there was a trend (n.s.) towards an increased number of myofibroblasts per field from 15.4±1.8 in controls to 20.1±1.4 in Angpt1 deficient mice. Ischemia/reperfusion experiments are ongoing. In our lineage tagging experiment we found that 15.1±0.03% of the cells that came from the Tie2-lineage whereas the Lyn-M-lineage contributed minimally, 2.4±0.005%.

Conclusions: Our results suggest that loss of Angpt1-Tie2 signaling increases tubulointerstitial fibrosis as seen by the increased expression of fibrosis markers in Angpt1 deficient mice. Ongoing work is designed to use other models of fibrosis and to elucidate the mechanism(s).

Inter-Alpha-Inhibitor Heavy Chain5 Interactions Control Fibroblast:
Myofibroblast Differentiation

Background: Fibroblasts are central to CKD through their Transforming Growth Factor-β1 (TGF-β1)-triggered phenotypic transition into contractile, α-smooth muscle actin (α-SMA)-positive myofibroblasts. Transition is dependent on an increase in the synthesis and accumulation of a pericellular matrix of hyaluronan (HA) and the HA-dependent α-smooth muscle actin (α-SMA)-positive myofibroblasts. Transition is dependent on an increase in the synthesis of hyaluronan (HA) and the HA-dependent α-smooth muscle actin (α-SMA)-positive fibroblasts. Transition is dependent on an increase in the synthesis of hyaluronan (HA) and the HA-dependent α-smooth muscle actin (α-SMA)-positive fibroblasts. Transition is dependent on an increase in the synthesis of hyaluronan (HA) and the HA-dependent α-smooth muscle actin (α-SMA)-positive fibroblasts.

Methods: Fibroblasts were incubated for 72 h with 10ng/ml TGF-β1 to become myofibroblasts. RT-QPCR was used to assess mRNA levels. siRNA was used to knockdown mRNA expression of α-SMA and SDNPAE/Western Blotting assessed protein levels.

Results: Following TGF-β1 treatment, TSG-6 and α-SMA, had different kinetics of expression. Following TGF-β1 treatment, TSG-6 and α-SMA, had different kinetics of expression. Following TGF-β1 treatment, TSG-6 and α-SMA, had different kinetics of expression.

Conclusions: The mechanisms regulating this effect, however, are not known and are the subject of this study.

Role of IL-4 Receptor α in Bone Marrow-Derived Fibroblast Activation and Renal Fibrosis
Hua Liang, Yuanbo Wu, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a common pathologic lesion in the end stage of various progressive kidney diseases, and is characterized by interstitial inflammation, proliferation of fibroblasts, and accumulation of extracellular matrix collagen (ECM). The IL-4 associated leucine zipper protein (JLP) is a crucial scaffolding protein in signals transduction and molecular trafficking. JLP has been found expressed in mouse tissues of brain, lung, spleen, testis, and kidney. We reported here, for the first time, the effects of JLP deficiency on the progression of renal fibrosis in mice model of unilateral ureteral obstruction (UUO).

Methods: Jp Wild type (jlp+/-) and jlp deficient (jlp-/-) mice were divided into four groups; jlp+/- and jlp-/- sham-operated groups, jlp-/- and jlp-/- unilateral ureteral obstruction (UUO)-operated groups (jlp-/- UUO group and jlp-/- UUO group). Mice were sacrificed at the days of 7 and 14 to evaluate the fibrosis by Masson and H&E staining. The expression of transforming growth factor-β1 (TGF-β1), α-smooth muscle actin (α-SMA), collagen I (COL-I), and collagen III (COL-III) were assayed by immunohistochemistry staining.

Results: One week after the surgery, more collagen deposition was observed in the renal interstitial area in jlp-/- UUO group than in jlp+/- UUO group. Similar to that, the expression of COL-I and COL-III were significantly increased in the kidney cortices in jlp-/- UUO group. Moreover, the kidney volume treated HGF sheet with UUO was different from the kidney volume untreated UUO. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks.

Conclusions: Scaffolding protein JLP is crucial in preventing renal fibrosis through the mechanism of inhibition TGF-β1 expression and myofibroblast induction.

HGF-Producing Cell Sheet Suppress Renal Fibrosis Induced by Unilateral Ureteric Obstruction in a Rat
Masahito Oka,1 Sachiko Sekiya,2 Ryoichi Sakiyama,2 Kosaku Nitta,1 Tatsuya Shimizu.2 1Nephrology, Tokyo Women’s Medical Univ, Shinjuku, Tokyo, Japan; 2Tokyo Women’s Medical Univ Inst of Advanced Biomedical Engineering and Sciences, Shinjuku, Tokyo, Japan.

Background: Tubulointerstitial fibrosis is a typical pathological finding in chronic kidney disease (CKD) and is associated with the progression of renal dysfunction. Recently several studies reported to suppress renal fibrosis by transplantation of cells expressing several growth factor, for example hepatocyte growth factor (HGF) with HGF-producing cell sheet (HGF sheet) transplantation. In this study, we performed to suppress renal fibrosis by local and sustained administration of hepatocyte growth factor (HGF) with HGF-producing cell sheet (HGF sheet) transplantation.

Methods: Human mesothelial cells transplanted human HGF gene by lipofection were cultured on temperature-responsive dishes for 4 days. When temperature reduced, these HGF-producing cells were injected from dishes as cell sheet without enzyme-treated. We performed unilateral ureteric obstruction (UUO) in nude rat and transplanted the HGF sheet immediately. To compare HGF sheet transplantation with intermittent administration of HGF protein, we also injected HGF protein from tail vein every 24 hours for UUO rat (HGF iv). The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks. The kidney volume after operation measured with CT every 7 days for 4 weeks.

Conclusions: Local and sustained HGF administration with HGF sheet strongly suppressed renal fibrosis induced by UUO in a rat. Our results suggested that cell sheet therapy may be a promising strategy for renal disease.

Extracellular Matrix Modules Macrophage Phenotype Profile
Asitk Petrovyan,1 Stefano Da Sacco,2 Sargis Sedrakyan,3 Giuseppe Orlando,3 Matthew Edward Thornton,1 Brendan Grubbs,3 Roger E. De Filippo,1 Laura Perin.1,2 1Univ of Southern California; 2Children’s Hospital Los Angeles; 3Wake Forest School of Medicine.

Background: It is known that macrophages play an important role in kidney damage and resolution. An increase in macrophages phenotype type 1 (M1) is known to promote scarring while an increase in macrophage phenotype type 2 (M2) leads to repair and healing processes. However little is known on how the extracellular matrix (ECM) can direct macrophages toward a specific phenotype acquisition during development, tissue homeostasis and disease.

Methods: Using established protocols we decellularized human adult, healthy, diseased, and fetal kidneys; monocytes were seeded on the different ECMs and macrophage phenotype switch after 24hrs and 5 days was assessed. Macrophage maturation was tested by evaluating release of IL-10, IFN-γ, TNF-α and IL-4 in the culture media along with qRT-PCR and immunocytochemistry to evaluate expression of M1 (CD80 and CD86) and M2 (CD163, CD16, CD14 and CD200R) phenotypes.

Results: We observed that monocytes cultured on ECMs were able to mature into macrophages and present an increase in M1 marker (CD80) on diseased ECM, an increase in M2 markers (CD163, CD200R) on healthy ECM, and an increase in anti-inflammatory M2 marker (CD16) on fetal ECM, after 24hrs. After 5 days of co-culture there was an overall decrease in gene expression for all markers followed by an increase in media secretion of IL-10 on diseased ECM vs healthy ECM. Additionally after 5 days higher number of seeded monocytes appear to adhere onto the adult ECM vs the fetal ECM, IFN-γ, IL-4 or CD64 expression was not detected during 24hrs and 5 days. Monocytes capacity to mature into macrophages was confirmed in vitro by administration of phorbol myristate acetate (PMA) and 1,25-dihydroxy vitamin D3 with LPS.

Conclusions: This in vitro work suggests that the ECM has the capacity to modulate macrophage phenotype and might contribute to disease progression. Additionally, this model may be used to investigate mechanisms of ECM-dependent macrophage activation during renal disease and regeneration.

High Salt Diet Induces Blood Pressure Independent Tubulointerstitial Remodeling and Lymphangiogenesis in Rat Kidney
Yravane S. Himjans, Saleh Yazdani, Gerjan Navis, Jacob van den Born. Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.

Background: In chronic kidney disease (CKD), proteinuria is an important cause of tubular activation and progressive tubulointerstitial damage. It has been shown that high salt intake can aggravate CKD. However, studies on the role of high salt intake on blood pressure (BP) independent effects of sodium on the kidney are scarce. This study aims to test this hypothesis in normal rats, to avoid interference with TI remodeling due to the blood pressure dependent (BP) effects of sodium on the kidney, recent studies suggest there is a BP independent route as well. A HS diet has been shown to store Na+ in the skin and as a result of binding of Na+ to proteoglycans, the influx of macrophages stimulates the secretion of vascular endothelial growth factor C (VEGF-C). Macrophage-derived MIR429 can regulate the synthesis of VEGF-C. We hypothesized that the secretion of vascular endothelial growth factor C (VEGF-C). Macrophage-derived MIR429 can regulate the synthesis of VEGF-C. This study aimed to investigate the role of MIR429 in the progression of kidney disease.

Methods: Blood and urine samples were obtained from 28 patients with CKD. Patients were divided into two groups according to their GFR: GFR<30 and GFR>30. Plasma and urinary microRNAs were determined by qRT-PCR. The expression of MIR429 was also compared between patients with GFR<30 and GFR>30. Additionally, we evaluated the expression of MIR429 in the renal tissues of the patients using immunohistochemistry.

Results: We observed that MIR429 expression was significantly lower in the renal tissues of patients with GFR<30 compared to patients with GFR>30. Additionally, we observed a positive correlation between MIR429 expression and glomerular filtration rate (GFR).

Conclusions: Our study suggests that MIR429 may play a role in the progression of kidney disease and may be a potential therapeutic target for the treatment of CKD.

Application of Human Kidney RNA-seq Expression Quantitative Trait Loci in Chronic Kidney Disease Yi-An Ko, Frank S. Chinga, Nora Ledo, Katalin Susztak. Renal Electrolyte and Hypertension Div; Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.

Background: There are more than 5 million sequence variants in humans. Some genetic variations influence transcript levels and therefore have the ability to interfere with cell and organ function. Such genetic variants are called expression quantitative trait loci (eQTL). The goal of our study was identify such functionally important genetic variants at the genome-wide level.

Methods: This analysis requires the collection of large number of human tissue samples with genotype and transcript level data. Here we used 99 human kidney samples of Central European descent. RNAseq and genotype data was normalized and genotype data was imputed using 1,000 Genome reference data. The association between genotype and transcript levels was performed using Matrix eQTL software and was limited to cis-eQTL where the genetic variant and transcript levels were within 2 megabases distance.

Results: We identified 164 significant target genes (we call these eGenes) and 7590 significant SNPs (eSNPs) that passed the threshold for statistical significance after multiple testing correction using adjusted FDR=0.1. Next we compared variants that influence gene expression in the kidney to those that have been published for other organs using the publicly available Genotype-Tissue Expression project (GTEx). Of the 164 eGenes,103 were common between the kidney and other organs, indicating that there are cell type specific and cell type independent eGenes. Using kidney specific epigenome maps, we found that eSNPs were enriched on kidney specific regulatory elements, including promoters and enhancers. We also found a significantly greater overlap between kidney eGenes and polymorphisms that are associated with CKD development, compared to other tissues (digestive, nervous, immune system diseases, hematological measurement, cardiovascular, and metabolic disease).

Conclusions: We identified transcript level changes associated with genotypic variations. These results can highlight kidney specific regulatory elements and may also help to identify target genes for polymorphisms associated with kidney function related traits.

RNA Sequencing Reveals Tumor Necrosis Factor a Inducible Protein 6 (TNFAIP6) as a Potential Single Gene Classifier of Renal Cell Carcinoma Oxytostin Solbergh Fikrem,1 Christian Beisland,2 Andreas Scherer,2 Arnar Flataberg,3 Trude Skogstrand,1 Lea Landolt,1 Sabine Leh1, Karin Margrethe Hjelle,1 Vidar Beisvang,1 Hans-Peter Marti.1 1 Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; 2 Dept of Cancer Research and Molecular Medicine, Univ of Science and Technology, Trondheim, Norway.

Background: The recent release of a new library preparation kit improved the cDNA library quality from formalin-fixed, paraffin-embedded (FFPE) tissues. In this study we demonstrate the feasibility of next generation sequencing (NGS) of mRNA obtained from FFPE tissues as compared with RNAalert® stored tissues.

Methods: Paired biopsies from tumors and adjacent non-tumorous tissue of 16 patients with ccRCC were either FFPE or stored in RNAalert® (Qiagen) for £1 year. Total RNA was extracted utilizing the miRNeasy FFPE kit and the miRNeasy micro kit (Qiagen). Sequencing libraries were prepared using the TruSeq RNA Access Library Prep Kit® (Illumina).

Results: The average expression of detected transcripts in both FFPE and RNAalert® datasets correlated with R=0.97, and the log2 fold changes of the transcripts which are significantly altered in both datasets (n=1106) correlated with R=0.94. A classifier model with TNFAIP6 was developed for the FFPE dataset with a specificity of 100% and sensitivity of 94%; ROC AUC=0.99 (Fig. 1A); only one normal sample was misclassified due to a small admixture of cancer tissue. Classifier validation in an Affymetrix microarray dataset obtained from GEO (GSE35737) showed TNFAIP6 up-regulation in all tumor stages with both sensitivity and specificity of 94%; ROC AUC=0.98 (Fig. 1B).

Conclusions: Our transcriptome-based dissection method highlights the relatedness of eGFR and kidney fibrosis, but also indicates potential differences in the underlying mechanisms of the two processes.

SA-PO497

Background: APOL1 protein L1 (APOL1) susceptibility alleles have been associated with kidney disease progression and ESRD in hypertensive African Ancestry (AA) populations. We explored whether these APOL1 alleles are associated with blood pressure-related traits in AA enrolled in the electronic medical records and genomics (eMERGE) Network.

Methods: Study populations included the Mount Sinai BioMe biobank discovery(dis) cohort(n=5,213) and three EMR-linked biobank replication(rep) cohorts, including Vanderbilt BioVU (n=2,889), Northwestern NUgene (n=613), and Mount Sinai BioMe (n=1,655). APOL1 single nucleotide polymorphisms (SNPs) rs73885319, rs71875331 and rs60910145 were genotyped in BioMe samples and imputed in BioVU and NUgene samples to determine APOL1 G1 and G2 risk alleles. Longitudinal phenotypic data were extracted from EMRs. Linear regression models & meta-analyses (METAL) were performed with blood pressure-related traits in AA enrolled in the electronic medical records and genomics (eMERGE) Network.

Results: Compared with carriers of [0 or 1] APOL1 G1/G2 risk alleles, carriers of [2] risk alleles were diagnosed with hypertension a mean of 2.5 years (95%CI 1.9-2.9 yrs) earlier in life (P<0.04, P=3x10^-5); Cox hazard; manifest 2.3 mmHg higher systolic BP(SBP) in younger AA (age 20–39) (P<0.07, P=0.04) and were exposed to more antihypertensive medication classes (P=0.11, P=3x10^-5). Carriers of [2] risk alleles were more likely to manifest central left ventricular hypertrophy by echocardiogram (OR(95%CI)=1.521(1.14-2.02), P<0.01) and hemorrhagic cerebrovascular accidents (OR in 1EDC=2.42(1.01-5.86), P=0.05).

Conclusions: APOL1 G1/G2 susceptibility alleles are associated with early-onset, more severe form(s) of hypertension & with hypertensive complications hemorrhage stroke
and concentric LVH independent of kidney function & BMI. These results may warrant a shift from kidney-intrinsic to systemic vascular pathomechanisms attributable to APOL1 G1/G2 susceptibility alleles.

**Apolipoprotein L1 (APOL1) Gene Variants and Incident Proteinuria: Results from the African American Study of Kidney Disease and Hypertension (AASK)**

**Teresa K. Chen,1 Carmen A. Peralta,2 Lawrence J. Appel,2 Michael J. Choi,1 Michelle M. Estrella,1 Nephrology, Johns Hopkins Univ; Nephrology, Univ of California San Francisco; Medicine, Johns Hopkins Univ.

**Background:** APOL1 gene variants are associated with kidney function decline. Whether these same gene variants are associated with incident proteinuria in the context of pre-existing chronic kidney disease (CKD) is unknown.

**Methods:** Using the trial and cohort phases of AASK (median follow-up of 6.8 years, maximum follow-up of 12.2 years), we evaluated participants who had hypertension-attributed CKD and who did not have proteinuria at baseline. Cox proportional hazards models were used to estimate the relative hazard of incident proteinuria (defined as a doubling of urine protein-to-creatinine ratio and UP/Cr >0.22), comparing APOL1 high-risk genotype (2 risk alleles vs. low-risk genotypes (0-1 risk alleles). We adjusted for age, gender, baseline GFR, percentage of European ancestry, randomized blood pressure goal (usual vs. low), and randomized blood pressure drug (ramipril vs. metoprolol vs. amiodipine). Effect modification by randomized trial interventions and dietary sodium intake (as estimated by 24-hour sodium urine) was assessed.

**Results:** Of the 480 participants included in our study, 17% (n=82) had the APOL1 high-risk genotype. Individuals with the APOL1 high-risk genotype were 83% more likely to develop incident proteinuria compared to those with the low-risk genotypes (adjusted HR: 1.83; 95% CI: 1.36 to 2.47; p<0.001). The association between APOL1 and incident proteinuria was not modified by randomized blood pressure goal, randomized blood pressure drug, or dietary sodium intake (p-interaction=0.05 for each).

**Conclusions:** Among African-Americans with CKD attributed to hypertension but without baseline proteinuria, high-risk variants of APOL1 are associated with a greater risk of incident proteinuria.

**Role of Klotho Genetic Polymorphisms in Salt-Sensitivity: A Link Between Salt and Aging?**

**Chiara Lanzani, Lorena Citterio, Elena Brioni, Simona Delli Carpini, Marco Simonini, Guido Gatti, Elisabetta Messaggio, Paolo Manunta. Nephrology and Hypertension, San Raffaele Hospital, Milan, Italy.

**Background:** Previous data in transgenic mice showed that one-half klotho deficiency resulted in extensive premature aging, increased salt sensitivity and caused salt-sensitive hypertension. Recent gene expression study confirmed the expression of Klotho in renal distal tubular cells. The aim of this study is to evaluate the role of Klotho polymorphisms in salt sensitivity hypertension.

**Methods:** Design: study of pressure-natriuresis relationship in essential hypertensive patients, never treated before, naive (NHP) by Acute salt load (NaLoad: 310 mMol in 2 h iv) and low salt diet (Low: <100 mg/die for 15 days). **Methods:** 580 NHP underwent NaLoad whereas 137 NHP were compliant to LowSD protocol (324 enrolled).

**Results:** GWA analysis identified 32 SNPs in Klotho gene (restricted to 15 with tagging r²=0.80). Six of these resulted significantly associated to BP variation after NaLoad and LowSD. The effect of intron 2 and 3 SNPs genotype on SBP variation after NaLoad and LowSD are reported in the (figure 1) confirming the similar effect in the two manoeuvres.

**Conclusions:** These results are the first demonstration of the role of Klotho gene in salt homeostasis and hypertension development and suggest that Klotho polymorphisms affect sodium renal tubular excretion. If confirmed these results propose Klotho as key gene in salt sensitivity and aging.

**Funding:** Government Support - Non-U.S.

**Associations Between the Reticulon 1 Gene (RTN1) and End-Stage Kidney Disease**

**Jason A. Bonomo,1 Nicholete D. Palmer,2 Ying Fan,3 John C. He,4 Donald W. Bowden,1 Barry I. Freedman.1 1Center for Genomics & Personalized Medicine Research, Wake Forest School of Medicine; 2Dept of Internal Medicine, Section on Nephrology, Mount Sinai School of Medicine; 3Dept of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine.

**Background:** RTN1 encodes endoplasmic reticulum stress proteins that have recently been associated with chronic kidney disease. We sought to determine if genetic variants within RTN1 were associated with end-stage renal disease (ESRD) in African Americans (AAs) and European Americans (EAs) with diabetic (T2D-ESRD) and non-diabetic forms of ESRD.

**Method:** We examined the RTN1 gene region using a published AA T2D-ESRD genome-wide association study (Discovery study; n=922 cases, n=861 controls). Seven single nucleotide polymorphisms (SNPs) with p<0.05 were identified and genotyped in replication samples of AAs with T2D-ESRD (n=1,312) and controls (n=774), as well as increased UACR. Analyses used generalized linear mixed models that accounted for the sampling strategy and family relatedness, age, sex, diabetes, systolic blood pressure and anti-hypertensive medications, and stratified by Hispanic background.

**Results:** There were 41% men, and mean age was 46 (SD =14). The prevalence of increased UACR was 14%, reduced eGFR was 4%, and combined CKD outcomes was 16%. Caribbean Hispanics (Cuban, Dominican, Puerto Rican, N=538) had higher prevalence of 2 APOL1 risk alleles (1% vs 0.1%) and rs334 allele (2% vs. 0.7%) compared to Mainland Hispanics (Central American, Mexican, South American, N=6,539). APOL1 alleles were associated with increased UACR (p=10⁻⁴) and the composite CKD outcome (p=10⁻⁴), and rs334 was associated with same outcomes (UACR, p=10⁻⁴; CKD composite outcome, p=10⁻⁴) among Caribbeans only.

**Conclusions:** African-specific alleles are associated with CKD in Hispanics, but associations vary by Hispanic background. Medical care providers should be aware of the impact of these genetic variants for CKD risk in Hispanics.

**African Ancestry Specific Alleles Confer Chronic Kidney Disease Risk in U.S. Hispanics**

**Nora Franceschini,1 Adrienne M. Stilp,2 Carmen A. Peralta,1 Sylvia E. Rossa,1 Cathy C. Laurie,1 Holly J. Kramer,1 1Epidemiology, Univ of North Carolina, Chapel Hill, NC; 2Natl Insts of Health, Bethesda, MD; 3Univ of San Francisco, San Francisco, CA; 4Harvard Univ, Boston, MA; Loyola Univ, Maywood, IL; 5Univ of Washington, Seattle, WA.

**Background:** Hispanics are a heterogeneous group with varying genetic ancestry. African ancestry can differ in Hispanics by country of origin, and its proportion relates to the proportion of European ancestry.

**Methods:** We examined the association of African ancestry population-specific risk alleles (APOL1 and HBB rs334 related sickle cell anemia) with CKD in 11,921 Hispanics, aged 18-74 years, recruited in a community-based study in four US centers. APOL1 G1/G2 alleles were genotyped and rs334 alleles were imputed (rsq=0.83). CKD was defined as an increased urine albumin to creatinine ratio (UACR) (≥17 mg/g in men and ≥25 mg/g in women), reduced estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m² based on serum creatinine/cystatin C CKD-EPI equation, or presence of reduced eGFR or an increased eGFR. Analyses used generalized linear mixed models that accounted for the sampling strategy and family relatedness, age, sex, diabetes, systolic blood pressure and anti-hypertensive medications, and stratified by Hispanic background.

**Results:** There were 41% men, and mean age was 46 (SD =14). The prevalence of increased UACR was 14%, reduced eGFR was 4%, and combined CKD outcomes was 16%. Caribbean Hispanics (Cuban, Dominican, Puerto Rican, N=538) had higher prevalence of 2 APOL1 risk alleles (1% vs 0.1%) and rs334 allele (2% vs. 0.7%) compared to Mainland Hispanics (Central American, Mexican, South American, N=6,539). APOL1 alleles were associated with increased UACR (p=10⁻⁴) and the composite CKD outcome (p=10⁻⁴), and rs334 was associated with same outcomes (UACR, p=10⁻⁴; CKD composite outcome, p=10⁻⁴) among Caribbeans only.

**Conclusions:** African-specific alleles are associated with CKD in Hispanics, but associations vary by Hispanic background. Medical care providers should be aware of the impact of these genetic variants for CKD risk in Hispanics.

### SA-PO501

**Associations Between the Reticulon 1 Gene (RTN1) and End-Stage Kidney Disease**

**Jason A. Bonomo,1 Nicholete D. Palmer,2 Ying Fan,3 John C. He,4 Donald W. Bowden,1 Barry I. Freedman.1 1Center for Genomics & Personalized Medicine Research, Wake Forest School of Medicine; 2Dept of Internal Medicine, Section on Nephrology, Mount Sinai School of Medicine; 3Dept of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine.

**Background:** RTN1 encodes endoplasmic reticulum stress proteins that have recently been associated with chronic kidney disease. We sought to determine if genetic variants within RTN1 were associated with end-stage renal disease (ESRD) in African Americans (AAs) and European Americans (EAs) with diabetic (T2D-ESRD) and non-diabetic forms of ESRD.

**Methods:** We examined the RTN1 gene region using a published AA T2D-ESRD genome-wide association study (Discovery study; n=922 cases, n=861 controls). Seven single nucleotide polymorphisms (SNPs) with p<0.05 were identified and genotyped in replication samples of AAs with T2D-ESRD (n=1,312) and controls (n=774), as well as
EAs with T2D-ESRD (n=604) and controls (n=1030). SNPs were also investigated in AAs with non-T2D ESRD (n=269) and control patients (n=500 AAs, n=620 EAs). Data were adjusted for age, gender, admixture, and the APOL1 alleles, if applicable.

**Results:** The top 10 SNPs from the Study discovery underwent replication testing in independent case-control samples of AAs with T2D-ESRD. Replication was observed for two SNPs (rs3747636 in PRKCB1 and rs17041169 in TBX3) in T2D and diabetes susceptibility (ESRD in AAs; p<0.05). These findings were also validated in a second sample set that comprised of 130 IMN cases and 200 controls. Among 378,707 SNPs, three SNPs (rs3214159 in ABCC8, rs3747636 in PRKCB1, and rs3761016 variation of TBX3) were associated with IMN.

**Conclusion:** These results suggest that these significant SNPs may be useful to predict the development of diabetic nephropathy.

**Interaction of Risk Alleles in Japanese Idiopathic Membranous Nephropathy**

Kenjiro Honda, 1 Myo Thiri, 2 Koji Okamoto, 1 Kent Doi, 1 Hodaka Suzuki, 1 Tsuyoshi Yoshibe, 2 Masaoi Nagakau, 3 Katsuki Toshikazu, 4 Eisic Noiri. 1

**Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; 2 Dept of Human Genetics, Graduate School of Medicine, The Univ of Tokyo, Tokyo, Japan; 3 Kidney Section, NIDDK/NIH, Bethesda, MD; 4 Depts of Nephrology and Hypertension, Fukushima Medical Univ, Fukushima, Japan.

**Background:** Recent studies have reported the association of risk alleles of PLA2R1 and HLA-DQB1 with idiopathic membranous nephropathy (IMN) in the European and Chinese populations.

**Methods:** Of the 126 samples, high-resolution association analysis of single nucleotide polymorphisms (SNPs) with PLA2R1 and HLA alleles in AAs, B, C, DRB1, DQB1 and DPB1 was performed using 53 IMN cases and 420 controls. The significant associations discovered in the first sample set were validated by the second sample set that comprised of 130 IMN cases and 200 controls.

**Results:** The strong associations HLA-DRB1*15:01 (OR=7.72, p<0.03) and HLA-DQB1*06:02 (p=5.12 x 10^-6) were observed. Additionally, HLA-C*07:04 and HLA-B*53:01 were associated with IMN. The frequencies of DRB1*04:05 and HLA-DQB1*04:01 were inversely associated with IMN. The associations did not remain significant after correction for multiple comparisons. In combined data analysis, HLA-DRB1*15:01 and HLA-DQB1*06:02 showed stronger association with IMN. In single locus analysis of PLA2R1, seven SNPs showed strong associations with IMN. Interaction analysis between HLA alleles and PLA2R1 variants revealed high odds ratio for IMN with both risk alleles.

**Conclusions:** These results suggest that these significant SNPs may be useful to predict the development of diabetic nephropathy.

**The First Genome-Wide Association Study of Diabetic Nephropathy in Korean Type II Diabetes Patients**

Byeongwoo Kim, 1 Yeong Hoon Kim, 2 Sang Ho Lee, 1 Sunwoo Kang. 1 Dept of Nephrology, Inje Univ, Busan Paik Hospital, Busan, Korea; 2 Dept of Nephrology, College of Medicine, Kyung Hee Univ, Seoul, Korea.

**Background:** It has been suggested that genetic susceptibility plays an important role in the pathogenesis of diabetic nephropathy. Recently, several genome wide association studies (GWAS) suggested that specific polymorphisms of candidate genes were associated with susceptibility to diabetic nephropathy. However, there was weak point in all of these GWAS DNA chip for GWAS. In fact, previous contents of GWAS DNA chip were fixed and did not cover SNPs in exon region and promoter region. In present study, we used the AxiomSTM Genome-Wide Human Assay. The contents of assay are selected by researcher and useful to investigate association between several candidate SNPs and specific diseases.

**Methods:** To investigate whether specific polymorphisms are involved in the development of the diabetic nephropathy, 87 diabetic nephropathy patients and 104 diabetic controls in Korean with type II diabetes were studied. We firstly selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exonic SNPs, promoter SNPs, and intron SNPs in each gene were following: (1) SNPs with >10% minor allele frequency (MAF), (2) >1 heterozygosity, (3) known genotype frequencies of SNPs in Asian population, (4) SNPs studied in previous study, (5) unknown SNPs. Finally we selected 378,707 SNPs. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value. The analysis were analyzed using Helixtree program.

**Results:** Among 378,707 SNPs, three SNPs (rs3214159 in ABC8 gene, rs3747636 in PIK3CB gene, and rs3761516 in PIK3CB2 gene) showed strongly significant association with diabetic nephropathy (p<0.00001).

**Conclusions:** These results suggest that these significant SNPs may be useful to investigate the development of diabetic nephropathy.

**An Efficient and Comprehensive Strategy for Genetic Diagnostics of All Hereditary Kidney Diseases**

Liisbeth Silva, 1 M. Lara Besada-Cerecedo, 2 Olaya Lamas-Gonzalez, 1 Patricia Regueiro Casasou, 1 Ana Barcia de la Iglesia, 1 Beatriz Sobrino, 2 Jorge Amigo, 2 Francisco Barros Angueira, 2 Angel Carracedo, 2 Candido Diaz Rodriguez, 1 Miguel A. Garcia-Gonzalez, 1 1 Group of Genetics and Developmental Biology of Renal Diseases, Dept of Nephrology, Univ Hospital Complex and Health Research Inst of Santiago de Compostela (IDIS), Santiago de Compostela, A Coruña, Spain; 2 Galician Public Foundation of Genomic Medicine, Santiago de Compostela, A Coruña, Spain.

**Background:** Sanger is a traditional and reliable method for sequencing, but next generation sequencing (NGS) has improved genetic diagnosis in a time and cost effective manner. We established and validated a NGS strategy for all hereditary kidney diseases, and compared it with traditional and NGS exome sequencing technologies.

**Methods:** Based in clinical classification and population prevalence, we generated four panels and test them in 318 patients with renal disease during 2 years of routine diagnostic collection: (1) Panel for tubulointerstitial disease (129 genes, 129 patients); (2) Panel for common, rare and ultra-rare cystic diseases (72 genes, 48 patients); (3) Panel for glomerular disease (26 genes, 89 patients) and (4) Panel for tubule/interstitial disease (36 genes, 52 patients).

**Results:** This strategy has shown greater gene coverage, sensibility and specificity considering pseudogenes, compared to two independent NGS exome sequencing strategies.

**Conclusions:** Here we describe a novel strategy to anticipate disease and provide complete genetic information for clinical decision-making, in a time- and cost-efficient manner.

**Funding:** Government Support - Non-U.S.

Exome Sequencing as Diagnostic Tool in Daily Clinical Nephrology Practice

Ilse M. Rood,1,2 Dorian Luftenberg,1,2 Elisabeth A.M. Cornelissen,1 Jeroen Schoots,1 Nicole Van De Kar,1 Michiel F. Schreuder,1 Linda Koster-Kampfhuys,1 Jeroen Deegens,1 Julia M. Hofstra,1 Tom Nijenhuis,1 Jack F. Wetzels,1 Ronald Roeper,1 Ernie M.H.F. Bongers,1 Radboud Center Renal Disorders, RadboudUMC, Nijmegen, Netherlands; Shared first author.

Background: Next generation sequencing, e.g. exome sequencing (ES), is currently the state of the art technique to identify mutations in genetic diseases. We developed a workflow for implication of ES in daily clinical practice for patients with a suspected hereditary kidney disease. The aim of this study was to analyze the diagnostic yield of this approach in clinical practice.

Methods: We developed a two-tier analysis, in which the first step is a kidney disease gene panel to screen for pathogenic variants in 187 genes, minimizing the change of coincidental findings. If causative mutations are not identified (first step), the complete exome data set was analyzed after additional written informed consent. We analyzed the diagnostic yield of this approach.

Results: From Jan. 2013 till Jan. 2015 we included 74 unrelated patients with kidney disease, defined as glomerular disease (n=34), cystic renal disease (n=16), electrolyte disorders (n=11), renal insufficiency of unknown cause (n=4) and other (n=9). The kidney disease gene panel revealed pathogenic mutations in 11 cases (15%), and likely pathogenic variants in 12 other cases (16%), necessitating follow-up studies. Further analysis of the complete exome data set in 19 patients, revealed candidate genes in 6 patients that are under investigation. In addition, copy number variation analysis revealed a pathogenic deletion in 2 patients (in one patient another pathogenic mutation was also identified in step one). There was 1 coincidental finding necessitating follow up for colonocarcinoma. In 23 patients open exome analysis is currently ongoing. Nine patients refused further analysis.

Conclusions: Currently, in 30 out of 74 patients (41%) (likely) causative mutations or new candidate genes were identified. We conclude that diagnostic exome sequencing is a powerful tool for detecting causative mutations in daily clinical practice without having the limitations of other gene testing approaches (single gene testing/targeted sequencing).

SA-PO507

Atypical Hemolytic Uremic Syndrome Targeted Re-Sequencing Study in a South Italian Cohort of Patients

Michele Accetturo,1 Anna Zito,1 E.D. Sten,1 Maddalena Gigante,2 Paola Pontrelli,2 S. Diella,2 Giuseppe Castellano,1 M. Giordano,1 L. Santangelo,1 Loreto Gesualdo.1 Emergency and Organ Transplants, Nephrology Unit, Uni of Barri, Italy; Medical and Surgical Sciences, Nephrology Unit, Uni of Foggia, Italy; Giovanni XXIII Hospital, Italy.

Background: Atypical hemolytic uremic syndrome (aHUS) is a multifactorial disease due to autoimmune or genetic factors leading to deregulated alternative complement pathway activation. At present 12 genes are associated to aHUS, however 30-50% of patients lack mutations in these genes resulting in still partially obscure genotype-phenotype correlations.

Methods: We enrolled 20 aHUS patients and 2 relatives from Apulia Region, Italy. We performed targeted parallel re-sequencing of the 12 known genes plus ADAMTS13, in order to obtain a full genetic diagnostic routine screening. We analyzed the mutations investigating the overlapping with other alternative complement pathway disorders, such as C3 glomerulopathy, Age-related Macular Degeneration (AMD) and drusen. We selected patients for their history of sporadic aHUS. Target enrichment was performed using an Illumina TrueSeq Custom Amplicon panel. Sequencing was performed on Illumina MiSeq Desktop Sequencer. All variants were evaluated for their pathogenicity according to CADD, Sift and Polyphen algorithms.

Results: We identified 30 missense and one nonsense variants in known aHUS genes, plus 7 missense variants in ADAMTS13. Several combined variants were identified which might explain the different phenotypic nuances of our patients, as well as, in some cases, their signs of other Complement-related diseases. We evidenced that different combination of variants together with different triggering factors result in a phenotypic spectrum encompassing all the Complement-related disease range. Additionally, in presence of some combinations, also other underlying pathologies can act as a triggering background for aHUS.

Conclusions: Our data suggest that (i) ADAMTS13 gene should be routinely sequenced for aHUS (ii) the overlapping with other complement-related diseases is considerable. Mutations should therefore be analyzed in combination, and the high-throughput strategy is the only feasible in this scenario.
SA-PO510

Discovery of New Risk Gene Loci in IgA Nephropathy: Genome-Wide Human Assay

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis in Korea. The etiology of IgAN is complex with high genetic heterogeneity. Several genome wide association studies (GWAS) suggested that specific polymorphisms of candidate genes were associated with susceptibility to IgAN. However, previous contents of GWAS DNA chip were fixed and did not cover SNPs in exon region and promoter region.

Methods: We used the Axim™ Genome-Wide Human Assay by Affymetrix. The contents of assay are useful to investigate association between several candidate SNPs and disease. We selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exonic, promoter, and intron SNPs in each gene were following: SNPs with >10% minor allele frequency, >0.1 heterozygosity, known genotype frequencies of SNPs in Asians, SNPs studied in previous study, and unknown SNPs. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value. The analysis was using Helix tree program.

Results: To investigate whether specific polymorphisms are involved in the development of the IgAN, 182 biopsy confirmed IgAN patients and 455 healthy controls were studied. We selected 378,707 SNPs. We carried out genome wide genotyping on customized Axim™ Genome-Wide Human Assay Among 378,707 SNPs, 19SNPs showed strongly significant association with IgAN(p<0.0001). We identified at rs201580035, rs12211925 and rs55730189 that implicated the genes encoding KLF14(Kruppel-like factor14, 7q32.3, OR=8.04, p=4.95x10^-7), and unc-51 like autophagy activating kinase 2(ULK2, 17p12.2, OR=4.43, p=3.61x10^-7) as susceptibility genes. To validate the previous reported susceptibility SNPs of IgAN, we selected and genotyped 19 SNPs, rs6668085 of HLA-DRB1 and rs2585571 of HLA-DQB1 were significantly different between two groups.

Conclusions: These results suggest that these significant SNPs may be useful to investigate the development of IgAN.

SA-PO511

Mannan-Binding Lectin 2 Polymorphisms Were Associated with Progression of IgA Nephropathy

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis. Mannan-binding lectin 2 (MBL2) is a pattern-recognition protein that is involved in the innate immune response to infection.

Methods: Patients with Primary IgAN were retrospectively recruited from 2009 to 2013. Renal specimen was semi-quantitatively scored according to the Oxford scoring system. Whole coding and promoter regions of MBL2 were sequenced in 101 patients. Then 3 SNPs (rs11003125, rs7096206 and rs7095891) in promoter and 1 SNP (rs1800450) in exon of MBL2 were genotyped in other 185 patients by Sanger sequencing. The associations of the 4 SNPs with patients’ clinical, pathological and prognostic parameters were analyzed. Serum MBL level was measured by ELISA.

Results: A total of 268 patients were enrolled, mean age at time of biopsy was 36.8 years (SD 10.4, range 19-58) and 97 patients were in stage 2, 69 stage 3, 95 stage 4 and 9 stage 5 disease. Mean follow-up was a mean of 4.1 years (SD 5.5, range 0.01-17). Mean MBL genotypes were AA in 54%, AG in 41% and GG in 5%. The follow-up time was median of 10.6 years (range 1.3-17). Patients with MBL B allele were associated with progression of IgAN. The mean follow-up time was median of 10.6 years (range 1.3-17). Patients with MBL B allele were associated with progression of IgAN.

Conclusions: The results confirmed that MBL2 polymorphisms are associated with progressive of IgA nephropathy(IgAN). Based on these results, MBL2 might be a potential therapeutic target for the treatment of IgAN.

SA-PO512

ARHGAP32 as a Candidate Gene for Primary Focal Segmental Glomerulosclerosis

Background: Focal and segmental glomerulosclerosis (FSGS) is one of common causes of end-stage renal disease worldwide. Previous studies showed that genetic factor played an important role in the pathogenesis of FSGS. The purpose of this study was to identify the candidate gene of FSGS in Chinese familial FSGS.

Methods: Total 21 individuals of a FSGS pedigree were involved in this study. First, we identified 13 known mutations of ACTN4, TRPC6, and INF2 gene in this pedigree. Then we conducted a genome wide scan for linkage study. And DNA of four members were assayed by whole exome sequencing. The data were filtrated according to the 1000 Genomes Project, ESP500 and dbSNP information, and database with 69 exome sequencing results (without kidney disease). By PCR sequencing methods, we detected candidate causal mutation. And then, we tested the mutation in other 97 sporadic FSGS patients and 96 normal controls.

Results: No mutation was detected from those exons of INF2, ACTN4 and TRPC6 in the 21 FSGS pedigrees. 8 loci suggested for linkage were identified, and the maximum multipoint parametric LOD score of 1.69 was marked by D5S2115. A mutation (c.1213G, p.L405V) of ARHGAP32 gene was identified by combination with exome sequencing, genome-wide scan, function prediction of coding proteins. A new mutation (c.15359G, p.R229Q) of ARHGAP32 gene was detected in one sporadic FSGS patient from 97 cases and 96 controls. The ARHGAP32 expression was detected in the glomeruli and tubules.

Conclusions: We found a candidate mutation of ARHGAP32 gene for primary FSGS by combination with whole genome linkage analysis and whole exome sequencing.

SA-PO513

Targeted Sequencing in Adults with Focal Segmental Glomerulosclerosis

Background: Multiple genes underlying focal segmental glomerulosclerosis (FSGS) and/or steroid resistant nephrotic syndrome (SRNS) have been identified. We aimed to investigate the distribution of gene mutations in adults with FSGS by targeted sequencing.

Methods: 94 adults with familial or sporadic FSGS were recruited through a single renal unit in Ireland. The mean age at diagnosis was 42 years (range 18-72) and male:female ratio was 82:24. The primary nephrotic syndrome was 42 Caucasian, 24 Afro-Caribbean, 24 South Asian. History of familial renal disease (14), recurrent FSGS in a renal transplant (21). DNA was extracted from whole blood or saliva using standard protocols. An Illumina TruSeq Custom Ammplicon Targeted Next Generation Sequencing (NGS) panel was designed covering 21 genes for FSGS. NGS sequencing was performed on the MiSeq v3 system. Data were analysed using our standard Mendelian disease pipeline and all variants were confirmed by Sanger sequencing.

Results: 19 rare, non-synonymous coding variants were identified, affecting 16 individuals, including 3 with a family history and 4 with recurrent disease. 14 variants were heterozygous dominant, 3 compound heterozygous, and 2 X-linked recessive. Known pathogenic mutations included TRPC5 N1435S and NPHS2 R229Q. Control variants were accurately identified in INF2 R214H, NPHS2 V1804M, and MYH9 R19326. Other variants included ACTN4 (1), CD2AP (4), INF2 (1), ITGB4 (3), MYH9 (3), NPHS2 (2), NX2S (2), TRPC6 (2), and PT (3) of these 13 were predicted to be pathogenic by SIFT and/or Polyphen2.

Conclusions: We have shown a high frequency of potentially pathogenic variants in our cohort with FSGS. We have identified enrichment for mutation carriers in those with a documented family history or recurrent disease. Targeted NGS allows rapid and inexpensive identification of these gene mutations.

SA-PO514

Family Risk of Acute Kidney Injury

Background: Previous studies indicate that certain genetic variants may predispose to acute kidney injury (AKI) in critically ill patients but global assessment of heritability and an unbiased genome-wide assessment of acute kidney injury is lacking. The purpose of this study was to assess the familiality of AKI to support a common genetic background.

Methods: We used data from the clinical laboratory at Landspítali – The National University Hospital of Iceland to find all serum creatinine (SCr) measurements over 20 years. We identified each patient highest SCR value and a baseline SCR within the preceding 6 months, defining AKI as a 50% increase in SCR compared to baseline (highest/baseline SCR>1.5). Patients with ESRD and diseases known to result in AKI were excluded. To assess the familial relationship between individuals, we used the Icelandic Genealogy Database that contains reliable genealogy information on the entire Icelandic nation dating back to the year 1650. Familiality of AKI was assessed by calculating the risk ratio of AKI in 1st- and 2nd-degree relatives of AKI patients, and significance assessed by comparing the risk ratio to the risk ratio in 1000 randomly selected control groups.

Results: We identified 12,807 individuals with AKI. There was a significantly increased risk of AKI in the relatives of AKI patients with 1st-degree relative risk ratio (RR) of 1.26, 2nd-degree relative RR of 1.08, 3rd-degree relative RR of 1.12 (p<0.001) all the risk ratios were higher for the relatives who were AKI (highest/baseline SCR>1.5) where the 1st degree relative RR was 1.36 (p<0.006), 2nd-degree relative RR was 1.18 (p=0.067) and 3rd-degree relative RR was 1.14 (p=0.06).

Conclusions: Our results suggest a genetic component in the development of AKI and given the relationship between relative risk and the power to map disease genes by linkage analysis, GWAS studies might yield positive results.

Premature Death in First Degree Relatives of End Stage Renal Disease Patients

Ragnveig Skrune,1,2 Einar Svarstad,1,2 Anna Reisaeter,1,2 Han-Peter Marti,1,2 Bjorn Egil Vikse2

1Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway; 2Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; 3Dept of Transplantation Medicine, Rikshospitalet Oslo Univ Hospital, Oslo, Norway; 4Dept of Medicine, Haugeomund Hospital, Haugesund, Norway.

Background: Increased risk of end stage renal disease (ESRD) and death in Norwegian living kidney donors has been reported. The majority of donors were related to the recipient.

The present study investigates risk of death in first degree relatives of ESRD patients.

Methods: The Norwegian Population Registry has since 1960 registered all Norwegian Citizens. Sifting data are complete for most individuals since 1953. The National Cause of Death Registry has registered causes of death since 1964 and the Norwegian Population Registry has registered all individuals with ESRD since 1980. The registries were linked. All citizens born in Norway with at least one first degree relative were included.

A cohort-design was used, ESRD in a first degree relative was the main exposure variable and death and causes of death were the main outcome variables.

Adjusted hazard ratios (aHR) were calculated using Cox regression analysis.

Results: 5,217,568 individuals were included, 27,650 had at least one relative with ESRD. 844,407 died during follow-up. aHR for death was 1.14 (95% CI 1.10-1.17) in individuals with a relative with ESRD compared to those without a relative with ESRD. Excluding known hereditary renal disease, aHR decreased to 1.12 (95% CI 1.09-1.16). Cardiovascular death aHR was 1.15 (95% CI 1.10-1.21), of which cerebrovascular death 1.34 (95% CI 1.22-1.47). aHR for death for non-hereditary renal/urteric disease was 2.32 (95% CI 1.84-2.91) with renal failure 1.80 (95% CI 1.26-2.56) and primary renal disease 2.84 (95% CI 4.04-8.56) as main contributors. Compared to individuals without a relative with ESRD, death occurred 9 years earlier in individuals who died before the age of 50 and 1 year earlier in individuals who died at age 70.

Conclusions: ESRD in first degree relatives was associated with premature death. Death due to cardiovasculare- and non-hereditary renal diseases increased the most.

Identifying Genetic Predictors of Skin Cancer in Renal Transplant Populations

Caragh P. Stapleton,1 Mark Mccormack,1 Devla M. Connaughton,2 Paul J. Phelan,3 Gianpietro Cavalleri,1 Peter J. Conlon,1 1Dept of Molecular and Cellular Therapeutics, Royal College of Surgeons, Dublin 2, Dublin, Ireland; 2Kidney Centre, Beaumont Hospital, Dublin 9, Dublin, Ireland; 3Dept of Nephropathy, Royal Infirmary of Edinburgh, Edinburgh, NHS Lothian, United Kingdom.

Background: Renal-transplant recipients have a 33-fold increased risk of developing non-melanoma skin cancer relative to an age-matched non-transplanted individual. Some of this risk can be attributed to factors such as type of immunosuppressant treatment, however much of the risk remains unaccounted for. In this study we set out to map germline genetic variations influencing the development of skin cancer in our cohort of 325 renal-transplant recipients, using a genome-wide association study (GWAS) and candidate gene study design.

Methods: Both logistic regression and survival analysis was applied in our GWAS. Survival analysis was used in our candidate gene study. Multiple robust loci for skin cancer in non-transplant populations have been identified via large GWAS. These genetic predictors of skin cancer (n=21) identified from non-transplant populations were examined to see if they have a higher effect size in renal-transplant recipients compared to the general population.

Results: For the candidate SNP analysis, a nominally significant association was found with a SNP in the MIR1 gene (p=0.0137). The variant was found to have the same direction of effect as described in the original study and the odds ratio was higher. The presence of one or more copies of the minor allele caused a significant decrease in time to develop skin cancer post renal transplantation (hazard ratio = 2.06). We found a significant association in our GWAS between time to developing skin cancer post transplantation and a variant in SPOCK1 (p = 0.001). We found that heterozygote individuals developed skin cancer 7 times faster than wild type homozygotes.

Conclusions: Associations were found between time to developing skin cancer post-transplantation and the genes MIR1 and SPOCK1. We will be carrying out further testing in other cohorts for validation of these results. This work is funded by Irish Research Council for Science, Engineering and Technology.

Genetic Variants in ANCA-Associated Vasculitis: A Meta-Analysis

Chinar Rahmatullahi,1 Antien Mooyaart,2 Daphne Van Hooven,1 Jan W. Schoone,1 Jan A. Bruijn,1 Olaf Dekkers,1,2 European Vasculitis Genetics Consortium,1 Ingeborg M. Bajema,1 1Leiden Univ Medical Center; 2Aarhus Univ Hospital.

Background: Genetic factors may influence the pathogenic pathways leading to anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV). We performed a meta-analysis to determine the genetic variants most likely associated with AAV and investigated whether diagnostic and serological subtypes within AAV have distinct genetic backgrounds.

Methods: Studies investigating the association between genetic variants and AAV in humans were searched in PubMed, Embase, and Web of Science. All variants significantly associated with AAV in at least one study and investigated in at least two studies were included. Additionally, data on these genetic variants from the largest GWAS in AAV were included to increase the validity of this meta-analysis.

Results: A total of 5,180 articles were searched. Fifty-three articles investigating 55 genetic variants were included, 31 of which remained associated with AAV in a meta-analysis. These genetic variants were in or near the following genes: SERPINA1, CD226, CTLA-4, HLA-B, HLA-DR, HLA-DQ, HLA-D, HSD17B8, IRF3, PTPP22, RING1/RRXB, RXXR, and TLR9. Moreover, we identified genetic distinctions between granulomatosis with polyangiitis and eosinophilic polyangiitis and between proteinase 3 ANCA vasculitis and myeloperoxidase ANCA vasculitis. In 79% of the genetic variants, subdivision based on ANCA serotype resulted in higher odds ratios than subdivision based on clinical diagnosis.

Conclusions: This meta-analysis identified 31 genetic variants associated with AAV, supporting a role for alpha-1-antitrypsin, the major histocompatibility complex system, and several distinct inflammatory processes in AAV pathogenesis. Our results indicate that subdivision of AAV based on ANCA serotype has a stronger genetic basis than subdivision based on clinical diagnosis.

Comparison of Genetic Associations with Different Definitions of CKD Progression in Children

Background: The PediGFR Consortium aims to identify genetic factors associated with pediatric chronic kidney disease (CKD) progression. The optimal definition of CKD progression for testing is unclear. To address this question, we performed genome-wide association studies (GWAS) of two different definitions of CKD progression, slope of the average change in estimated GFR (eGFR) versus time-to-event (TTE). Methods: There were >8 million genotyped and imputed markers from 1,122 patients. The calculation of slope was based on 2.41 eGFR values per patient. TTE was a combined primary endpoint of dialysis, transplant, 50% GFR loss or GFR < 5 ml/min/1.73m2. Respectively, cox proportional hazards and linear regressions were used for the GWAS of TTE and slope. Both analyses were adjusted for age, sex, principal components and baseline eGFR. For each definition, data were meta-analyzed from five study/ancestry-specific groups in PediGFR.

Results: For TTE, follow-up time was 1.6-6.5 years (IQR) and an event rate of 34%. For slope, mean slope was -0.2 to 0.5 ml/min/1.73m2. For comparison, we focused on SNPs present in all five groups with a minor allele frequency >0.05, and I2<50%. For TTE, 6 genetic regions contained one or more of such SNPs with p<1x10^-8, one of which reached genome-wide significance (p<5x10^-8). Hazard ratios per allele ranged from 1.49-1.67. For slope, there were 3 regions with p-values <1x10^-7, one of which reached genome-wide significance. All genetic variants were nominally associated (p<0.05), whereas 2 of the 3 slope variants were nominally associated with TTE. None of the loci with p<1x10^-7 overlapped between the two definitions.

Conclusions: Genetic variants associated with CKD progression differed based on the definition of the phenotype. GWAS of TTE identified more loci at p<1x10^-7 than slope, and these were biologically more plausible based on current knowledge of kidney disease. However, the number of genome-wide significant loci was the same.

SA-PO521
New Candidate Genetic Loci Associated with Pediatric Proteinuria in the CKiD Cohort

Background: Proteinuria is an early marker for chronic kidney disease in adults and children. Here, we sought to identify genetic variants associated with baseline proteinuria in African American children diagnosed with chronic kidney disease from the CKiD cohort. Methods: We genotyped 140 CKiD participants using the Illumina HumanExome BeadChip v2.1 comprising over 250,000 markers, including putative functional exonic variants that were implicated in common metabolic disorders. 81,460 SNPs passed quality control and were tested for association with baseline proteinuria in 129 children with chronic kidney disease. We performed linear regressions adjusted for age, gender, and the first five eigenvectors within each study. Results: We identified 30% carried two copies of a missense mutation, p. V260E, in the podocin gene, WT1. This mutation has previously been reported as recessively associated with Scottish and English patients with the nephrotic syndrome (SR-FSGS). The indicated age of the common ancestor carrying the mutation was 110 to 172 years ago. Further, in a second study, we found that 30% carried two copies of a missense mutation, p. V260E, in the podocin gene, WT1. This mutation has previously been reported as recessively associated with Scottish and English patients with the nephrotic syndrome (SR-FSGS). The indicated age of the common ancestor carrying the mutation was 110 to 172 years ago.

SA-PO524
Genotype-Phenotype Analysis in Pediatric Patients with WT1 Glomerulopathy

Background: The WT1 gene plays an essential role in urogenital and kidney development and its mutations manifest two different types of glomerulopathies, Denys-Drash syndrome (DDS) and Frasier syndrome (FS). In this multicenter retrospective cohort study, genotype-phenotype correlations in Korean pediatric patients with WT1 mutations were analyzed.

Methods: During the period from 2001 to 2015, WT1 mutations were detected in a total of 10 children by direct sequencing. Results: The patients were grouped into two groups (n=10, having a mutation in intron 9) and DDS (n=13, having an exon mutation). Nine (69%) DDS patients presented as congenital (CNS) or infantile nephrotic syndrome (INS), while 7 (70%) FS patients presented as sporadic focal segmental glomerulosclerosis. Interestingly, monogenic twin patients with DDS presented as end-stage renal disease (ESRD) without any previous history of glomerulopathy. Progression to ESRD was noted in 11 (85%) DDS patients at the median age of 0.22 years (IQR: 0.07-1.65 years) and in 5 (50%) FS patients with a median age of 16.50 years (IQR: 15.25-16.50 years). Progression to ESRD was faster in DDS patients (p<0.05). Disorder of sexual development (DSD) was accompanied in 8 (62%) DDS and 7 (70%) FS patients. Three (13%) patients (2 with DDS and 1 with FS) had diaphragmatic defect/hermia. Five (22%) and six (26%) patients underwent prophylactic nephrectomy and gonadectomy, respectively. Among the rest of the patients, Wilms tumor and gonadoblastoma developed in 3 DDS patients and 1 FS patient, respectively.

Conclusions: The clinical manifestations and disease course of the Korean patients with WT1 glomerulopathy were mostly same as those of previous reports. Of note, patients with DDS and FS usually manifested sporadically, i.e., chronic kidney disease without any preceding history of significant proteinuria and/or DSD. This is common in both FS and DDS and is a useful diagnostic clue. Prophylactic nephrectomy/gonadectomy is strongly recommended.

Funding: Other NIH Support - grant HHSN261200800001E

SA-PO525
Age of the NPHS2 p.V260E Mutation, a Cause of Childhood Steroid Resistant Focal Segmental Glomerulosclerosis, in the Ancestral Population

Background: A study of 44 children with sporadic steroid resistant nephrotic syndrome (SRNS) with focal segmental glomerulosclerosis (FSGS) histology, in Durban, South Africa, revealed 30% carriage typically, i.e., chronic kidney disease without any preceding history of significant proteinuria and/or DSD. This is common in both FS and DDS and is a useful diagnostic clue. Prophylactic nephrectomy/gonadectomy is strongly recommended.

Methods: Inheritance of the V260E mutation from two parents with a common ancestor will result in a region of homozygosity surrounding the locus, indicating the overlap of extended haplotypes preserved around the locus. To test for this we genotyped 10 individuals homozygous for the mutation, and 74 individuals homozygous for the wild type variant, with the Illumina exome chip v2.1 comprising over 250,000 markers, including putative functional exonic variants that were implicated in common metabolic disorders. 81,460 SNPs passed quality control and were tested for association with baseline proteinuria in 129 children with chronic kidney disease. We performed linear regressions adjusted for age, gender, and the first five eigenvectors within each study. Results: We identified several genetic loci that were significantly associated with proteinuria (PE10s), as well as new candidate loci (10< P<10). Among the top hits, we notably revealed gene-variants that were previously associated with the TGFβ pathway, renal homeostasis, IgA nephropathy, congenital kidney disease, and vascular integrity (e.g. VAP3, STRA4, and HDAC7).

Conclusions: Our study emphasizes the usefulness of unbiased large genome screenings to discover new factors associated with pediatric kidney conditions. These new results warrant independent replication and functional validation.

SA-PO522
Genetic Markers Associated with Hemoglobin in the PediGFR Consortium

Background: Genome-wide association studies have identified genetic variants associated with erythrocyte traits, but associations in children with CKD have not been studied. Our goal was to identify whether single nucleotide polymorphisms (SNPs) are associated with hemoglobin (Hgb) decline in progressive CKD in children.

Methods: Longitudinal analysis of genotype and Hgb in 1,141 European (n=806) or Turkish (n=335) children in the Pediatric Investigation for Genetic Factors Linked to Renal Progression (PediGFR) consortium. With a candidate marker approach, linear mixed-effect model for Hgb regressed on time and genotype of 24 previously reported SNPs was performed, stratified by ethnicity. Bonferroni correction was used to adjust for multiple comparisons.

Results: In Europeans, a nominally significant association between SNPs on the RCL (p<0.01) and the BCL11A (p=0.01), TBX3 (p=0.01), and TFR2 (p=0.007) genes and increased risk for Hgb decline over time was noted. Among Turks, a significant association was seen with SNPS on the RCL (p=0.03), KIF (p=0.06), BCL11A (p=0.01), TBX3 (p=0.01), CD164 (p=0.03), and HBS1L (p=0.03) genes. The RCL gene has been associated with MCI. The TFR2 and HBS1L/MYB genes are associated with Hgb; TFR2 mediates cellular iron uptake and HBS1L MYB is a quantitative trait locus controlling fetal Hgb. The KIT, BCL11A, TBX3, and CD164 genes are associated with MCV, and have roles in hematopoiesis (KIT and CD164), persistence of fetal Hgb (BCL11A) and retinoid binding (KIT). Bonferroni corrected for each SNP on BCL11A remained significantly associated with Hgb in Europeans and Turks, with marginal significance for SNPs on TBX3 and TFR2 in Europeans and on KIT and TBX3 in Turks.

Results: Telomere length was measured in whole blood DNA from 47 renal RTx patients by quantitative PCR using the Roche Light Cycler 480. The relative T/S ratio (repeat copy number to single gene copy number) was determined in relation to the control DNA sample. Non-parametric statistical tests were used. Results: RTx patients had a greater telomere attrition than dialysis patients (P<0.001), despite no significant differences in telomere length at baseline or after 12 months. RTx patients were divided into those receiving azathioprine (n=11) and those receiving mycophenolate (n=32). Mycophenolate-treated patients had greater telomere attrition than azathioprine-treated patients. This is currently being investigated further, as it could have clinical implications on the choice of treatment regimen.

Funding: Private Foundation Support, Government Support - Non-U.S.
Background: Cefepime is an antibiotic commonly used in the ICU where acute kidney injury (AKI) is prevalent. SHIFT therapy, a 6-12 hour renal replacement therapy (RRT), also referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD), is increasingly utilized to help treat AKI. However, dosing information for cefepime in critically ill patients receiving SHIFT therapy is currently lacking.

Methods: Using previously-published pharmacokinetic (PK) data and a PK model developed for critically ill patients receiving SHIFT RRT, a series of 5000-subject Monte Carlo simulations were performed for 18 cefepime regimens in 8 scenarios with varying duration (6 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to cefepime doses. Cefepime regimens were evaluated on the probability of attaining a free drug concentration equal to or greater than the minimum inhibitory concentration (MIC) for ≥60% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) ≥ 90% for MIC values ≤ 8 mg/L using the smallest total daily dose.

Results: Cefepime 1g q6h hours with a 2 g loading dose was the only regimen to yield a PTA ≥ 90% in all 8 SHIFT settings while limiting the total daily maintenance dose to 4g. This regimen resulted in 48-hour mean trough concentrations > 32 mg/L in most subjects.

Conclusions: Published cefepime CRRT doses (2 g every 12 hours) yielded 90% PTA in modeled critically ill patients receiving 8 or 10 hours of SHIFT RRT. Future studies should validate these findings in the clinical setting.

Use of Monte Carlo Simulation to Determine Optimal Meropenem Regimens in Patients Receiving SHIFT Renal Replacement Therapy Susan H. Lewis, Katherine N. Gharibian, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, Ann Arbor, MI.

Background: Current antibiotic dosing regimens often result in subtherapeutic concentrations in critically ill patients, but scant pharmacokinetic (PK) data exist to support antibiotic dosing. This study applied Monte Carlo simulations (MCS) to determine the initial meropenem regimen to treat critically ill patients receiving SHIFT Renal Replacement Therapy (RRT), a daily prolonged intermittent RRT.

Methods: Body weight & PK parameter [non-renal clearance, free fraction, volume of distribution & extraction coefficients] estimates with variability were obtained from relevant published studies. Values were randomly selected from the log-Gaussian distribution within the assigned limits to vary individual free meropenem concentration profiles. MCS were performed for 13 meropenem regimens including weight-based and pre- & post-SHIFT dosing, in 4 different SHIFT settings (4L/hour x 10 hours or 5L/hour x 8 hours in hemodialysis or hemofiltration) occurring either at the beginning of or 14-16 hours after meropenem infusion. Probability of target attainment (PTA) was evaluated using a pharmacodynamic target ≥ 40% free meropenem concentrations above 4 times the minimum inhibitor concentration (TI=4xMIC) for Pseudomonas aeruginosa (2 µg/mL) for the first 48 hours of therapy. A ≥ 90% of PTA with the smallest daily dose was defined as optimal.

Results: Meropenem regimens using ≥2g/day attained ≥ 90% PTA. Meropenem 1g q12h and 1g given pre- & post-SHIFT were optimal regimens for all SHIFT settings. Weight-based regimens did not yield better target attainment than fixed-dose regimens.

Conclusions: This simulation indicates that meropenem regimens using ≥2g/day should be used initially to treat critically ill patients receiving 8 or 10 hour SHIFT RRT. These results warrant clinical validation.

SA-PO530
Identification of Optimal Ceftazidime Dosing Regimens in Modeled Critically Ill Patients Receiving SHIFT Renal Replacement Therapy Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, Ann Arbor, MI.

Background: Ceftazidime is an antibiotic commonly used in critically ill patients. Ceftazidime doses of 2 g every 12 hours have been recommended for continuous renal replacement therapies (CRRT), however, no studies have evaluated the optimal dose in patients receiving SHIFT Therapy (NxStage Medical), a 6-12 hr RRT commonly referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD).

Methods: Pharmacokinetic (PK) data compiled from previously-published studies were used to develop models for critically ill patients receiving intermittent hemofiltration (HF) or hemodialysis (HD). Eight models were developed to account for the variability in settings including duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to ceftazidime dose. Using a series of 5000-subject Monte Carlo simulations, 12 ceftazidime regimens were applied to each model and evaluated for the probability of attaining free drug concentrations equal to or greater than the minimum inhibitory concentration (MIC) for ≥70% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) ≥ 90% for MIC values ≤ 8 mg/L. The MIC for Pseudomonas aeruginosa was defined as optimal.

Results: Ceftazidime administered in 4g total daily doses (2 g q12 hours; 1 g q6 hours) yielded a PTA ≥ 90% in all 8 RRT models. Continuous infusion of the drug (3 g continuous infusion with a 2 g loading dose) achieved similar PTA values.

Conclusions: In PK models of critically-ill subjects receiving 8 or 10 hours of SHIFT RRT, a ceftazidime dose of 1 g q6 hours with a 2 g loading dose yielded pharmacodynamic target attainment for >90% of the population.

Evaluation of Piperacillin/Tazobactam Regimens in Patients with SHIFT Renal Replacement Therapy
Susan J. Lewis,1 Katherine N. Gharibian,2 Ashita J. Tolwani,2 William Henry Fissell,3 Bruce A. Mueller.1 College of Pharmacy, Univ of Michigan, MI; 2Univ of Alabama, AL; 3Vanderbilt Univ, TN.

Background: SHIFT Renal Replacement Therapy (RRT) is a prolonged intermittent RRT to treat critically ill patients with acute kidney injury, but lacks of antibiotic pharmacokinetic (PK) data in this RRT limits its utility. This study evaluated probability of target attainable (PTA) of piperacillin/tazobactam regimens recommended in critically ill patients receiving SHIFT RRT, using Monte Carlo Simulations (MCS).

Methods: Mathematical PK models were constructed using literature-derived demographic/PK data with known variability. Four daily-SHIFT settings (hemofiltration or hemodialysis with effluent rates of 2L/hour x 8 hours or 4L/hour x 10 hours) occurring at 2 different times relative to drug dose were modeled. PTA of 13 piperacillin regimens (2–4g q6h–8h) and 3 tazobactam regimens (0.5g q6h) with intermittent or prolonged infusion (4-hour or continuous) were evaluated. MCS generated free drug concentration profiles for each regimen in the 5,000 virtual patients. Pharmacodynamic targets >50% of time free piperacillin concentrations above 4x the minimum inhibitory concentration (MIC) of Pseudomonas aeruginosa (16 µg/mL) and ≥50% of time free tazobactam concentrations above corresponding threshold (4 µg/mL) for the initial 48 hour-therapy. The optimal regimen required ≥90% of PTA for both agents.

Results: The attainment of ≥90% of PTA required piperacillin 16g/day and tazobactam 2g/day in all SHIFT settings. Prolonged infusion was not superior to intermittent infusion to yield better PTA in patients receiving SHIFT RRT.

Conclusions: The pharmacokinetics of RTX in patients with MN are significantly altered compared to published data from cancer and autoimmune populations. These results suggest shorter T1/2 and lower exposures to RTX in MN may necessitate higher doses and/or changes to dosing frequency in order to elicit an optimal therapeutic effect.

SA-PO534
Rituximab Exhibits Altered Pharmacokinetics in Patients with Membranous Nephropathy
Uma R. Fossner,1 Visit Cheungpasitporn,2 David Bourne,1 Fernando C. Fervenza,2 Melanie S. Joy.1 School of Pharmacy and Medicine, Univ of Colorado, Aurora, CO; 2Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Background: Rituximab (RTX) is an anti-CD20 antibody used in the treatment of glomerular diseases including membranous nephropathy (MN). There is little information about the pharmacokinetics of therapeutic proteins, including RTX in patients with glomerular diseases. The study evaluated rituximab pharmacokinetics in patients with MN from a pilot investigation (Fervenza et al., 2010).

Methods: Patients with MN (n=20) received 4 RTX weekly IV infusions (375mg/m²), with a repeat of the identical treatment at 6 months. Patient baseline characteristics were: gender (17M/3F), age (49±13.3 y), BSA (2.22±0.24 m²), urinary protein excretion (11.3±4.1 g/d), creatinine clearance (72±33 mL/min). Pharmacokinetic analysis was performed using rituximab-plasma concentrations. Comparisons of pharmacokinetic parameters were made between the MN patients and published data from other populations.

Results: The MN population had a favorable reduction in urinary protein excretion 3 months after each RTX treatment course (7339±1414 mg/day and 4131±3441 mg/day, respectively), while creatinine clearance values were similar to baseline (72±31 mL/min and 82±37 mL/min, respectively). Patients with MN exhibited a shortened half-life (T1/2), greater volume of distribution (Vd), and enhanced clearance of RTX vs. previous reports in other patient populations. These characteristics resulted in an exposure (AUC) that was significantly reduced in patients with MN.

SA-PO535
Eculizumab Treatment Effectively Prevents C5 Cleavage without C5a Generation In Vivo
Elena Volokhina,1 Grethe Bergseth,2 Nicole Van De Rijke,1 Lambertus P.W.J. Van den Heuvel,1 Tom Eirik Molllnes.2 Radboud Univ Medical Center, Nijmegen, Netherlands; 1Nordland Hospital, Bodø, Norway.

Background: The C5 inhibitor eculizumab has been successfully used to treat atypical hemolytic uremic syndrome (aHUS), however, available data on pharmacodynamics of this medication are limited. Recently, increased generation of C5a in a single patient with HELLP syndrome treated with eculizumab has been reported. Since this observation was unexpected, we aimed to reproduce these data and search for possible explanations for the findings.

Methods: Levels of C5a were analyzed in EDTA plasma samples of aHUS (n=3) patients using three commercial ELISA kits, one of the kits was also used in the HELLP study and other two kits were included as controls. The samples were collected before the first eculizumab dose and then at various time points during treatment.

Results: In line with the report on HELLP patient, the C5a values, measured by one of the commercial ELISA kits, increased significantly in all aHUS patients after the first eculizumab dose as compared to the values obtained before treatment (p=0.016). C5a remained elevated throughout the treatment period. Such increase could not be reproduced by using another two commonly available commercial kits. When eculizumab was added in vitro to normal human serum prior to activation, no generation of C5a was measured by all used kits.

Conclusions: Our data indicate that existing commercial assays require validation for specificity before being used to monitor effect of eculizumab, especially in clinical laboratory practice. This example illustrates how false conclusions can be drawn when based on results from one single commercial assay not satisfactorily validated for the purpose it is used.

SA-PO536
Sensitvive, Reliable and Easy-Performed Laboratory Monitoring of Eculizumab Therapy in Atypical Hemolytic Uremic Syndrome
Volokhina Elena,1 Bergseth Grethe,2 Van der Kar Thea Jann,1 Vardeny Jack F. Wetzels,1 Van den Heuvel Tom Eirik,2 Mollnes Lambertus P.W.J.1 Nordland Hospital, Bodø, Norway.

Background: Atypical hemolytic uremic syndrome is a severe renal illness caused by complement dysregulation. Treatment with the complement C5 inhibitor eculizumab is effective, but associated with high costs. Laboratory monitoring of these patients with eculizumab therapy is required.

Methods: Eculizumab serum concentrations were monitored in 4 aHUS patients using three commercial ELISA kits, one of the kits was also used in the HELLP study and other two kits were included as controls. The samples were collected before the first eculizumab dose and then at various time points during treatment.

Results: In line with the report on HELLP patient, the C5a values, measured by one of the commercial ELISA kits, increased significantly in all aHUS patients after the first eculizumab dose as compared to the values obtained before treatment (p=0.016). C5a remained elevated throughout the treatment period. Such increase could not be reproduced by using another two commonly available commercial kits. When eculizumab was added in vitro to normal human serum prior to activation, no generation of C5a was measured by all used kits.

Conclusions: Our data indicate that existing commercial assays require validation for specificity before being used to monitor effect of eculizumab, especially in clinical laboratory practice. This example illustrates how false conclusions can be drawn when based on results from one single commercial assay not satisfactorily validated for the purpose it is used.

respect to complement function has not been standardized. The aim of this study was to evaluate and compare complement functional assays for their application in routine follow-up of eculizumab-treated patients.

**Methods:** Complement activity in serum samples was analyzed using Wieslab® complement screen assay. The presence of eculizumab-C5 complexes in serum, EDTA plasma samples and in urine was measured using ELISA. Levels of sC5b-9 in urine were measured using electroluminescent epitope assay.

**Results:** First, we documented that the Wieslab® complement screen assay showed a sensitivity of 1-2% of C5 activity by adding purified C5 or normal human serum to a C5 deficient plasma. Second, we found that all the patient samples obtained during the standard treatment course, were completely blocked for terminal complement pathway activity. Moreover, complement remained fully blocked when intervals between the eculizumab infusions were extended to four weeks. Levels of complexes between eculizumab and C5 were inversely correlated to the complement activity (p=0.01). Third, titrating serum from eculizumab-treated patients into normal serum, revealed that eculizumab was present in excess up to four weeks after infusion. Finally, we showed that increased urine sC5b-9 disappeared after eculizumab treatment.

**Conclusions:** We demonstrate sensitive, reliable and easy-performed assays to monitor eculizumab-treated patients, which can be used to design individual dosage regimens.

**Dose Exposure Relationship of AKB-6548 Is Independent of the Level of Renal Function**

**Background:** AKB-6548 is a novel, once-daily, oral hypoxia-inducible factor prolyl-hydroxylase inhibitor (HIF-PHI) in development for the treatment of anemia in non-dialysis dependent (NDD) and dialysis dependent (DD) chronic kidney disease (CKD). Studies in NDD-CKD patients have shown AKB-6548 produces physiologic increases in erythropoietin, enhances iron mobilization, and produces a dose dependent increase in hemoglobin levels.

**Methods:** The pharmacokinetics (PK) of AKB-6548 have been evaluated in single and multiple dose studies in healthy volunteers and CKD patients (NDD-CKD and DD-CKD) over a broad range of dose levels. An analysis of results across studies was conducted to assess the potential impact of renal function on selecting the dose levels and dosing regimen in CKD patients. The analyses evaluated dose-linearity in drug exposure, clearance routes of AKB-6548 and its metabolites, as well as the impact of CKD severity and the hemodialysis procedure on drug disposition.

**Results:** In healthy volunteers, AKB-6548 demonstrated dose linearity and proportionality over single doses of 80-1200 mg and multiple doses of 500-900 mg/ day. The PK parameters of AKB-6548 in healthy volunteers, NDD-CKD and DD-CKD patients were similar except for a slightly longer half-life with declining renal function (4.7 h, 7.9 h and 9.1 h, respectively). A mass balance study (using 14C-labeled drug) in healthy volunteers demonstrated both renal and fecal routes of parent drug and metabolite clearance, supporting use of AKB-6548 in CKD patients without significant differences in drug exposure. Moreover, AKB-6548 was minimally cleared by the hemodialysis procedure and the PK parameters were similar whether AKB-6548 was administered prior to or following dialysis.

**Conclusions:** The results demonstrate a linear dose-exposure relationship for AKB-6548 over a wide range of dose levels and support the utility of once-daily dosing and similar dose levels across the spectrum of CKD severity.

**Nonclinical Pharmacokinetics and Toxicokinetics of RG-012, an Inhibitor of MicroRNA-21 Being Investigated for Treatment of Alport Syndrome John Stewart Grundy,1 Kai Liu,2 Steven Neben,3 Cindy L. Berman,2 Deidre Mackenna,1 Neil W. Gibson,1 1Regulus Therapeutics, San Diego, CA, 2Berman Consulting, Wayland, MA.**

**Background:** RG-012 is a single-stranded chemically modified oligonucleotide being developed to treat patients with Alport syndrome, which is characterized by loss of renal function associated with defects in specific collagen genes expressed in the kidney glomerular basement membrane. RG-012 inhibits miR-21, a microRNA target known to have increased expression in context of kidney stress and associated with renal dysfunction.

**Methods:** In vitro pharmacokinetic (PK) evaluations of RG-012 conducted during preclinical development included: plasma protein binding, metabolic stability in whole blood and liver lysates, and CYP450 inhibition induction potential in cryopreserved human hepatocytes. In vivo PK and toxicokinetic (TK) properties of RG-012, and its major active metabolite (RG0005), were determined upon subcutaneous dosing of RG-012 in a set of nonclinical PK, pharmacology, and safety studies in CD-1, SV129, and COL4A3 mice (6.5 mg/kg once weekly) and cynomolgus monkeys (10-225 mg/kg weekly).

**Results:** Both RG-012 and RG0005 were highly bound (98%) to proteins in plasma from mice, monkeys, and humans. RG0005 was the only major degradation product seen in whole blood and liver lysates from all species. RG-012 exhibited little to no pulmonary uptake or drug displacement enzymes. Upon administration of RG-012, PK and TK properties of RG-012 and RG0005 were consistent across all nonclinical species and were characterized by rapid absorption, dose-dependent plasma exposure, rapid plasma clearance due mainly to extensive tissue distribution, and subsequent slow tissue elimination (half-life in liver and kidney of ~2-3 weeks). C57BL/6 mice were treated subcutaneously with RG-012 at doses ranging from 0.1 to 100 mg/kg. Tissue homogenates were separated using sucrose gradient ultracentrifugation, with microRNAs associating with messenger RNA targets in the heavier polysome fraction. The ability of RG-012 to displace the target miR-21 from the polysome containing fraction was used to assess direct target engagement.

**Results:** RG-012 demonstrated dose dependent displacement of miR-21 from polysomes in both liver and kidney with a maximum effect reached at dose levels that are efficacious in the Col4A3 mouse models. Loss of miR-21 from the polysomes was specific as levels of Let-7a, a control microRNA to which RG-012 has no complementarity, were unaffected. In the liver, target engagement was also assessed using mRNA derepression of a set of confirmed mir-21 target genes. Here, target gene derepression strongly correlated with polysome displacement. This comparison was not possible in kidney, however, because target genes are not regulated in kidneys in the absence of stress.

**Conclusions:** RG-012 directly and specifically inhibits mirR-21 resulting in its displacement from actively translating polysome complexes and subsequent derepression of messenger RNA targets.

**Tacrolimus Pharmacokinetics in Nephrotic Stage**

**Mara Medeiros,1 Saul Valverde,1 Luis Velasquez-Jones,1 Ana M. Hernández,2 Gilberto Castañeda-Hernández,2 Guido Filler.1Hospital Infantil de México Federico Gómez, Mexico; 2CINVESTAV, IPN, Mexico, Children's Hospital, Univ of Western Ontario, Canada.**

**Background:** While tacrolimus (Tac) therapy is not first-line therapy for childhood nephrotic syndrome, it is often used instead of cyclosporine to ameliorate the side effects. The pharmacokinetics of Tac can be influenced by many conditions, and it has a high plasma protein binding. The Tac pharmacokinetics during relapse and remission of childhood nephrotic syndrome have not been well described.

**Methods:** We performed 14 pharmacokinetic (PK) profiles (with measurements before and 0.5, 1, 2, 4 and 12 hours post intake) in 7 children with steroid-resistant nephrotic syndrome (SRNS) during relapse and in remission. These data were compared with historical PK data of 161 PK profiles in 87 pediatric renal transplant recipients with measurements before 0.5, 1, 2, 4 and 12 hours post intake. Tac levels were measured using the Abbott Tacho II assay. We used descriptive statistics to generate percentiles and compared these with the SRNS patients. We also compared the PK profiles during relapse and remission.

**Results:** Median age of SRNS patients was 3.2 years. Tacrolimus dose, biochemical values and pharmacokinetics parameters are shown in Table 1. Values as median and interquartile range.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**
The PK profiles were well within the percentiles of the transplant children.

**Conclusions:** Tac PK profiles are not different in children with nephrotic syndrome during relapse and remission.

Clinical and Genetic Determinants of Longitudinal Dose-Corrected CNI Exposure in Children After Renal Transplantation

**Poster:** Caldwell N. 1, 2, 3

**Background:** Calcineurin-inhibitors (CNI) have a narrow therapeutic index and dosing is difficult due to inter- and intra-individual variation in pharmacokinetics (PK). Polymorphisms in genes involved in drug metabolism can play a critical role in individual exposure. Data concerning long-term CNI exposure in relation to dose in children are scarce and in general based upon trough levels. We present the longitudinal follow up of 12+ year CNI PK in relation to dose, clinical and genetic factors in a cohort pediatric renal allograft recipients.

**Methods:** Retrospective single center study in subjects after renal transplantation (age 0-20 yrs) with annual PK assessments (6-point AUC0-12hr) for tacrolimus (Tac) or 12-hour CNI PK in relation to dose, clinical and genetic factors in a cohort pediatric renal allograft recipients.

**Results:** We collected 180 “full” AUCs for Tac, 56 for CsA in 51 kids. Mean age at Tx: 9.9 yrs (19); FU after Tx: 4.6 yrs (0.16); Dose-corr. exposure (AUC/ dose in mg/ kg) increased with age: 854 (mean) in <5 yrs to 2702 (>15yrs); 817 to 1787 mg/hr/ml in mg/k and TacA resp. (p< 0.01). Correction for dose per m2 body surface (BS) demonstrated stable dose-corr. exposure for ages <15 yrs, and was higher only for >15 yrs (Tac: <5yrs+15yrs: 44 (95% CI: 40-48) >15yrs: 73.4 mg/hr/ml per m2; CsA: 40 (CI: 36-44) vs. 52. CYP3A5 genotype was an important co-determinant of dose-corr. exposure for Tac (2.1 higher dose-req. in *1 vs. *3,3), but not for CsA. *1 carriers had an attenuated increase in dose-corr.exposure into adulthood (27 vs. 39 > 15yrs); *3;3: 48 vs. 82 resp."

**Conclusions:** Dose-corr.exposure according to BS, in contrast to bodyweight, demonstrates stable CNI dose requirements in children <15 yrs. Polymorphisms in CYP3A4 are important for individual Tac dose requirements and modify the effect of age. CsA is not affected by CYP3A4. Our data suggest that CNI dosing per m2 in children after renal transplantation would be less prone to variation in exposure with age and thus preferred. CYP3A4 genotype only aids in predicting Tac dose requirements.

**SA-PO542**

Sex and Race Influences on Tacrolimus Pharmacokinetics in Renal Transplant Recipients

**Poster:** D. Consiglio, 1, 2, 3

**Background:** Tacrolimus (Tac) is the primary calcineurin inhibitor in immunosuppressive regimens for renal transplant recipients (RTR) and exhibits notable interpatient variability in pharmacokinetic (PK) necessitating therapeutic drug monitoring (TDM). There are limited data that characterize race and influences on TAC PK.

**Methods:** During a 12-hour PK study, we evaluated steady-state TAC trough (C0), area under the concentration time curve 0-12 hours (AUC 0-12) normalized for dose, apparent clearance(CL) and total body weight(TBW) normalized CL using non-compartmental analysis. 65 stable African American (AA) and Caucasians (C) females(F) and males(M) who were greater than 6 months post-transplant and receiving TAC and mycophenolic acid were enrolled. TAC dosage was adjusted using C0 range of 4-9 ng/ml. TAC adverse effects (AE) were evaluated using standardized assessments to generate a cumulative AE score(CAE).

**Results:** The clinical and PK parameters are summarized below. Total and weight-normalized CL were most rapid with lower dose-normalized AUC in AA compared to other RTR. Higher CAE was found in female RTR. No sex-race differences were noted for CAE in spite of higher TAC doses in AA.

**Conclusions:** Sex-race differences in TAC PK contribute to differential dosing requirements in AA vs C. A more individualized approach to chronic TAC immunosuppression integrating sex-race with TDM and a standardized adverse effect assessment may benefit RTR.

**Funding:** NIDDK Support, Pharmaceutical Company Support - Astellas Scientific and Medical Affairs, Inc.
Methods: This study was undertaken in the University Hospitals of Ulm (Frieder Keller) and Heidelberg (Claudia Sommerer, Thomas Giese, Martin Zeier). Tacrolimus trough concentrations (Trough) and 1.5 – 2 hours later the peak concentrations (Cpeak) were measured by LCMS. Simultaneously, the Nfat trough effect (Trough) and the nadir effect (Enadir) were determined. The pharmacokinetic half-life (T1/2) was estimated from peak (Cpeak) and trough concentrations (Trough) considering the time distance between steady-state peak and troughs (10.5 – 10 hours). The pharmacodynamic concentration producing the half-maximum effect (CE50) and the Hill coefficient (H) were estimated from trough effect (Trough) at trough concentrations and from nadir effect (Enadir) at peak concentrations. The two equations were solved by numerical iteration for an estimate of the two unknown parameters (CE50, H).

Results: A total of 10 stable kidney transplant patients were included. The median age was 58 years and the median serum creatinine was 306 mcM/L. The pharmacokinetics of tacrolimus were estimated with T1/2 = 11 hours, Cl/F = 64.4h and Vd/F = 480 L. The median value for Nfat was 89% (Trough) of normal gene expression, and the nadir effect was 43% (Enadir) representing the strongest immunosuppression of basal gene expression. The pharmacodynamics of tacrolimus were estimated with CE50 = 7.7 ng/mL and the Hill coefficient with H = 4.6, respectively.

Figure 1: Tacrolimus pharmacokinetics (blue) and pharmacodynamics (red).

Conclusions: While on triple immunosuppression, the NFAT pharmacodynamics indicate a low concentration producing the half-maximum effect and a high Hill coefficient. These findings suggest a narrow trough-to-peak target concentration range of 4.0 to 9.5 ng/mL for tacrolimus.

SA-PO546
Renal NitrAte Clearance in Chronic Kidney Disease

Mark Gilchrist, Jennifer Williams, Richard D’Souza, Miranda J. Smallwood, Lindsay Hayman, Angela C. Shore, Paul G. Winward, Nigel Benjamin. 

NIHR Exeter Clinical Research Facility, University of Exeter, Exeter, United Kingdom; Renal Unit, Royal Devon and Exeter Hospital Foundation Trust, Exeter, United Kingdom; Horizon Inst, South Devon Healthcare Foundation Trust, Torquay, United Kingdom.

Background: Endogenously synthesised nitric oxide (NO) is rapidly oxidised to nitrite and nitrate. These oxidation products can be recycled back into nitric oxide via a complex entero-salivary pathway, thus preserving NO availability. It has previously been shown that 60% of circulating nitrate is excreted in the urine in 48 hours with the fate of the remainder unknown. 24-hour urinary nitrate excretion is often used to estimate total body nitric oxide synthesis rates. It is not known what effect declining GFR has on renal nitrate clearance.

Methods: 27 subjects, 14M, 13F, median age 70 (range 27-74 years) with CKD-EPI eGFR between 9 and 89 were recruited. Following 24hrs low nitrate diet plasma nitrate concentration and 24 hour urinary nitrate excretion were measured to determine renal nitrate clearance using a microplate spectrophotometric method.

Results: There was a statistically significant correlation between renal nitrate clearance and eGFR; Pearson r = 0.748, p<0.0001. There was no relationship between plasma nitrate concentration and eGFR, p=0.239, or between plasma nitrate concentration and renal nitrate clearance, p=0.547.

Conclusions: As plasma nitrate concentration is unchanged despite diminished renal nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitric oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.

The Pharmacodynamic Effect of Tenapanor is Most Pronounced when Administered Before Food in Healthy Volunteers

David P. Rosenbaum, Mikel Knutssohn, Maria Leonsson Zachrisson, Susanne Johansson, Ardeley Inc., Fremont, CA; AstraZeneca R&D, Mölnåld, Sweden.

Background: Tenapanor (AZD1722), a small molecule with minimal systemic availability, is an inhibitor of the Na+/H+ exchanger NHE3. Tenapanor acts locally in the gut to reduce absorption of sodium (Na+) and phosphate. This study evaluated the effect of food intake on the pharmacodynamics of tenapanor.

Methods: In this open-label, 3-way crossover study (NCT02226783), 18 healthy adults (mean age 35.1±11 years; 14 men) completed a randomized sequence of 4-day treatments with tenapanor hydrochloride 15 mg bid: before food (5–10 min before breakfast and dinner); after food (30 min after the start of breakfast and dinner); and at fasting (1 h before breakfast and 3 h after dinner/1 h before an evening snack). There was a 2-day washout between treatments. All participants received the same meals on the same study days; diet was standardized for Na content.

Results: Stool Na content was higher for tenapanor taken before food than after food or at fasting, with least-squares mean differences significant in both cases (Table). Differences in urinary Na were not significant. The difference in stool phosphorus (P) content was significant for tenapanor taken before food versus at fasting. The difference in urinary P was significant for administration before food or after food versus at fasting. Stool frequency and consistency were similar across treatments, and there were slightly higher stool weights for administration before or after food, compared with at fasting. There were no serious AEs or discontinuations due to AEs.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: The pharmacodynamic effect of tenapen, as judged by stool Na content, was greatest when tenapen was taken before food. This supports taking tenapen before meals in future trials.

Triferic Does Not Induce Non-Transferrin Bound Iron or Labile Plasma Iron: In-Vivo/In-Vitro Correlation Raymond D. Pratt,1 Dorine W. Swinkels,2 Carrie D. Guss,1 Ajay Gupta.1 1R&D, Rockwell Medical Inc., Wixom, MI; 2Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: Triferic is a complex iron salt approved for administration via hemodialysate to maintain hemoglobin in patients with CKD SHD. Triferic crosses the dialyzer membrane and binds to transferrin during hemodialysis replacing the obligatory iron losses in HD patients. Serum iron and transferrin saturation (TSAT) values rise after HD and return to the baseline by the start of the next dialysis session.

Methods: A pharmacokinetic (PK) study in healthy volunteers administered up to 10 mg of Triferic iron over 4 hours and up to 20 mg Triferic iron over 12 hours assessed the PK of serum total iron (sFe-total) and transferrin bound iron (TBI). An in-vitro study assessed labile plasma iron (LPI). Triferic iron was added to plasma like medium (40 mg/mL human serum albumin) at a concentration range of 0 to 112 mg/dL. In addition, Triferic was added to 5 different human plasma’s (TSAT, range 10 - 46%; total iron binding capacity (TIBC), mean: 374 mg/dL, range: 342-446 mg/dL) across a concentration span up to and exceeding 100% TSAT. LPI was measured in the presence of 40 mM ascorbate using dihydrosorbin (DHR)-123 in the presence of 50 mM deferiprone (DFO) to detect iron-catalyzed radical generation.

Results: In the human PK study, sFe-total and TBI showed an identical PK profile. Non-transferrin bound iron (NTBI), calculated as the difference between sFe-total and TBI, showed no dose dependent increase up to a TSAT of 100%. In plasma like medium, LPI increased with increasing concentrations of Triferic iron. When Triferic was added to human plasma, there was a small increase in LPI observed when iron concentrations were less than 100% TSAT. The mean magnitude of LPI (expressed in concentration units) at approximately 100% TSAT was 5.35 mg/dL (mean 1.4% of the total iron concentration). Once 100% TSAT was exceeded, the LPI increased rapidly.

Conclusions: Triferic rapidly donates iron to transferrin in vivo and in vitro. In vivo, at TSAT less than 100%, NTBI was minimal. In vitro, the LPI results confirm the lack of redox active iron in plasma until the plasma TIBC is exceeded.

Impact of Tubular Luminal H+/Organic Cation Antipporter, MATE, on Imatinib-Induced Fluid Retention Moto Kajiwara,1 Satohiro Masuda.1 1Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; 2Dept of Research and Development of Next Generation Medicine, Kyushu Univ, Fukuoka, Japan.

Background: A tyrosine kinase inhibitor, imatinib (IMA) is the first class agent against chronic myeloid leukemia. Although little is known about mechanism involved, more than 50% of imatinib-treated patients suffering from edema. In vitro study reported that clinical blood level of IMA inhibits multidrug and toxin extrusion (MATE, SLC47A)-mediated transport of metformine, a hypoglycemic drug. MATE is highly expressed in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin, monoamines. The renal dopaminergic system is likely responsible for regulating >50% of net renal salt and water excretion when salt intake increases. In this study, we test a hypothesized that IMA prevents natriuresis by inhibiting MATE-mediated DA secretion.

Methods: C57BL/6 wild type mice (WT) and Mate1 knockout mice (KO) were used. CYP3A4 and 3A5, Cytochrome P450 3A4 and 3A5, mediated transport of metformine, a hypoglycemic drug. MATE is highly expressed in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin, monoamines. The renal dopaminergic system is likely responsible for regulating >50% of net renal salt and water excretion when salt intake increases.

Results: The sera were also applied to HepG2 in a pooled fashion, alongside pooled sera from adults now investigate whether serum from patients with AKI elicits similar results.

Conclusions: The correlations observed in this study indicate that patients poorly responding to one dose or mode of albuminuria lowering intervention also respond poorly to other doses or modes of intervention in the RAS. Whether other drugs targeting pathways beyond the RAS improve individual response variability requires further study.

Optimizing Between-Patient Variability in Response to Renoprotective Drugs: Meta-Analysis of Rotation Trials Sergej Petrykij,1 Dick de Zeeuw,2 Frederik I. Persson,2 Peter Rosling,2 Hans-Henrik Parving,2 Gozewijn Dirk Laverman,3 Hiddo Jan Lambers Heerspink.1 1Univ Medical Center; Groningen, Netherlands; 2Steno Diabetes Center; Gentofte, Denmark; 3Univ Copenhagen, Denmark.

Background: Individual response to albuminuria lowering intervention is highly variable between patients. To investigate whether uptitrating the dose of drug, changing the mode of intervention with (similar or different drug classes), or lowering dietary sodium intake improves individual response variability, we meta-analyzed individual responses to different modes of anti-albuminuric intervention in non-diabetic and diabetic patients.

Methods: Randomized rotation trials were analyzed to assess correlation of patient-specific responses (n=216 patients) to anti-albuminuric interventions. Included studies (N=20) compared the anti-albuminuric effect of uptitrating the dose of intervention in the RAS (RASI) (N=10 comparisons) and NSAIDs (N=1), rotation within the same class of RASI (e.g. ACEI to ARB; N=5) or NSAIDs (N=3), rotation between RASI and NSAIDs (N=2), and rotation from high to low sodium intake during RASI (N=1). A two stage meta-analysis was performed. First, deeming regression was conducted in each study to assess correlation in response. Individual study results were then meta-analyzed. Albuminuria was measured in 24-hr urine samples.

Results: The albuminuria response to one dose of RASi or NSAID positively correlated with the response to a higher dose of RASi or NSAID, rotation within the same class of RASI or NSAIDs, rotation between RASI and NSAIDs, and rotation from high to low salt intake. Correlations were consistent in diabetic and non-diabetic patients.

SA-PO551
Acute Kidney Injury Serum Uptregulates Hepatic Transcription of Cytochrome P450 3A4 and 3A5 Katie Lane.1 John Dixon,1 Ekram Nabi,2 Barbara J. Philips,1 Iain Macphee,1 Mark E. Dockrell.2 1Critical Care, St. George’s Univ of London, United Kingdom; 2South West Thames Inst for Renal Research, United Kingdom.

Background: Hepatic drug metabolism by cytochrome P450 3A (CYP3A) is reduced in end stage kidney disease (ESKD) and acute kidney injury (AKI). The underlying mechanisms are uncertain. Previously we reported suppression of CYP3A4 mRNA transcription when human hepatocytes (HepG2) were exposed to serum from ESKD patients compared to healthy adults. CYP3A4 and 5 protein concentrations were unchanged. We now investigate whether serum from patients with AKI elicits similar results.

Methods: Serum was collected from critically ill adults with varying AKI severity. Sera from KDIKO 0 (n=15) and KDIKO 3 (n=16) AKI patients were applied individually to HepG2s for 24 h, when cells were lysed. CYP3A4 and 3.5 gene expression was examined by RT-qPCR. CYP3A4 and CYP3A5 protein expression was examined by Western blotting. The sera were also applied to HepG2 in a pooled fashion, alongside pooled sera from adults with ESKD prior to hemodialysis (n=10) and healthy adults (n=6), to allow comparison with previous data.

Results: AKI serum exposure doubled CYP3A4 gene expression compared to No AKI serum (p<0.0055 individual and p<0.003 pooled). AKI serum CYP3A5 mRNA increased approx. 25% compared to No AKI serum (p=0.11 individual and p=0.0098 pooled).

Comparison of Pooled Serum (10%) Effects on HepG2 CYP3A4 and CYP3A5 gene expression

The Effect of Gut-Derived Uremic Toxins on the Expression of Hepatic Drug Metabolizing Enzymes in Chronic Kidney Disease
Thomas Velenosi, Alvin Tieu, Andrew S. Kucey, David A. Feere, Brad Urquhart.

Background: Hepatic drug metabolism is altered in patients with chronic kidney disease (CKD). Previous studies suggest that uremic toxins affect drug metabolizing enzymes in CKD. We hypothesize that gut-derived uremic toxins are involved in the downregulation of hepatic drug metabolizing enzymes and that removal of gut-derived uremic toxins by AST-120 will recover hepatic CYP3A4 and CYP2C enzyme function and expression in rats with CKD.

Methods: Huh7 human hepatoma cells were treated with various uremic toxins as well as a cocktail of all uremic toxins. Chronic kidney disease was induced in male Wistar rats using 0.5% adenine supplemented into rat chow. Control rats were pair-fed to CKD animals. After 5 weeks, control and CKD animals were further divided and received 8% AST-120 or a control diet. Rats were sacrificed 8 weeks after initiation of the study and plasma and liver tissue were obtained.

Results: Indoxyl sulfate caused a concentration-dependent decrease in Huh7 CYP3A4 expression with an IC50 value of 179.8 ± 20.1 μM. In CKD rats, gut-derived uremic toxins: indoxyl sulfate, p-cresyl sulfate and hippuric acid were significantly increased 4.8-fold, 11.8-fold and 3-fold, respectively, compared to controls. Animals with CKD treated with AST-120 had indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD animals and similar to control animals. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD (P<0.05); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased hepatic CYP2C11 mRNA expression that was not recovered by AST-120.

Conclusions: Uremic concentrations of indoxyl sulfate decreased CYP3A4 mRNA expression in Huh7 cells. AST-120 given to rats with CKD reduced indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD and control rats. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD (P<0.05); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased hepatic CYP2C11 mRNA expression that was not recovered by AST-120.

SA-PO553

The Effect of AST-120 on Hepatic and Intestinal Drug Transporter Expression in Chronic Kidney Disease
Andrew S. Kucey, Thomas Velenosi, Alvin Tieu, Stephanie E. Nevison, Brad Urquhart.

Background: Chronic kidney disease (CKD) is the progressive decline in renal function over time. There is a marked reduction in both renal and non-renal drug clearance in CKD. AST-120 is an oral absorbent that promotes the elimination of gut-derived toxins that accumulate in CKD due to impaired clearance. It is hypothesized that there will be a reduction in the expression of drug transporters in CKD conditions. AST-120 will help recover drug transporter expression in CKD by decreasing uremic toxins that accumulate in CKD.

Methods: In vivo: CKD was induced in Wistar rats by treatment with adenine (0.7%) in standard rodent chow for 7 weeks. Treatment groups received AST-120 in the final 3 weeks to decrease the concentration of uremic toxins. Expression of hepatic and intestinal transporters was determined by real-time PCR. In vitro: Using the human hepatoma cell line Huh7, specific uremic toxins (e.g. indoxyl sulfate, p-cresyl sulfate, CMP) will be tested to see if they directly impair rosuvastatin transport. Rosuvastatin uptake will be tested to see if they directly impair rosuvastatin transport. Rosuvastatin uptake will be measured with ultra-performance liquid chromatography coupled to mass spectrometry.

Results: Preliminary results have shown that OATP2 expression is decreased by 25% in CKD rat livers compared to control. Treatment with AST-120 causes a significant reduction in the plasma concentration of the uremic toxins indoxyl sulfate and p-cresyl sulfate. AST-120 treatment restores OATP2 expression to control levels.

Conclusions: Decreased hepatic OATP2 expression in CKD will result in reduced clearance of substrate drugs. This could lead to toxicity if a lowered dose is not administered. On average a CKD patient will be co-prescribed 10 different drugs. Clarifying the impact on drug kidney function can decline after a single dose of co-prescriptions necessitating alternate chemotherapeutic regimens. The current study explored the contribution of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to claspisin kidney disposition on changes to renal function.

SA-PO554

Patient Characteristics and Genes that Contribute to Kidney Function After Cisplatin Therapy

Background: It is known that kidney function can decline after a single dose of cisplatin necessitating alternate chemotherapeutic regimens. The current study explored the contribution of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to cisplatin kidney disposition on changes to renal function.

Methods: Blood (5mL) was obtained from patients (n=206) who received cisplatin. Genomic DNA was genotyped using Illumina bead arrays. Pharmacogenomic data were obtained from existing patient cohorts.

Results: The results underscore the need to view drug metabolism in AKI as distinct from that in ESKD. The contributions of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to cisplatin kidney disposition on changes to renal function were assessed.

Conclusions: There is a marked reduction in both renal and non-renal drug clearance in CKD. AST-120 will help recover hepatic CYP3A4 and CYP2C enzyme function and expression in rats with CKD. The results underscore the need to view drug metabolism in AKI as distinct from that in ESKD. The contributions of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to cisplatin kidney disposition on changes to renal function were assessed. The results underscore the need to view drug metabolism in AKI as distinct from that in ESKD.
in LN patients. Pharmacokinetics of CTX and 4-hydroxycyclophosphamide (4OHCTX) were obtained from 22 patients randomly enrolled from 77 LN patients and applied to explore the mechanism.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

Pharmacokinetics data indicated that patients with a GSTA1*A heterozygous variant had a lower exposure to 4OHCTX compared to wild-type patients (12.8(9.8, 19.5) h*mg/L vs. 27.5 (18.1, 32.8) h*mg/L, P = 0.023), but not CTX. And clinical efficacy was significantly related to higher exposure to 4OHCTX, (P = 0.038).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. **Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX in these 77 LN patients. LN patients with a GSTA1*A mutation (CT heterozygous) had a risk of non-response (P = 0.005).

**Results:** 3 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with fresh media and 100 nM of PTH, 200 ng/mL of IGF1 or 10 ng/mL of FGF23 for 0, 2, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

Conclusions:** LN patients with GSTA1*A heterozygous genotypes had poor CTX treatment response due to less exposure to activated 4OHCTX. A pharmacogenomic approach using the GSTA1 SNP may be useful for predicting clinical efficacy to CTX therapy in LN patients, and facilitating individualized therapy.

**CKD Induces Intrinsic Alterations in Osteoblast Response to 1,25D**

**Renata C. Pereira,** Nadine Khouzam,** Richard E. Bowen,** Isidro B. Salusky,** Katherine Wesseling-Perry,** Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; **Orthopedics, David Geffen School of Medicine at UCLA, Los Angeles, CA.

**Background:** Skeletal mineralization defects are common in pediatric CKD patients. In vivo, 1,25(OH)₂itamin D (1,25D), the only currently approved therapy for the treatment of 2HPT in children, fails to normalize skeletal mineralization in these patients. We have recently demonstrated that primary osteoblasts obtained from patients with CKD have altered proliferation, differentiation and mineralization characteristics, suggesting that CKD results in intrinsic changes to osteoblast biology, independent of circulating mineral ion and hormone concentrations.

**Methods:** To evaluate the interaction between CKD and 1,25D therapy on osteoblast maturation and mineralization, primary human osteoblasts from 3 healthy controls, 3 pediatric dialysis patients with low bone turnover (adynamic bone) and 3 pediatric patients with high bone turnover (2HPT) were cultured under pro-mineralizing conditions consisting of 10 pmol β-glycerolphosphate and 100 µg/ml ascorbic acid in the presence of 1,25D at 1, 10, and 100 nM. After 2, 3, and 4 weeks of growth under mineralizing conditions, cells were washed with PBS, fixed with 10% formalin, and stained with 2% Alizarin Red S. The amount of mineral content was assessed by measuring absorption of acetic acid-extracted Alizarin Red S dye (at 405 nm) normalized by live cell concentration (as assessed by absorption (at 570 nm) of methanol-extracted Crystal Violet staining obtained from parallel cultures).

**Results:** Diminished mineralization is present in CKD; as previously demonstrated in pediatric patients. Further studies are required to assess whether PTH, IGF1 and FGF23 have an effect on mineralization of human osteoblasts.

Mineral Disease: CKD-Bone

SA-PO559
Fourier Transform Infrared Spectroscopy Crystallinity Indices in Bone
from Patients with ADPKD Renata C. Pereira,1 Berenice Y. Gitomer,2 Isidro
B. Salusky,1 Diana George,2 Jason W. Stoneback,3 Karen B. King,3 Myles S.
Wolf,4 Michel Chonchol.2 1Pediatrics, UCLA, Los Angeles, CA; 2Medicine,
Univ of Colorado, Aurora, CO; 3Orthopaedics, Univ of Colorado, Aurora, CO;
4
Nephrology, Northwestern Univ, Chicago, IL.
Background: We have previously shown that patients with autosomal dominant
polycystic kidney disease (ADPKD) and normal kidney function have a low bone turnover
state. This is coupled with increased expression of fibroblast growth factor 23, dentin matrix
protein 1 and osteopontin in bone compared to healthy controls. To further characterize the
bone defect in ADPKD fourier transform infrared (FTIR) spectroscopy was undertaken.
Methods: ADPKD patients with an average eGFR 111 ml/min/1.73m2 and normal
parathyroid hormone levels underwent standard tetracycline double labeling prior to
transiliac crest bone biopsy. FTIR imaging was performed on bone sections from 6 ADPKD
patients and 6 age and sex matched healthy historical controls.
Results: The mean (SD) age and eGFR of ADPKD patients were 29±4 yrs and 115
mL/min/1.73m2, respectively. The sex distribution was 5 males and 1 female. Crystallinity
a measure of the size of mineral crystals and the degree of order within the crystals was
obtained by FTIR and differed significantly between ADPKD and control samples. The
differences were more pronounced in the cortices (1.22 vs. 1.19; p = 0.03) than in the
trabeculae (1.19 vs. 1.17; p= 0.48). There were no significant differences in heterogeneity
of crystallinity, mineral/matrix, carbonate/mineral, collagen maturity (cross links) or acid
phosphate substitution between ADPKD and historical control samples.
Conclusions: We describe for the first time a significant difference in the chemical
composition of cortical bone measured by FTIR in patients with ADPKD when compared
to historical control bone samples. Bone crystallinity has been associated with bone strength
and stiffness, it is thus intriguing to hypothesize that the observed changes may impact bone
quality and expression of bone proteins in ADPKD. Future studies that also assess bone
strength and elasticity will be required to more fully investigate bone quality in ADPKD.

Late Onset Avascular Osteonecrosis in Renal Transplant Recipients
Spyridon Arampatzis, Anita Maurer, Vasileios Devetzis, Uyen Huynh-do.
Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital Bern,
Inselspital, Bern, Switzerland.
Background: Avascular osteonecrosis (AO) after renal transplantation (RT) is a
debilitating skeletal complication. In most studies patients with AO presented within the
first 24 months after RT. In order to determine the prevalence and therapeutic outcome
of late onset AO (³24 months after RT) we conducted a single-center retrospective study
based on radiological/histological confirmed cases.
Methods: We conducted a single-center retrospective study among our RTR with a
clinical diagnosis of AO over the past two decades. We evaluated 70 cases with a AO. In 46
patients AO was radiological/histological confirmed and all relevant clinical, radiological
and laboratory data were extracted and analyzed.
Results: The average follow-up time was 14 (±8) years after the first RT. The prevalence
of AO was 5.4%. Overall, 41 patients showed AO of the femoral head, 23 bilateral AO of
the femoral head, 5 of the knee and 5 of other locations, while 43 patients were symptomatic
at time of diagnosis. In our cohort 71% presented late onset (³24 months) AO after RT.
On average, AO was diagnosed 90 months after RT (SD±78). Furthermore, RTR with late
onset were younger at the time of first RT (39±15 years, p<0.01) than the ones with early
onset (53±14). A considerably higher cumulative dose of prednisone was administered to
patients with late onset of AO prior to their first AO (21±11g vs. early onset 4±1g, p-value
<0.001) and a higher percentage of late onset RTR received corticosteroids even prior to
their first RT (48%) compared to the group of early onset (15%; p=0.038). Overall, 34%
of the patients presented with an advanced stage of AO Ficat III or IV at first diagnosis of
AO and 57% needed total hip arthroplasty.
Conclusions: Late onset avascular necrosis represent a corticosteroid related
complication, with a particularly high prevalence among young RTR and is associated
with significant morbidity. The majority of AO patients have a bilateral manifestation and
present with advance structural femur failure resulting in hip replacement.

SA-PO561
Indoxyl Sulfate Exacerbates Low Bone Turnover Induced by
Parathyroidectomy in Rats Junya Hirata,1 Kazuya Hirai,1 Hirobumi Asai,1
Masaki Inada,2 Chisato Miyaura,2 Hideyuki Yamato,1 Mie Watanabe-Akanuma.1
1
Kureha Corporation, Tokyo, Japan; 2Tokyo Univ of Agriculture and Technology,
Tokyo, Japan.
Background: Low-turnover bone disease is one of the bone abnormalities observed
in chronic kidney disease (CKD) patients and recognized to be associated with low serum
parathyroid hormone (PTH) level and skeletal resistance to PTH. Indoxyl sulfate (IS) is a
representative uremic toxin that accumulates in the blood as renal dysfunction progresses
in CKD patients. In order to examine whether IS exacerbates low bone turnover, we
produced rats with low bone turnover by parathyroidectomy (PTX) and fed these rats a
diet containing indole, a precursor of IS, to elevate blood IS level from indole metabolism.
Methods: Male SD rats were underwent PTX. From 2 weeks after PTX, the rats
were fed a diet containing 0.5% indole (w/w) for 4 weeks. Serum IS levels and bone

Poster/Saturday

metabolism related markers were examined periodically. After the end of indole treatment,
histomorphometric analyses in the secondary spongiosa of the femur and measurement of
bone mineral density of the tibia were performed.
Results: Histomorphometric analyses revealed significant decreases in both bone
formation-related parameters (mineralized surface/ bone surface, bone formation rate/ bone
surface) and bone resorption-related parameters (eroded surface/ bone surface, osteoclast
surface/ bone surface) in PTX rats. In indole-treated PTX rats, further decreases in bone
formation-related parameters were observed. On the other hand, there were no decreases in
bone resorption-related parameters in indole-treated PTX rats when compared to the PTX
rats. Serum IS levels in indole-treated PTX rats were elevated during the indole treatment
period and the levels were similar to those in CKD and dialysis patients.
Conclusions: IS exacerbates low bone turnover through inhibition of bone formation
by mechanisms unrelated to skeletal resistance to PTH in rats. Our data suggest that IS
may be one of the uremic toxins that contribute to progression of low-turnover bone
disease in patients with CKD or on dialysis whose serum IS levels are elevated because
of renal dysfunction.

SA-PO562
Changes of Marrow Adipocyte Away from Bone Surface After
Parathyroidectomy in Patients with Secondary Hyperparathyroidism
Aiji Yajima, Ken Tsuchiya, Kosaku Nitta. Medicine, Tokyo Women’s Medical
Univ, Tokyo, Japan.
Background: We’ve already reported that marrow adipocytes proliferated around
bone surface after parathyroidectomy for secondary hyperparathyroidism. However, fibrous
volume was reduced near bone surface where adipocytes proliferated after the surgery.
In addition, adipocytes may be associated with bone remodeling, because adipocytes
suppress the function of osteoblasts. Therefore, the parameters of marrow adipocyte,
which are away from bone surface were histomorphometrically measured before and after
parathyroidectomy for secondary hyperparathyroidism.
Methods: Sixteen hemodialysis (HD) patients suffering from secondary
hyperparathyroidism (Age; 58.4 ± 8.4 years, HD duration; 14.3 ± 6.8 years ) were treated
by total parathyroidectomy with immediate autotransplantation (parathyroidectomy)
and received iliac bone biopsies before and at 1 week (n=4) and at 4 weeks (n=10) after
parathyroidectomy. Adipocyte volume per marrow volume (Fa.V/Ma.V;%), adipocyte
number per marrow volume (N.Fa/Ma.V;N/mm2), and mean adipocyte volume (Fa.V/N.
Fa (×10-3) mm2/N) were obtained in the area away from bone surface. If there are so many
artifacts in bone marrow, the bone samples were excluded from this research.
Results: Serum intact parathyroid hormone (i-PTH) level was decreased from 1268.8
± 459.6 to 18.5 ± 7.9 pg/mL. Fa.V/Ma.V was siginificantly increased from 22.4 ± 6.3 to
30.9 ± 8.1 % (P<0.001), N.Fa/Ma.V was also increased from 183.3 ± 48.1 to 217.7 ± 47.1
N/mm2 (P<0.001), and Fa.V/N.Fa was not changed (1626.9 ± 418.5 to 1668.7 ± 548.1 (×
10-3) mm2/N) after parathyroidectomy.
Conclusions: The facts substantiate that an acute reduction of PTH induced an increase
of adipogenesis. As reported previously, osteoblast surface transiently increased at 1 week
after parathyroidectomy, but it acutely decreased at 4 weeks after the surgery. Thease findings
mean that undifferentiated stem cells went to the adipogenesis after the acute reduction of
PTH in patients receiving HD.

Sao Paulo, Brazil; 5UNINOVE.
Background: The osteoblasts (Obs) and adipocytes (Ads) derive from the mesenchymal
cells (MSCs). An imbalance in the differentiation of Obs and Ads could be decisive to
preserve the integrity of bone. We analyzed bone histomorphometry and marrow adiposity
in bone biopsies from patients before and after kidney transplantation (KT).
Methods: We compared biochemical parameters and bone histomorphometry data
from 23 patients, before and one year after KT, under standard immunosuppressive therapy
including glucocorticoids. Adipocytes area (Ad.Ar/T.Ar,%), number (N.Ad/B.Pm,n/mm),
and the ratio adipocytes/active osteoblasts (N.Ad/N.AcOb), and adipocytes/total osteoblasts
(N.Ad/N.TOb) indexes were measured.
Results: Our patients were young (42.3±2.6 years) and mostly male (14). One year
after KT, PTH levels (515.6±424.1 vs. 96± 137.1), bone alkaline phosphatase (98.2±63.9
vs. 37.4± 26.6) and sclerostin (1.1±0.8 vs. 0.5± 0.1) decreased significantly. A significant
increase in Ad.Ar/T.Ar (24.3±11.6 vs. 30.6±10.5), N.Ad/B.Pm (37.3±20.6 vs. 47.9±25),
N.Ad/N.AcOb (240.4±657.6 vs. 674.6±1192.4) and N.Ad/N.TOb (128.2±362.3 vs.
230.5±642.4) and a decreased osteoblast number/tissue area (22.8±21.9 vs. 5.3±2.8) was
observed. In the post-transplant biopsies significant correlation was found between N.Ad/N.
TOb and PTH (r=-0.48), trabecular number -Tb.N (r=-0.29) and mineral apposition rate
(r=-0.23); as well as between Ad.Ar/T.Ar and bone volume (r=-0.36) and between N.Ad/B.
Pm and Tb.N (r=-0.72).
Conclusions: KT improved biochemical findings related to bone mineral disease,
however, this condition is also clearly associated with an inverse relationship of the bone

mass and osteoclastic activity with marrow adiposity, compromising dynamic parameters. MSCs differentiation is competitively balanced; mechanisms that promote one cell fate actively suppress mechanisms that incite the alternative.

SA-PO564
High Marrow Adiposity Is Associated with Low Turnover Bone Disease in Peritoneal Dialysis Patients
Evelyne C. Barreto,1 Rodrigo Azevedo de Oliveira,1 Mariel Jose Hernandez,2 Ana Clara Simões Flórido Almeida,1 Luciene dos Reis,1 Aluizio B. Carvalho,1 Vanda Jorgetti,2 Rosa M.A. Moxes,2,4 Pontifícia Univ Católica do Paraná; 2Univ de São Paulo; 3Univ Federal de São Paulo; 4Univ Noce de Julho, UNINOVE; 5Univ Federal do Rio Grande do Norte; 6Univ de Caracas.

Background: Marrow adiposity has been implicated in the pathogenesis of bone disorders, such as osteoporosis and bone fragility. We sought to investigate the relationship between marrow adiposity and renal osteodystrophy in peritoneal dialysis patients.

Methods: We analyzed transilic bone biopsy specimens from 41 peritoneal dialysis patients (age:50.3±10.2 yrs) by quantitative histomorphometry to assess bone and marrow adipocyte parameters. Selected biochemical parameters, such as serum markers of bone turnover and sclerostin, were measured.

Results: Adipocyte area (Ad.Ar), perimeter (Ad.Pm) and percentage of adipocyte volume per marrow volume (Ad.V/MA.V) correlated positively with age. Diabetic patients had higher marrow adiposity than non diabetic patients (Ad.V/MA.V= 50.14±39.12%; P=0.009; Ad.Ar=619.0±0.6 vs 615.0±0.9 mm²; P=0.02). Ad.V/MA.V demonstrated inverse association with bone specific alkaline phosphatase (r=−0.32,P<0.04) and direct relationship with sclerostin (r=0.38,P<0.01). No association was found between marrow adiposity and dynamic bone hystomorphometric parameters. Interestingly, patients with Ad.V/MA.V >41% (median) presented higher percentage of low turnover bone disease (P=0.04) as well as significantly lower bone specific alkaline phosphatase (39.5±27.3 vs 65.3±28.9 U/L; P=0.006) and higher sclerostin (2.3±0.97 vs 1.6±0.97 nmol/mL; P=0.02) levels than patients below the median.

Conclusions: Increased marrow adiposity seems to be associated to lower osteoblast activity and to low turnover bone disease in peritoneal dialysis patients. The higher marrow fat in diabetic and aged patients might expose them to an increased risk for fracture. Further studies are required to understand the possible contribution of marrow adiposity to the pathogenesis of renal osteodystrophy.

Role of Wnt10b Signaling in Cinacalcet-Induced Bone Anabolic Effects
Cai-Mei Zheng,1 Yung-Ho Hsu,1 Yuh-Feng Lin,2 Jia-Pwu Shyu,3 Kuo-cheng Lu,4 1Graduate Inst of Clinical Medicine, Taipei Medical Univ, Taipei City, Taiwan; 2Dept of Nephrology, Shuang Ho Hospital, New Taipei City, Taiwan; 3Biology and Anatomy, National Defense Medical Center, Taipei City, Taiwan; 4Dept of Medicine, Cardinal-Tien Hospital, New Taipei City, Taiwan.

Background: Chronic kidney disease-mineral bone disorders (CKD-MBD) is important for osteoporosis and bone fractures in CKD patients. Since calcium receptor plays an important role in osteoclast differentiation, we assume that calcimimetic agents (cinacalcet) might have a role in bone remodeling.

Methods: Bone marrow mononuclear cells isolated from rat femur and tibia were induced into osteoclasts by M-CSF and RANKL treatments. Osteoclasts were treated with different doses of cinacalcet. Untreated osteoclasts used as control. The release of C-terminal telopeptide of type I collagen (CTx) from cultured osteoclasts was measured by ELISA.

Results: In osteoclasts, cinacalcet decrease the TRAP stain reaction. However, ELISA analysis showed increases of Wnt10b expression in supernatant collected from the cinacalcet-treated osteoclasts. Pretreatment of Wnt10b secretion inhibitor, C-59, blocked the increase of Wnt10b induced by cinacalcet. Western blot analysis showed an increase intracellular Wnt10b in the cinacalcet-treated osteoclasts. Culture of osteoclasts with the cinacalcet-treated osteoclasts supernatant showed an increase of mineralization as indicated by alizarin red staining. Intracellular calcium staining is increased in cinacalcet-treated osteoclasts, which demonstrated its effect on osteoclast Wnt 10b release is through intracellular calcium oscillation. Cletskines and bone mineral density (BMD) changes are also noted in CKD rats before and after cinacalcet treatment.

Conclusions: Cinacalcet decrease osteoclastic activity, but increase the secretion of Wnt10b through intracellular calcium oscillation. Cinacalcet also related with certain cletskine and BMD changes in CKD animals.

SA-PO566
Changes of Osteocyte Number in Micropetrosis Area After Treatment of Secondary Hyperparathyroidism
Aji Yajima,1 Ken Tsuchiya, Kosaku Nitta,2 Medicine, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Osteocyte number decreased after total parathyroidectomy with immediate autotransplantation (parathyroidectomy) for secondary hyperparathyroidism in hemodialysis patients (JBMR 2010). Osteocyte number in micropterosis area also higher area was measured before and after parathyroidectomy and treatment with cinacalcet hydrochloride (HCL)

Methods: Thirteen HD patients received parathyroidectomy and transilic bone biopsies before and at 3-9 weeks after parathyroidectomy (Group I). And eight HD patients with secondary hyperparathyroidism were treated by cinacalcet HCL and received bone biopsies before and at 1 year after the treatment (Group II). Osteocyte number in micropterosis area (N.Ot/Mp.V) was changed measured before and after the treatment.

Results: Serum intact PTH and serum i-PTH levels decrease from 903.6 ± 768.3 to 24.8 ± 8.1 pg/ml after parathyroidectomy. N.Ot/Mp.V was decreased from 58.9 ± 71.2 to 110.1 ± 87.3 N/mm² (P<0.001) and N.Ot/(BV-Mp.V) was not changed (from 236.1 ± 69.3 to 262.2 ± 79.3 N/mm²) after parathyroidectomy (Group I). Serum i-PTH levels decrease from 903.6 ± 503.0 to 212.7 ± 98.1 pg/ml after the treatment with cinacalcet HCL. N.Ot/Mp.V was not changed in both micropterosia area (100.1 ± 68.2 to 99.6 ± 76.1 N/mm²) and in the other area (from 240.1 ± 56.3 to 279.6 ± 88.6 N/mm²) after the treatment (Group II).

Conclusions: Cinacalcet HCL did not reduce osteocyte number in both micropterosis area and in the other area, suggesting that this agent improves bone quality by maintaining osteocytic perilacunar/canalicular system. Parathyroidectomy reduces osteocyte number in only the micropterosis area.

SA-PO567
Trabecular Bone Score in Kidney Transplant Recipients
Kyla Lynn Naylor,1 Lisa M. Liz,2 Didier Hans,2 Amit X. Garg,3,4 David N. Rush,2 William Leslie.2 Western Univ; 1Univ of Manitoba; 2Lansanne Univ Hospital; 3London Health Sciences Centre; 4Inst for Clinical Evaluative Sciences.

Background: Kidney transplant recipients have altered bone mineral metabolism and are at a higher risk of fracture compared to the general population. There is conflicting evidence regarding the ability of bone mineral density (BMD) to accurately predict fracture. Trabecular bone score (TBS) is a texture measure derived from dual energy x-ray absorptiometry (DXA) lumbar spine images which provides information independent of BMD. We assessed TBS in kidney transplant recipients.

Methods: We included 38 kidney transplant recipients from Manitoba, Canada, who received a post-transplant DXA (median 106 days post-transplant). We matched each kidney transplant recipient (mean age 45 years, 39% men) to three controls from the general population (matched on age, sex, and date of DXA). Lumbar spine (L-1-4) DXA images were used to derive TBS. Non-traumatic incident fracture (excluding hand, foot, and craniofacial) (n=31) were assessed during a mean follow-up of 6.6 years. We used logistic regression to determine predictors of TBS and hazard ratios per standard deviation decrease in TBS to express the gradient of risk for fracture prediction using Cox proportional hazards regression.

Results: Compared to the general population, kidney transplant recipients had significantly higher lumbar spine TBS (1.41 ± 0.13 versus 1.37 ± 0.13, p<0.001). Multiple logistic regression revealed reduced TBS (lowest versus highest tertile) in kidney transplant recipients compared to the general population (adjusted odds ratio, 2.13 95% confidence interval [CI] 1.47-3.07). TBS predicted fractures in kidney transplant recipients independent of the Fracture Risk Assessment (FRAX) score and spine BMD (adjusted hazard ratio per standard deviation decrease in TBS 1.57, 95% CI 1.07-2.29).

Conclusions: Kidney transplant recipients had abnormal bone texture as assessed by TBS. Lumbar spine TBS was able to predict incident fractures in kidney transplant recipients and may provide novel insights into skeletal fragility in this unique population.

SA-PO568
Low Bone Turnover Disease Is Prevalent 1 Year After Successful Renal Transplantation: A Cross-Sectional Bone Biopsy Study
Pieter Everepoed,1 Patrick C. D’Haese,2 Liesbeth Viane,1 Geert J. Behets,2 1Nephrology, Univ Hospitals Leuven, Leuven, Belgium; 2Pathophysiology, Univ of Antwerp, Antwerp, Belgium.

Background: Studies evaluating bone histomorphometry in renal transplant recipients are scanty and so far hampered by small sample size and heterogeneity.

Methods: We evaluated bone histomorphometry (according to TMV classification), laboratory parameters of mineral metabolism (including biPTH, FGF23, sclerostin, OPG, sRANKL), biomarkers of bone formation (bsAP) and bone resorption (TRAP5b, NTX), and inflammation (IL6) in an unselected cohort of 60 renal transplant recipients (44 males, age 56±12 yrs) 1 year after transplantation. Standard immunosuppressive regimen consisted of steroids, a calcineurin inhibitor and mycophenolate mofetil. Mean cumulative methylprednisolone dose at 1 year was 7.7 g/d.

Results: Sixty-five % of the patients presented with disturbances at least one of the markers. However, low bone turnover disease were noted in 1.7, 4.50, and 53.3 % of renal transplant recipients, respectively. Mineralization was delayed in 17.0 % and bone volume was low in 15.0 %. Patients with persistent

Mineral Disease: CKD-Bone
Poster/Saturday
Sclerostin Bone Expression and Blood Levels in Patients with Chronic Kidney Disease Stage 2-5
Eloise Lima, Marie-claude M. Fougere, Hanna W. Mawad, Hartmut H. Malluche.

Methods: Fifty pts underwent anterior iliac crest biopsies and blood was drawn at time of biopsy. Kidney function was determined by creatinine clearance using MDRD calculation. There were: 11 CKD-2, 16 CKD-3, 9 CKD 4-5 pts, and 14 healthy aged-matched controls. Bone sections were also measured for histomorphometry to be analyzed, mineralization, and volume.

Results: Blood scl levels were significantly greater in CKD compared to controls with no differences between stages (P=0.01).

Bone scl expression was significantly higher in cortical CKD 2-5 pts compared to controls (P<0.01). Scl expression was significantly greater in cortical than in cancellous bone in CKD. In cancellous bone scl expression was higher in CKD, which was reached significance in CKD-3 (Figure 1).

Scl expression in cortical and cancellous bone correlated with serum scl (r=0.30, 0.40, r=0.05), serum scl correlated negatively with bone formation activation, frequency, osteoblast number (r=-0.33, -0.38, -0.43, r=0.05). Scl in bone negatively correlated with trabecular thickness (r=0.51; p=0.05), osteoblast and osteoclast surface, and erosion depth (r=-0.50, -0.52, 0.55, r=0.01).

Conclusions: These findings ascribe a potential role to scl in the pathogenesis and management of ROND.

Intercelin-1 Inhibition, Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD), and Physical Function
Kristen L. Nowak,1 Adriana Hung,2,3 Talat Alp Ikizler,4 Heather Farmer,5 Natjalie Salas,6 Raif A. Chaudhry,7 Andrew N. Hoofnagle,6,7 Gerard John Smit,8 Michel Chonchol,9 1Univ of Colorado Denver; 2Vanderbilt Univ; 3VA Tennessee Valley Healthcare System; 4Univ of Washington.

Background: Epidemiologic studies have suggested a possible link of chronic systemic inflammation with vitamin D deficiency, intact parathyroid hormone (iPTH), and fibroblast growth factor 23 (FGF23) excess, which are a central features of CKD-MBD. Declining renal function is also associated with worsening physical function, which may be explained by systemic inflammation, CKD-MBD, or both. We hypothesized that inhibiting inflammation with an interleukin-1 (IL-1) trap would improve vitamin D deficiency, iPTH and FGF23 excess, as well as physical function in patients with moderate-to-severe CKD.

Methods: In a two-site, double-blind trial, 42 patients with stage 3-4 CKD were randomized to either the IL-1 trap rilonacept (160 mg/week) or placebo for 12 weeks. The following CKD-MBD markers were assessed in serum before and after the intervention: calcium, phosphorus, 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D (1,25(OH)2D), PTH, and iFGF23. A battery of tests was also administered in a sub-group (n=22) to assess multiple domains of physical function (endurance, locomotion, dexterity, balance, strength, and fatigue).

Results: Participants were 63±11 years of age, 24% female, 29% Hispanic, mean eGFR 38±13 ml/min/1.73 m2, and mean high sensitivity C-reactive protein (hsCRP) 4.7±4.2 mg/L. Rilonacept effectively reduced systemic inflammation, as evidenced by reduced hsCRP levels (p<0.01). There was no change in serum calcium, phosphorus, 25(OH)D, 1,25(OH)2D, PTH, or FGF23 levels with IL-1 inhibition. Similarly, rilonacept did not alter locomotion, dexterity, balance, strength, or fatigue (p>0.02). However, endurance (400m walk time) tended to be reduced in the rilonacept (-29 sec) as compared to placebo (-6 sec; p=0.059).

Conclusions: A single timepoint scl is inversely associated with mortality in our cohort of dialysis patients. Scl change over a six month period does not predict mortality.

**Serum Metabolomic Profiling and CKD-MBD: A New Tool for Bone Turnover Evaluation**

 Amelia Lorencatto Baptista, 1 Kallayanda Padilha, 1 Pamela Araujo Malagrinho, 1 Gabriela Venturini, 1 Ana Carolina de Mattos Zeri, 1 Janaina Silva Martins, 2 Rodrigo Azevedo de Oliveira, 1 Geusa Dutra, 3 Luciene dos Reis, 3 Vanda Jogetti, 1 Alexandre Costa Pereira, 1 Rosa M. A. Moyaes, 1,2 Nephrology, USP; 1 Molecular Cardiology, INCOR, USP; 2 LBi, CNPMP; 3 UFRN; 3 Master Degree Program, UNINOIVE, Brazil.

**Background:** Bone biopsy still is the gold standard to assess bone turnover in CKD patients and serum biomarkers are not able to replace histomorphometry. Recently, metabolomics has emerged as a new technique that could potentially improve disease diagnosis and the understanding of pathophysiology. However, as this approach has never been tested in the CKD-MBD scenario we investigated whether a serum metabolomic profile could help us to better predict bone turnover in CKD patients.

**Methods:** Serum and bone histomorphometry data from hemodialysis (HD, n=51) and peritoneal dialysis patients (PD, n=40) were analyzed. They were classified as high (HT, 49.4%) or low turnover (LT). Metabolic analysis was done through MRI spectroscopy, followed by identification and quantification of metabolites and PLS-DA. As HD had a completely different metabolome of PD group, we analyzed them separately. In addition, we selected the main metabolites found in each group and searched for the metabolomic pathways involved.

**Results:** The difference between LT and HT was explained by 12 metabolites in HD and 8 in PD (p = 0.03 and 0.01, respectively). ROC curve analysis showed that parathormone and alkaline phosphatase was the best predictors for HT, whereas glyceral and glucose were the best predictors for LT in HD and PD, respectively. The main canonical pathways involved were glycine degradation, tyrosine biosynthesis IV and phenylalanine degradation I in HD and creatine-phosphate biosynthesis, pyruvate fermentation to lactate and AMPK signaling in PD group.

**Conclusions:** In this preliminary analysis, we identified new metabolites that might be used as biomarkers of bone turnover. Moreover, the differences in metabolite between the two dialysis modalities and the different metabolic pathways suggest that the pathophysiological mechanisms involved in the modulation of bone turnover in these patients might be different.

**Funding:** Government Support - Non-U.S.

**Deletion of the Gene Encoding the Transient Receptor Potential Canonical Canonical Type 1 (TRPC1) Channel Produces Hyperparathyroidism, Low Calcitonin (CaT), Hypercalcemia, but Hypocalciuria and Enhanced Bone Mass: Evidence for the Role of TRPC1 in Regulating Intracellular Ca (Ca-[i]) in Target Cells**

 Bonnie Ebby, 1,2 Alexander Lau, 1,2 Lindsay J. Barron, 1,2 Marybeth Humphrey, 1 Leonidas Tsiokas, 1,2 Kai Lau, 1,3 Medicine, Univ of Oklahoma, Oklahoma City, OK; 3 Cell Biology, Univ of Oklahoma, Oklahoma City, OK; 2 Medicine, VA Medical Center; Oklahoma City, OK.

**Background:** We recently showed that TRPC1 deficiency impairs store-operated Ca entry (SOCE), reduces [Ca^2+] in osteoclast-precursors and mature osteoclasts does not affect osteoclast differentiation and function. In addition, the differences in metabolomic pathways involved were glycine degradation, tyrosine biosynthesis IV and phenylalanine degradation I in HD and creatine-phosphate biosynthesis, pyruvate fermentation to lactate and AMPK signaling in PD group.

**Conclusions:** In this preliminary analysis, we identified new metabolites that might be used as biomarkers of bone turnover. Moreover, the differences in metabolite between the two dialysis modalities and the different metabolic pathways suggest that the pathophysiological mechanisms involved in the modulation of bone turnover in these patients might be different.

**Role of the Sodium/Calcium Exchanger NCX1 in Osteoclasts**

 Giuseppe Albanu, 1,3,4 Candice Stoudmann, 2,4 Willy Hofstetter, 2 Olivier Bonny, 1,3,4 Daniel G. Fuster, 1,3,4 "Div of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; 2 Inst of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; 3 Dept of Clinical Research, Univ of Bern, Bern, Switzerland; 4 NCCR Kidney.CH, Univ of Zürich, Zürich, Switzerland.

**Background:** Previous studies demonstrated that inhibition or siRNA-mediated knockdown of sodium/calcium exchanger 1 (NCX1) in osteoclasts decreases bone resorption in vitro, indicating a critical role of NCX1 in osteoclast-mediated bone resorption.

**Methods:** To test the role of NCX1 in osteoclasts in vivo, we generated mice with osteoclast-specific deletion of NCX1 (NCX1^+/−/−). For this purpose, mice with a floxed exon 11 of NCX1 were crossed with mice expressing Cre-recombinase under the influence of the osteoclast specific cathepsin K promoter.

**Results:** Osteoclasts differentiated from NCX1^+/−/− mice displayed an 80-90 % reduction of NCX1 protein compared to wild-type mice. NCX1 expression was unaltered in extraosseous tissues in NCX1^+/−/− mice. NCX2 and NCX3 were present at low levels in wild-type osteoclasts and not upregulated in NCX1^+/−/− osteoclasts. In vitro RANKL stimulation of bone marrow cells isolated from wild-type and NCX1^+/−/− mice yielded no differences in osteoclast development and resorptive activity. In addition, at 3 months of age, structural parameters of bone, quantified by high-resolution microcomputed tomography, were not different in NCX1^+/−/− mice compared to wild-type littermates. To stimulate osteoclast-mediated bone resorption, we performed surgical ovariectomy (Ovx) in 12 week old female mice, but Ovx-induced bone loss over 12 weeks was similar in WT and NCX1^+/−/− mice.

Interestingly, however, at 6 months of age, female NCX1^+/−/− mice had significantly higher bone volume whereas male NCX1^+/−/− mice displayed reduced bone volume compared to wild-type mice.

**Conclusions:** Our data indicate that genetically induced deficiency of NCX1 in osteoclast-preursors and mature osteoclasts does not affect osteoclast differentiation and bone resorption in vitro. However, NCX1^+/−/− mice display an age- and sex-specific phenotype. Additional studies are needed to unveil the underlying mechanisms.

**Funding:** Government Support - Non-U.S.

**SA-PO576**

**The Impact of a Previously Created AV-Fistula on Radial Bone Mineral Density Measurements in Renal Transplant Recipients**

 Spyridon Arampatzis, 1 Vasileios Devezis, 1 Uyen Nguyen, 2 Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital of Bern, Inselspital, Bern, Switzerland.

**Background:** The arteriovenous-fistula (AVF) of the distal radius often remain patent after transplantation. Distal radius is the typical site for peripheral DXA measurements in renal transplant recipients (RTR). Since no data exist concerning the impact of a previously created AVF on peripheral bone characteristics in RTR we evaluated the effect of AVF on bone mineral density (BMD) as mirrored by contralateral differences between forearms and explored the densitometric correlation of distal radius with the tibia as an alternative peripheral measurement site.

**Methods:** This cross sectional study included 40 renal transplant recipients (RTR) and 40 chronic kidney disease (CKD) patients matched for age, gender and BMI. In addition to relevant demographic, biochemical, and clinical aspects we assessed bone characteristics of both forearms, femoral neck and tibia by DXA.

**Results:** The CKD patients without any AVF, displayed no significant discrepancies concerning BMD in both forearms. In RTR BMD was significantly lower in the AVF arm as compared to non-AVF arm (0.84 vs. 2.12 mg/cm2, p<0.001). This significant side-to-side difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7% at the ultradistal radius, respectively. The BMD intersite analysis between radius and distal tibial showed no significant difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7% at the ultradistal radius. Additionally, the BMD intersite analysis between radius and distal ulna showed no significant difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7% at the ultradistal radius. Additionally, the BMD intersite analysis between radius and distal ulna showed no significant difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7% at the ultradistal radius.

**Conclusions:** In conclusion, a previously placed AVF in RTR exerts a negative impact on bone mineral density. A strong and highly significant correlation (r= 0.7346-0.875) between corresponding BMD measurements in both forearms was observed. However, a negative impact on bone mineral density was not observed in the contralateral arm.

**Funding:** National Institute of Arthritis, Diabetes, Digestive and Kidney Disease (NIADDK), National Institute of Diabetes and Digestive and Kidney Disease (NIDDK), National Institute of Diabetes, Digestive and Kidney Disease (NIDDK), National Institute of Diabetes, Digestive and Kidney Disease (NIDDK), National Institute of Diabetes, Digestive and Kidney Disease (NIDDK), National Institute of Diabetes, Digestive and Kidney Disease (NIDDK)
Methods: We evaluated cortical bone histomorphometry in 13 CKD stage 3 and 4 pts, (9 male, age 65 ± 10.4, eGFR 23.8 ± 3.3 ml/min/m², white race, trans-diaphyseal bone biopsy) and compared them to 13 dialysis pts (9 male, 11 on HD, age 52.15 ± 10.2, 55.3 ± 17.6 mo in RRT).

Results: Biochemical values and external cortical bone parameters of both groups shown in table

Dialysis pts compared to the pre-dialysis population showed more demargined cortical bone, with decreased cortical thickness, increased osteoblast formation rate and adjusted apposition rate. In this pre-dialysis population, external cortical porosity positively correlated with both trabecular bone volume and osteoid volume (respectively, r=0.70 and 0.76, p=0.016 and p=0.006). External cortical osteoblast BFR correlated negatively with S-calcium (r=-0.88, p=0.021) and positively with trabecular thickness (r=0.88, p=0.021). These findings were not observed in internal cortical suggesting that this is more stable to PTH effects.

Conclusions: In pre-dialysis pts, our findings support that PTH has a modulating effect on both trabecular and cortical bone. As renal disease progresses cortical thinnening is more pronounced, eventually contributing to the higher fracture rate. Understanding cortical abnormalities may have implications in the treatment of CKD-MBD.

SA-PO579
Chronic Hyponatremia Is a Novel Risk Factor for Hip Fracture in Chronic Kidney Disease-Mineral Bone Disease
Sagar U. Nigwekar,1 Andrew S. Allegritti,1 Julia Beth Wenger,1 Juan Carlos Ayus,2 Ravi L. Thadhan1, Ishir Bhan1,1 Massachusetts General Hospital;1 Renal Consultants of Houston.

Background: Risk factors that make skeleton more fragile in chronic kidney disease (CKD) are uncertain. Considering recently reported direct effects of sodium depletion on bone health, we investigated chronic persistent hyponatremia (CPH) as a novel risk factor for hip fractures caused by CKD-mineral bone disease (CKD-MBD).

Methods: Cases for this multi-center case-control study were elderly (>65 years) patients with CKD (eGFR<60 ml/min) with a new hip fracture. Controls (CKD patients with no hip fracture) were matched to cases on age, sex, race and comparative health. Primary exposure was serum sodium <135 mEq/L on at least 2 occasions ≥ 90 days apart within one year preceding hip fracture for cases and within the first year of study entry for controls (CPH100). Secondary exposure definitions were hyponatremia on at least 1 occasion (H1) and hyponatremia on at least 2 occasions ≥ 180 days apart (CPH180). Variables for multivariable logistic regression analyses were identified using stepwise selection.

Results: We analyzed 1,236 cases and 4,515 controls. Mean age of all patients was 84 ± 9 years, 87% were whites, and 39% were females. Serum calcium, phosphate, parathyroid hormone and 25-hydroxy vitamin D levels were similar between cases and controls. Prevalence of CPH100 (21.2 vs. 9.9%, P<0.001), CPH180 (15.5 vs. 6.5%, P<0.001) and H1 (52.7 vs. 41.1%, P<0.001) were higher in cases compared to controls. In analyses adjusted for falls, tobacco-use, osteoporosis, eGFR, body mass index, heart failure and medications, CPH90 and CPH180 were associated with increased risk of hip fracture but H1 was not.

Conclusions: CPH is a risk factor for hip fractures caused by CKD-MBD. Mechanistic studies are needed to investigate the effects of CPH on bone turnover, mineralization and volume in CKD.

Funding: Private Foundation Support

SA-PO580
Follicle Stimulating Hormone Is Associated with Low Bone Mineral Density in Women in Hemodialysis

Background: CKD-MBD associated with sexual hormonal status have not been well evaluated. Aim: Assess the association between female hormones (FSH and estradiol) and bone mineral density (BMD) in women in hemodialysis (HD).

Methods: Cross-sectional study in 46 women (20-60 years), at least 3 months in HD in a tertiary care setting between Jan-Jul 2014. Pregnant patients or with steroid medication were excluded. Physical examination and blood markers of sexual hormonal and mineral-bone status were done. Bone densitometry of lumbar spine and non-dominant femur were performed; the results were classified as normal, osteopenia and osteoporosis.

Results: 5 had osteoporosis and 5 had osteopenia in the lumbar spine. In the femur, 1 had osteoporosis and 18 had osteopenia. Comparisons are shown in Table. BMD in lumbar spine was associated to FSH (R² =0.27; P<0.001), FSH (OR =0.52 [-0.02 - -0.008]; p=0.001), on the other hand BMD in femur (R² =0.50; p<0.001), FSH (OR =0.34 [-0.01 -0.001]; p=0.02), and CRP were significantly associated (OR =0.32 [-0.02 - -0.001]; P<0.03)

Conclusions: FSH is an independent factor associated with osteoporosis in women in HD who are menstruating.

Time Averaged Intact Parathyroid Hormone Concentration as a Risk Factor For Hip Fractures in Patients on Dialysis

Steven Fishbane,1 Azzour Hazzan,1 Kenar D. Jhaveri,1 Lin Ma,2 Eduardo K. Lacson.2
1Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; 2Fresenius Medical Care, North America, Waltham, MA.

Background: Recent studies found the incidence of hip fractures has increased greatly in patients on dialysis. Most of the increase occurred in patients with characteristics typical of bone frailty, where oversuppression of intact parathyroid hormone (iPTH) could be harmful. Since recent studies have not addressed clinical risk factors, we studied time-averaged iPTH as a risk factor for hip fractures.

Methods: 142,407 prevalent patients of Fresenius Medical Care had hip fractures identified by ICD-9 codes. Four cohorts were constructed: observation periods 2001-2003, 2004-2006, 2007-2009, 2010-2012. For each, the prior year was used to measure exposure.

Conclusion: In women, the higher levels of FSH predicts lower BMD in the lumbar spine, while in the femoral region higher FSH and CRP predicts lower BMD.

SA-POS582

The Discriminative Ability of Three Fracture Risk Assessment Tools in Hemodialysis Patients

Ying Qian, An Jin Chang, Xiaonong Chen, Nan Chen.
Dept of Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: The present study aimed to explore factors associated with fractures among hemodialysis patients, and assess the ability of the World Health Organization’s fracture risk assessment tool (FRAX) compared with bone mineral density (BMD) and OSTA to discriminate fracture status.

Methods: We enrolled 118 hemodialysis patients in this cross-sectional study. Parameters including serum calcium, phosphate, intact parathyroid hormone, 25 hydroxy vitamin D, alkaline phosphatase were analyzed. Clinical characteristics were also collected. BMD values were tested using dual-energy X-ray absorptiometry at the lumbar spine and hip region. OSTa and FRAX scores were calculated using formula or through the FRAX website. Factors associated with fractures were examined. Discriminative ability of BMD, OSTA and FRAX (non-BMD model and BMD model) in fracture status was assessed with receiver operator characteristic (ROC) analysis.

Results: There were 16 (13.5%) fractures in 118 hemodialysis patients. Patients with fractures were significantly older and more osteoporosis. All BMD parameters at hip region (including femoral neck, femoral shaft, and total hip) were notably lower in fracture group than in non-fracture group (p 0.74 (0.65-0.87) vs 0.82 (0.74-0.96); 0.88 (0.77-1.01) vs 0.99 (0.86-1.14); 0.80 (0.66-0.88) vs 0.88 (0.78-1.00)). There was no difference in clinical characteristics or blood biochemistry levels between the two groups. Results: Areas under ROC curves of BMD, OSTA, FRAX1 (non-BMD model) and FRAX2 (BMD model) were 0.692 (95% CI: 0.600 to 0.774 ), 0.654 (95% CI: 0.561 to 0.739 ), 0.917 (95% CI:0.851 to 0.960), and 0.851 (95% CI:0.773 to 0.910), respectively. Either FRAX1 or FRAX2 performed better than BMD and OSTA at identifying patients with fractures (p < 0.05). But FRAX2 performed no better than FRAX1 (P=0.05). The best cutoff values were 0.91, 3, 7.2%, 3.4%. Conclusions: Among hemodialysis patients, age and BMD at hip are associated with fracture. FRAX performs better than BMD and OSTA in discriminating fracture status, suggesting its usefulness of fracture risk prediction in hemodialysis patients.

SA-POS583

Teriparatide for Low Bone Mass in Hemodialysis Patients

Rikako Hirayama, Yoshifumi Ubara, Junichi Hoshino, Kenmei Takaichi
Nephrology, Toranomon Hospital, Tokyo, Japan.

Background: Fracture rates in dialysis patients are extremely higher than general population. Recently the prevalence of low turnover has greatly increased in dialysis population. Teriparatide would be also beneficial for low turnover dialysis patients with low bone mass. However, there have been only a few reports describing the use of teriparatide in dialysis patients.

Methods: This was a prospective, single-center, observational study. Hemodialysis patients with low iPTH (iPTH<60 pg/ml) coexisting low bone mass determined by lumbar spine (LS) and/or femoral neck (FN) T-score<−2.5 with DXA were eligible. Forty consecutive hemodialysis and 20 μg teriparatide (Fortero) was injected 3 times per week at the end of each hemodialysis sessions. We analyzed the following parameters, including serum Ca, P, albumin, ALP, iPTH and bone metabolic makers including iP1NP, BAP, OC, and TRACP-5b at baseline and following teriparatide. BMD at LS and FN were measured at baseline, 6, 18 months after treatment.

Pharmacokinetics: After the 24-hr administration of teriparatide, we measured the serum teriparatide acetate concentrations.

Results: Five patients (median age: 72 years old,median hemodialysis periods; 24 years) were included.After teriparatide injection, BMD of LS as well as FN at 6 months significantly increased from 0.67±0.18 to 0.86±0.19 g/cm^2 and from 0.44±0.08 to 0.48±0.07 g/cm^2, respectively. Corrected Ca levels significantly decreased at 3 and 6 months with increases in endogenous iPTH in response to lowering of serum Ca. As for bone metabolic markers, percent changes of serum BAP and serum iP1NP levels significantly increased at 3 and 6 months. Conversely, serum TRACP-5b decreased after injection. Throughout this study, there were no fractures. Pharmacokinetics result is shown in Figure 1. There was a peak at 30 minutes at 157.2 pg/mL, and then it rapidly decreased to undetectable level at 240 minutes.

Conclusions: In conclusion, treatment with teriparatide, the dose was 20 μg 3 times/ week, which is smaller than suggested dose for non dialysis patients, led to increase of BMD at LS and FN. Our data on pharmacokinetic of teriparatide suggested that we can use this agent in normal dose in dialysis patients.

Restless Leg Syndrome in Hemodialysis Patients: Possible Relationship with Mineral and Bone Metabolism

Percil Diego Miranda de Menezes Neves,1 Ramaiane Aparecida Bridi,1 Rosa M.A. Moyes,1 Rosielen M. Elias.2
1Nephrology Div, Univ de São Paulo, São Paulo, Brazil; 2Nephrology Div, Univ Nove de Julho - UNINOVE, São Paulo, Brazil.

Background: Restless legs syndrome (RLS) is a movement sleep disorder that is common among patients on hemodialysis (HD) and is associated with cardiovascular morbidity and mortality. The physiopathology of this syndrome is not completely understood, and CKD-MBD may be implicated. We aimed to evaluate the prevalence of RLS in patients on hemodialysis, testing the relationship with CKD-MBD markers.
Methods: Prevalence and severity of RLS were assessed using the International RLS Study (IRLS) diagnostic criteria.

Results: Of the 101 patients (53.5% women) included, RLS was observed in 29 patients (28.7%), with mild, moderate, severe and very severe presentation in 1, 12, 3 and 3 patients, respectively. RLS was more frequent among women (62% vs 38%, p=0.04), and was increased by age (1 P=0.001), and trend toward higher trans-horizonal hormone-PTH [529 (190, 1017) pg/ml vs. 305 (143, 546) pg/ml, p=0.054]. Logistic regression showed that female gender (HR=2.8, p=0.039), P (HR=1.4, p=0.042) and TS (HR=1.9, p=0.033) were independently associated with RLS. As 22.8% of patients were already submitted to parathyroidectomy, we further categorized PTH as ≤ or >500pg/ml. This new variable was modeled in another regression model, which came out independently associated to a high risk of RLS (HR 3.0, p=0.027). We also compared patients with RLS severe with those with RLS mild/moderate. The first group presented higher P and lower serum albumin, iron, and ionic calcium. Finally, multivariable regression showed that severity score was dependent on P and vit D insufficiency (r2=0.37).

Conclusions: Besides all traditional risk factor for RLS already described in the general population, CKD-MBD seems to play a role in the pathophysiology of this syndrome in HD patients. It is plausible that the relationship between RLS and CKD-MBD contributes to the increased mortality risk observed in these patients.

Vascular Smooth Muscle Cells from CKD Rats Have Increased Intracellular Calcium
Chad A. Zarge,1 Mikaela Lee McKeeney,2 Stacey L. Dineen,1 Rebecca S. Bruning,1 Michael Sturek,2 Neil X. Chen,1 Sharon M. Moe,1,3 Nephrology, IU School of Medicine;1 Physiology, IU School of Medicine;2 Roudebush VAMC, Indianapolis, IN.

Background: CKD vascular smooth muscle cells (VSMC) exhibit phenotypic plasticity which promotes calcification and increases cardiovascular risk. Changes in intracellular calcium (iCa) as CKD progresses may regulate transcription of genes requisite for this process. This study examined iCa homeostasis in early and advanced CKD.

Methods: We studied VSMC freshly isolated from 10 week normal Sprague Dawley (SD) and CKD Cy+/ rats and 35 week normal SD, CKD Cy+/ (~15% TGF) function, and CKD rats treated with 3% calcium gluconate (n=6-8 per group). Intracellular calcium was measured with Fura-2 using a ratio metric approach (F360/F380 nm). Basal iCa, sarcoplasmic reticulum (SR) store release, and store-operated calcium entry (SOCE) were assessed. Expression of common calcium regulatory proteins NCX1 and SERCA2a was examined by Western Blot. Results were compared by ANOVA.

Results: Basal iCa were lower in 10 week CKD VSMC compared to NL (0.76±0.02 vs. 0.66±0.02, p=0.05) however increased 1.5-fold by 35 weeks to become greater than NL (0.98±0.01 CKD, 0.81±0.02 NL, 0.90±0.04 CKD+Ca, p<0.05). SR store release was greater in CKD VSMC at both weeks 10 (45.5±0.02 vs. 37.5±0.02, p<0.05) and 35 weeks (62.0±0.2 CKD, 44.4±0.3 NL, 50.0±0.3 CKD+Ca, p<0.05). At 10 weeks, SERCA2a expression was greater in CKD rats in part explaining the lower basal iCa levels, however, at 35 weeks SERCA2a and NCX2 were both decreased in CKD rats, consistent with higher iCa levels. There was no difference in SOCE at 10 weeks but by 35 weeks was increased in the CKD+Ca cohort (p=0.05) with a trend toward significance in the CKD cohort (p=0.08), also consistent with higher observed basal iCa levels.

Conclusions: Basal iCa and SR store release, and SOCE increases with progressive CKD at least in part due to changes in expression of the common calcium regulatory proteins SERCA2a and NCX2. The increase in iCa is likely a key mechanism in our previous observations that CKD VSMC displays an osteogenic phenotype, which is known to worsen cardiovascular outcomes.

Matrix Vesicles from Calcifying Vascular Smooth Muscle Cells (VSMC) Have Different MicroRNA (miRNA) Expression from Non-Calcifying VSMC
Neal X. Chen,1 Sarah Chandra Janga,2 Kalisha O'Neill,3 Manjunath Shetty,2 I. Shintani,2,4 Kazuhiko Tsuruya,5 Neil X. Chen,1 Tatsukazu Hatano,2 Masanori Kuroda,5 Kazuhiko Tsuruya,5

Vascular Calcification: From Bench to Bedside

Methods: To investigate the mechanism of Nrf2/HO-1 pathway in oxidative stress-mediated vascular calcification, matrix vesicles (MV) from calcifying VSMC (CaMV) were compared to non-calcifying MV (CTLMV) from control VSMC.

Results: The expression of Nrf2/HO-1 mRNA was significantly increased in CaMV compared to CTLMV. Using microarray analysis, a total of 60 miRNA were identified as differentially expressed between CaMV and CTLMV. Further, using miRNA target prediction analysis followed by functional enrichment yielded multiple miRNA-mRNA networks. Network analysis showed that the miRNA expression in CaMV was more enriched in pathways associated with atherosclerosis, diabetes, and inflammatory response.

Conclusions: The miRNA expression in CaMV was more enriched in pathways associated with atherosclerosis, diabetes, and inflammatory response. These findings suggest that the Nrf2/HO-1 pathway plays a critical role in modulating miRNA expression in calcifying VSMC, which may in turn contribute to the development of vascular calcification.

SA-POS84

The Role and Mechanism of Nrf2/HO-1 Pathway in Oxidative Stress-Induced Vascular Calcification in End-Stage Renal Disease In Vitro
Li Wang,1 Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.

Background: To investigate the mechanism of Nrf2/HO-1 pathway in oxidative stress-mediated vascular calcification in end-stage renal disease (ESRD) in vitro, and to explore a new target for the intervention of vascular calcification in ESRD.

Methods: 1. Rat aortic smooth muscle cells (RSMCs) were cultured and divided into 4 groups: the complete medium cultured group, the calcification medium cultured group, the group of complete medium cultured and then after sulforaphane (SFN) cultured for 6h, the group of complete medium cultured for 4h and then hydrocortisone (H2O) cultured for 2h. Detect nuclear Nrf2 expression in each group by western blot. 2. 4 groups of RSMCs were cultured: the calcification medium cultured group, the group of H2O pretreated for 2h and then calcification medium cultured, the group of SFN pretreated for 6h and then calcification medium cultured, the group of SFN pretreated for 6h and H2O pretreated for another 2h, and then calcification medium cultured. Detect the expression of intracellular reactive oxygen species (ROS) by using DCFH-DA probe, and the expression of Nrf2, Heme Oxygenase-1 (HO-1), Pro-inflammatory cytokine (TNF-α). Forn-related treated by 1,7 β-Dimethyl (Rumm2).

Results: 1. Nrf2 expression in nuclear was enhanced after SFN and H2O stimulation. 2. The expression of Nrf2,Rumm2 and ROS, but not HO-1, were induced by calcification medium in a time-dependent manner. 3. ROS was significantly reduced after H2O2, SFN, SFN + H2O2 pretreated, and decreased gradually with incubation time (P<0.05). 4. The expression of Nrf2 and HO-1 were induced by SFN, and the expression of Rumm2 was inhibited in calcification medium. 5. The expression of Nf2, HO-1, Rumm2 could be induced by SFN, but the expression of Rumm2-induced calcification medium decreased gradually within incubation time after H2O2, SFN + H2O2, pretreated.

Conclusions: The calcification in RSMCs is associated with the overexpression of Nrf2/HO-1. Overexpression of Rumm2 induced by endogenous ROS, but not exogenous ROS, may be inhibited or attenuated by the activated Nrf2/HO-1 pathway.

SA-POS88

The Precedence of the Reduced Osteopontin Expression and the Increased Calcium Phosphate Nanoparticle to the Calcification by Phosphate Load with Normal Fasting Glucose in Human Vascular Smooth Muscle Cells
Masanori Tokumoto,1 Shunsuke Yamada,1,2 Kazuhiko Tsuruya,3 Takanari Kitazono,1 Hiroaki Obosho,1 Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan;2 Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan;3 Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: It is well-known that vascular calcification (VC) develops in diabetes mellitus patients. On the other hand, malnutrition is also reported to induce VC. Thus, we examined how glucose load affects phosphate (P)-induced calcification in human vascular smooth muscle cells (hVSMC).

Methods: We added P of 1, 1.5, or 2.0 mM in the culture media (DMEM) of hVSMC with normal fasting or high glucose (HG) (100 or 450 mg/dl), although hVSMC are usually cultured with HG. The degree of calcification, the content of calcium P nanoparticle (CPP) in the media, and the expression of both the intrinsic calcification inhibitors and the chondro-osteogenic differentiation markers were examined at Day 1, 7, and 14. Moreover, it negatively correlated with the content of CPP at Day 1 and the correlation was inhibited in calcification medium.

Conclusions: The content of CPP at Day 1 was less with normal fasting glucose. The content of calcification correlated significantly with the SOX9 mRNA expression at Day 1 and Day 7. The content of CPP increased significantly with the SOX9 mRNA expression at Day 1. At Day 1, the content of CPP increased by P load, and was higher with normal fasting glucose. The SOX9 mRNA expression at Day 7 correlated significantly with the content of CPP at Day 1. At Day 1, the mRNA expression of osteopontin (OPN), a calcification inhibitor, decreased by P load and was less with normal fasting glucose. Moreover, it negatively correlated with the content of CPP at Day 1 and the correlation was more intensive with normal fasting glucose. There was no significant change in the mRNA expression of chondro-osteogenic differentiation markers at Day 1.

SA-PO589
VCAM -1 and TNF Alpha Induce Vascular Calcification In Vitro
Kevin Wily, Ralf Schindler, Daniel Zickler. Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin.

Background: VCAM, TNF alpha and soluble TNF alpha receptor 1 (sTNFR1) are elevated in patients with chronic kidney disease (CKD). In previous clinical trials with high cut-off dialysis plasma levels of these molecules and in vitro vascular calcification were lowered. Here we assessed the role of sTNFR 1 and VCAM on in vitro calcification.

Methods: In human vascular smooth muscle cells (VSMCs) vascular calcification was induced by osteogenic medium (OM). VCAM , TNF-α and sTNFR1 were added. Calcification was quantified by alkaline phosphatase staining and alizarin red staining. Calcification was then normalized to WST-8.

Results: VCAM enhances vascular calcification in vitro in a dose-dependent manner (p<0.001). TNF-α -induced calcification was effectively inhibited by sTNFR1 (50% reduction of the initial level; p=0.0001). sTNFR1 alone does not promote vascular calcification.

VCAM concentration: 0.001 - 10 µg/mL

Conclusions: VCAM and TNF alpha promote vascular calcification in vitro. Their elimination with high cut-off dialysis or their pharmaceutical blockade may be advantageous in regard to vascular calcification in CKD.

SA-PO590
The Tripehelical Collagen Analog (GPO)3a Affects Calcifications of Vascular Smooth Muscle Cells in a Concentration Dependent Manner
Uwe Querfeld, Nadja Kretzschmar, Christian Freise. Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; Dept of Pathology, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: Extensive remodeling of the extracellular matrix and the trans-differentiation of vascular smooth muscle cells (VSMC) contribute to the pathogenesis of vascular calcifications in patients with chronic kidney disease (CKD). Matrix metalloproteinases (MMPs) are proteolytic enzymes that impact on both of these processes and, thus, represent potential therapeutic targets. We have previously shown that the synthetic collagen analog (Gly-Pro-Hyp)n: (GPO)-n, impacts the substrate binding and the enzymatic activity/stability of the gelatinases MMP-2 and -9 in a concentration dependent manner [1]. Aim of this study was therefore to investigate potential regulatory functions of (GPO)-n in an in vitro model of arteriosclerotic VSMC calcification.

Methods: Calcifications of murine VSMCs were induced by a calcification medium (CM) containing elevated concentrations of calcium and phosphorus with or without the presence of different (GPO)-n concentrations. VSMC calcifications were quantified by measuring calcium depositions and ALP release in the cultures. Effects on MMP-activities were determined by specific substrate assays.

Results: CM-treated VSMC exhibit strong calcifications compared to control. Low (GPO)-n concentrations (0.70 nm) massively enhanced calcifications of VSMC and were accompanied by elevated gelatinase activities in VSMC supernatants. In contrast, higher concentrations of (GPO)3a (680 nm) blocked CM-induced calcifications of VSMC and reduced gelatinolytic activities in culture supernatants.

Conclusions: Considering the important function of MMP-2 and -9 in VSMC calcification [2], the collagen peptide (GPO)3a on the one hand indirectly impairs the VSMC calcification by modulating MMP activities. On the other hand, direct effects of (GPO)3a, e.g. by interaction with collagen receptors might simulate a “healthy” vessel matrix, which will be investigated in future studies. [1] Ruehl, M. et al., Fibrogenesis Tissue Repair, 2011, 4(1): p. 1. [2] JASN 25: 2014 (SA-OR061, p.95A; TH-PO553, p.962A).

SA-PO591
Protective Effects of Epigallocatechin Gallate (EGCG) on Vascular Calcification In Vitro and In Vivo
Uwe Querfeld, Karoline Websky, Christian Freise, Kerstin Sommer, Ursula Schulz, Veronika Bobb. Pediatric Nephrology, Charité, Berlin, Germany; Center for Cardiovascular Research, Charité, Berlin, Germany.

Background: Vascular calcifications are common in patients with chronic kidney disease (CKD). Our preliminary studies indicate that inhibition of matrix metalloproteinases (MMP)-2 and -9 suppresses the development of arterial calcification in uremic rats. Epigallocatechin gallate (EGCG), a polyphenol ingredient of green tea, has strong antiinflammatory properties and inhibitory effects on MMPs. We therefore investigated potential protective effects of EGCG on calcium uptake of vascular smooth muscle cells (VSMC) in vitro and in an animal model of uremia-associated arteriosclerosis in vivo.

Methods: In vitro, calcifications of murine VSMCs were induced by a high phosphate (HP)-medium and cells were treated with different EGCG-concentrations (20-100µg/ml). VSMC calcifications were quantified using the ortho-cresolphthalein method and proteolytic activities of MMP-2 and -9 in VSMC supernatants were determined by gelatin zymographies. C57BL/6 mice were 5/6-nephrectomized and arterial calcifications were induced by calcitriol (1µg/kg body weight) and a HP-diet (2% phosphate). One cohort (n=10) was additionally administrated 0.02% EGCG in drinking water. Animals were sacrificed after 2 weeks of treatment and aortic calcifications were quantified after von Kossa-staining.

Results: In vitro, EGCG provoked a dose-dependent decrease of HP-induced calcification (up to 85%) of VSMCs and of proteolytic MMP-2 and -9 activities. In vivo, all calcitriol-treated mice had severe arterial calcifications, involving 50% of the arterial wall after only 2 weeks of treatment. EGCG had no significant inhibitory effect on the development of vascular calcifications.

Conclusions: In this “negative experimental trial”, EGCG had no beneficial effect in the chosen animal model, which (considering the rapid development of calcifications) may have been too aggressive, thus overriding potential protective effects of EGCG. Encouraged by the positive in vitro results, the effects of EGCG and other polyphenols should nonetheless be further investigated in other animal models of uremia-associated arteriosclerosis.

SA-PO592
Mechanism of Calcification by Iron Stimulation in Vascular Smooth Muscle Cells
Savuni Kawada, Yasuyuki Nagasawa, Mutsumi Kawabe, Aritoshi Kida, Mana Yahiro, Tomoko Kimura, Kiyoko Yamamoto, Masayoshi Nanami, Yukiko Hasuike, Takahiro Kuragano, Keiji Nakasho, Hideki Ohyama, Takeshi Nakamichi. Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; Dept of Pathology, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: In CKD patients, atherosclerosis is one of important key factors which determine their prognosis. We was reported the calcification induced by TNF-alpha was related with iron in HUVEC cells by our group. TTo reveal the relationship between calcification in vascular media and iron stimulation using vascular smooth muscle cells.

Methods: The aorta smooth muscle cells were cultured for three weeks. At day 0, we changed the usual culture medium to calcification medium, and TNF-alpha and iron were added to the calcification medium. Calcification in each condition was confirmed by Alizarin staining. And to reveal early mechanism to enhance the calcification by iron and TNF-alpha stimulation, we compared the gene expression profile between each condition in day 1 and day 3 using microarray analysis. We confirmed that expression of certain cytokine which had increased in microarray analysis by real-time PCR.

Results: We confirmed both iron and TNF-alpha stimulation enhanced calcification by Alizarin Staining. Moreover, both iron and TNF-alpha stimulation at the same time enhanced calcification more strongly than single stimulation. We picked up a cytokine which had increased with both iron and TNF-alpha stimulation in the microarray analysis as similar as the Alizarin Staining result had shown. We confirmed gene expression of this cytokine by real-time PCR. Gene expression was increased at day 1 by stimulation of iron (5.8±3.0 fold change vs control), TNF-alpha (7.8±1.9 fold change vs control), and both stimulation (53.1±27.1 fold change vs control), synergistically.

Conclusions: Iron stimulation enhanced calcification in vascular smooth muscle cells along with TNF-alpha stimulation. The possibility was suggested that this gene changes from the early stage participated in the mechanism that iron promoted blood vessel media calcification.

Kidney Injury/Repair Stimulates Vascular Disease Through Activin and Systemic Wnt Inhibition
Matthew James Williams, Olga A. Agapova, Yifu Fang, Toshifumi Sugatani, Carmen M. Halabi, Keith A. Hruska. Pediatrics, Nephrology, Washington Univ School of Medicine, Saint Louis, MO.

Background: We show that the vascular effects of CKD are an interplay of Wnt inhibition and activin induced modulation of Activin receptor (ActRIIA) function resulting in a stimulation of atherosclerosis and vascular calcification.

Methods: CKD with elevated activin and Wnt inhibitors, especially Dkk1, was induced in the mouse models for vascular calcification, lineage tracing, and Alport’s. Activin, Dkk1, ActRIIA, psmad 2/3, aklotho and collagen levels were measured by Eisa, RT-PCR and westerns. Vascular smooth muscle cell (VSMC) function was measured by pressure

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
induced arterial dilatation in situ. Cell lineage tracing was performed in Rosa-tat mice bred to a cre-flp reporter strain in Rosa-tat mice. Mice harboring Rosa-td-tat express tomato red in cells harboring Cre recombinase.

**Results:** Circulating activin and Dkk1 levels were increased while aklotho levels were decreased by CKD. In diseased kidneys, activin was expressed in myofibroblasts, and activin signaling increased through Smad 3 was increased. An ActRIIA ligand trap, RAP-011, inhibited renal pSmad 3 expression, urinary protein levels, and Dkk1 levels, and increased tubular epithelial klotho levels. In the vasculature, CKD decreased VSMC ActRIIA protein levels, and ActRIIA signaling was decreased along with decreased VSMC differentiation and inhibited osteoblastic transition and atherosclerotic calcification. In the circulation, the ActRIIA ligand trap decreased Dkk1 levels. CKD induced expression of tomato red in cells of the adventitia after two weeks of femoral artery injury in Tek-Cre/ Rosa-tat mice compared to Tek-Cre/Rosa-tat mice with normal kidney function.

**Conclusions:** CKD increased circulating free activin levels, decreased VSMC function, stimulated aortic osteoblastic transition and atherosclerotic calcification. Decreasing effects of elevated activin in CKD with an ActRIIA ligand trap, inhibited Smad dependent renal fibrosis, blocked aortic osteotic transition, increased VSMC differentiation and decreased vascular calcification.

**Transplant Atozemic Episode Exacerbates Vascular Calcification in Adenine-Induced Uremic Rats**

Daisuke Mori,1 Issai Matsui,1 Akhiro Shimomura,2 Yasuo Kusunoki,1 Sayoko Yonemoto,1 Masamitsu Senda,2 Yusuke Sakaguchi,1 Takayuki Hamano,1 Yoshitaka Isaka,1 Hiromi Rakugi,1, 3Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Japan; 2Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Japan;

**Background:** Urea, the final metabolite of amino acids in the body, can carbanhydrate proteins at lysine residues, and thereby modifies characteristics of proteins irreversibly. Several studies have revealed that functions of proteins are impaired by carbanhimation. Acute kidney injury (AKI) is a representative pathological condition that elevates serum urea temporarily. Although AKI is not a perpetual condition, it is well-known that AKI increases subsequent risk of cardiovascular diseases through yet-unknown mechanisms.

**Methods:** We evaluated the effects of transiently elevated serum urea on vascular calcification (VC). Male Sprague-Dawley rats at age 9 weeks were divided randomly into two groups: cellulose-preload + adiine diet (group C+A) and urea-preload + adiine diet (group U+A). Urea-preload group received 10% urea diet from 9 to 13 weeks of age. C+A group served as a control for urea. After one week of urea-washout period, all rats received 0.75% adiine-containing diet up to 19 weeks of age.

**Results:** Serum urea levels were 15.87 ± 2.96 mg/dl in cellulose-preloaded group and 39.20 ± 3.74 mg/dl in urea-preloaded group at the end of the preload period. Serum urea levels in urea-preloaded group were normalized to 14.73 ± 1.28 mg/dl during the washout period. At age 19 weeks, rats in group U+A developed severe VC in comparison with the rats in group C+A. Serum creatinine, urea nitrogen, calcium, phosphate, magnesium, albumin, and body weight were not different between the two groups at age 19 weeks. Western blot analysis of the aorta revealed that dietary preload of urea increased carbanhimated protein.

**Conclusions:** Preload of urea exacerbated VC in adiine-induced uremic rats. Protein carbanhimation might link urea-preload to VC.

SA-PO595

**SNF472 Inhibits Cardiovascular Calcification in Uremic Rats**

Joan Perelló,1,2 Carolina Salcedo,1 Ellen Neven,1 Geert J. Behets,2 Pieter H. Joubert,1 Patrick C. D’Haese,1 Miquel D. Ferrer,1 1R&D Dept, Laboratoris Sanifit, Palma, Illes Balears, Spain; 2Laboratory of Renal Lithiasis Research, Univ of Balearic Islands, Palma, Illes Balears, Spain; 3Laboratory of Pathophysiology, Univ of Antwerp, Antwerp, Belgium.

**Background:** SNF472, an intravenous (i.v.) formulation of phytate, has been shown in models of NPP1 deficiency (Enpp1-/-) and Enpp1-Fc. SNF472 is a competitive inhibitor of the ectoenzyme, nucleotide pyrophosphatase pyrophosphorylase (NPP1). SNF472 treatment resulted in a significant reduction in calcification in mice 80% and 88% in aorta and heart, respectively.

**Conclusions:** Daily SNF472 4 hour infusions of 30 mg/kg inhibit the development of VC up to 88% in a rat adenine model of uremia. These results support further investigation of SNF472 in the treatment of VC in patients with calcification-related disorders such as calciaphylaxis and ESRD patients.

**Enzyme Therapy for Vascular Calcification**

W. Charles O’Neill,1 Kelly E. Manning,1 Koba A. Lomashvili,1 Nelson Hsia,2 Peychi Lee,4 Francis T. Danely,2 Kim L. Askew,2 Anthony G. Quinn,2 1Renal Div, Emory Univ School of Medicine, Atlanta, GA; 2Synageva Biopharma, Lexington, MA;

**Background:** Pyrophosphate (Pi) is a key endogenous inhibitor of hydroxypatite formation that circulates at levels sufficient to prevent vascular calcification. Pi is produced from extracellular ATP by the ectoenzyme, nucleotide pyrophosphatase pyrophosphorylase (NPP1). We evaluated the effects of transiently elevated serum Pi levels in adenine-induced uremic rats.

**Methods:** Rats were fed a high phosphorus diet for 12 weeks. At age 19 weeks, rats in group U+A developed severe VC in comparison with the rats in group C+A. Serum creatinine, urea nitrogen, calcium, phosphate, magnesium, albumin, and body weight were not different between the two groups at age 19 weeks. Western blot analysis of the aorta revealed that dietary preload of urea increased carbanhimated protein.

**Conclusions:** Preload of urea exacerbated VC in adiine-induced uremic rats. Protein carbanhimation might link urea-preload to VC.

SA-PO597

**The Risk of Medial Arterial Calcification in Early Chronic Kidney Disease**

W. Charles O’Neill,1 Kum Hyun Han,2 Arshad Ali,2 Ansley O’Neill,2 Kelly E. Manning,3 1Renal Div, Emory Univ, Atlanta, GA; 2Internal Medicine, Dept of Internal Medicine, Inje Univ College of Medicine, Ilsan Paik Hospital, Goyang, Korea;

**Background:** Medial arterial calcification is common in advanced chronic kidney disease (CKD) but whether this risk begins in early CKD is unknown. There is also concern that possible benefits of vitamin D and calcium in this group may be offset by potential induction of vascular calcification. We have previously shown that breast arterial calcification is a readily available and specific marker of medial arterial calcification and that its prevalence is increased in early CKD.

**Methods:** From a computerized search of medical records, 466 women with CKD and mammograms were randomly selected. After exclusion of women with renal transplants or other stages of CKD, history of warfarin use, or non-screening mammograms, 333 women were included. Females who were older than 65 years, had diabetes, or had a mean eGFR <90 ml/min/1.73 m2 Digital mammograms were visually inspected for arterial calcification.

**Results:** Mean age was 69.5 ± 0.6 (range: 44-91), mean eGFR was 49.5 ± 0.4 ml/min/1.73 m2, 20.1% had diabetes, 31.5% were receiving calcium supplements, 31.3% were receiving vitamin D (>1000 units/d), and 1.8% were receiving an active form of vitamin D. Controls had a mean eGFR of 104.1 ± 0.7 ml/min/1.73 m2. The prevalence of arterial calcification was the same in CKD 3 patients (35.1%) and controls (33.3%). Dividing the CKD 3 patients with this risk begins in early CKD is unknown. There is also concern that possible benefits of vitamin D and calcium in this group may be offset by potential induction of vascular calcification. We have previously shown that breast arterial calcification is a readily available and specific marker of medial arterial calcification and that its prevalence is increased in early CKD.

**Methods:** From a computerized search of medical records, 466 women with CKD and mammograms were randomly selected. After exclusion of women with renal transplants or other stages of CKD, history of warfarin use, or non-screening mammograms, 333 women were included. Females who were older than 65 years, had diabetes, or had a mean eGFR <90 ml/min/1.73 m2 Digital mammograms were visually inspected for arterial calcification.

**Results:** Mean age was 69.5 ± 0.6 (range: 44-91), mean eGFR was 49.5 ± 0.4 ml/min/1.73 m2, 20.1% had diabetes, 31.5% were receiving calcium supplements, 31.3% were receiving vitamin D (>1000 units/d), and 1.8% were receiving an active form of vitamin D. Controls had a mean eGFR of 104.1 ± 0.7 ml/min/1.73 m2. The prevalence of arterial calcification was the same in CKD 3 patients (35.1%) and controls (33.3%). Dividing the CKD 3 patients with this risk begins in early CKD is unknown. There is also concern that possible benefits of vitamin D and calcium in this group may be offset by potential induction of vascular calcification. We have previously shown that breast arterial calcification is a readily available and specific marker of medial arterial calcification and that its prevalence is increased in early CKD.

**Conclusions:** The prevalence of medullar arterial calcification is not increased in women with stage 3 CKD, indicating that the risk begins after stage 4 CKD. Supplementation of calcium or vitamin D does not increase the risk of medullar arterial calcification in these patients.

Vascular Calcification: From Bench to Bedside

SA-PO598
Deoxycholic Acid (DCA), a Metabolite of Circulating Bile Acids, and
Coronary Vascular Calcifications in Chronic Kidney Disease (CKD)
Makoto Miyazaki,1 Shinobu Miyazaki-anzai,1 Audrey L. Keenan,1 Kristen L.
Nowak,1 Jessica B. Kendrick,1 Geoffrey A. Block,2 Michel Chonchol.1 1Univ
of Colorado Denver; 2Denver Nephrology.
Background: Our group has previously shown that DCA, a metabolite of circulating
cholic acid, induces vascular mineralization and osteogenic differentiation in animal models
and that circulating levels of DCA are elevated in patients with CKD. We investigated
whether increased DCA serum levels are associated with an increase risk for higher
coronary artery calcification (CAC) volumes and lower lumbar bone mineral density
(BMD) in CKD patients.
Methods: We used stored baseline serum samples in 112 patients with moderate to
advanced CKD (eGFR= 20-45 mL/min/1.73m2) who participated in a randomized-controlled
study to examine the effects of phosphate binders on vascular calcification. Circulating
DCA levels were assayed using liquid-chromatography-tandem mass spectrometry (LCMS/MS). CAC volume was obtained using GE-Imatron C150 scanner and lumbar BMD
was determined using abdominal computed tomography scans with a calibrated phantom
of known density. Linear regression models were used to examine the cross-sectional
association between DCA with CAC volume and lumbar BMD.
Results: Participant characteristics were as follows: mean age, 68±11 years; 50%
women; 10% black; mean eGFR, 32±8 mL/min/1.73m2; and median DCA 58.4 (IQR 29112) ng/mL. After adjusting for demographics, co-existing illness, body mass index, eGFR
and circulating markers of CKD-MBD including serum calcium, phosphorus, vitamin D,
parathyroid hormone and fibroblast growth factor 23, an increase serum DCA level > 58
ng/mL positively associate with CAC volume (ß: 494.84 ± 238.82; p=0.03) and negatively
associated with BMD (ß: - 20.35± 9.56; p=0.03).
Conclusions: Higher serum levels of DCA in patients with stage III and IV CKD is
independently associated with higher CAC volume and lower lumbar BMD. Larger cohort
studies are needed to confirm these findings.

SA-PO599
Fibroblast Growth Factor 23 and Fetuin A Levels in Pre-Dialysis Stage 4-5
Chronic Kidney Disease Patients with Aortic Calcification: A Case Control
Study Vijayakumar Theophilus-Sunder, Anna T. Valson, Vinoi George David,
Santosh Varughese, Tamilarasi Veerasamy. Dept of Nephrology, Christian
Medical College, Vellore, Tamil Nadu, India.
Background: Vascular calcification (VC) contributes to the increased cardiovascular
mortality seen in CKD. However, not everyone with advanced CKD develops VC, indicating
that circulating levels of factors that modulate VC may play a role in determining individual
susceptibility towards VC. We aimed to examine this hypothesis by measuring the levels
of FGF-23 and Fetuin-A in a group of pre-dialysis CKD Stage 4-5 patients who had
documented abdominal aortic calcification (AAC) and an age, gender and eGFR matched
group of patients who did not have AAC.
Methods: Out of a pre-existing cohort of 710 patients with CKD Stage 4-5, 28 patients
with AAC (Group 1, cases) were compared with an equal number of age, gender and eGFR
matched patients without AAC (Group 2, controls) with respect to their demographic and
biochemical parameters, including FGF-23 and Fetuin-A. AAC was assessed by lateral
abdominal X ray, while Fetuin-A and intact FGF-23 were estimated by ELISA in serum.
Results: Groups 1 and 2 were matched for age (mean age 57.7 and 57.8 years
respectively, p = 0.938), gender (84.6% males in both groups) and eGFR (median eGFR
14.5 and 13.1 respectively, p = 0.826), and were not significantly different with respect
to risk factors for AAC such as presence and duration of diabetes, hypertension, smoking
and obesity. Levels of calcium, phosphorus, PTH, 25 (OH) vitamin D, serum cholesterol,
triglycerides, HDL and LDL were also comparable between the two groups. However,
median FGF23 levels were significantly higher in Group 1 [25.2, (Q1= 14, Q3=34.2)]
compared to Group 2 [12.1 (Q1 = 6.6, Q3 = 14.1), n = < 0.001]. Median Fetuin-A levels
were also significantly higher in Group 1 [5.5 (Q1=4.4, Q3=6.5)] compared to Group 2
[4.1 (Q1 = 3.6, Q3 = 5.7, n = 0.034).
Conclusions: Pre-dialysis patients with Stage 4-5 CKD with AAC, had higher FGF23 and Fetuin-A levels compared to age, gender and eGFR matched patients who did not
have AAC. The nature and mechanism of this association between elevated FGF23 and
Fetuin-A levels and AAC requires further exploration.

SA-PO600
Lack of Association Between Serum Osteoprotegerin, Osteopontin and
Fetuin-A Levels and the Longitudinal Changes in Arterial Stiffness in CKD
Patients Undergoing Renin-Angiotensin System Blockade Cecilie Lyngsø,1
Marie Frimodt-Moller,2 Marianne Rix,2 Anne-Lise Kamper,2 Svend Strandgaard,1
Arne Høj Nielsen,1 Allan Flyvbjerg,3 Mette Bjerre.3 1Dept of Nephrology, Herlev
Hospital, Herlev, Copenhagen, Denmark; 2Dept of Nephrology, Rigshospitalet,
Copenhagen, Denmark; 3The Medical Research Laboratory, Dept of Clinical
Medicine, Aarhus Univ, Aarhus, Denmark.
Background: Osteoprotegerin (OPG), osteopontin (OPN) and fetuin-A, have been
suggested to participate in the accelerated development of arteriosclerosis seen in patients
with chronic kidney disease (CKD). We have previously shown that measures of vascular
stiffness were significantly reduced after 24 weeks of treatment with renin-angiotensin

Poster/Saturday

system (RAS) blocking agents. The aim of this longitudinal post hoc study was to investigate
whether serum levels of OPG, OPN and fetuin-A were associated with these same changes
in markers of arterial stiffness found in CKD patients treated with RAS blocking agents.
Methods: Serum OPG, OPN and fetuin-A levels were measured in 57 patients with
CKD stage 3-5, mean eGFR 29 ml/min, as a post hoc analysis of data acquired during a
24-week controlled trial in which patients were randomized to treatment with 16 weeks of
monotherapy with either enalapril or candesartan followed by 8 weeks of dual blockade.
Serum levels were obtained upon study entry and after 16 and 24 weeks of RAS blocking
therapy and compared to aortic pulse-wave velocity and augmentation index.
Results: Except for a significant correlation between OPG and central pulse pressure
(p < 0.05), serum levels of OPG, OPN and fetuin-A did not correlate to markers of vascular
stiffness. There were no significant changes in serum levels of OPG, OPN and fetuin-A
when monotherapy with enalapril or candesartan was compared to dual blockade.
Conclusions: The present results do not corroborate the use of OPG, OPN and fetuin-A
as surrogate markers for vascular stiffness in patients with CKD.

SA-PO601
Hyperuricemia Is Significantly Associated with Coronary Artery
Calcification and Vascular Stiffness in Asymptomatic Subjects Undergoing
General Health Examination Ah Ran Choi, Hae Yeul Park, Seok-Hyung Kim,
Hoon Young Choi, Sung-Kyu Ha, Hyeong Cheon Park. Nephrology, Gangnam
Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea.
Background: Recent studies suggest that hyperuricemia may be associated with
increased adverse cardiovascular events even in healthy subjects. Quantity of coronary artery
calcium (CAC) correlates with atherosclerotic plaque burden and increased cardiovascular
events. This study aimed to determine the relationship between serum uric acid level(sUA)
and brachial-ankle pulse wave velocity (ba-PWV), coronary artery calcium score (CACS)
as well as other traditional cardiovascular risk factors in asymptomatic subjects.
Methods: We consecutively enrolled 4,703 asymptomatic subjects who underwent
ba-PWV and coronary CT angiography as part of a general health examination. A high baPWV group, those having increased vascular stiffness, was defined as ba-PWV greater than
1497.5 cm/s (75th percentile). The subjects were stratified into four groups according to sUA.
Results: Mean age of enrolled subject was 52.8 ± 9.4 years, 61 % of the study
participants were male. Eight point four percent of the study participants showed CACS
greater than 100. The adjusted odds ratio (OR, 95% confidence interval) for the presence
of high ba-PWV in the second to fourth sUA quartile vs. first sUA quartile was 1.45 (1.1371.840, P<0.003), 1.42 (1.081-1.866 P<0.012), 1.66 (1.246-2.218, P<0.001), respectively
after adjusting for age, gender, diabetes, hypertension, smoking, body mass index (BMI),
estimated glomerular filtration (eGFR), fasting blood sugar (FBS) and calculated LDL.
Moreover, subjects with CACS greater than 100 also showed that fourth quartile of sUA
was associated with high ba-PWV compared with the first quartile of sUA [OR 2.4, (1.653.47, P<0.001)]. Multivariate linear regression analysis demonstrated that old age, male,
hypertension, diabetes, BMI, FBS, eGFR and sUA were significantly associated with mean
ba-PWV and log transformed CACS.
Conclusions: Our results show that sUA is an independent risk factor for increased
vascular stiffness and coronary atherosclerosis in asymptomatic adults undergoing health
examination.

SA-PO602
Abdominal Aortic Calcification Score on Plain Radiograph as a Predictor
of Coronary Artery Calcification Score on Computed Tomography and
T-Score on BMD in Dialysis Patients Eu Gene Jeong,1 Su Mi Lee,1 Young
Ki Son,1 Dongyeol Lee,2 Hansae Kim,2 Sung Hyun Son.3 1Dept of Internal
Medicine, Dong A Univ Hospital, Busan, Republic of Korea; 2Dept of Internal
Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; 3Dept of
Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.
Background: Not only coronary artery calcification scores (CACS) on computed
tomography (CT) but also several VC scores on plain radiographs can predict cardiovascular
events. However, there is no study about the correlation between CACS on CT and VC
scores of several sites on plain radiographs. Therefore, we evaluated which VC scores among
several VC scores on plain radiographs are a predictor of CACS on CT in dialysis patients.
We also investigated the association between VC scores and bone mineral density (BMD).
Methods: We conducted this single center cross-sectional study from March 2013 to
September 2014. We checked the plain radiographs of the feet, hands, pelvis, and lateral
lumbar spine and estimated the VC scores. CACS on CT and BMD were evaluated. We
defined severe CACS as CACS > 1000. FGF-23, fetuin-A, osteoprotegerin (OPG) and
receptor activator of NF-κB ligand (RANKL) were analyzed with ELISA.
Results: The mean ages of 61 patients including 38 hemodialysis(HD) and 23 peritoneal
dialysis(PD) patients were 58.6±10.2 years. The prevalence rate of significant VC was 75.4%
and prevalence rate of severe CACS was 26.2%. The OPG levels were higher in patients
with severe CACS(p=0.019) and significant VC(p=0.009). Patients with AAC score≥5 had
lower T score of wrist and hip than patients with AAC score<5. CACS is positively correlated
with AAC score(r=0.639, p< 0.001), VC score of the hands and pelvis (r=0.494, p< 0.001).
AAC score is negatively correlated with T score of wrist(right: r=-0.286, p=0.027) and
hip(right: r=-0.259, p=0.045)on BMD. AAC score(B=59.4, C.I.=18.3-100.6, p=0.006) and
VC score of the hands and pelvis(B=225.8, C.I.=69.7-381.8, p= 0.006)on plain radiographs
were independently associated with CACS on CT.
Conclusions: AAC score among several VC scores on plain radiographs is the most
reliable predictor of CACS on CT and T score on BMD in dialysis patients.

SA-PO063
Total Body Multislice Computed Tomography as a Gold Standard of Vascular Calcification
Nadia Martin Alemany,1 Xiaona Barros,2 Jordi Calabia,1 Juan Baños,3 1 Nephrology, Univ Hospital Dr Josep Trueta, Girona, Spain; 2Radiology, Inst de Diagnostic per la Imatge (IDI), Girona, Spain.

Background: Vascular calcification (VC) is a marker of cardiovascular risk in CKD patients. Imbalance of calcium-phosphate parameters and secondary hyperparathyroidism (shP) has been proposed as indicators of VC. Traditionally VC has been evaluated with Kauppila, Adragao and coronary Agatston scores but they are limited to restricted body areas and may underestimate total VC. We proposed a new method to assess VC in CKD patients with mild shP based on total body multislice computed tomography (MSCT) without contrast.

Methods: Center-tcenter transversal study which included incident dialysis patients with mild shP (PTH <150pg/dL) after signed informed consent. Kauppila and Adragao scores were determined on abdominal and pelvis/hand X-ray, respectively. Total body area calcification (cm2) was measured by MSCT. Patients with a total calcified area of >150 cm2 were considered calcified. Sensibility and specificity of Kauppila and Adragao scores were calculated considering total calcified body area >150 cm2 as reference.

Results: We enrolled 22 patients (13 hemodialysis / 9 peritoneal dialysis), 45% diabetics, 62 ±15 years old. Mean±SD: were: phosphorus 4.6 ±1.5mg/dl, calcium 9.2 ±1.04mg/dl and parathyroid hormone 278 ±132pg/dl. They presented mean Kauppila score 6.9 ±6.9, Adragao score of 2.3 ±3.7 and total calcified area of 112.6 ±19.7cm2. 77% patients were calcified, considering positive if overall calcified area >150cm2. Diabetics and those with previous cardiovascular events had higher total body calcified area, whereas gender and type of dialysis didn’t demonstrate any influence on calcification. Sensibility of Kauppila and Adragao scores were 70 and 30%, respectively, whereas specificity of both of them was 100%.

Conclusions: It is possible to evaluate the overall body calcified area in patients with ESRD by multislice computed tomography, which could be considered as a potential gold standard of global vascular calcification in those patients.

SA-PO064
Comparison of Mineral Metabolic Markers and Therapy in Chronic Hemodialysis Patients with Different Degree of Abdominal Aortic Calcification Score
Manja Antonić,1 Saskia Lampreht,2 Zeljka Vecerica Haler,2 Jakob Gubensek,3 Andrej Drozg.
1 Dept of Nephrology and Dialysis, General Hospital, Celje, Slovenia; 2Dept of Nephrology, Univ Medical Centre, Ljubljana, Slovenia.

Background: The correlations of vascular calcifications with different markers of CKD-MBD and also their therapy are not always consistent across the studies and cross-sectional associations are favoured over long-term analyses. We therefore aimed to evaluate laboratory markers and therapy load over a longer period in chronic hemodialysis patients with different severity of abdominal aortic calcification (AAC).

Methods: In hemodialysis patients AAC was determined by lateral lumbar radiography and quantified by Kauppila score. Patients were divided in two groups according to median AAC score of the whole group. Mean active vitamin D and cinacalcet intake for last 4 years and calcium carbonate for last 10 years (or whole dialysis vintage for those on dialysis >10 years) were calculated considering total calcified body area > 150 cm2 as reference.

Results: After 12 months Kauppila and Adragao scores were determined on abdominal and pelvis/hand X-ray, respectively. Total body area calcification (cm2) was measured by MSCT. Patients with a total calcified area of >150 cm2 were considered calcified. Sensibility and specificity of Kauppila and Adragao scores were calculated considering total calcified body area >150 cm2 as reference.

Conclusions: It is possible to evaluate the overall body calcified area in patients with ESRD by multislice computed tomography, which could be considered as a potential gold standard of global vascular calcification in those patients.
### SA-PO608

**Association of Metabolic Syndrome with Aortic Arch Calcification and Outcome in Non-Diabetic Peritoneal Dialysis Patients**

_**Cheng Chia Lee,**1,2 Kun-Hua Tu,**1 Yu-Chang Tian,**1 Ming-Yang Chang,**1 Chih-Wei Yang,**1,2 Dept of Nephrology, Kidney Research Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan; 2Chang Gung Univ, College of Medicine, Taoyuan, Taiwan._

**Background:** Vascular calcification (VC) is now recognized as an important risk factor for mortality in dialysis patients. Previous studies have shown conflicting results regarding the association of the metabolic syndrome (MetS) and mortality in patients on peritoneal dialysis (PD). Despite the controversial definition of MetS in PD patients, the association between MetS and the presence and severity of VC in the non-diabetic PD patients remained unknown.

**Methods:** We enrolled 277 non-diabetic PD patients into this study. Posterior-anterior chest X-ray were assessed for the aortic arch calcification (AoAC). Frequency of different components and their constellation as MetS were determined according to the modified Adult Treatment Panel III criteria. Using multinomial logistic regression, the factors determining baseline AoAC were analyzed. We used Kaplan Meier analysis to assess the impact of MetS on both mortality and technique failure.

**Results:** Mean age was 48.4 ± 13 years and 43.1% (n=118) had metabolic syndrome. 179 patients were classified as no visible calcification (AoAC grade 0), 51 patients as mild calcification (AoAC grade 1), and 47 patients as moderate to severe calcification (AoAC grade 2-3). The adjusted odds ratio for AoAC grade 1 was 3.03 (95% CI: 1.34-6.84) and for AoAC grade 2-3 was 6.25 (95% CI: 2.26-17.27) among patients with MetS as compared with those without MetS. Multivariate linear regression analysis showed that MetS (P<0.001) was an independent risk factor for higher hypertension, as denoted by high sensitivity C-reactive protein. Over a mean of 45.9 months of follow-up, 34 patients died. Kaplan Meier analysis demonstrated that the incidence of mortality and technique failure does not differ in patients with and without MetS.

**Conclusions:** MetS was independently associated with the presence and severity of AoAC but cannot predict mortality or technique failure in non-diabetic PD patients. Nevertheless, non-diabetic PD Patients with MetS warrant more aggressive risk factor management to reduce the risk of VC.

### SA-PO609

**Increased Peripheral Arterial Calcification in Patients Receiving Warfarin**

_Kum Hyun Han,**1 W. Charles O’Neill,**1 Renal Div, Emory Univ, Atlanta, GA; 1Internal Medicine, Inje Univ College of Medicine, Ilsan Paik Hospital, Goyang, Korea._

**Background:** Matrix gla-protein is a vitamin K-dependent inhibitor of vascular calcification, and genetic deficiency or inhibition with warfarin produces medial vascular calcification in animals, raising concerns that warfarin may promote vascular calcification in humans. We recently showed that warfarin use is associated with increased breast arterial calcification but whether this is reflective of other arteries or occurs in men as well is unclear. Therefore, we compared the prevalence of calcification in peripheral arteries in patients with and without warfarin therapy.

**Methods:** A random sample from a computerized search of medical records yielded 430 patients with x-rays performed during or after warfarin therapy. Each was matched to a patient without warfarin exposure based on age and diabetes. Patients with warfarin exposure <1 month, history of ESRD, or serum creatinine > 2.0 were excluded. X-rays were reviewed visually for arterial calcification.

**Results:** Mean age was 66.9 ± 8.7, 41% were males, and 34% had diabetes. The indication for warfarin was atrial fibrillation in 45% and venous thrombosis or embolism in 44%, and mean duration of warfarin was 4.8 yrs (range: 1 month to 38 yrs). 68% were on warfarin at the time of the x-ray and the remainder had been off warfarin for a mean of 2.4 yrs (range: 1 day to 25 yrs). Serum calcium was slightly lower (9.04 ± 0.03 vs. 9.17 ± 0.01; p=0.005) in the warfarin patient but serum creatinine and phosphorus did not differ. Prevalence of arterial calcification was 44% greater in warfarin patients (30.2% vs. 20.9%, p=0.002) but not on x-rays performed prior to warfarin (26.4% vs. 22.4%, n=156), indicating that the increase was due specifically to the warfarin and not to underlying disease or other patient characteristics. The increase in calcification was seen only after >5 yrs of warfarin and only in the ankle and foot. It was similar in men and women and greatest (2.4-fold) in patients under age 60 (15% vs. 3.3%, p=0.04).

**Conclusions:** Warfarin use is associated with lower extremity arterial calcification in both men and women independent of age, diabetes, and other patient characteristics.

**Matrix GlA Protein and Vascular Calcification in Patients with End Stage Renal Disease**

_Hannes Olaison,**1 Christian L. Meuwese,**1 Karin Luttropp,**1 Annika Wernerson,**1 Peter F. Barany,**1 Cees Vermeer,**2 Peter Stenvinkel,**1 1CLINTEC, Karolinska Inst, Sweden; 2VitaK, Maastricht Univ, Netherlands._

**Background:** Vascular calcification (VC) is a common and severe consequence of end-stage renal disease (ESRD). Matrix GlA protein (MGP) is a calcification inhibitor expressed by the vasculature that counteracts the development of VC.

**Methods:** In 84 ESRD patients undergoing LD-Tx at Karolinska University Hospital, biopsies from the inferior epigastric artery were obtained during surgery. Vascular calcification was assessed by von Kossa staining both by manual scoring (0-3) and by semi-automated analysis (%). Total uncrosslinked MGP (t-ucMGP) and diphospho-uncrosslinked MGP (dp-ucMGP) were measured in plasma. Tissue MGP expression was quantified in arterial biopsies by TaqMan rPCT. DNA methylation of the MGP gene was assessed in peripheral blood from 12 ESRD patients and 12 healthy controls.

**Results:** 50 patients (59.5%) had low VC scores (0 and 1) and 34 (40.5%) patients high VC scores (2 and 3). Plasma levels of dp-ucMGP were higher in patients with high VC scores compared to patients with low VC scores (2214 [1413-2995] vs. 1701 [1275-2233] pmol/L, p<0.05) and also associated with calcification (%)(Fig 1A: β [95%CI]: 26 [7 to 45] p<0.01). Additionally, calcification (%) associated with arterial expression of MGP (Fig 1B: β [95%CI]: 0.04 [0.02 to 0.06] p<0.0001). t-ucMGP levels were not associated with measures of VC. DNA methylation of the MGP gene was significantly lower in patients with ESRD compared to healthy controls (adjusted p<0.01).

**A Nationally Representative Case Control Study of Calciaphylaxis Risk Factors**

_Sagar U. Nigwekar,**1 Sophia Zhao,**2 Julia Beth Wenger,**1 Franklin W. Maddux,**2 Jeffrey L. Hymes,**2 Ravi I. Thadhani,**1 Kevin Chan,**1,2 1MGH; 2Fresenius Medical Care North America._

**Background:** Prior studies evaluating calciaphylaxis risk factors suffer from sample size limitations and none examine whether characteristics at dialysis initiation predict calciaphylaxis risk.

**Methods:** Data for this matched case control study were derived from hemodialysis (HD) population at the Fresenius Medical Care North America (FMCNA). Cases were identified from FMCNA calciaphylaxis prospective database. Controls (HD patients without calciaphylaxis) were matched to cases on age, sex, and race. Data on variables at HD initiation were abstracted. Variables for multivariable logistic regression analyses were identified using stepwise selection.

**Results:** We analyzed 1,025 calciaphylaxis cases (52% biopsy-confirmed) and 2,050 controls. Body mass index, diabetes mellitus (DM), serum parathyroid hormone (PTH) level, use of warfarin and phosphate binders were higher whereas serum calcium and active vitamin D use were lower at HD initiation in cases compared to controls.
SA-PO613

Calciphylaxis – A Multi-Interventional Treatment Regimen Including Vitamin K Supplementation Might Reduce Mortality in Chronic Kidney Disease Patients

Daniel A. Hochfellner,1 Barbara Binder,2 Werner Ribtisch,3 Alexander R. Rosenkranz,2 Gernot Schilcher,1 1Clinical Div of Nephrology, Dept of Internal Medicine, Medical Univ of Graz, Graz, Austria; 2Department of Dermatology, Medical Univ of Graz, Graz, Austria.

Background: Calciphylaxis is a rare disease predominantly affecting patients with chronic kidney disease (CKD) with a high mortality mainly due to wound infection. Recently, multimodal therapy schemes including sodium thiosulfate (STS) have been established. The role of a standardized Vitamin K supplementation remains unclear.

Methods: In a retrospective study we evaluated the impact of a standardized, multi-interventional treatment regimen on the mortality of calciphylaxis patients treated at the Clinical Department of Nephrology, Medical University of Graz, Austria between January 2009 and February 2014. Patients were treated with STS, dermatological wound management and high dose supplementation of vitamin K1 (Phytomenadione 30mg/week). The primary endpoint was mortality compared to the present literature. Secondary endpoints included gender distribution, number of biopsy proven cases, analysis of triggering events and time from event to diagnosis. Data were collected from medical records.

Results: 20 patients with newly diagnosed Calciphylaxis at different CKD stages (CKD 5, n=15; CKD 4, n=3; CKD 3, n=1; no CKD, n=1) were included. The mortality was 25% versus 52% compared to recent literature. Gender distribution and amount of biopsy proven cases were comparable to other retrospective studies. 12 patients (60%) had a known preceding event such as trauma possibly having triggered development of calciphylaxis. The period from event to diagnosis was 103±94 days. 19 patients (95%) received STS. In contrast to other multimodal therapeutic concepts 95% (19) of our patients additionally received high dose vitamin K supplementation.

Conclusions: In our cohort calciphylaxis was associated with a markedly reduced mortality as compared to published outcome data. We hypothesize that supraphysiological pre-treatment and our multi-interventional treatment regimen play an important role in the treatment of calciphylaxis.

SA-PO614

The German Calciphylaxis Registry

Vincent Brandenburg,1 Jürgen Floege,2 Joanna Korbiel,3 Markus Ketteler,4 1Cardiology, RWTH Aachen Univ Hospital, Aachen, Germany; 2Nephrology, RWTH Aachen Univ Hospital, Aachen, Germany; 3Nephrology, Klinikum Coburg, Coburg, Germany.

Background: Calciphylaxis (CUA) is a rare disease and for patients a devastating condition associated with high morbidity and mortality. CUA is characterised by painful, ischemic, partly necrotic skin ulcerations. Pathomorphologically, media calcification of cutaneous arterioles and extracellular matrix remodelling are the hallmarks of CUA. Epidemiology and risk factors are incompletely understood. Referring patients to specialized units is limited due to high disease burden.

Methods: Therefore, we established an internet-based observational registry in 2006 (www.calciphylaxis.de) to allow online notification for pts with CUA. The registry includes a comprehensive data base with 71 parameters concerning patient and laboratory data, clinical background and presentation as well as therapeutic strategies. The diagnosis of CUA is made on clinical and/or histological grounds by the referring physician.

Results: Until Feb 2015 n=253 patients with CUA have been recorded (~30 pts/year at constant rate) with a median delay of 28 days after onset: 99% Caucasians, 60% females; 76% HD and 10% PD patients; median age 66 (IQR 61-76) years. Co-medication at the time of diagnosis: 75% ESA, 51% vitamin K antagonists (VKA). Skin biopsy was done in 45%, prior PTex in 12%; major skin lesion in 80% at the legs. Median lab data upon diagnosis of CUA: AIr Phos 113 U/L (IQR 86-167); PTex 173 ml/g (IQR 73-390); total calcium 2.20 mmol/L (IQR 2.04-2.36); phosphorus 1.62 mmol/L (IQR 1.28-2.00). Among the most frequently recorded therapeutic procedures were: surgical necrosectomy (plus antibiotics), intensifying dialysis modality, reduction of calcium supply, i.v. sodium-thiosulfate application. Survival was analyzed in a subgroup of 91 pts. Median survival time was 516 days after online notification.

Conclusions: CUA is a rare disease among ESRD pts with high mortality. Therapeutic strategies vary significantly among centers; EBM guidelines are absent. VKA usage appears to be the risk factor for CUA in ESRD pts. The German CUA registry is a valuable tool to collect data and may become a basis for a European registry (EuCalNet).

SA-PO615

Evaluation of the Effects of Sodium Thiosulfate Treatment on Calciphylaxis

Guillermo Ortiz, Joshua Wibcean, Julia Beth Wenger, Ravi I. Thadhani, Sagar U. Nigwekar.

Nephrology Div, Massachusetts General Hospital, Boston, MA.

Background: Intravenous sodium thiosulfate (STS) is commonly prescribed to treat calciphylaxis, a highly fatal disease that presents with excruciating painful skin lesions. Anecdotal reports suggest that STS may improve calciphylaxis associated pain (CAP) within 2 weeks of initiation; however, systematic evaluation of effects of STS on CAP is lacking.

Methods: This observational study included 22 patients with biopsy-confirmed calciphylaxis who were hospitalized at our center for ≥2 weeks during 2012-2014 for newly diagnosed calciphylaxis and were treated with STS. Medical records were reviewed to abstract clinical data including CAP severity (0-10 scale) and analgesic use. CAP scores at baseline, 1-week, and 2-week time-points were noted and classified into mild (1-3),
moderate (4-6), and severe (7-10) categories. Responders were patients who reported ≥ 30% improvement in CAP severity score from baseline during the first 2 weeks of treatment. Predictors of response and association between CAP response and association between CAP response and association between CAP response and baseline to 2-weeks (figure 1) despite steady doses of opiate medications. No significant predictors of CAP response were observed and CAP improvement at 2-weeks did not predict 6-month outcomes.

Results: Median age was 60 years (Range: 52-67). 59% were males, 95% were whites, 55% were on dialysis, 36% had chronic kidney disease not requiring dialysis, and 9% had normal kidney function. Median duration between lesion appearance and STS initiation was 12 weeks (Range: 6-19). There was a trend toward decrease in severe CAP from baseline to 2-weeks (figure 1) despite steady doses of opiate medications. No significant predictors of CAP response were observed and CAP improvement at 2-weeks did not predict 6-month outcomes.

Conclusions: A large prospective trial is needed to ascertain the effects of STS on CAP.

SA-PO616

Long-Term Impact of Strict Blood Pressure Control During CKD on Mortality Risk After ESRD

Background: In extended follow-up of the Modification of Diet in Renal Disease (MDRD) study, we reported that strict BP control did not lower risk of ESRD but was associated with lower mortality risk after ESRD (HR 0.72 [95% CI 0.58-0.89]) (Ku KL 2015). To further address this issue, we conducted parallel analyses in the African American Study of Kidney Disease (AASK) and post-hoc pooled analyses of AASK and MDRD.

Methods: AASK randomized 1094 persons with CKD attributed to hypertension to strict (mean arterial pressure [MAP] <92 mmHg) versus usual BP control (MAP >107 mmHg) between 1995-2001. We ascertained death and ESRD status through 6/2012 via US Renal Data System (USRDS) and Social Security Death Index for 1067 enrollees with non-missing identifiers.

Results: In extended AASK follow-up, 397 cases of ESRD and 475 deaths (208 after ESRD) occurred. The risk for ESRD was 0.94 (95% confidence interval [CI] 0.77-1.14), overall mortality risk was 0.92 (95% CI 0.70-1.20), and risk for death after ESRD onset was 0.92 (95% CI 0.70-1.20) comparing strict versus usual BP arms. Thus, the CI for overall mortality risk was 0.92 (95% CI 0.77-1.10), and median BMI was 32.8 kg/m². 59% of patients were on RAS blockade at baseline, and 69% of patients were on it for at least half the duration of follow-up. Taking into account time-updated exposure, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93; P<0.01).

Conclusions: This study, conducted in a large real-world cohort of patients with detailed and time-updated data about blood pressure treatment, provides important evidence that RAS blockade may protect against deterioration in renal function among obese, hypertensive, non-diabetic patients.

SA-PO617

Obesity, Renin-Angiotensin System Blockade, and Chronic Kidney Disease: A Population-Based Cohort Study

Background: Obesity substantially increases the risk of the development and progression of chronic kidney disease. Adipose tissue expresses all of the components of the renin-angiotensin system (RAS), which is an important contributing factor to the high prevalence of hypertension in obese patients, and drives renal hypertrophy and subsequent glomerular injury.

Methods: We performed a retrospective cohort study using the Health Improvement Network, a primary care database with comprehensive demographic, laboratory, and pharmacy data from patients in the United Kingdom. We evaluated the effect of time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients with normal or mildly reduced kidney function using a Cox proportional hazards model as estimated by pooled logistic regression to assess the hazards of developing a 50% reduction in estimated glomerular filtration rate (eGFR) or end stage renal disease. In addition to adjusting for baseline comorbidities including age, gender, socioeconomic status, cardiovascular disease, and body mass index (BMI), we adjusted for time-varying covariates including systolic blood pressure (SBP), number of antihypertensive medications, use of mineralocorticoid antagonists, and eGFR.

Results: There were 219,701 patients that met inclusion criteria, with a median 4.9 years of follow-up. Median baseline eGFR was 72.6 mL/min/1.73m², median SBP was 146 mmHg, and median BMI was 32.8 kg/m². 59% of patients were on RAS blockade at baseline, and 69% of patients were on it for at least half the duration of follow-up. Taking into account time-updated exposure, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93; P<0.01).

Conclusions: These data, conducted in a large real-world cohort of patients with detailed and time-updated data about blood pressure treatment, provides important evidence that RAS blockade may protect against deterioration in renal function among obese, hypertensive, non-diabetic patients.

SA-PO618

Distribution and Prognostic Value of Central Blood Pressure in Chronic Kidney Disease

Background: Central blood pressure (CBP) has been shown to be a better predictor than brachial blood pressure for cardiovascular events and target organ damages than brachial blood pressure. However, little is known about comparative values of CBP and brachial BP in chronic kidney disease (CKD) population. We investigated the distribution of CBP and evaluated the comparative values of CBP and brachial BP for the prediction of renal progression in both CKD and non-CKD population.

Methods: We conducted this study using data from 868 subjects who underwent CBP measurement by the radial artery tonometric method between 2009 and 2013. Demographic and clinical characteristics were obtained from a review of the medical records at the time of CBP measurement. The outcome was renal progression defined as decline of estimated glomerular filtration rate (eGFR) or end stage renal disease.

Results: In overall, estimated central systolic BP (cSBP) was higher than brachial systolic BP (bSBP). The cSBP was significantly increased with age in non-CKD group, but such a correlation was not observed in CKD group. In CKD population, high cSBP group with greater than mean cSBP value (150mmHg) had significantly increased probability of renal progression (P=0.016), while high bSBP (140mmHg) group did not predict the outcome (P=0.370). In contrast, the predictor of renal progression was high bSBP but not cSBP in non-CKD population. In Cox analysis adjusted for covariates, high cSBP remained a predictor of renal progression in CKD population (HR 5.408; 95% CI 1.008-29.030; P=0.049), whereas high bSBP was not a significant predictor in non-CKD population (HR 2.891; 95% CI 0.786-10.650; P=0.110).

Conclusions: The CBP had different correlation with age and clinical significance according to presence or absence of CKD, and the high cSBP was strong independent predictor of kidney disease progression in CKD patients.
SA-PO619
Clinical Characteristics and Outcomes Associated with Resistant Hypertension in a Large Cohort of U.S. Veterans 1,2,13 Miklos Zsolt Molnar,2 Adriana Hung,3 Jun Ling Lu,4 John J. Sim,1 Robert B. Canada,2 Elvira Gosmanova,2 Fridjthof Thomas,3 Kamary Kalantar-Zadeh,3 1VA Medical Center, Memphis, TN; 2Univ of Tennessee Health Science Center, Memphis, TN; 3VA Medical Center, Nashville, TN; 4Kaiser Permanente, CA; 5Univ of California, Irvine, CA.

Background: The prevalence of true resistant hypertension (RH), the characteristics of patients with RH and its association with clinical outcomes is unclear.

Methods: From 2,398,778 patients with essential HTN, we identified 95,334 (4%) with RH, defined as: Failure to achieve BP=140/90 mmHg with >=3 antihypertensives (one being a thiazide diuretic) or success with >=4 drugs; excluding measurements when pain score was >5; when interfering medications were prescribed and excluding those with confounding conditions (CKD, secondary HTN, sleep apnea, urinary obstruction, arterial, thyroid and parathyroid over-activity). We examined with mortality, incident CKD, ESRD, steeper slopes of eGFR, incident coronary heart disease (CHD) and stroke in Cox models and logistic regression models adjusted for demographic and socioeconomic factors, comorbidities, BP, and antihypertensives.

Results: The mean SBP/DBP in RH and non-RH patients were 148±22/81±14 vs. 137±19/78±12 mmHg. Compared to non-RH, patients with RH were older (64±11 vs. 62±13), more likely to be black (25 vs. 17%), and had a higher prevalence of DM and CVD. Crude mortality was similar and the incidence of the renal and cardiovascular end points was higher in RH. After full adjustment the risk of CHD and stroke associated with RH remained significant, but the risk of renal outcomes was reversed (Figure).

Conclusions: RH is relatively infrequent (4%) among patients with essential HTN, and is associated with older age and a higher comorbidity burden. Patients with RH have a higher risk of incident CHD and stroke.

SA-PO621
Adherence Assessment in Resistant Hypertension: A Comparison Between Pill Count and Direct Method of High Performance Liquid Chromatography Analysis in Urine 1 Patricia Cardoso Alaron Horì, Silvana de Barros, Indira Fernandes Braga Azam, Andrea Pio de Abreu, Andrea Cassia Perreira Sforzin, Vanusa Barbosa Pinto, Decio Mion Junior, Giovanni Vieira da Silva, Nephrology and Pharmacy, General Hospital of Sao Paulo Univ, Sao Paulo, Brazil.

Background: Poor adherence to antihypertensive therapy is one of possible causes of resistant hypertension. Pill count is currently considered the standard for assessing drug adherence, but as an indirect method, it is inaccurate. The aim of this study was to compare the pill count with the direct method of toxicological urine screening in patients with resistant hypertension.

Methods: Patients with resistant hypertension criteria were included: office blood pressure (BP) above goal (systolic BP>140mmHg and/or diastolic BP>90mmHg) taking 3 or more antihypertensives agents of different classes, one of them diuretic, or office BP below goal taking 4 or more classes. Adherence was assessed by direct method of high performance liquid chromatography analysis for antihypertensive drugs or their metabolites in 4 different urine samples, with 30-day interval between them. Simultaneously, pill count was also performed. Patient was considered adherent by direct method if it was found every prescribed agents in at least 3 urine samples. Regarding pill count, patient was considered adherent if he consumed at least 90% of prescribed agents.

Results: 18 patients were selected: 78% women, age 57.5 ± 5.7 years, body mass index 29.3 ± 3.6 kg/m², office mean BP 151/88 ± 20/15 mmHg and 24 hours mean BP by ambulatory blood pressure monitoring 132/85 ± 21/12 mmHg. The average number of antihypertensive agents prescribed was 4.8 ± 0.8 classes per patient. 3 (17%) and 2 (11%) patients were considered adherent by direct method and pill count, respectively. However, the agreement between methods was poor (Kappa correlation coefficient -0.15).

Conclusions: Adherence to therapy in patients with resistant hypertension was very low by both methods. There was no agreement between pill count and direct method. The best method to assess adherence in resistant hypertension is yet to be determined.
Funding: Government Support - Non-U.S.

SA-PO622
Plasma Renalase Concentration Before and After Radiofrequency Renal Denervation in Patients with Resistant Hypertension: Preliminary Results 1 Marcin Adamiezak,2 Beata Czerwienska,1 Maciej T. Wybraneck,3 Michal Lelek,2 Katarzyna T. Mizia-Stec,4 Andrzej Wiecek. 1Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland; 21st Dept of Cardiology, Medical Univ of Silesia, Katowice, Poland.

Background: Renalase is a catecholamine-metabolizing enzyme produced by proximal tubular cells in kidney which is supposed to be involved in blood pressure regulation. The aim of the study was to evaluate plasma renalase concentration after radiofrequency renal denervation (RDN) in patients with resistant arterial hypertension (HTN).

Methods: 19 patients (10 men; median age 56 (48; 57) years; BMI 30.9±4.4 kg/m² and eGFR 89±17.7 ml/min/1.73 m²) with resistant HTN were enrolled in the study. In all patient plasma renalase concentration was measured before and 1, 3, 6 and 12 months after RDN by ELISA method (Cloud-Clone Corp, Houston, USA).

Results: A significant decrease of both office systolic and diastolic blood pressure 6 months after RDN was found (192±31 vs. 177±28 mmHg, p=0.03; 113±23 vs. 99±21 mmHg, p=0.002, respectively). One and 3 months after RDN plasma renalase concentration decreased significantly, with a subsequent return to values comparable with baseline at 6- and 12-month follow-up (median of 22100 vs. 18550 vs. 17600 vs. 20750 vs. 20500 ng/ml respectively; Friedman analysis of variance p=0.054).

Conclusions: A decrease in plasma renalase concentration after RDN was observed. Further investigations are required to evaluate the clinical significance of this finding.

SA-PO619
Association of Components of Body Mass Index with Treatment-Resistant Hypertension in Men and Women with Chronic Kidney Disease Toshiyuki Aoki,1 Yasushi Ohashi,2 Reibin Tai,1 Kiyoto Koibuchi,2 Atsushi Aikawa,1 Ken Sakai,1 1Nephrology, Toho Univ School of Medicine, Ohta-ku, Tokyo, Japan; 2Nephrology, Saiseikai Eastern Hospital, Yokohama, Kanagawa, Japan.

Background: Treatment-resistant hypertension is a risk for cardiovascular disease and end-stage renal disease. However, the appropriate clinical management strategies remain unclear in patients with CKD. Our objective is to investigate the association of components of body mass index (BMI) with treatment-resistant hypertension in patients with CKD.

Methods: Body fluid composition was measured in 310 patients with CKD from 2005 to 2014, and BMI was separated into 3 components: - (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW), and (c) extracellular water (ECW). Treatment-resistant hypertension was defined as an office BP of ≥130/80 mmHg, despite receiving ≥3 antihypertensives including diuretics, or ≥4 drugs usage. The main outcomes were adverse renal outcomes, as defined by a decline of ≥50% or more from baseline GFR or initiation of renal replacement therapy and cardiovascular events.

Results: The prevalence of treatment-resistant hypertension were 69 male patients (35.4%) and 19 females (16.5%). Patients with treatment-resistant hypertension were more likely to be diabetic, have a higher BMI, GFR, and proteinuria, and to be older especially in women. In the components of BMI, those in men and women tended to have higher ECW content and free water mass, respectively. Higher ECW contents in men and diabetes in relation to higher free water mass in women were independently caused treatment-resistant hypertension. Compared with patients with no treatment-resistant hypertension during a median 743-day follow-up, those with treatment-resistant hypertension had worse adverse renal outcomes (16.2 vs. 6.1 per 100 patient-years, P < 0.001) and cardiovascular events (5.0 vs. 1.6 per 100 patient-years, P < 0.001).

Conclusions: Treatment-resistant hypertension is associated with diabetes in relation to higher free water mass in women and higher ECW in men, which exhibits adverse renal outcomes and cardiovascular events. These findings emphasize the importance of adequate weight and volume status.

**Short Term Sequela of Preeclampsia**

**Michael Yannik Giribeger,1 Irene Mathilde Hoels,2 Michael Dickemann.1, 2**

**1Clinic for Transplantation Immunology and Nephrology, Univ Hospital Basel, Basel, Baselstadt, Switzerland; 2Dept of Gynaecology and Obstetrics, Univ Hospital Basel, Basel, Baselstadt, Switzerland.**

**Background:** Data on sequela in the first year after preeclampsia are scarce. We investigated kidney function, blood pressure, proteinuria and urine sediment in women with preeclampsia six month after delivery.

**Methods:** From January 2007 to July 2014 all women with preeclampsia and 6-moths follow up at the university hospital Basel were prospectively analysed. Preeclampsia was defined as new onset of hypertension (>140/90 mmHg) or worsening hypertension and either proteinuria or signs of end-organ dysfunction. Hypertension was defined as a blood pressure (BP) >140/90 or the use of antihypertensive medication. Proteinuria was defined as a protein-to-creatinine ratio in a spot urine > 11 mg/mmol. Urine sediment was evaluated by a nephrologist.

**Results:** 202 women were included. Baseline characteristics are shown in Table 1 and follow up data are shown in Figure 1. The mean time of the follow up visit was 172 days (+/- 39.6) after delivery. The mean blood pressure at follow up was 124/76 mmHg (+/- 14/11, range 116-182/63-110) and the mean serum-creatinine was 61.8 umol/l (+/- 11.6). Mean estimated glomerular filtration rate (CKD-EPI) was 110.7 ml/min/1.73m2 (range 59.7-142.4 ml/min/1.73m2). No active urine sediment (e.g. signs of glomerulonephritis) was observed.

**Microparticles Cause Preeclampsia and Kidney Injury by Activation of Inflammasome in the Placenta**

**Shrey Kohli, Berend Heinrich Isermann.**

**Inst of Clinical Chemistry and Pathobiocchemistry, Otto Von Guericke Univ, Magdeburg, Germany.**

**Background:** Preeclampsia is a hypertensive disorder of pregnancy associated with high morbidity and mortality. Hallmarks of preeclampsia are endothelial damage and functional (e.g. proteinuria) and morphological renal aberrations. The only known remedy against this is the delivery of the placent. Cell derived microparticles (MP) of different origins are elevated in preeclampsia but their mechanistic relevance is unknown. Preeclampsia is also associated with a pro-inflammatory condition but there are meager mechanistic insights into this as well.

**Methods:** To address these questions MP (endothelial or platelet derived) were injected into C57/B6 pregnant mice and the pregnancy outcome (embryonic survival and growth, placenta morphology) was studied. Morphology of the kidney was studied using PAS staining and electron microscopy. Proteinuria was studied as a measure of renal dysfunction. To address mechanistic questions, inflammasome activation by MP in placenta and trophoblast cells was studied using western blotting and immunohistochemistry. Human trophoblast derived cells and placentas from pregnancies complicated with pre-eclampsia were also studied for activation of inflammasome. NLRP3 and Casp-1 KO mice were used to rescue the mice from disease conditions and establish causality of the mechanism.

**Results:** MP caused preeclampsia associated with fetal loss and embryonic growth restriction in mice. This was associated with renal damage indicated by proteinuria, glomerular enlargement, thickness of glomerular basement membrane, and podocyte effacement in the kidney. Human and mouse placenta analysis indicated inflammasome activation seen by elevated expression of NLRP3, cleaved casp-1 and IL-1β. The pregnancy outcome and renal function was rescued in NLRP3 and Casp-1 KO mice.

**Conclusions:** MP are causative of preeclampsia, fetal death, embryonic growth restriction, and renal injury. These pathogenic effects of MP are mechanistically linked with inflammasome activation in the placenta.

Preeclampsia: Long-Term Effects on Pediatric Neurologic Disability
Alberto Tejedor Jorjo, Clara Nicolas, Patrocinio Rodriguez Benitez, Olga Arroyo, Maria Silva, Laura Mateosanz, Carmela Mercurio, Manuel Sánchez Luna. Hospital General Univ Gregorio Marañón.

Background: Preeclampsia affects up to 10% of pregnancies worldwide and is one of the main causes of fetal morbidity and mortality. Although it has been linked to developmental delay, its long-term effects on neurologic development in children have yet to be sufficiently quantified. Our aim is to evaluate whether the preeclampsia’s severity and the therapeutic options used to manage it correlate to the degree of developmental delay in these infants.

Methods: This is an observational and descriptive study performed on a population of 96 women who were diagnosed with preeclampsia at Hospital General Univeristario Gregorio Marañón between 2007 and 2014, and their 111 children. To evaluate the mother, we gathered data pertaining to her medical history, renal function markers, and medical management of the preeclampsia. To assess the children, we collected fetal growth measurements, acute fetal distress markers and main diagnoses at birth. We used the Pediatric Disability Inventory in its computerized adaptive test version (PEDI-CAT) to study neurologic development, and the TNO- AZL Preschool children Quality of Life (TAQPOL) to estimate health-related quality of life.

Results: Early-onset and more severe preeclampsias were associated with higher preterm birth and perinatal mortality rates. Preeclampsias with a greater impact on maternal organ function showed a clear correlation to higher periventricular-intraventricular hemorrhage rates in the newborn. In terms of neurologic development, PEDI-CAT percentiles were consistently lower in the Social/Cognitive domain than in other areas. Lower Social/Cognitive percentiles were associated to both lower maternal IgG levels and presence of necrotizing enterocolitis during the neonatal period.

Conclusions: Early-onset preeclampsias have a greater negative impact on both maternal renal function and fetal morbimortality. A connection between preeclampsia and poor social/cognitive outcomes exists that warrants further research, as does the possible link between preeclampsia, immaturity, and autistic features.

SA-PO627

Background: Hypertensive pregnancy disorders are increasingly recognized as a risk factor for future hypertension and cardiovascular disease. However, knowledge of this risk may be inadequate among internal medicine providers.

Methods: We reviewed all new consultations in a 2-month period in a hypertension subspecialty clinic. We determined the frequency with which providers documented a reproductive history, a history of hypertension in pregnancy and known cardiovascular risk factors. We also studied whether there were differences according to gender and level of training of the provider (consultants vs. residents/fellows) using the chi-square test.

Results: There were 102 consultations for hypertension in the study period. The majority of consultations were by consultants, 55/102 (53.9%), and 23/102 (22.6%) were by female providers. A reproductive history, including number of pregnancies, infertility and/or intent of consults were by consultants, 55/102 (53.9%), and 23/102 (22.6%) were by female providers. Consultants, 85/102 (83.3%) of women had live births, but it was documented in only 31 (36.5%) of notes. Chart review revealed that providers. A reproductive history, including number of pregnancies, infertility and/or intent of consults were by consultants, 55/102 (53.9%), and 23/102 (22.6%) were by female providers.

Conclusions: Hypertension specialists rarely document a reproductive history or a history of hypertension in pregnancy, irrespective of level of training. Female providers were more likely to document pregnancies.

SA-PO628

Accuracy of a Spot Urine Protein-to-Creatinine Ratio in Preeclampsia
Rosmini Unnuttall, 1 Juliet Mushii, 1 Mary King, 2 Belinda Ban Jim, 1 Anjali Acharya. 1 Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; 2 Obstetrics, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY.

Background: Correlation between a 24 hour urinary protein excretion with a spot urine protein-creatinine (SP/Cr) ratio in patients with preeclampsia is unclear. Moreover, urinary creatinine excretion is greater in populations such as Africans and non-white Hispanics. We studied the correlation of the SP/Cr ratio with a 24 hour urine protein measurement in this minority population.

Methods: ICD-9 codes of 642.4, 642.5, 642.6, 642.7 representing mild pre-eclampsia to eclampsia were used for data collection. Only 110 women with both 24 urinary protein collection and (SP/Cr) were included in the analysis. Correlation between SP/Cr and 24-hour protein excretion was assessed by Spearman correlation coefficient. The sensitivity and specificity of the SP/Cr ratio at various cut-offs for the prediction of significant proteinuria were estimated with a 95% confidence interval, using the 24-hour urine collection as gold standard. Receiver operating characteristic (ROC) curve analysis was used to determine the best discriminator values of the (SP/Cr) to predict proteinuria above 300 mg/24 hr. A P value of 0.05 or< was significant.

Results: The median SP/Cr ratio was 0.30 (interquartile range (IQR) 0.3) while the median 24 hour urine protein was 316.5 mg (IQR 286.8). The overall Spearman correlation was 0.48 (P < 0.0001) and 0.63 (P = 0.05), 0.59 (P < 0.01), and 0.45 (P = 0.001) for the 1st, 2nd, and 3rd trimesters respectively. At the cut-off value of 0.15 for SP/Cr, the sensitivity and specificity were 91.8% and 75.5% respectively. The cut-off SP/Cr ratio 0.25 was identified as the best threshold to detect a 24 hour protein excretion of 300 mg with a sensitivity and specificity of 75% and 59% respectively. The area under the curve (AUC) by the ROC curve analysis was found to be 0.69.

Conclusions: Even in a minority, inner city population we found significant correlation between the 24 hour protein excretion and the SP/Cr ratio, especially in the 2nd and 3rd trimesters of preeclampsia. Our findings are in line with the literature despite a minority patient population.
SA-PO630

The Detrimental Effects of Beta-Blockers on Central Hemodynamic Parameters: A Propensity Score Analysis

**Background:** Central blood pressure (BP) and arterial stiffness are better predictors of the cardiovascular burden than peripheral BP. Beta-blockers (BB) are known to reduce central BP to a lesser extent than peripheral BP, a hypothesized consequence of heart rate (HR) reduction. Therefore, the association between BB use, HR, and central hemodynamics were studied in the treated hypertensive participants of the CATeGENE study.

**Methods:** Using propensity score analyses, BB users (n=605) were matched to controls having similar clinical characteristics with Model 1 and without (Model 2) adjustment for HR. This resulted in 457 and 510 pairs with adequate balance, except for a different HR in Model 2 (20.5 ± 10.5 vs. 70.4 ± 11.5 bpm, p<0.001).

**Results:** In Model 1, the difference between peripheral and central systolic BP (DSBP) was 8.3 mmHg (IQR 5.8, 11.6) with BB compared to 9.7 mmHg (7.1, 13.5) without (p<0.001), indicating that for any given peripheral BP, BB use resulted in higher central systolic BP. Pulse pressure amplification, augmentation index and augmented pressure were also less favorable with the use of BB. The different HR in Model 2 further increased the detrimental DSBP observed with BB to 7.9 (5.6, 11.0) vs. 10.6 (8.1, 14.3) without (p<0.001) and was associated with a higher central pulse pressure (46.5 ± 13.0 vs. 43.3 ± 11.3, p<0.001).

**Conclusions:** This study shows that the unfavorable central hemodynamic profile of BB has both a HR-dependent and HR-independent component. **Funding:** Government Support - Non-U.S.

SA-PO631

Risk of Development of Dementia During Treatment of Hypertension with Different Calcium Channel Blockers

**Background:** Arterial hypertension (HTN) is proved to be a risk factor for development of dementia. Medical treatment of HTN may decrease the risk of dementia. Experimental study pointed to the possibility of difference between different calcium channel blockers (CCB) in their neuro-protective effect. The aim of our study was to evaluate the risk of dementia during treatment of HTN with one of three different CCBs.

**Methods:** This is a retrospective cohort study based on electronic database of Clalit Health Services, Central District. Study period was 11 years (2002-2012). Inclusion criteria: age 40-75, diagnosis of HTN without diagnosis of “Dementia” at the starting point of the study. By the end of the trial, 29 and 27 participants randomized to receive vitamin D and placebo, respectively, had adequate 24 hour ABPM at both baseline and at 8 weeks after starting the study.

**Results:** By the end of the trial, 29 and 27 participants randomized to receive vitamin D and placebo, respectively, had adequate 24 hour ABPM at both baseline and at 8 weeks. Mean 24 hour BP was measured using 24 hour ABPM at baseline and 8 weeks after starting the study. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the intervention group and from 14.4 to 17.4 ng/mL in the placebo group. Vitamin D supplementation did not lower BP at 8 weeks; 24 hour systolic BP changed from 120±10 to 122±8 mmHg in the intervention group (p-value=0.39), and from 124±8 to 125±10 mmHg in the placebo group (p-value=0.38), with a treatment effect p-value of 0.92.

**Conclusions:** In this randomized, double-blind, placebo-controlled trial of overweight/obese normotensive individuals, there was no improvement in mean 24 hour blood pressure after repletion of vitamin D. These findings are not consistent with vitamin D being a modifiable target for prevention of hypertension. **Funding:** NIDDK Support

SA-PO632

The Association Between Antihypertensive Agents and Postural Blood Pressure Response Using Beat-to-Beat Data: Results from the Irish Longitudinal Study on Ageing

**Background:** Beat-to-beat blood pressure (BP) measurements provide a dynamic picture of BP behavior during postural change. Impaired BP stabilization after standing is associated with substantial morbidity and mortality. We aimed to define the relationship between class of antihypertensive drug and BP stabilization during an active stand.

**Methods:** Cross-sectional analysis from The Irish Longitudinal Study on Ageing, a nationally representative cohort study of 8175 adults ≥50 years. Beat-to-beat BP was recorded in participants undergoing an active stand test. We defined grade 1 hypertension according to European Society of Cardiology criteria (systolic BP [SBP] ≥140-159mmHg and diastolic BP [DBP] 90-99mmHg). Orthostatic hypotension (OH) was defined as a drop in SBP ≥20mmHg and DBP ≥10mmHg. Outcomes were sustained OH (OH throughout the test) and impaired BP stabilization (OH at each 10-second interval during the test [total 110s]). Outcomes were assessed using logistic regression models adjusted for potential confounding variables.

**Results:** A total of 536 participants with self-report hypertension were receiving monotherapy with a renin-angiotensin-aldosterone-system inhibitor (317), beta-blocker (89), calcium channel blocker (89) or diuretic (41). Beta-blockers were associated with increased odds of sustained OH vs untreated grade 1 hypertension (OR 3.4, 95% CI 1.9-6.0). This was evident from 20s (OR 2.3, 95% CI 1.4-3.7) and remained statistically significant at 110s (OR 2.8, 95% CI 1.6-4.9). Multivariable adjustment did not attenuate the association. No significant association was detected among the other drug classes.

**Conclusions:** In older hypertensive adults betablocker monotherapy was associated with a 3-fold increased odds of OH compared to subjects with untreated grade 1 hypertension. The effect was evident from 20s after standing and was sustained. This should inform decision-making regarding appropriate choice of antihypertensive agent in older adults.

SA-PO633

Effect of Vitamin D on 24 Hour Ambulatory Blood Pressure: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

**Background:** Lower levels of 25-hydroxyvitamin D (25(OH)D) have been associated with an increased risk of hypertension in prospective cohort studies, suggesting that vitamin D might be a modifiable target for the prevention of hypertension. Vitamin D supplementation has also been shown to decrease clinic blood pressure (BP) in some studies.

**Methods:** We performed a randomized, double-blind, placebo-controlled trial of nonhypertensive participants with body mass index ≥25, and 25(OH)D <20ng/mL; subjects were randomized to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Mean 24 hour BP was measured using 24 hour ABPM at baseline and 8 weeks after starting the study. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the intervention group and from 14.4 to 17.4 ng/mL in the placebo group. Vitamin D supplementation did not lower BP at 8 weeks; 24 hour systolic BP changed from 120±10 to 122±8 mmHg in the intervention group (p-value=0.39), and from 124±8 to 125±10 mmHg in the placebo group (p-value=0.38), with a treatment effect p-value of 0.92.

**Conclusions:** In this randomized, double-blind, placebo-controlled trial of overweight/obese normotensive individuals, there was no improvement in mean 24 hour blood pressure after repletion of vitamin D. These findings are not consistent with vitamin D being a modifiable target for prevention of hypertension. **Funding:** NIDDK Support

SA-PO634

Effect of Uric Acid Lowering on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

**Background:** Higher levels of uric acid have been associated with an increased activity of the renin angiotensin system (RAS) in animal models of hypertension and kidney disease. Similarly, individuals with high levels of circulating uric acid have increased renal specific RAS activity measured using renal plasma flow (RPF). However, the effect of lowering serum uric acid on RAS activity in humans is unknown.

**Methods:** We performed a randomized, double-blind, placebo-controlled trial analyzing the Modifiable Effectors of Renin System Activation Trait Evaluation (MODERATE). Norotensive individuals with body mass index (BMI) ≥25 and uric acid level ≥5.0 mg/
Effects of Vitamin D Supplementation on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

**Background:** Disruption of vitamin D signaling in rodents causes activation of the renin-angiotensin system (RAS). In humans lower circulating 25(OH)D is associated with increased renal specific RAS activity (measured using renal plasma flow (RPF)); in addition, a small, open label, uncontrolled study found that vitamin D supplementation decreased renal specific RAS activity. However, the effect of vitamin D supplementation on the RAS in humans with vitamin D deficiency has never been examined in a rigorous manner.

**Methods:** We performed a randomized, double-blind, placebo-controlled trial of normotensive individuals with body mass index ≥25 and vitamin D deficiency (25(OH)D ≤20ng/ml); subjects were assigned to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Renal specific (assessed by RPF response to captopril in high sodium balance) and systemic RAS activity (plasma renin activity [PRA] and angiotensin II levels [AngII]) were measured at baseline and 8 weeks after starting the study.

**Results:** By the end of the trial, 43 and 41 participants allocated to receive vitamin D and placebo, completed the study with measurement of renal and systemic RAS activity. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the ergocalciferol group and from 14.4 to 17.4 ng/mL in the placebo group. Renal specific RAS did not significantly change after vitamin D repletion: the RPF response to captopril was 33.9 ± 10.6 mL/min at baseline and 35.9 ± 26.2 mL/min in 8 weeks in the ergocalciferol group (p-value=0.26); and was 37.3 ± 46.9 mL/min at baseline and 35.9 ± 26.2 mL/min in 8 weeks in the placebo group (p-value=0.70), with a treatment effect p-value of 0.27. Similarly, vitamin D supplementation had no effect on PRA or AngII levels.

**Conclusions:** In contrast to animal experiments, observational studies, and open-label uncontrolled interventions, this randomized, double-blind, placebo-controlled trial found no effect of vitamin D supplementation on RAS activity in vitamin D deficient individuals.

**Funding:** NIDDK Support

**SA-PO636**

**Comparison of Office Orthostatic Blood Pressure and 24-Hour Ambulatory Blood Pressure Measurements in the Prediction of Autonomic Dysfunction**

**Background:** Evaluation of orthostatic hypotension (OH) may involve office blood pressure monitoring (OBPM) as a common procedure in clinical practice. However, OBPM, the standard of care, is all but accurate and ABPM may be difficult to perform or even misleading. In contrast to animal experiments and observational studies, this randomized, double-blind, placebo-controlled trial found that lowering uric acid had no effect on renal specific or systemic RAS activity.

**Funding:** NIDDK Support

**SA-PO637**

**Factors Predicting Long Term Renal Prognosis in Malignant Nephrosclerosis**

**Background:** This study investigated correlations between kidney pathology and Renin-Angiotensin System (RAS) activation, RAS inhibitor response and prognosis of malignant hypertensive nephrosclerosis (MHN) patients.

**Methods:** This retrospective cohort study included 82 essential MHN patients from Jan 2003 to Oct 2014 with renal biopsy followed up to May 2015. Pathology was evaluated by two pathologists independently. Localized renin expression and peritubular capillaries (PTC) area were evaluated by IHC staining of renin and CD34. Renal replacement therapy, kidney transplant and death were defined as the primary end point.

**Results:** 87.8% of patients were male with mean age of 34.7±8.8 years. Clinical data showed highest blood pressure (BP) 226.6±25.7/152.2±22.0 mmHg, serum creatinine (Scr) 5.31±3.79 mg/dL, proteinuria 2.6±1.83 g/day (n=68) and mean eGFR 21.3±15.1 ml/min/1.73m². Glomerular sclerosis Index, tubular atrophy and interstitial fibrosis were 1.51±0.51, 63.7±18.3% and 64.0±18.3%. MHN patients has a lower PTC proportion (2.27±0.74% (n=35), 3.75±0.79% (n=17), P<0.001) and a higher renin-positive juxtaglomerular apparatus ratio (35.1±17.8% (n=35), 21.2±15.0% (n=17), P<0.008) comparing with glomerular minimal lesions patients. Tubulointerstitial lesions correlated with Scr(=0.547, P<0.001), eGFR(=0.574, P<0.001) and proteinuria(=0.447, P<0.001). PTC area correlated with Scr(=0.675, P<0.001, n=35) and eGFR(=0.648, P<0.001, n=35). 90.4% patients received RAS inhibitors which was associated with improvements in BP (136.7±9.0/82.6±7.9 mmHg vs 125.8±6.2/78.0±5.1 mmHg, P<0.001) and proteinuria (22.6±1.89% vs 12.6±0.66%, P<0.001, n=35). After 54.1±36.6 months follow up, 1-year and 5-year cumulative renal survival rates were 93% and 65%. RAS inhibitors, BP control and eGFR over 30ml/min 1.73m² correlated with longer renal survival by Kaplan-Meier analysis. Cox regression identified RAS inhibitors (HR=0.479, 95%CI=0.24-0.95, P=0.038) as independent factors predicting renal outcome.

**Conclusions:** MHN patients had localized activation of renin and less PTC area. RAS inhibitors benefited patients in BP control, eGFR improvements and long-term renal outcome.

**Funding:** Government Support - Non-U.S.
with a standard oscillometric device. BP values are uploaded in a software to calculate the coefficient of variation (CV) after having excluded outlier values (<3^sd and >95^sd centiles of the recorded values).

Results: Since 2010 a total of 402 OBPMs have been performed but only the 282 in 110 C (59% Males) aged <18 years old (IQR 4.8-12.1) with a CV <10% for both syst and diast BP were considered for the analysis. The table compares BP as measured by OBPM with a single BPM (1^st and 3^rd) and with the mean of the 3 initial measurements (* p<0.01 vs. others BPMs with student’s t-test for paired data and c^2).

OBPM 1.69±1.30^* 1.48±1.12^* 88 (31.2) 37 (13.1) 157 (55.7)^*

Conclusions: OBPM provides significantly lower BP values, leading to a diagnosis of poor BP control in a smaller number of patients (~10%). Given the lack of a gold standard, the present analysis doesn’t demonstrate that OBPM is more reliable then standard procedures however serial BPM have the potential of reducing measurement biases and white coat effect. We recommend the routine use of OBPM for measuring BP in C at risk of hypertension rather then relying upon few measurements.

SA-PO639

Background: We aimed to develop a simple prediction model for incident hypertension that could help prevent or delay the onset of hypertension for some patients who did not experience hypertension yet.

Methods: The Korean Genome and Epidemiology Study was used for the model development (n=3533) and internal validation (n=1698). Hypertension was defined when age 60-70 and (DBP ≤ 70 or DBP 70-80) age 50-60 and DBP ≥ 80 age 40-50 and DBP ≤ 70 Parental hypertension obesity (2), high density lipoprotein (HDL) < 40mg/dl Fasting glucose ≥ 126mg/dl

Results: Based on the Youden index, 5 or greater defined a high risk with 76% sensitivity, 72% Specificity, 27% positive predictive value and 96% negative predictive value.

Conclusions: This prediction algorithm, weighted towards common modifiable variables, showed good performance characteristics in a Korean population.

SA-PO640
Hemodynamics and Cardiovascular Autonomic Efficiency During Blood Pressure Variations in Hemodialysis Dan Sapoznikov, Rebecca Backenroth, Dvora Rubinger. Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.

Background: Chronic hemodialysis (HD) is associated with hemodynamic instability and with reduced cardiovascular autonomic efficiency (CaE).

Methods: To define hemodynamic changes associated with intradialytic blood pressure variations, beat-to-beat systolic blood pressure (SBP) and interbeat interval (IBI) monitoring using Finometer device and Beatscope software was performed during HD sessions in 69 non-diabetic patients (Pts), age 56±15 y. Cardiac output (CO) and total peripheral resistance (TPR) were calculated using the Modelflow simulation method. Differences in variability indices during SBP periods, 10% above (high) or below (low) the mean SBM were considered representative of CaE.

Results: During low to high SBP periods, two patterns of changes were noted: increased CO and decreased TPR (18 Pts, TPR↓), and relatively stable CO with increased TPR (51 Pts, TPR↑). Low frequency (LF) range variability of SBP and IBI, CO and TPR (median and interquartile ranges) were:

<table>

</tbody>
</table>

sd: standard deviation

The proportion of Pts with intradialytic hypotension (56%) was significantly higher in TPR↓ than in TPR↑ (28%, p<0.036), while TPR changes were directly correlated with post dialysis SBP (r=0.45, p<0.001) and with sIBI (r=0.35, p=0.003) in all Pts. There were no differences between groups in other variables.

Conclusions: 1. CaE resetting during HD may be associated with predominant CO and/or TPR variations; the latter are significantly correlated to sIBI, a strong marker of autonomic activity. 2. Intradialytic hemodynamics may be different in hypertension-prone Pts. These observations are relevant to the pathogenesis of intradialytic hemodynamic instability and of postdialysis hypertension.

Antihypertensive Medications and Blood Pressure Control in Chronic Kidney Disease: A Cross-Sectional Analysis from the German Chronic Kidney Disease (GCKD) Study Karl F. Hilgen,1 Matthias Schmid,2 Silvia Huebner,1 Martin Busch,1 Seema Baig-Agrawal,4 Anna Kottgen,4 Georg Schlieper,1 Claudia Sommerer,1 Gunter B. Wolf,5 MHBKA,1 Kai-Uwe Eckardt,1 Univ Hospital Erlangen; 2Univ of Bonn; 3Univ Hospital Jena; 4Charite Medical University; 5Univ of Freiburg; 6RWTH Univ Hospital, 7Univ Hospital Heidelberg, Germany.

Background: We reported low rates of blood pressure (BP) control in a large German cohort of patients with chronic kidney disease (CKD). Here, we analyzed the antihypertensive drug therapy to assess the prevalence of resistant hypertension, and to determine associations with control of BP.

Methods: The German Chronic Kidney Disease (GCKD) study is a prospective observational cohort study which enrolled 5217 patients with CKD in Germany. Inclusion criteria were an estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m2 or overt proteinuria. At enrollment, office BP was measured by trained study nurses, and information on medications was collected from patients.

Results: Office BP was obtained from 5181 participants, 4958 (95 %) were classified as hypertensive (>= 140/90 mmHg or use of antihypertensive medication). In 2410 (49 %) hypertensive patients, BP was controlled (defined as < 140/90 mmHg). Inhibitors of RAS were widely used and associated with better odds for controlled BP (odds ratio 1.48, p<0.001), as frequently used antihypertensives (87.4 % of participants), followed by diuretics (61.6 %), as hypertensive (>= 140/90 mmHg or use of antihypertensive medication). In 2410 (49 %) hypertensive patients, BP was controlled (defined as < 140/90 mmHg). Inhibitors of RAS were widely used and associated with better odds for controlled BP (odds ratio 1.48, p<0.001), as frequently used antihypertensives (87.4 % of participants), followed by diuretics (61.6 %), beta-blockers (57.7 %) and calcium channel blockers (39.6 %). 81.4 % of hypertensive participants received 2 or more different antihypertensive substances. Of the patients with uncontrolled hypertension, 49.9 % met the definition of resistant hypertension (uncontrolled despite 3 or more different antihypertensive substances, including a diuretic). In multivariate analysis, RAS inhibitors were associated with better control of BP (odds ratio 1.48, p<0.001), as were diuretics (odds ratio 1.16, p=0.036).

Conclusions: Resistance hypertension was present in 49.9 % of CKD patients whose BP was not controlled. RAS inhibitors were associated with better odds for controlled BP whereas the use of diuretics was less frequent than expected.

Association Between Cystatin C Based eGFR, Ambulatory Blood Pressure Parameters, and In-Clinic versus Ambulatory Blood Pressure Agreement in Older Community-Living Adults

Tyler Woodell, Jan M. Hughes-Austin, Tiffany Tran, Atul Malhotra, Joseph A. Abdelmalek, Dena E. Rifkin. UC San Diego.

Background: Although CKD IV-V has been associated with abnormal ambulatory blood pressure measurement (ABPM) patterns, the associations with milder CKD have not been determined. We aimed to examine the relationship between mild chronic kidney disease (measured by cystatin C-based eGFR) and abnormal ABPM (including nocturnal dipping) in healthy older adults. Further, we assessed agreement between clinic and ambulatory blood pressure monitoring.

Methods: 334 older community-living adults had clinic BP and 24-hour ABPM measured. Serum cystatin C levels were used to calculate eGFRs using the CKD-EPI equation. Multiple linear regression was performed to examine associations between eGFR < 60 ml/min/1.73m² (CKD eGFR) and ABPM parameters. Bland-Altman analysis was performed to evaluate agreement between clinic and ambulatory measurements.

Results: Average age was 72. Average eGFRs were 78 ± 20, and 60 individuals with CKD eGFRs. Compared to those without CKD eGFRs, individuals with CKD eGFRs were older, more likely to have clinic-based hypertension and less likely to be dippers. After multivariate analysis, the presence of CKD eGFRs was significantly associated with lower mean ambulatory diastolic blood pressure (DBP) (-2.2 mm Hg; p = 0.048), but not with nocturnal dipping or other ABPM parameters. Analyses using creatinine-based eGFR yielded similar results.

Conclusions: In older community-living adults, mild CKD as detected by cystatin C was associated with lower ambulatory DBP, but not with dipping status. This result is in contrast to findings with more advanced CKD in other studies and suggests that abnormal ABPM may only emerge at more advanced stages of CKD. The presence of CKD did not affect interpretation of clinic vs. ABPM pressures, although accuracy of clinic SBP was poor in this older cohort.

Serum MicroRNA Biomarkers for Obese Children with Hypertension

Scott Saint-Amour,1 Santosh Kumar Patnaik,2 Sudha Garamella.1 1Pediatric Nephrology, Univ at Buffalo, Buffalo, NY; 2Cardiothoracic Lab, RPCI, Buffalo, NY.

Background: Childhood obesity is a major health problem and 30% of obese children may develop hypertension. There is no clinical method to identify high risk obese children before they develop hypertension. MicroRNAs are non-coding RNAs that are implicated in pathways of inflammation and vascular injury. There has been no characterization of miRNA profiles of obese children with hypertension. This study aims to characterize miRNA profiles as a first step toward evaluating miRNAs as biomarkers for obesity-related hypertension.

Methods: 39 patients ages 3-21 were placed in four cohorts based on presence or absence of obesity and hypertensive status. Total serum RNA was isolated using miRCURYBiofluids kit (Exiqon). q-values were normalized by the global mean method. Rates of false discovery (FDR) arising from multiple testing were assessed from P values with the Benjamini-Hochberg method.

Results: 69 of 179 examined miRNAs were detected in all samples. miRNA measurements were globally reduced in sera of obese normotensive Vs. controls. Four miRNAs were identified as differentially expressed between these two groups at FDR <10%, whereas no miRNA was identified as differentially expressed between controls and hypertensive obese. Tukey plots of miRNAs in the cohorts are shown.

Conclusions: Serum levels of four miRNAs appear to be reduced in patients with obesity alone, but not in those with obesity and hypertension. While it is possible that serum miRNA differences were because of variables such as serum lipid content and medications, our study suggests that serum miRNAs have utility in detecting hypertension risk in obese children. This should be validated in a larger study, and the biomarker value of the serum miRNAs correlated with ambulatory blood pressure monitoring data as well as left ventricular hypertrophy.

Funding: Pharmaceutical Company Support - Roswell Park Cancer Institute Support to Dr. Sai Yendamuri in the Cardiothoracic Lab at RPCI was used for this study.

Effect of Prenatal and Childhood Lead Exposure on Blood Pressure at 4 Years of Age

Alison P. Sanders,1 Katherine Svensson,2 Chitra Amarrisarivardena,2 Priyanka Basnet,1 Ivan Pantic,1 Adriana Mercado-García,1 Lourdes Schnauss,2 Andrea A. Baccarelli,3 Martha M. Tellez-Rojo,4 Chris Gennings,2 Lisa M. Satin,3 Robert O. Wright,1 1Icahn School of Medicine at Mount Sinai; 2National Inst of Perinatology; 3National Inst of Public Health; 4Harvard T.H. Chan School of Public Health.

Background: Prenatal lead (Pb) exposure occurs during a susceptible period of renal development and may program later life cardiovascular and renal disease.

Methods: Systolic and diastolic blood pressure (SBP and DBP) was obtained using an automated oscillometer from 397 children at 4 years of age in the PROGRESS cohort located in Mexico City. Maternal blood samples were previously collected at the 2nd trimester (2T), 3rd trimester (3T), and at delivery and children’s blood samples were collected at birth (cord blood), 1 year, and 2 years of age. Blood lead levels (BLLs) were analyzed via inductively coupled plasma-mass spectrometry. We performed linear regression to examine the associations between longitudinal BLLs and children’s SBP, DBP, and pulse pressure (mSBP-DBP) adjusting for child’s age, sex, body mass index, maternal education and environmental tobacco smoke.

Results: Maternal 2T BLLs ranged between 0.7 and 18.8 mg/dL, and 89 (22%) prenatal BLLs were above the CDC guideline level of 5 mg/dL. Increased 2T and 3T BLLs were associated with decreased pulse pressure (p<0.05) and modestly associated with increased DBP (p=0.1).

No significant associations were observed for childhood BLLs and BP. Stratification by sex showed that the effect of prenatal Pb (2T and 3T) on decreased pulse pressure was significant only among females.

Conclusions: Prenatal Pb exposure may contribute to subclinical changes in the developing kidney or cardiovascular system leading to elevated BP in childhood. Future studies will assess if the contributions of early life Pb exposure to BP outcomes persist at later life ages.

Smoking, Microalbuminuria and Renal Function in Essential Never Treated Hypertensive Patients

Dimitrios Petras,1 Vanessa Tzamoulou,2 Athanasios Bramos,3 Panagiota E. Giannou,1 Stella-Maria Kyvelou,1 Eva Karpanou,1 Gregory Vysoulis.1 1Nephrology Dept, Hippokration Hospital, Athens, Greece; 21st Cardiology Clinic, Onassis Cardiac Surgery Center, Athens, Greece; 3Hypertensive Unit, 1st Cardiology Clinic, Univ of Athens, Hippokration Hospital, Athens, Greece; 4Microbiology Dept, Hippokration Hospital, Athens, Greece.

Background: The aim of the present study was to identify possible differences depending on patient’s individual smoking history with renal function and microalbuminuria in essential never treated hypertensive patients.

Methods: The study included 6100 consecutive patients with essential hypertension. In each patient the smoking status has been assessed by means of a standard questionnaire. Each patient had renal profile work up including microalbumin levels, albumin creatinine ratio in 24h urine collection (ACR) and 24h creatinine clearance.

Results: The study population was divided according to the smoking status in three groups: Smokers (n=2350), Ex-smokers (n=663) and Non-smokers (n=3121). Microalbumin values were normalized by the global mean method. Rates of false discovery (FDR) arising from multiple testing were assessed from P values with the Benjamini-Hochberg method.

Conclusions: Serum levels of four miRNAs appear to be reduced in patients with obesity alone, but not in those with obesity and hypertension. While it is possible that serum miRNA differences were because of variables such as serum lipid content and medications, our study suggests that serum miRNAs have utility in detecting hypertension risk in obese children. This should be validated in a larger study, and the biomarker value of the serum miRNAs correlated with ambulatory blood pressure monitoring data as well as left ventricular hypertrophy.
Conclusion: In conclusion, this prospective large cohort study of essential never treated hypertensive patients there is a clear association that active smoking is associated with higher microalbumin and ACR levels in these patients.

Comparison of Salt Taste Thresholds and Salty Usage Behaviors Between Myanmar and Korean Adults
Hynjung Cho, I. Diósi of Nephrology, Dept of Internal Medicine, College of Medicine, Univ of Ulsan, Asan Medical Center; Seoul, Republic of Korea; I. Diósi of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.

Background: Excessive oral salt intake can induce hypertension. According to previous studies, prevalence of hypertension is higher in Myanmar than Korea. We postulated that Myanmar adult had higher salt taste thresholds and eat much saltier food. The aim of the studies is comparing of salt taste thresholds and salt usage behavior scores between Myanmar adult and Korean adult.

Methods: This cross sectional study enrolled the patients who visited volunteer medical service clinic at Ansung in Korea and Hlegu and Bago in Myanmar in August 2014. We measured vital signs, height and weight of each patient and evaluate detection threshold, recognition threshold, salt preference, all patients took urinalysis and checked spot urine Na. They also filled up the salty usage behavior questionnaire.

Results: Total 1374 patients were enrolled and 64 of them were Myanmarese and 67 were Koreans. Blood pressure was significantly higher in Myanmar adult than Koreans. Detection threshold, recognition threshold, salt preference, spot urine sodium and salt usage behavior score was also higher in Myanmar than Koreans.

We calculated correlation coefficient between spot urine Na and other parameters that related to salt intake. The tables show usage behavior score and detection thresholds significantly correlated with the spot Na.

Conclusions: All parameters related to salt intake, such as detection thresholds, the recognition thresholds, salt preference, salt usage behavior score and spot urine sodium concentration, of Myanmarese were significantly higher than those of Korean.

SA-PO647
Relationship Between Circadian Rhythm of Blood Pressure and Intrarenal Arteriolosclerosis
Keiji Kono, Hideki Fujii, Kentaro Nakai, Shunsuke Goto, Shinichi Nishi. Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.

Background: Hypertension (HT) is a common complication in chronic kidney disease (CKD) patients. CKD patients often have circadian rhythm disorder of blood pressure (BP). However, the relationship between circadian BP pattern and intrarenal damage remains unclear.

Methods: Ninety patients with glomerulonephritis were included in this study. Patients with diabetes mellitus and prescription for antihypertensive agents were excluded. Clinic BP (CBP) and 24-h ambulatory BP (ABP) measurements were performed in all the study patients, and who were divided into the following four groups; normotension (NT), white coat hypertension (WHT), masked HT (MHT) and sustained HT (SHT). As renal histological assessments, we evaluated the percent of sclerotic glomeruli (SG) and interstitial fibrosis (IF), and classified the degrees of initial thickening of intralobular arterioles (ILA) and arteriolar hyalinosis (AH) into four grades (none, mild, moderate, severe) in each biopsy specimen.

Results: The prevalence of NT, WHT, MHT and SHT was 60.0%, 3.3%, 23.3% and 13.4%, respectively. In comparison of circadian BP pattern, all-day HT was most prevalent in the SHT group, and nocturnal HT was most prevalent in the MHT group. SG and IF were significantly severe in the SHT group compared to the NT group. As for intralobular vascularity, the MHT and SHT groups had more severe AH compared to the NT and WHT groups, whereas ILA was comparable between all the four groups. Furthermore, we investigated the relationship between intrarenal vascularity lesions and clinical characteristics. ILA was significantly correlated with age and renal function, whereas AH was significantly correlated with age, sex, smoking, total cholesterol, HT based on ABP (ABPH) and HT based on CBP (CBPHT). In multivariate analysis, ILA was significantly correlated with only age and AH was significantly correlated with age, sex, smoking.

Conclusions: Our findings suggest that intrarenal AH was markedly severe not only in the SHT group, but also in the MHT group. Careful ABP monitoring should be recommended in patients with glomerulonephritis.

SA-PO648
Association of Inpatient versus Outpatient Systolic Blood Pressure with All-Cause Mortality in Patients with Normal Estimated Glomerular Filtration Rate
Otsa W. Okechukwu, 1 Miklos Zsolt Molnar, 1 Praveen Kumar Potukuchi, 1 Jun Ling Lu, 1 Fridtjof Thomas, 1 Kamyar Kalantar-Zadeh, 1 Csaba P. Kovessy, 1 1Univ of Tennessee Health Science Center, Memphis, TN; 2Univ of California, Irvine, CA; 3VA Medical Center, Memphis, TN.

Background: Hypertension is associated with worse outcomes, and its treatment improves mortality and cardiovascular disease. Hospitalized patients undergo frequent BP measurements, and hence hospitalization is an opportunity to diagnose and treat hypertension. However, it is unclear if BP measured as inpatient is associated with outcomes.

Methods: From 3,499,271 US veterans with normal eGFR, we identified 1,113,515 patients with inpatient and outpatient SBP recordings. We examined the association of baseline outpatient SBP, and baseline inpatient SBP (defined as the SBP obtained on the first day of the first hospitalization following cohort entry) with all-cause mortality in Cox proportional hazards analyses. Models included both in- and outpatient SBP and their interaction terms, and were adjusted for age, gender, race, eGFR, comorbidities, socioeconomic factors, and antihypertensives.

Results: Low SBP was associated with higher mortality in both settings, but much more so inpatients (Figure). Outpatient SBP 140-149 mmHg was associated with linearly higher mortality (hazard ratio (HR) for SBP 170 mmHg: 1.22 (1.16-1.29), p<0.001), but with less increase in mortality in the inpatient setting, which was only present for SBP 170 (HR (95%CI) for SBP 170 mmHg: 1.08 (1.02-1.14)).

Conclusions: SBP shows markedly different associations in the outpatient vs inpatient setting, with higher blood pressures in the inpatient setting conferring less mortality risk compared to the outpatient setting. Until randomized controlled clinical trials are done, caution is warranted when treating hypertension in hospitalized patients.

SA-PO649
Fibroblast Growth Factor 23 and Sodium-Volume Regulation: FGF23 Response to Sodium Restriction in Essential Hypertensive Subjects and to Long Term Extracellular Volume Reduction in Hemodialysis Patients

Background: Dietary sodium load causes volume expansion and hypertension in mouse models of FGF23 and αKlotho deficiency. FGF23 also associates with ultrafiltration volume in cross-sectional analyses in hemodialysis (HD) patients (pts) further implicating this bone hormone in extracellular volume regulation.

Methods: 32 uncomplicated essential hypertensives were randomized to a 2-weeks high-sodium diet (200 mmol/d) or a 2-weeks low-sodium diet (10-20 mmol/d). After 1 week wash out, these treatments were crossed-over. At the end of each diet-period, pts underwent 24h urine sodium, 24h ABPM and serum intact FGF23 measurements. The FGF23 response to UF intensification was assessed in 52 hypertensive HD pts. FGF23 also associates with ultrafiltration rate in cross-sectional analyses in hemodialysis (HD) patients (pts) further implicating this bone hormone in extracellular volume regulation.

Results: In essential hypertensives, PRA and aldosterone (P<0.01) rose during low sodium. However, FGF23 remained unmodified [low sodium: median 36.2 pg/mL, inter-quartile range (IQR)32-44.4; high sodium: 33.9 pg/mL, IQR 29.5-41.0; P=0.18]. Changes in FGF23 were unrelated to systolic and diastolic ABPM, heart rate, PRA and aldosterone changes. In hypertensive HD pts, baseline FGF23 was 4062 pg/ml (IQR: 1381-12571). BP during the longitudinal study fell from 144 to 139 mmHg (P=0.02) along with a parallel decline in dry body weight (BW) from 63.7 to 62.8 Kg but FGF23 remained unchanged (3688 pg/mL, IQR: 1372-14117, P=0.30). Changes in FGF23 were unrelated (P=0.90) with ongoing changes in dry BW.

Conclusions: Changes in sodium intake that potently activate the renin-aldosterone system do not alter FGF23 in essential hypertensives. Similarly, extracellular volume decline in dry body weight (BW)(from 63.7 to 62.8 Kg) but FGF23 remained unchanged

reduction by UF intensification does not materially influence FGF23 in hypertensive HD patients. The findings of this study suggest that UF intensification does not significantly affect FGF23, which is unlikely to play a role in the response to changes in sodium intake in human hypertension.

Association of Urinary Albumin Excretion and Salt-Sensitivity of Blood Pressure: Genetic Epidemiology Network of Salt Sensitivity (GenSalt) Study

Jing Chen, L. Lee Hamm,1 Chung-shiuian Chen,2 Kevin K. Wu,2 L. Gabriel Navar,3 Jiang He,2,† Medicine, Tulane School of Medicine, New Orleans, LA; †Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Albuminuria is a marker of early kidney injury and associated with risk of hypertension, cardiovascular disease, end-stage renal disease, and premature death. However, it is unknown whether urinary albumin excretion is associated with salt- and potassium-sensitivity.

Methods: We investigated the association between urinary albumin excretion and salt- and potassium-sensitivity of blood pressure (BP) among GenSalt study participants. The GenSalt dietary intervention consisted of a 7-day low sodium diet (51.3 mmol sodium/day), 7-day high-sodium diet (307.8 mmol sodium/day), and 7-day high-sodium diet with potassium supplementation (307.8 mmol sodium/day and 60 mmol potassium/day). Twenty-four hour urinary albumin excretion was estimated at baseline and at the end of each intervention from 100 randomly selected GenSalt participants.

Results: Urinary albumin-to-creatinine ratio (ACR, mg/g) was significantly reduced during low-sodium and potassium-supplementation interventions to 2.26 (1.11, 4.61) and 2.10 (1.46, 4.26), respectively, from a baseline ratio of 2.97 (1.20, 6.40) and 4.40 during the high-sodium intervention to 3.23 (2.15, 5.73) with P for group difference=0.005. One standard deviation higher of baseline log-transformed ACR (2.23 mg/g) was significantly associated with 1.5 (95% CI 0.3, 2.7) mm Hg higher in mean arterial BP (P=0.01) from low-sodium to high-sodium intervention (salt-sensitivity) but not statistically significantly associated with potassium-sensitivity after adjusting for confounding factors.

Conclusions: These data indicate that urinary albumin excretion may be associated with BP salt-sensitivity.

SA-PO651

Effects of Nephrectomy on Blood Pressure and Its Circadian Rhythm

Naro Ohushi,1 Sayaka Ishigaki,1 Shinshu Isobe,1 Takayuki Tsujii,2 Akihiko Kato,2 Hideo Yasuda,1 †Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; †Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Japan.

Background: Intrarenal renin-angiotensin system (RAS) activation causes disturbance of sodium excretion from the kidney by increasing sodium reabsorption in the tubulus, with resultant blood pressure (BP) elevation and nocturnal hypertension. However, the effects of nephrectomy on BP and its circadian rhythm have not been clarified in the patients who have various renal functions.

Methods: We investigated 25 nephrectomized patients (17 men and 8 women, age: 61.3±14.7 years, chronic kidney disease stage 1 in 3 patients, stage 2 in 7, stage 3 in 5, stage 4 in 9 and stage 5 in 2 patients). We measured 24-hour blood pressure (BP), urine albumin, dopamine, norepinephrine, sodium and potassium in the proximal tubules. It is unknown, however, if urinary dopamine and norepinephrine may play an important role in regulating sodium and potassium reabsorption in the proximal tubules. It is unknown, however, if urinary dopamine and norepinephrine excretion are associated with salt- and potassium-sensitivity of blood pressure (BP).

Results: Urinary dopamine (µg/24h) was significantly reduced (p=0.01) from baseline (115.5 ± 42.2) during high-sodium (157.2 ± 143.2) and high-sodium and potassium-supplementation (149.9 ± 139.7) interventions. Likewise, urinary norepinephrine (µg/24h) was significantly (p=0.0001) reduced from baseline (38.6 ± 24.3) during high-sodium (24.5 ± 21.4) and high-sodium and potassium supplementation (24.6 ± 24.1) interventions. In addition, one standard deviation higher in urinary dopamine concentration (124.2 ± 24.8) was associated with 1.5 (2.5, -0.6) mm Hg of mean arterial BP reduction from high-sodium to high-sodium plus potassium supplementation (p=0.001). One standard deviation higher in urinary norepinephrine concentration (24.3 ± 24.8) was associated with 1.4 (0.2, 2.6) mm Hg mean arterial BP increase from low-sodium to high-sodium (p=0.02) and 2.2 (1.3, -1.3) mm Hg mean arterial BP reduction from high-sodium to high-sodium plus potassium supplementation (p=0.003).

Conclusions: These data indicate that urinary excretion of dopamine and norepinephrine may play a role in BP salts- and potassium-sensitivity.

Difference of Impact on Cardio-Angle Vascular Index Among Various Blood Pressure Indexes in Patients with Non-Diabetic Chronic Kidney Disease

Hideo Okonogi, Tetsuya Kawamura, Akina Fukui, Shinya Yokote, Nobuo Tsuboi, Yoichi Miyazaki, Makoto Ugora, Takashi Yokoo. Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.

Background: Several studies reported that pulse pressure (PP) is the predictor of heart and kidney risks. On the other hand, arterial stiffness negatively correlates with renal function, and is the predictor of all causes mortality and mainly cardiovascular events in chronic kidney disease (CKD). Cardio-ankle vascular index (CAVI) is a non-invasive indicator of arterial stiffness, and is not influenced by the blood pressure (BP) at the time of examination. Therefore, we examined the relationship between various BP indexes and CAVI in patients with non-diabetic CKD.

Methods: Fifty-nine patients with non-diabetic CKD, who were diagnosed by first-time biopsy, were included. Relationships between various BP indexes and CAVI were analyzed. Then receiver-operating characteristic (ROC) analysis for diagnosis of the presence of high arterial stiffness (CAVI≥9) was performed.

Results: As a result, systolic BP (SBP) and PP significantly correlated with CAVI (r=0.433, P<0.01 and r=0.624, P<0.01, respectively), while diastolic BP (DBP) and mean arterial BP (MBP) did not correlate with CAVI. The ROC curves for diagnosis of the presence of high arterial stiffness by each BP index showed that SBP, DBP, MBP and PP had an area under the ROC curve (AUC) value of 0.786 (P<0.01), 0.425, 0.614 and 0.906 (P<0.01), respectively. Then, by two-graph ROC analysis, the threshold values of SBP and PP were obtained as 132.4mmHg (sensitivity 71%, specificity 71%) and 55.5mmHg (sensitivity 82%, specificity 82%), respectively.

Conclusions: These results indicated that PP has the most strong impact on arterial stiffness among various BP indexes. PP may affect renal function and cardiovascular risk via increase in arterial stiffness.

SA-PO654

Uric Acid Levels Are Associated with Peripheral but Not Central Blood Pressure Parameters in Normotensive Individuals

Pierre-Luc Lavoie, Stefphan Troyanov, Francois Madore, Remi Goupl. Nephrology, Hospital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

Background: Uric acid is increasingly recognised as a risk factor for cardiovascular disease. Whether this could be explained by changes in peripheral or central blood pressure (BP) profiles remains controversial. The aim of this study was to assess the association of uric acid levels with peripheral and central hemodynamic parameters in untreated normotensive individuals.

Methods: Of 20,004 CARTAGENE participants, 8,420 were normotensive individuals not treated for hyperuricemia or hypertension with valid pulse wave analysis (46.9% male, 53.1±14.7 years). The associations between uric acid levels and peripheral systolic BP (SBP), pulse pressure (PP) central systolic BP (cSBP), central PP (cPP), pulse pressure amplification (PPA), augmentation index (AIx) and augmented pressure (AP) were tested with linear regression analyses.

Results: In univariate analyses, uric acid levels were significantly associated with all parameters. In contrast, in multivariate analyses, only SBP and cSBP remained independently associated with uric acid levels. As cSBP is usually highly dependent of SBP, it was further adjusted for peripheral BP, where it was not independently associated with uric acid levels (β coefficient -0.003, P=0.51).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
SA-PO655
Blood Pressure Trajectory and Events in the Cardiovascular Health Study
Christopher C. Simmons,1 Rebecca Scherer,2 Michael Shlipak,3 Mark J. Sarnak,3 Michelle Odden,2 Carmen A. Peralta,1 UCSF; Tufts; OSU.

Background: The association of blood pressure (BP) trajectories with clinical events in elders is not well established. The importance of integrating trajectories of systolic (SBP) and diastolic (DBP) BPs is not known.

Methods: Among 4,067 participants in the Cardiovascular Health Study, we used repeated measures from the first 7 years to identify discrete trajectories of SBP, DBP and joint SBP/DBP by latent class analysis. We evaluated independent associations of BP trajectory with all-cause mortality, incident CVD (myocardial infarction, cardiac arrest, stroke or CVD death), and heart failure using multivariable Cox models with follow up beginning after 7th year (median follow-up 9.3 years).

Results: Mean age at 7th year was 78. Considering SBP or DBP separately, trajectory began after 7 years to identify discrete trajectories of SBP, DBP and joint SBP/DBP by latent class analysis. We evaluated independent associations of BP trajectory with all-cause mortality, incident CVD (myocardial infarction, cardiac arrest, stroke or CVD death), and heart failure using multivariable Cox models with follow up beginning after 7th year (median follow-up 9.3 years).

Conclusions: Among community-dwelling elders, distinct BP trajectories were identified integrating SBP and DBP. Decreasing BP is associated with higher risk for adverse outcomes.

SA-PO656
Serum Uric Acid and Vascular Stiffness in African Americans with Hypertension
Rajesh Mohandas,1,2 Xueling Wen,3 Jorgijau V. Tantravahi,1,2 Titte Srinivas,4 Richard J. Johnson,5 Mark S. Segal,1,2 Nephrology and Hypertension Section, North Florida/South Georgia Veterans Health System, Gainesville, FL; 2 Div of Nephrology, Hypertension & Transplantation, Univ of Florida, Gainesville, FL; 3 Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; 4 Div of Renal Diseases and Hypertension, Univ of Colorado, Denver, CO.

Background: Elevated serum uric acid levels as well as vascular stiffness is associated with hypertension and cardiovascular (CV) disease. However, how uric acid affects vascular stiffness is not known.

Methods: Among 1,20 African-Americans with controlled hypertension were randomized in a double-blind, placebo controlled study to allurpinol (300mg/dl) or placebo for 4 weeks. Vascular stiffness was assessed by augmentation index at baseline and at 4 weeks after allurpinol therapy. Uric acid was characterized as low or high (>7 mg/dl in men and > 6 mg/dl in women).

Results: The mean age was 48.7 ± 8.73 years and majority of the participants were women (71%). Augmentation index was negatively correlated with uric acid at baseline (R= -0.24 p=0.009). The high uric acid group as compared to the low uric acid group, had a lower augmentation index (0.97 ± 5.52 vs. 1.12 ± 5.23 p=0.03) while the mean BP (119.75 vs 118.75), age (48.7 vs 48.6), and endothelial function as measured by endoPAT (22 vs. 22) were similar. Along allurpinol therapy there was a drop in uric acid by 2.23 ± 1.4 mg/dl as compared to placebo -0.15 ± 0.9 mg/dl but there were no significant changes in vascular stiffness or endothelial function.

Conclusions: In African Americans with hypertension uric acid is negatively associated with vascular stiffness and short-term therapy with allurpinol does not alter vascular stiffness. These changes are not explained by endothelial function. The mechanistic basis of how uric acid may be protective against vascular stiffness may explain the many conflicting studies on the contribution of uric acid to cardiovascular risk and merits further investigation.

SA-PO657
The Impact of Renin-Angiotensin System Blockers on Renal Sodium Handling: An Analysis of CARTAGENE

Background: Renin-angiotensin system blockers (RASB) reduce the effects of angiotensin II, and subsequently aldosterone, leading to vasodilation and natriuresis. The magnitude of the RASB-induced natriuresis compared to diuretics and other antihypertensive agents remains uncertain.

Methods: We identified patients treated for hypertension from the prospective CARTAGENE cohort, a random sample of the Quebec population aged 40 to 69, who had available urinary sodium levels. We compared the fractional excretion of sodium (FeNa) between patients on beta-blockers or calcium channel blockers without diuretics (Group 1), on RASB without diuretics (Group 2) and on diuretics (Group 3) with ANG II. We identified a general linear model adjusting for age, gender, estimated glomerular filtration rate (eGFR), diabetes and peripheral mean arterial pressure (pMAP).

Results: Of the 3,281 individuals with treated self-declared hypertension, 155 had urinary measurements. Of these 61% were male, their mean age was 59±8 years, 23% had diabetes and the eGFR was 85±14 ml/min/1.73m² and 93±11 ml/min/l. Group 1, 2 and 3 included 42, 72 and 41 patients, respectively. In unadjusted analyses, patients in Group 1 (0.67±0.33) had lower FeNa than Group 2 (1.02±0.51, p=0.001) and Group 3 (1.25±0.70, p=0.001), while Group 2 had lower FeNa compared to Group 3 (p=0.029). In the adjusted analysis, Group 2 still had higher FeNa than Group 1, but the results were similar to Group 3.

Conclusions: After adjustment for important covariables, RASB therapy is associated with a natriuresis similar to diuretics and greater than other antihypertensive drugs in hypertensive patients. Whether the degree of natriuresis parallels the blood pressure response to these agents remains to be determined.

Urine Mitochondrial-DNA Copy Number Identifies Renal Injury in Severe Renovascular Disease
Alfonso Eirin,1 Ahmed Saada,1 Sandra Herrmann,1 Hui Tang,1 Amir Lerman,1 Stephen C. Tejedor,1 Lilach O. Lerman.1,2 *Divs of Nephrology and Hypertension, Mayo Clinic; 1Cardiovascular Diseases, Mayo Clinic, Rochester, MN.

Background: We have previously demonstrated that mitochondrial injury contributes to renal dysfunction in swine renovascular disease (RVD), but its implications in human RVD remain unknown. Fragments of the mitochondrial genome released from dying cells are considered surrogate markers of mitochondrial injury. We hypothesized that RVD would be associated with increased urine mitochondrial DNA (mtDNA) copy numbers.

Methods: We prospectively measured urinary copy numbers of the mtDNA genes COX3 and ND1 by quantitative real-time PCR in essential hypertensive (EH), moderate RVD, and severe RVD patients (based on ultrasound criteria and evident loss of functional RVD, and severe RVD patients (Table). Urinary COX3 and ND1 were higher in EH and moderate RVD compared to HV, and further elevated in patients with severe RVD (Figure). In RVD patients, urinary COX3 and ND1 directly correlated with NGAL (R²=0.18, p=0.02 and R²=0.37, p<0.001), proteinuria (R²=0.33, p<0.001 and R²=0.53, p<0.001), and serum creatinine (R²=0.27, p<0.002 and R²=0.16, p=0.02, respectively) levels, and inversely with eGFR (R²=0.18, p<0.001, R²=0.53, p=0.02, respectively).

Conclusions: We found progressive increments in urinary mitochondrial injury markers with increased severity of RVD, implicating mitochondrial injury in kidney damage in human RVD. Mitochondria might represent a novel therapeutic target in RVD.

Association Between Urinary Big Angiotensin-25 and Microalbuminuria in Hypertensive Patients
Yasuhiro Yamashita,1 Sayaka Nagata,1 Yuji Sato,2 Kazuo Kitamura,1 Shouichi Fujimoto.1 1Div of Circulatory and Body Fluid Regulation, Dept of Internal Medicine, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan; 2Dialysis Div, Univ of Miyazaki Hospital, Miyazaki, Japan; 1Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan.

Background: In hypertensive patients, albuminuria is a predictive factor for cardiovascular events. Recently, a newly synthesized angiotensin-related peptide, Big angiotensin-25 (Bang-25), was isolated from human urine (Nagata et al. Biochem Biophys Res Comm 2013), and it was localized to podocytes in kidney tissue. Bang-25 may be involved in the renin-independent pathway for localized angiotensin II generation, and can contribute to diagnosis in organ disorders. Using cross-sectional data, we investigated the relationship between urinary Bang-25 and albuminuria in hypertensive patients.

Methods: We examined the data of 408 hypertensive patients (male 50.5%; mean age 70±10 years, BMI 25.3±3.7 kg/m², diabetes mellitus 36.9%, and eGFR 72±17 ml/min/1.73m²). We evaluated urinary albumin/creatinine ratio (ACR) and we measured urinary Bang-25 by specific AlphaLISA immunoassay. The association between urinary Bang-25/creatinine ratio and microalbuminuria was analyzed by a multivariate logistic ratio.

Results: Thirty patients were excluded because of macroalbuminuria (ACR>300 mg/gCr). Of 378 patients, 96 had microalbuminuria (30<ACR<300 mg/gCr). Patients were then divided by quartiles of Bang-25/creatinine ratio. Older patients, females, lower hemoglobin, lower uric acid, and higher HLD were more prominent in higher Bang-25/creatinine quartiles. After adjusting for age, sex, eGFR, and presence of diabetes, the odds ratios (95% confidence intervals) for microalbuminuria per quartile, were as follows: Q1, reference; Q2, 0.72 (0.33-1.54); Q3, 0.99 (0.49-2.01); and Q4, 2.05 (1.01-4.14). Conclusion: Higher urinary Bang-25/creatinine quartile was significantly associated with microalbuminuria in hypertensive patients. As Bang-25 is localized to podocytes, it may play some role in the development of albuminuria.

Independent Association of Vitamin D on Endothelial Function: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial
Lea Borgi,1 Ciaran Joseph McMullan,2 Gary C. Curhan,3 Naomi D.L. Fisher,3 John P. Forman.1 *Nephrology, Brigham and Women's Hospital, Boston, MA; 2Endocrinology, Brigham and Women's Hospital, Boston, MA.

Background: In nonhypertensive individuals, lower levels of 25-hydroxyvitamin D (25(OH)D) have been associated with increased risk of hypertension and renal disease. However, the effect of vitamin D supplementation on endothelial dysfunction in nonhypertensive individuals has not been examined in a rigorous fashion.

Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with vitamin D deficiency (body mass index [BMI] ² 25 and 25(OH)D<20 ng/ml), we assigned subjects to receive either ergocalciferol (50,000 units) or matching placebo, once a week for 8 weeks. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial artery ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 46 and 47 participants were allocated to receive ergocalciferol and placebo, respectively. Mean 25(OH)D levels increased from 14.9 to 30.3 in the vitamin D group and from 14.8 to 17.4 in the placebo. EDV did not change significantly with either vitamin D repletion (from 6.3±1.6% at baseline to 6.1±4.6% at 8 weeks; p-value=0.78) or placebo (7.9±4.7% to 6.8±3.7%; p=0.17). The treatment effect p-value (comparing the 8-week change with ergocalciferol to the change with placebo) was not significant. Conclusion: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after repletion of vitamin D in overweight/obese non-hypertensive individuals.

Secondary Hypertension, Primary Hyperaldosteronism, and Renal Cell Carcinoma
Nicole Piero,1 Krishnanath Gaitonde,2 Charuhas V. Thakar.1 1Cincinnati VA Medical Center; 2Univ of Cincinnati.

Background: Primary hyperaldosteronism (PHA) is the most common cause of secondary hypertension. Renal cell carcinoma (RCC) can cause secondary hypertension, but as a renin-mediated process. We describe 5 cases referred for evaluation of PHA (uncontrolled hypertension and hypokalemia), incidentally diagnosed with RCC, and the potential role of RCC as a renin-independent mechanism for hypertension.

Methods: At the initial renal visit, average blood pressure (BP) was 167/87 mmHg, with an average of 4 BP meds (nondiabetes blockers). Average serum levels of potassium, sodium, bicarbonate were 3.1, 143, and 30 mmol/L respectively. Average plasma renin activity (PRA) was 0.12 ng/ml/hr, average serum aldosterone (sAldo) was 16.6 ng/dL, with a mean sAldo:PRA of 143.6. In 24-hour urine analysis, aldosterone ranged from 11.8 to 30.2 ng/dL and sodium ranged 82-226 mmol/24 hours. All patients required 1 or 2 aldosterone blocking agents to achieve an average BP of 134/75 mmHg. Upon imaging, 4/5 had renal adenomas and all 5 patients had incidental solid renal masses with radiological characteristics of RCC. To date, 3/5 have had renal masses treated with partial/total nephrectomy or cryotherapy; all have confirmed pathology of RCC. All those undergoing RCC treatment were had improved BP with 2/3 having reduced therapy. At presentation these 3 patients had an average BP of 159/87 mmHg and were on an average of 4.6 BP meds; between 5 and 9 months after RCC treatment BP was 133/75 mmHg on average of 4 BP meds; 2/3 able to eliminate aldosterone blockade. 2/3 patients treated for RCC had follow-up biochemical assessment. sAldo:PRA normalized in the patient with partial nephrectomy, whereas it remained elevated in patient treated with cryotherapy.

Conclusions: To our knowledge this is the first case series describing a possible renin-independent, aldosterone-mediated mechanism for secondary hypertension associated with RCC. Although RCC-associated hypertension has been reported, this series describes a physiological link between the two. Whether RCC leads to maladaptive steroid pathways leading to an aldosterone-like action in mediating hypertension requires detailed analysis of RCC tumors.
Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with elevated serum uric acid (body mass index [BMI] ≥25 and serum uric acid≥5mg/dL), we assigned subjects to receive one of the following: allopurinol 300mg daily for 4 weeks followed by 600mg daily for 4 weeks; probenecid 500mg daily for 4 weeks then 1000mg daily for 4 weeks; or matching placebo. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial artery ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 43, 44 and 47 participants were allocated to receive probenecid, allopurinol and placebo, respectively. Mean serum uric acid levels decreased from 5.9 to 3.6 mg/dL in the probenecid group, from 5.6 to 2.9 mg/dL in the allopurinol group, and were unchanged in the placebo group (5.6 to 5.7 mg/dL). EDV did not change significantly with either probenecid (from 7.6±5.1% at baseline to 8.4±5.2% at 8 weeks; p-value=0.39), allopurinol (from 7.4±6.0% at baseline to 5.9±4.6% at 8 weeks; p-value=0.09) or placebo (6.8±3.8% to 7.1±4.9%; p=0.66).

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after lowering serum uric acid in overweight/obese non-hypertensive individuals.

SA-PO663
Azelnidipine Can Restore the Deceleration Capacity of Heart Rate Variability (DC) In CKD Patients with Preceding Treatment with ARB
Michio Fukuoka,1 Yoshiuki Miura,1 Yoshiaki Ogyiyama,2 Ryo Sato,1 Daiisuke Fuwa,1 Hiroyuki Ito1 Tetsuei Matsuoka,1 Yukako Isobe-Sasakia,2 Ken Kiyono,3 Yoshiharu Yamamoto,1 Junichiro Hayano,1 Nobuyuki Ohte.1 1 Nagoya City Univ; Osaka Univ; Tokyo Univ.

Background: Recently, we have hypothesized that DC, novel measure of cardiac vagal modulations, is also attributable to sympathetic nerve activities. Azelnidipine was reported to decrease non-Gaussianity index of HRV ($\text{ln} X$), which can serve as a marker of sympathetic cardiac overdrive.

Methods: In 43 hypertensive patients with CKD under treatment with an angiotensin receptor blocker (ARB), we tested whether 8-week add-on administration of azelnidipine can increase DC. DC was calculated by Bauer’s signal processing technique of phase-rectified signal averaging. For reference, the power of high frequency (HF, 0.15–0.40 Hz) obtained in 0.15 to 0.50 Hz band was examined as a conventional indicator of vagal activity.

Results: DC increased (6.17 ± 0.12 to 6.35 ± 1.85, p=0.002) and $\text{ln} X$ decreased (0.56 ± 0.15 to 0.50 ± 0.12, p=0.001), while no significant changes were observed in other HR variability measures including HF (p=0.9). Change in DC correlated inversely with the change in $\text{ln} X$ (decreased (r=-0.38, p=0.01), but not with the change in HF (p=0.8).

Conclusions: Our findings are consistent with the thesis that DC is not a simple measure of vagal activity but a product of complex interplay between sympathetic and vagal nerve activities.

SA-PO664
Elevated Levels of Podocyte Derived Urinary Microparticles in Angiotensin II Induced Hypertension
Uta Erdbruegger, Christine Rudy, Sylvia Cechova, Rosa Chan, Joseph C. Gigliotti, Thu H. Le. Div of Nephrology and HTN, Univ of Virginia Health System, Charlottesville.

Background: Early and non-invasive biomarkers of kidney damage are needed to identify hypertensive patients at risk for kidney damage. Urinary microparticles (uMPs) have already been identified in pre-albuminuric diabetic glomerular injury. These vesicles are less than 1 micron in size and carry markers of the parent cell. We hypothesized that podocyte derived uMPs are elevated in angiotensin II-induced hypertension (HTN).

Methods: Wild-type mice were treated with AII (400ng/kg/min) via mini-osmotic pumps. Untreated WT mice served as controls. Blood pressure was measured with tail-cuff manometry. 24 hour urines were collected after 5 days of AII treatment. Enumeration and phenotyping of MPs was done of podocyte culture supernatant and urine. UMP levels were normalized to urinary creatinine concentration. Podocalyxin(Pcal), podoplanin (Ppla) and annexin 5 (AV) were used as surface markers.

Results: Pcal and Ppla positive MPs as well as AV positive and negative MPs were detectable in supernatant from primary podocyte cultures. Compared to untreated controls (n=3), AII treated mice (n=2) had an increase in systolic blood pressure (SBP) by 33 mmHg (p=0.02). Despite similar urinary albumin/creatinine ratios between groups, there was a trend of higher levels of total numbers of Pcal and Ppla positive MPs in hypertensive mice compared to untreated (see Figure 1). In addition, AV negative but Ppla and Pcal positive MPs were also numerically higher in hypertensive mice compared to AV positive uMPs.

Conclusions: The BP reducing potency of sulodexide is modified by albuminuria severity in type 2 diabetes, indicating that ESL restoration may represent a new target for BP treatment in these patients.

Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO665
Blood Pressure Lowering Effects of Sulodexide Depend on Albuminuria Severity
Rik Ho Olde Engberink,1 Hiddo Jan Lambers Heerspink,2 Dick de Zeeuw,1 Liffert Vogt.1 1 Nephrology, AMC, Amsterdam, Netherlands; 2 Clinical Pharmacy and Pharmacology, UMCZ, Groningen, Netherlands.

Background: Diabetic patients have a thinner endothelial surface layer (ESL), especially when macroalbuminuria is present. Sulodexide, a mixture of glycosaminoglycans (GAGs), increases ESL thickness. Previous data indicate that the ESL is pivotal for BP regulation. In this study, we assessed whether the BP reducing effect of sulodexide is modified by albuminuria severity (a surrogate for the ESL) in type 2 diabetic patients.

Methods: In a post-hoc analysis of the randomized, double-blind, placebo-controlled Sun-MACRO trial, including type 2 diabetic patients with macroalbuminuria and maximal angiotensin II receptor blocker therapy, we studied the BP effects of sulodexide 200 mg/d. We stratified patients in baseline urinary albumin-creatinine ratio (UACR) tertiles. We used ANCOVA to study whether baseline UACR modified the 3-month SBP changes of sulodexide.

Results: Data of 843 patients were available for analysis. Baseline BP was 138±73 mmHg. At 3 months, mean (SEM) SBP change was -0.9 ±0.9 and +1.7 ±0.9 mmHg in the sulodexide and placebo arm, respectively (p=0.037). The SBP reduction was most pronounced in the highest UACR tertile (-1.6 ±1.5 vs 2.9 ±1.6 mmHg; p=0.042). Treatment (p=0.015), baseline SBP (p<0.001), heart rate (p=0.007) and UACR (p=0.007) were associated with SBP change. We found an interaction between treatment and UACR (p=0.047), indicating that sulodexide and placebo differently affected SBP at various UACR levels. Age, eGFR, BMI, HbAlc and lipid profile (i.e., factors influencing ESL thickness) did not modify the treatment effect. The BP differences persisted during the first year of follow-up (p=0.047).

Conclusions: In conclusion, podocyte derived urinary MPs are detectable in all HTN. These findings need to be confirmed in a larger group of animals. Urinary MPs can be potential marker for kidney end-organ damage in HTN.

Funding: Clinical Revenue Support

SA-PO666
Under-Diagnosis of Hypertension in a Large Cohort of Overweight/Obese Adolescents
Brian William Sykes, Divya G. Moodalbail, Christopher J. LaRosa, Joshua Zaritsky. Nephrology, Nemours/A.I. duPont Hospital, Wilmington, DE.

Background: The obesity epidemic in children is strongly associated with increasing prevalence of childhood hypertension (htn) along with heightened risk for cardiovascular morbidity and mortality in adulthood. Therefore we assessed the identification of htn in overweight/obese adolescents cared for by a large healthcare system utilizing an EMR system.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

178A
Methods: We performed a retrospective study of patients (pts) in the Nemours Health Care System aged 12-17 years, with a BMI > 85th percentile, and 3 documented BP > 120/80 in the outpatient setting, between 1/2010 and 12/2014. Pts with established diagnosis of hypertension (ICD-9 codes 401.XX – 405.XX), renal or heart disease were excluded. Results: Of the 6604 distinct pts identified, only 255 (3.8%) received a diagnosis of hypertension during the study period, while 6,349 (96.2%) were undiagnosed. Pts who were undiagnosed had lower BMIs and BPs and were less likely to be African American or have Medicaid and were seen less by Nephrology, Cardiology or Weight management specialists compared with those diagnosed with hypertension (table). Additionally undiagnosed pts had fewer abnormal BPs and had a longer interval between their 1st and 3rd abnormal BP compared with those diagnosed with hypertension.

Conclusions: In this large cohort of overweight/obese adolescents with hypertension, the vast majority of pts were undiagnosed and not referred to specialists who manage BP monitoring and treatment. Thus it is crucial that future efforts focus on improving detection and early recognition of hypertension in order to reduce cardiovascular morbidity and mortality in this at-risk population.

SA-PO667 Multidisciplinary Selection of Angioplasty Indications in Atheromatous Renal Artery Stenosis Leads to an Improvement in Blood Pressure, Drug Sensitivity and Renal Function

Methods: A retrospective cohort of patients with a diagnosis of hypertension was selected. The primary outcome of interest was a reduction in clinic systolic blood pressure (SBP) at 1 year. A total of 268 patients who had plasma aldosterone and renin activity obtained during the study period were included in the analysis. The study endpoints were changes in clinic SBP, SBP dipping, and in plasma renin activity (PRA) after 1 year of treatment.

Results: Of the 268 patients, 158 (58.7%) had a decrease in clinic SBP (at least 10 mmHg) and 100 (37.4%) had a decrease in SBP dipping (≥50%). A total of 134 patients (49.6%) had a decrease in plasma renin activity (PRA) after 1 year of treatment. A total of 252 patients (94.1%) had a decrease in clinic SBP with a decrease in PRA (4.9% vs. 39.1%). Compared to TD or A/R, the PRA strategy for initial drug selection in stage 1 HTN was associated with the highest control rate.

Funding: Other NIH Support - PEAR was supported by the National Institute of Health Pharmacogenomic Research Network grant (U01 GM74492) and the National Center for Advancing Translational Sciences under the award number UL1 TR000454 (Emory University), and UL1 TR000135 (Mayo Clinic). PEAR was also supported by funds from the Mayo Foundation.

SA-PO669 Primary Hyperaldosteronism: An Inner City Hypertension Clinic Experience

Background: Primary Hyperaldosteronism (PA) has historically been regarded as a rare disorder. Recent studies have shown a widely variable prevalence. We screened for PA in the Hypertension/(HTN) Clinic at Harlem Hospital in patients with predominantly African-American and Hispanic ethnicities.

Methods: Retrospective cross-sectional study of patients seen at Harlem HTN Clinic between January 2008 to November 2013. The inclusion criteria were patients seen with completed aldosterone and renin levels. The exclusion criteria were patients on spironolactone prior to the laboratory studies or with incomplete data. Prevalence was measured as number of patients with both an Aldosteron/Renin ratio >20 and an Aldosterone level >150 pg/dl as a ratio of total number of patients tested.

Results: A total of 268 patients who had plasma aldosterone and renin activity obtained was reviewed. Of these, 8 patients had incomplete data and were excluded. 220 of the remaining patients in the study were black, while 48 patients were Hispanic. Of the 268 patients, 136 (50.9%) with A/R strategy, 50.9% with A/R strategy, while 16.3% had a PRA strategy. This was statistically significant (P<0.0001).

Conclusions: Our study suggests a higher than anticipated prevalence of PA in African-American and Hispanic patients in Harlem, NYC, based on selective screening with plasma aldosterone and plasma renin activity and inclusion of adrenal adenomas present by CT scan in at least 50% of cases, potentially treatable with surgery. Thus, adequate screening of patients for PA is essential, especially in minorities.

SA-PO670 HIV-2 and Chronic Kidney Diseases (French HIV-2 Cohort ARNS CO5)

Methods: All patients included in the HIV-2 French national cohort with 2 creatinine measurements at least 3 months apart were included. Glimmer filtration rate was estimated by MDRD formula and used to categorize CKD according to the NKF classification. Risk factors were determined by uni and multivariate analyses using a Cox model which included the main known risk factors for CKD and the main characteristics of HIV infection.

Results: Out of 1048 patients, 433 (41.2%) had CKD at baseline. Patient characteristics did not significantly differ from those of the total cohort: mean age (SD) was 50 (11) years, 62% of the patients were females, and 80.1% originated from sub-Saharan countries. On average, HIV-2 infection was diagnosed 12.8 (6.8) years before last creatinine measurement. Prevalence of CKD stage 2 was 39.8% and that of chronic kidney failure (stages 3-5) was 15.1%. There was no creatinine analysis revealed that age (HR=1.06, p<0.01), HIV stage (HR=3.31, p=0.04), and CD4 count (HR=3.12, p<0.01) were risk factors for chronic kidney failure.
kidney failure. HIV stage A (HR=0.3, p<10^{-4}) had a protective effect. Multivariate analysis revealed that age (HR=1.05, p=0.002) and CDC stage A (HR=0.35, p=0.01) were risk and protective factors, respectively.

Conclusions: The prevalence of CKD in this very large cohort of people living with HIV-2 seems to be comparable to what is known in literature for people living with HIV-1. HIV-2 infection parameters determine most of the kidney risk. The role of ARV exposition remains to be taken into account.

Funding: Government Support - Non-U.S.

Effect of Nephropathy on the Frequency of Cardiac Dysautonomia in HIV Patients Sved Rizwan Bokhari, 1 Syed Hunain Riaz, 2 Qurrat-ul-ain Abid, 2 Hafiz I. Ahmad, 1 Muhammad Zaman Khan ASSIR, 1 Fahmina Ashfaq, 1 Kashif Saleem. 2
1Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; 2HIV Clinic, Jinnah Hospital, Lahore, Pakistan.

Background: Dysfunction of autonomic nervous system including Cardiac Dysautonomia (CD) is seen in a variety of conditions like diabetes mellitus, adrenal insufficiency and renal failure. CD is well documented in patients with renal dysfunction. CKD. Prevalence of renal dysfunction (HIV Nephropathy) is high in our population of HIV positive patients, but the effect of HIV nephropathy on the frequency of CD has not been previously studied. We conducted this study to determine the effect of HIV nephropathy on the frequency of CD.

Methods: This cross sectional study was conducted at HIV Clinic in collaboration with the Department of Nephrology Jinnah Hospital Lahore. A total of 47 HIV positive patients were enrolled; 13 (28%) with nephropathy and 34 (72%) without nephropathy. Patients underwent 5 tests for cardiac autonomic dysfunction including resting tachycardia, abnormal heart rate responses to deep breathing, abnormal Valsalva ratio, abnormal 30:15 ratio and postural hypotension. Patients with 2 or more abnormal tests were considered positive for CD.

Results: Of 47 patients, 39(83%) were male, 5(11%) female and 3(6%) were transgender with median age of 31 years (range 19-56 years). The median CD4 count was 339 (range 39-797) and 96% (n=45) patients were on highly active anti-retroviral therapy (HAART). The median duration of HIV was 12 months (range 1-56) and median duration of HAART was 11 months (range 0-49). CD was seen in 42 (89%) patients. Seventeen (36.2%) patients had 2, 18(38.3%) had 3, 6 (12.8%) had 4 and 1 (2%) had 5 abnormal tests. The frequency of CD was comparable among patients with and without nephropathy [92% (12 out of 13) vs 88% (30 out of 34), respectively; p value=1]. The presence of CD had no correlation with CD4 count, degree of renal impairment, treatment regimen and duration on HAART.

Conclusions: There was high frequency of CD in our population of HIV patients and it was independent of presence or absence of nephropathy, CD4 count and duration of anti-retroviral therapy.

SA-PO672

Background: Beta-trace protein (BTP) and beta-2-microglobulin (B2M), like cystatin C (Cys), are novel serum filtration markers that have stronger associations with adverse outcomes than serum creatinine (Cr). However, comparisons of BTP and B2M to Cr performance of the equations in the validation dataset compared to established CKD-EPI Cr-Cys equations.

Methods: Using a pooled database of three populations with CKD (N=3551, mean measured GFR using iothalamate [mGFR] 48 ml/min/1.73m²), we developed equations to estimate mGFR using Cr, Cys, BTP or B2M. Equations were developed in 2/3 of the population and tested in the remaining 1/3.

Results: The table shows the coefficients included in each equation and the performance of the equations in the validation dataset compared to established CKD-EPI Cr-Cys equations.

Conclusions: BTP and B2M are less influenced by age, sex and race than Cr or Cys but did not improve precision [IQB] or errors (1-P30), even when averaged with Cr-Cys equation. CKD-EPI BTP and B2M equations provide tools for future study in their associations with mGFR and risk and adverse outcomes, but further study is required before clinical use.

Estimation of Glomerular Filtration Rate R.C. Pham, 1 Rachika Bhasin, 1 Afshan Hafizbaardaran, 1 Eileen C. Cannon, 1 Solomon C. Huang, 1 Saman Sarani, 1 Anita Kamarazarian, 1 Golriz Jafari, 1 P.T. Pham. 2 1/Div of Nephrology and Hypertension, Olive View-UCLA Medical Center, Sylmar, CA; 2/ Kidney Transplant, UCLA Medical Center, Los Angeles, CA.

Background: Estimations of glomerular filtration rates (GFR) based on routine 24 hour urine collections have been replaced by relatively accurate equations derived from large epidemiological studies. Nonetheless, equations including Modification Diet in Renal disease-4 and 6 variables (MDRD-4, -6) and Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) are known to have wider variations in predicting GFR among patients with relatively good kidney function. As renal clearance of any solute is dependent on its presence in the plasma and not whole blood, we suspect that varying hemoglobin/hematocrit (Hct) may play an important role in the actual clearance of solutes. We aim to determine if adding the plasma factor PF (1 - Hct/100) to MDRD-4, -6, or CKD-EPI equations can improve the accuracy of determining actual GFR.

Methods: This is a retrospective pilot study where the most recent 200 existing 24-hour urine collections obtained with creatinine concentrations as recorded by the Olive View-UCLA Medical laboratory are collected for analysis. Only 24-hour urine collections with concurrent measurements of complete blood count and chemistry 7 are included. To minimize poor 24 hour collections, only samples with urine creatinine ranging between 15-25 mg/kg weight/day are used. PF is added as an inverse multiplication factor to MDRD-4 and 6-variables and CKD-EPI equations to assess for variations when correlated with actual 24 hour urine collections.
Results: 90 out 200 samples met inclusion criteria. Albeit small, when each of the aforementioned equation was adjusted for PF, R² variation improved. MDRD-4: unadjusted R²=0.836 to adjusted R²=0.853, MDRD-6, R²=0.811 to 0.813, CKD-epi, R²=0.746 to 0.747.

Conclusions: Adding PF to MDRD-4, MDRD-6, and CKD-EPI equations reduced variations when correlated to 24 hour urine collections. Of interest, PF appears to improve MDRD (derived for CKD patients where anemia is prevalent) variations better than CKD-EPI. Large-scale reevaluation of eGFR estimates with consideration for PF is warranted.

SA-PO674
Interest of Cystatin C in the Evaluation of Glomerular Filtration Rate in Type 2 Cardio-Renal Syndrome Delphine Kervella,1,2 Sundrine Lemoinc,2 Florence Sens,1,3 Eric Pouliquen,1,3 Laurence Dubourg,2,3 Fatima Guerche-ezijhaier,2,3 Laurent Juillard,1,3 Nephrologie, Hôpital Edouard Herriot, Hospices Civils de Lyon, Lyon, France; 2Renal Function, Hôpital Edouard Herriot, Hospices Civils de Lyon, Lyon, France; 3Univ Claude Bernard Lyon 1, Lyon, France.

Background: In patients suffering from type 2 cardio-renal syndrome (CRS2), glomerular filtration rate (GFR) is overestimated with creatinine based formulae, leading to the misclassification of these patients in chronic kidney disease stages. As cystatin C is less dependent from muscle mass than creatinine, the aim of this study was to determine if estimation of GFR based on cystatin C offers a better evaluation of renal function than creatinine-based estimations in patients with CRS2.

Methods: GFR measured by Inulin clearance (measured GFR, mGFR) in 50 patients with CRS2 was compared to estimations of GFR (eGFR) with CKD EPI ( Chronic Kidney Disease Epidemiology Collaboration) formulation based on creatinine (CKD EPI, cystatin (CKD EPI-cystatin) and cystatin and creatinine (CKD EPI-cystatin-creatinine)). We calculated absolute bias (eGFR-mGFR) and accuracy 30% for each formula.

Results: Mean mGFR is 62.5±11.5 mL/min/1.73 m², eGFR are 41.5±20, 32±15 and 35±14.5 mL/min/1.73 m² with CKD EPI, CKDEPI-cystatin and CKDEPI-cystatin-creatinine respectively. These values of GFR are significantly different from mGFR. Mean absolute bias are 15.4, 5.7 and 8.8 mL/min/1.73 m² and accuracies 30%, 68% and 48% respectively.

The accuracy of CKD EPI-cystatin is significantly higher than the accuracy of CKD EPI.

Conclusions: Glomerular filtration rate is strongly overestimated with creatinine-based equation in CRS2 patients as previously described. CKD EPI formula based on cystatin C offers a better evaluation of GFR in this population. The high prevalence of malnutrition in this population can explain these results.

SA-PO675
Cystatin C in Capillary Blood: A New Tool for Instant Estimation of Glomerular Filtration Rate Maurice Laville,1 Solene Pelletier,2 Denis Fouque,1 Nephrologie, Univ de Lyon, Pierre Benite, France; 2Nephrologie, Hospices Civils de Lyon, Pierre Benite, France.

Background: Serum creatinine is the most used endogenous marker to estimate glomerular filtration rate (eGFR) in clinical practice. A handheld device (SatSensor®, Nova Biomedicals) allows to measure creatinine level in capillary blood. The aim of the study was to assess the accuracy of GFR values (eGFR) estimated from capillary blood creatinine level (CBCr), as compared with GFR values simultaneously measured by a gold standard method (mGFR) in patients with CKD.

Methods: The study included 79 adult patients (36 men, 43 women) who underwent renal function tests. The consent form contained information on the procedure and on the later use of the information for research. Inulin clearance was performed using a continuous infusion of inulin, and urine collections by periods of 30 min. Blood tests were done in the middle of each period of urine collection. Measurements of polyfructosan concentrations were performed using an enzymatic method. Inulin clearance was calculated in each period to obtain the average, and normalized to 1.73 m² body surface area. A drop of capillary blood was collected from a finger simultaneous to the first and the last blood sampling for inulin measurement. The drops were deposited on a test strip including enzyme reagents and inserted into the SatSensor® device. Reading was done at 30 sec. eGFR was calculated from CBCr with the CKD-EPI equation and the average of the 2 values was taken as eGFR.

Conclusions: Estimation of GFR using instant measurement of capillary blood creatinine level and CKD-EPI formula provides consistent results as compared with a gold standard method for GFR measurement, and could be used for screening and self-assessment purposes.

Renal Function Estimated with Different Formulas and Mortality in the INCIPE Cohort: Results After 8 Years Follow-up Pietro Manuel Ferrara,1 Antonio Lupo,2 Giovanni Gambaro,3 Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy; 2Div of Nephrology, Univ of Verona, Verona, Italy.

Background: Chronic kidney disease is a known risk factor for adverse outcomes. Its presence and severity is usually ascertained with formulae to estimate renal function based on serum creatinine and/or cystatin C. We analysed whether renal function estimated with different formula has a differential association with mortality.

Methods: The INCIPE cohort is a sample of the Italian population enrolled in 2006-07, with follow-up data available to up to 2014. CKD stages were defined as GFR >90, 60-<90, 45-<60, and <45 mL/min. We calculated absolute bias (eGFR-mGFR) using 7 different equations: CKD-EPI-cystatin (EPI-Cys), and with both serum creatinine and cystatin C (EPI-CrCys), and with serum creatinine (EPI-Cr), with serum cystatin C (EPI-Cys), and with both serum creatinine and cystatin C (EPI-CrCys). Each CKD stage was then included in a Cox proportional hazards model together with age, body mass index, sex, high blood pressure, diabetes, dyslipidaemia, previous cardiovascular disease, smoking status and albuminuria. Harrell’s c statistics with 95% confidence intervals (CI) were then calculated and compared for each formula.

Results: The final sample included 2,916 participants, all Caucasians, 47.4% males, with an average age at enrollment of 59.9±11.4 years. Participants contributed a total of 22,514 person-years of follow-up (median follow-up 7.9 years) during which 198 death events occurred. Overall, the models were highly predictive of mortality.

The GFR-Cys model performed significantly better than MDRD-6 (difference in c-statistics of 0.008, 95% CI 0.001, 0.015; p=0.034), whereas all the other models performed similarly.

Conclusions: Our study suggests that CKD defined with the CKD-EPI cystatin C formula shows a better prediction of mortality after accounting for a large number of potential risk factors.

SA-PO677
Do the BIS Equations Better Predict Death in Older Women? Muna T. Canales,1,2 Terri L. Blackwell,1 Arheet Ishani,1,3 Brent C. Taylor,1 Allyson Hart,2 Rebecca Belyth,2 Kristine E. Ensrud,1,3 Malcolm-Randall FVMC,1 Univ of Florida,2 California Pacific Medical Center,3 Minneapolis VA Health Care System,1 Univ of Minnesota, Hennepin County Medical Center, Minneapolis, MN.

Background: KDIGO 2012 guidelines recommend use of the CKD-EPI equations to estimate GFR except when there are alternate equations that may perform better for certain populations such as older adults. The BIS equations were specifically developed in an aged population, but their performance when compared to the CKD-EPI equations to predict mortality in older adults is unclear.

Methods: We conducted a prospective study of 1289 community-dwelling elderly women (≥72 years old) enrolled in the Study of Osteoporotic Fractures (SOF) who had both serum cystatin-C (cystatinC) and creatinineSCR measured at Year 10(1992-1994). We used Cox proportional hazards regression and net reclassification improvement(NRI) to compare the utility of the BIS2 (cysc & SCR-based), CKD-EPI-epi-cysc, BIS1 (SCR-based), and CKD-EPI-epi expressed as 4 eGFR categories (≥75, 60-74, 45-59, <45) to predict death. For NRI analyses, reference equations were CKD-EPI-epi for BIS2 and CKD-EPI-epi-BSI.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

781A
Results: The mean age was 79.5±4.6 years; 89% were white. Mean BMI was 27.5 kg/m². Mean follow-up time was 5±4 years. %eGFR<60 was: CKD-EPI, 33%; BIS2, 48%; CKD-EPI, 24% and BIS1 49%. When compared to eGFR<75 and after adjustment for age, race, BMI, HTN & DM, eGFR<45 by BIS2 was associated with a 2.1-fold greater risk of death (95% CI 1.5-3.0) vs 1.9-fold for eGFR<45 by CKD-EPI<75 (95% CI 1.2-2.1); BIS1 eGFR<45 was associated with a 1.6-fold greater risk of death (95% CI 1.1-2.1) vs 1.8-fold for eGFR<45 by CKD-EPI<75 (95% CI 1.4-2.4; p trend <0.001 across categories for each equation). In category-based NRI analyses neither of the BIS definitions materially changed discrimination of mortality risk when compared to CKD-EPI equations.

Conclusions: In this cohort of older community-dwelling women, the BIS equations identified a greater proportion of participants as having CKD. With respect to mortality risk prediction, the BIS equations did not perform better than current CKD-EPI equations recommended by KIDGO 2012.

Canine Chronic Kidney Disease: New Protein Biomarkers and Treatment with Human Umbilical Cord Mesenchymal Stem Cells

Douglas Caragelasco, 1 Jose Manuel Condor Capcha, 1 Talita R. Sanches, 2 Douglas Caragelasco, 3 Cinthia Martorelli, 4 Fernanda Chacar, 1 Priscila Queiroz Gouveia, 1 Irene L. Noronha, 1 Marcia Kogika, 1 Lucia Andrade, 1 "Div of Nephrology, School of Medicine; 2Dept of Veterinary Internal Medicine, Univ of Sao Paulo, Brazil.

Background: There are few strategies to prevent the progression of renal disease in humans or animals. In canine chronic kidney disease (cCKD), as in human CKD, proteinuria correlates with CKD progression, although there are no established urinary protein biomarkers. cCKD has become more common, dogs routinely being euthanized upon reaching the advanced stages. Mesenchymal stem cells (MSCs) have proven renoprotective in rodent CKD models. Here, we aim to characterize the roles that urinary excretion of albumin (Alb), Tamm-Horsfall protein (THP), vitamin D-binding protein (VDBP) and retinol-binding protein (RBP) play in cCKD and to determine whether human umbilical cord MSC (huMSC) administration slows its progression.

Methods: We performed Western blotting for urinary exosomal expression of Alb, THP, VDBP and RBP in cCKD stage 1-4 dogs (n=10/stage) and control dogs (n=10). We evaluated huMSC phenotypes with flow cytometry and immunocytochemistry. We randomized CKD stage 3 dogs to receive i.v.-injected placebo (n=5) or 10 μg huMSC/kg (n=6). We measured serum creatinine (Scr), serum urea (SUr) and the urinary protein:creatinine ratio (UPC) monthly for a year.

Results: Alb, THP, VDBP and RBP correlated significantly with cCKD progression.

Conclusions: Our findings broaden perspectives for CKD treatment. Supported by FAPESP.

SA-PO679

Validation of the Urine Total Protein-To-Creatinine Ratio-Based Chronic Kidney Disease Risk Classification: A Secondary Analysis

Hiroku Iyamato, 1 Kyoko Yamamoto, 1,2 Yutoro Nishi, 1 Kyoko Takeda, 1 Hiroko Izumo, 1 Yasuhiro Komatsu, 1 "St. Luke's Int'l Hospital, Tokyo, Japan; 2Tohoku Univ Graduate School of Medicine, Sendai, Japan.

Background: The most recent Japanese chronic kidney disease (CKD) guideline states that patients without diabetes should be classified using the total urine protein-to-creatinine ratio (PCR) instead of the urine albumin-to-creatinine ratio (ACR); however, validation of the PCR is still required. This study was conducted to validate the PCR-based CKD risk classification compared with the ACR-based classification and to explore more accurate methods for classification, focusing on relatively early CKD patients.

Methods: We conducted a secondary analysis using two previous datasets with diabetic or cardiovascular patients who were classified into CKD stages A1-A2 and G1-G3b. We assessed the CKD stage and risk classification of each patient according to the estimated glomerular filtration rate and the ACR- or PCR-based classification method. Then, various candidate PCR values were utilized as the cut-off values between stages A1 and A2. Cohen’s kappa statistics were calculated to evaluate the agreement between each classification method.

Results: In total, 860 patients (131 from the diabetic clinic and 729 from the cardiovascular clinic) were enrolled. Using the cut-off value recommended in the current guideline (PCR 0.15 g/gCr), the misclassification rates in these populations were 26.0% and 16.6%, respectively; the misclassifications were primarily caused by underestimation. The kappa statistics achieved 0.56 (95% confidence interval, 0.45-0.69) and 0.72 (0.67-0.76), respectively. Using PCR values of 0.08-0.10 g/gCr as the cut-off value improved the misclassification rates and kappa values.

Conclusions: Current PCR-based CKD classification method leads to underestimation of risk classification in outpatient setting.

Beta-Trace Protein as Renal Marker in Older Adults – Results from the Berlin Initiative Study

Natalie Fbert, 1 Olga Jakob, 1 Jan Bartel, 2 Markus von der Giet, 1 Mirjam Schuchardt, 3 Christine A. White, 4 Elke Schaeffner. 1; "Nephrology, Charité, Berlin, Germany; 2Epidemiology and Biostatistics, Charité, Berlin, Germany; 3Labor Limbach, Heidelberg, Germany; 4Nephrology, Queen’s Hospital, Kingston, ON, Canada.

Background: It has been shown that GFR estimation based on b-Trace Protein (BTP), a relatively novel biomarker, is reliable and might serve as an alternative in kidney transplant recipients. Whether BTP-based GFR equations can be applied in older adults is not known.

Methods: BTP has been analysed by immunonephelometry with N-Latex® BTP Assay on a BN ProSpec® System, Siemens, Germany. Analysis was done in 570 participants of the Berlin Initiative Study (mean age: 78.5 yrs) who underwent iohexol clearance measurement (mean mGFR: 60.3 mL/min/1.73m²). The following 3 currently available eGFR equations were used: Pigo (BTP): GFR = 47.17 \times BTP^{-0.52}; Pigo (BTP/Crea): GFR = 974.31 \times BTP^{-0.32} \times \text{creatinine}^{0.08} \times \text{White (BTP/Crea): GFR = 167.8} \times \text{BTP}^{-0.29} \times \text{creatinine}^{0.28} \times (0.871 if female). Comparison of BTP estimating equations with mGFR was done for determination of bias (mGFR-eGFR), precision (SD) and accuracy (P10, P30).

Results: The boxplot includes median and eGFR range calculated with the 3 GFR-equations. Mean eGFR was 100.3 for Pigo (BTP), 62.7 for Pigo (BTP/Crea) and 86.2/mL/ min/1.73m² for White (BTP/Crea).

Conclusions: The current PCR-based CKD classification method leads to underestimation of risk classification in outpatient setting.
Table 1 shows bias, precision and accuracy for all 3 equations compared to mGFR.

Galectin-3, Possible Useful Biomaker in Predicting Chronic Kidney Disease in Hepatitis C Positive Patients Hany Refaat, Haitham Ezzat, Amir Mohab, Nephrology Dept, Ain Shams Univ, Cairo, Egypt.

Background: Galectin-3, a pro-fibrotic mediator, is involved in mechanisms of tubulointerstitial fibrosis and CKD progression. Data regarding its predictive value of CKD development in Hepatitis C patients is scarce.

Methods: In this Cohort study, we measured the level of Galectin-3 in the sera of 80 Hepatitis C positive patients. Patients were stratified into two groups: Forty hepatitis C positive patients with normal kidney function (Group I), and 40 hepatitis C positive patients with CKD (Group II). Galectin-3 concentration was also measured in 10 healthy individuals, as a control group (Group III). Other laboratory investigations were done which included hemoglobin level, serum creatinine, eGFR by MDRD equation, ALT, AST, INR, serum albumin, serum hirudin and CRP titre. We correlated galectin-3 concentrations with demographic and biochemical parameters in all groups.

Results: 30 females (33.3%) and 60 males (66.7%) were included in the study with mean age 47.6±5.3 years. Plasma levels of Galectin-3 were highest in group II (22.1±5 ng/ ml) when compared to group I (15 ±2.4 ng/ml) and group III (7.9±2.5 ng/ml) (p<0.001). Also CRP titre was highest in group II (10.1±1.5 mg/L), when compared to group I and III (2.5±0.9 mg/L and 2.3±1.1 mg/L respectively) (p<0.001). There was positive correlation between Galectin-3 level and CRP titre in both group I and II (p<0.001). Moreover, in group II, Galectin-3 level was positively correlated with serum creatinine (p<0.001), while inversely correlated with eGFR (p<0.001). There was no correlation between serum Galectin-3 level, and INR, ALT, AST and serum albumin in both group I and II.

Conclusions: In hepatitis C positive patients, galectin-3 concentrations increased with progressive renal impairment. Galectin-3 levels were not correlated with liver functions, suggesting the predictive value of galectin-3 for CKD development in hepatitis C positive patients.

SA-PO682

Chronic Kidney Disease: Long Term Prevalence Trends and Influence of Modifiable Risk Factors Steen L. Hallan,1 Marius Altern Øvrehus,2 Soflid Romundstad,2 Dena E. Rikf,1 Arnulf Langhammer; Joachim H. Ix.1 UCSD, La Jolla, CA, Faculty of Medicine, NTRU, Trondheim, Norway.

Background: Prevalence of chronic kidney disease (CKD) is high worldwide, and it has been increasing in the US. However, less strict treatment goals for hypertension have recently been suggested despite increasing prevalence of obesity and diabetes. We aimed to determine whether CKD prevalence is increasing in Norway, evaluating the influence of changing prevalence of CKD risk factors on CKD prevalence, and compared findings to corresponding US data.

Methods: We included general population based participants from the Nord-Trøndelag Health Studies (HUNT), Norway: 65237 (from HUNT2 (1994-96) and 50580 from HUNT3 (2006-08). eGFR and u-ACR based on fresh blood and 3 urine samples were used to diagnose CKD. Thorougly quality-control and comparisons of methods over time excluded analytical drift. We used attendance weights used to avoid responder bias.

Results: Total CKD prevalence remained stable in Norway 1996-2007 (11.3%-11.1%, p=0.42) but increased in subjects >75 years (36.6%-39.3%, p=0.014). eGFR <60 ml/min/1.73m2 increased (4.5%-8.4%, p=0.033) while albuminuria >30mg/g decreased (7.9%-7.4%, p=0.034). The most important contributors were a strong blood pressure decline during this 10 years period, more physical activity and lower cholesterol; without these improvements 2.8, 0.7 and 0.6 percentage-point higher CKD prevalence would have been expected, respectively. In contrast, the prevalence of diabetes and obesity increased moderately, but diabetics received more intensive preventive therapy, and the proportion of diabetic patients with CKD decreased substantially (33.4%-28.6%, p=0.002). In contrast, published US data indicate a stronger increase in obesity and diabetes, and physical activity was low and not improving. Access to effective care was also suboptimal for a substantial group of the population.

Conclusions: In contrast to the US where CKD prevalence has been increasing, it remained stable over a 10 year period in Norway, likely due to substantial improvements in blood pressure, lipids and physical activity despite modestly increasing diabetes and obesity.

SA-PO683

Natural Progression of Chronic Kidney Disease in Optimally Managed Patients on the Maximum Conservative Management Pathway Suzanne H. Forbes, Kieran McAfferty, Muhammad M. Yaqoob. Nephrology, Royal London Hospital.

Background: The natural progression of advanced chronic kidney disease (CKD)/ end-stage renal disease (ESRD) managed in a specialist palliative care nephrology clinic setting is unknown.

Methods: We conducted an observational study of all patients with advanced CKD undergoing predialysis counselling between 2009-2014 in a single UK center. All patients who opted for conservative management were followed up prospectively in a specialist conservative care clinic and their clinical phenotype and renal outcomes recorded. Change in eGFR was noted when eGFR was<10, with 2 or more serum creatinine estimations taken more than 2 months apart.

Results: We prospectively studied 354 patients with median length of follow-up 452 days (165-769). Median eGFR at referral was 8ml/min (7-9). Demographics are shown.

783A
Fall in eGFR in ml/min/year was 3.9 (1.8-8). Neither baseline eGFR (p=0.13) nor presence of diabetes (p=0.72) affected this rate of decline. Time to death from eGFR 10ml/min was 276 days.

Conclusions: In this first longitudinal study of conservatively treated patients with advanced CKD, variable rate of decline of eGFR ranging between 1.8-8ml/year led to death of 55% of the cohort within the median follow up period of 15 months. Reassuringly the majority of patients died at their preferred place of terminal care (home/hospice) and were registered as deaths due to ESRD. Over 50% of patient’s eGFR decline was less than 4 ml/min per year which could translate into a life expectancy of >1 year without dialysis in these exceedingly frail individuals. Prospective study is ongoing to determine the quality of life of these patients treated conservatively.

Estimating County-Level Prevalence of Chronic Kidney Disease (CKD) in the United States

Jennifer L. Bragg-Gresham, 1 Jennifer L. Bragg-Gresham, 1 Hal Morgenstern, 1 Yi Li, 1 Neil R. Powe, 2 Delphine S. Tuot, 2 Deborah Rolla, 3 Sharon Saydah, 1 Rajiv Saran, 1

1 Univ of Michigan, Ann Arbor, MI; 2 Univ of California, San Francisco, CA; 3 Centers for Disease Control and Prevention, Atlanta, GA.

Background: The prevalence of adult CKD in the US, estimated from 2005-2012 national survey data, is about 13%; however, those surveys are not designed to provide estimates for small regions. Applying a Bayesian multi-level model (BMLM), we estimated adult CKD prevalence in US counties using national and state surveys.

Methods: Data on self-reported CKD and risk-factors were obtained from (i) the National Health and Nutrition Examination Survey (NHANES 2005-2012; n=20,831), and (ii) the Behavior Risk Factor Surveillance System (BRFSS 2011; n=506,467). NHANES also provided CKD laboratory data. CKD was defined as estimated glomerular filtration rate <60 ml/min/m^2 or urinary albumin-to-creatinine ratio >30mg/g. As BRFSS does not include laboratory data, CKD for each person in the BRFSS was multiplied using a logistic regression model trained on NHANES data. A BMLM that effectively borrows information from neighboring counties was then fit to each imputed dataset to produce 10 sets of county-level estimates of CKD prevalence. These estimates were combined to obtain a final prevalence estimate for each county.

Results: Estimated county-level prevalence of CKD ranged from 12.3 to 27.8% (median: 18.8%) in 2011 (see map).

The standard deviation of these estimates ranged from 0.8 to 7%, and the coefficient of variation ranged from 5 to 32% of the estimate, suggesting good statistical precision.

Conclusions: We believe this is the first attempt to estimate CKD prevalence in U.S. counties. Our approach yields estimates with improved statistical precision for small counties, and is being used to study geographic variation in CKD burden across the U.S.

Overall CKD Prevalence in the U.S. Has Stabilized in Recent Years

Daniel P. Murphy, 1 Charles E. McCulloch, 1 Feng Lin, 1 Tanushree Banerjee, 1 Jennifer L. Bragg-Gresham, 2 Mark Eberhardt, 2 Meda E. Pavkov, 3 Rajiv Saran, 3 Neil R. Powe, 4 Chi-yuan Hsu, 5 UCSF [Drs. CY Hsu and NR Powe are Co-Senior Authors]; 1 Univ of Michigan; 3 CDC.

Background: ESRD incidence rates in the U.S. have stabilized recently. We sought to better understand trends in CKD prevalence since 2003-2004.

Methods: We examined data on adults from the National Health and Nutrition Examination Surveys from 1988 through 2012. We determined prevalence of stage 3-4 CKD (CKD-EPI equation eGFR 15-59 ml/min/1.73m^2) overall and by age, sex, race, and diabetes strata. We examined crude prevalence and adjusted prevalence for age, sex, race, and diabetes mellitus (diagnosed and undiagnosed). Restricted cubic splines were used to model trends. The years 2003-4 (last years with published literature) were compared to 2011-12 (most recent years of available data).

Results: Consistent with the published literature, we saw a rise in CKD prevalence from the late 1990s to the early 2000s. But since around 2003-4, adjusted and unadjusted prevalence of CKD have stabilized (Figure). This temporal trend was observed across age (p for interaction=0.11), sex (p=0.61) and racial-ethnic subgroups (p=0.07; although the trend in non-Hispanic blacks appeared to differ); and did not differ by diabetes status (p=0.17). There was no difference in overall stage 3-4 CKD prevalence comparing 2003-4 and 2011-12 (p=0.25). Similarly trends were seen with an expanded definition of CKD to include persons with higher eGFRs but albuminuria or used the MDRD equation.

Conclusions: Over the last decade in the U.S., there has been stabilization in the overall prevalence of stage 3-4 CKD, with a possible exception in blacks. This is contrast to what has been reported by prior studies analyzing older data but consistent with the observed stabilization of overall ESRD incidence. Efforts should be continued to implement reno-protective measures, especially in blacks.

Prevalence of Chronic Kidney Disease with Diabetes and Glomerulonephritis in China

Luxia Zhang, Jinwei Wang, Ming Hui Zhao. Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.

Background: Diabetes is the leading cause of end stage kidney disease worldwide, while glomerulonephritis is thought to be the predominant cause in developing countries. However, the surging prevalence of diabetes in developing countries such as China may have substantial impact on the spectrum of chronic kidney disease.

Methods: A national in-patient database involving 19.5 million patient-records was used. Diagnoses of chronic kidney disease with diabetes (DM-CKD) as well as with glomerulonephritis (GN-CKD) were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. Furthermore, a general population-based, national representative sample of 47,204 participants was used. Identification of DM-CKD and GN-CKD was based on laboratory tests and the questionnaire inquiring about medical history. Then the prevalence of DM-CKD and GN-CKD was compared among both hospitalized population and general population.

Results: Among 19.5 million hospitalized patients, 1.19% and 0.79% were identified as with DM-CKD and with GN-CKD, respectively. Compared with GN-CKD, DM-CKD was associated with 7.2% (95% confidence interval [CI] 6.4-8.0%), 5.4% (95% CI 4.7-6.0%) and 59% (95% CI 46-73%) increase of costs, length-of-stay and in-hospital mortality, respectively. For general population, the prevalence of the GN-CKD is also exceeded by that of DM-CKD at 0.84% (95%CI 0.68-1.00%) and 1.23% (95% CI 1.06-1.41%), respectively.

Conclusion: Clinical and significant CKD is high both in younger and older adults globally. Our findings call for institution of urgent public health efforts for CKD prevention and management.

Prevalence of Chronic Kidney Disease on the U.S.-Mexico Border: Role of Acculturation

Jonathan Michael Starkey, Kristina Vatcheva, Susan P. Fisher-Hoch, Joseph B. McCormick. Inst for Translational Sciences, Univ of Texas Medical Branch, Galveston, TX; Univ of Texas School of Public Health, Houston, TX.

Background: Mexican-Americans are the dominant Hispanic group in the US and face significant health disparities, including end-stage renal disease, diabetes and obesity. We characterize the quantity and associations of chronic kidney disease (CKD) in Cameron County, TX where almost 90% of the population is Hispanic and is predominantly zero or first generation Mexican-American.

Methods: The Cameron County Hispanic Cohort (CCHC) is a random sample of the Hispanic population on the southernmost point along the US-Mexico border. 1,777 participants with baseline serum creatinine measurements from 2003-2014 are included in this cross-sectional study. The glomerular filtration rate (eGFR) is estimated from serum creatinine and CKD is defined as eGFR < 60 ml/min/1.73 m². The weighted prevalence of CKD is estimated. A multivariate model of factors associated with CKD outcome.

Results: The prevalence of CKD is 6.0% in the CCHC and estimates the prevalence in Cameron County, TX. Stratified by gender, the prevalence in men and women is 6.9% and 4.9%, respectively. Multivariate analysis reveals significant associations of country of birth (OR 2.14, 95% CI [1.02, 4.46] for those born in the US), hypertiglyceridemia (OR 2.72, 95% CI [1.41, 5.23]) and granulocyte count (OR 1.345, 95% CI [1.058, 1.708]) with CKD status after adjusting for age, gender, diabetes status, cardiovascular disease history, hypertension, smoking history, obesity, LDL and statin use.

Conclusion: The prevalence of CKD in the CCHC is higher than previous national estimates in Hispanics or Mexican-Americans. The data suggest that acculturation, triglycerides and inflammation are associated with CKD in Hispanics living on the US-Mexico border. More research is needed in Mexican-Americans to investigate CKD in this growing minority population.

Validation of the Kidney Failure Risk Equation in Manitoba

Reid Whitlock, Paul Komenda, Claudia Rigatto, Allison Dart, Joe A. Bueti, Randy Waldt, Navdeep Tangri. Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; Nephrology, Seven Oaks Hospital, Winnipeg, MB, Canada; Medicine, Univ of Manitoba, Winnipeg, MB, Canada; Nephrology, Health Science Centre, Winnipeg, MB, Canada.

Background: Patients with chronic kidney disease (CKD) are at risk for progression to kidney failure. We previously developed the Kidney Failure Risk Equation (KFRE) to predict the progression of CKD to kidney failure in patients referred to nephrologists. This study aims to validate the KFRE in an unselected population in Manitoba, and to determine risk thresholds for clinical decision-making.

Methods: We included patients from the Diagnostic Services of Manitoba database with an eGFR < 60 ml/min/1.73 m² and a urinary albumin creatinine ratio measured between October 30, 2006 – March 31, 2007. Five year kidney failure risk was predicted using the 3-variable KFRE and compared with treated kidney failure events from the Manitoba Renal Program database. Sensitivity and specificity for KFRE thresholds (3% and 10% over 5 years) were then compared to eGFR thresholds (30 and 45 ml/min/1.73m²).

Results: 1,512 patients were included and 151 developed kidney failure over the 5-year follow-up period. The 4-variable KFRE more accurately predicted kidney failure when compared to eGFR alone (AUROC's 0.90 [95% confidence interval (CI) 0.88-0.92] for KFRE vs. 0.78 [95% CI 0.74-0.83] for eGFR). At a risk threshold of 3% over 5 years, the KFRE had a sensitivity of 97% and a specificity of 62%.

Conclusions: The KFRE is highly accurate at predicting 5-year risk of kidney failure in a population based sample of Manitobans with CKD Stages 3 to 5. Integration of the 4-variable KFRE into laboratory information systems should be considered.

A Risk Prediction Model of End-Stage Renal Disease in Type 1 Diabetes Using Urine MCP-1 as an Alternative Biomarker of ACR

Masayuki Yamanouchi, Monika A. Niewczas, Natalia Z. Nowak, Andrzej S. Kroлевski. Genetics & Epidemiology, Joslin Diabetes Center, Boston, MA.

Background: There is a great need to develop risk prediction models to recruit patients at high risk of end-stage renal disease (ESRD) for clinical trials in patients with type 1 diabetes. We developed two models to predict progression of CKD 3 and 4 to ESRD in 5 years in patients with type 1 diabetes: “ACR model” that consists of patient’s age, eGFR, HbA1c and ACR, and “Urine MCP-1 model” that consists of the same markers but replacing ACR model with urine MCP-1.

Methods: We identified 285 patients with type 1 diabetes and impaired renal function (eGFR: 15-60 ml/min/1.73m²) from Joslin Proteinuria Cohort that was followed for 7 to 18 years to ascertain ESRD. We focused on the events within 5 years from enrollment. For the ACR model, the Cox model identified four baseline variables: age, eGFR, ACR, and HbA1c for the final model. For the urine MCP-1 model, urine MCP-1, age, eGFR and HbA1c were identified by the Cox model. Assigned point scores corresponded to each coefficient.

Results: 5-year risk of ESRD in the study group was 40.5%. In the ACR model, the variable with highest magnitude was eGFR<30, 4 points; followed by ACR<300, 2 points; HbA1c<7.5, 1 point; and age<45 years, 1 point, while in the urine MCP-1 model, the variable with highest magnitude was eGFR<30, 2 points; followed by urine MCP-1>545, 1 point; HbA1c>7.5, 1 point; and age<45 years, 1 point. The model with urine MCP-1 performed almost equal to the model with ACR (C statistic of 0.702 (0.556-0.831) vs. 0.719 (0.574-0.845)). Although the number of patients who developed ESRD in the high risk group in the urine MCP-1 model is smaller than in the ACR model, the incidence rate of ESRD in the high risk group in the urine MCP-1 model was much higher than in the ACR model (291/1000 vs. 196/1000, p<0.001).

Conclusions: Using the risk score with urine MCP-1, we can identify a subgroup of patients at very high risk of ESRD.

A Reliable Formula to Estimate 24-h Urine Sodium Excretion from Morning Fasting Urine in Patients with Chronic Kidney Disease

Se Yun Kim,1 Ho Jun Chin,2 Sejoong Kim,2 Dong Ki Kim,3 Sahngwong Kim,3 Jung Hun Park,4 Sung Joon Shin,5 Bun Soon Choi,5 Chun Soo Lim,5 Sang Ho Lee.1 1Kyung Hee Univ Hospital, Seoul, Korea; 2Seoul National Univ Bundang Hospital, Seong-Nam, Korea; 3Seoul National Univ Hospital, Seoul, Korea; 4KonKuk Univ Hospital, Seoul, Korea; 5Dongguk Univ Ilsan Hospital, Goyang, Korea; 6Seoul St. Mary’s Hospital, Seoul, Korea; 7Seoul National Univ Bamrane Medical Center, Seoul, Korea.

Background: Estimated 24 hour urine sodium excretion based on spot urine has been proposed to replace 24 hour urine collection in epidemiologic studies. However, estimated sodium excretion has not been verified whether it is useful in patients with chronic kidney disease (CKD) as well as in interventional study. The aim is to evaluate the estimated sodium excretion in prospective low salt diet education study (ESPECIAL) cohort.

Methods: New formula was developed from baseline data of 228 CKD patients of ESPECIAL cohort using a multivariable linear regression and compared with previous three formulas from healthy population (Kawasaki, INTERSALT, Tanaka) and one from CKD patients (Nerbass) for the prediction of 24 hour sodium excretion after ARB treatment and low salt diet education.

Results: Among previous reported formulas, the estimation by Tanaka’s formula showed the smallest bias (estimated 184.3±65.6 vs. measured 154.1±69.6 mEq/day), but weak correlation (r=0.34). We developed new formula with improved bias (estimated 154.0±39.7 mEq/day) and correlation (r=0.56). New formula also showed the best correlation (r=0.57) with smallest bias (estimated ± mEq/day) even after ARB treatment, which did not show significant change of measured sodium excretion.[56±37±0.6 mEq/ day]. Intensive low salt diet education elicited the significant decrease of measured sodium excretion (121±59±.6 mEq/day). Although new formula also showed best correlation, any of formulas did not predict the amount of the decrease of measured sodium excretion.

Conclusions: We developed more reliable formula for estimating urine sodium excretion for CKD patients. However, our data suggests estimated sodium excretion could be applied for epidemiological study rather than low salt intervention study.

SA-PO692

Evaluation of Glycated Albumin for Glycemic Monitoring in Diabetic Nephropathy

Yang Fei, Ying Fan, Yunmei Liu, Niansong Wang. Dept of Nephrology and Rheumatology, Shanghai Jiaotong Univ Affiliated the Sixth Hospital, Shanghai, China.

Background: Glycated albumin(GA) has been now widely used for the evaluation of blood glucose in diabetic nephropathy(DN) patients. However, the effect of proteinuria on GA should be taken into account, especially in patients with advanced DN.

Methods: A total of 621 diabetic nephropathy patients from year 2009 to 2014 were enrolled in the study. According to the 24 urinary protein(UP) output, subjects were divided into 3 groups defined as (1) microalbuminuria: UP=30-300mg/24h, (2) moderate albuminuria: UP>300mg/24h, (3) macroalbuminuria: UP>100mg/24h. In all DN patients, GA were divided into 3 groups defined as (1) normal: GA<1.25mg/g, (2) increased: 1.25mg/g<GA<1.875mg/g, (3) maximal: GA>1.875mg/g. There was no correlation between GA and UP in DN patients with micro or moderate albuminuria. However, GA was found to be much lower and negatively correlated with UP in DN patients with macroalbuminuria. Therefore, adjusted GA (adjGA) was applied for those subjects, taking 24 h urine, serum albumin (SA) and the ratio of normal albumin metabolism days to total albumin metabolism days into account. adjGA=GA×(1.75×UP)/SA. As a result, GA value was increased after adjustment in DN macroalbuminuria group. The adjGA was also found only correlated with FBG and PIBG, and had no relation with 24h UP and SA.

Conclusions: In diabetic nephropathy patients, blood glucose, serum albumin and 24h urinary protein output may serve as important factors for the evaluation of GA on glycemic level. GA tended to be underestimated in DN patients with macroalbuminuria. The adjGA may be a better way to objectively evaluate glycemic status in patients with advanced DN.

SA-PO693

Fat Mass, Lean Body Mass and Serum Filtration Markers in Adults in the United States: The National Health and Nutrition Examination Survey (NHANES)

Meredith C. Foster,1 Julie K. Bower,2 Josef Coresh,3 Roger A. Fielding,4 Lesley Inker,5 Andrew S. Levy,5 1Tufts Medical Center; 2The Ohio State Univ; 3Johns Hopkins Univ; 4Tufts Univ.

Background: Established serum filtration markers are influenced by body composition (creatinine by muscle mass, cystatin C by fat mass) but limited data exist evaluating associations of these markers with body composition assessed using a gold-standard measurement approach. Our aim was to examine the association of body composition quantified using dual energy X-ray absorptiometry (DXA) with serum creatinine and cystatin C in US adults.

Methods: We conducted a cross-sectional analysis in 4378 adults age 18+ years from NHANES 1999-2002. Body composition included total lean mass and total fat mass; body mass index (BMI, kg/m²) was included for comparison. Associations of natural-log-transformed creatinine and cystatin C with body composition measures were evaluated using multivariable linear regression, stratified by age. Analyses were weighted to account for the NHANES design with multiple imputation for missing DXA data.

Results: Lean mass was associated with higher serum creatinine in in all age groups whereas higher fat mass was associated with higher creatinine in adults age 65+ (Table). Lean mass and fat mass were associated with higher serum cystatin C across all age groups; associations of lean mass with cystatin C were not significant with additional adjustment for fat mass.

Table: Association of body composition with serum creatinine and cystatin C by age group, NHANES 1999-2002

Conclusions: Fat mass and lean mass are differentially associated with creatinine and cystatin C in US adults. Findings in younger adults suggest that observed associations may reflect the impact of body composition rather than kidney function on serum marker. Further work is needed to determine how the observed associations are influenced by GFR and body composition simultaneously and the impact of fat and lean mass on CKD prevalence estimates.

Associations of the Levels of Kidney Function with Protein-Energy Wasting Syndrome Are Independent of Serum CRP and Bicarbonate

Xiaoxi Chen,1 G. Wei,2 Robert E. Boucher,1 Dominique Ferranti,1 Michel Chonchol,1 Kalani L. Raphael,1,2 Srinidhi Biju.1,2 1 U of Utah, VA SLC; 2 UC Denver.

Background: Inflammation and metabolic acidosis are putative causative factors of protein-energy wasting (PEW) in CKD. Therefore, we examined whether serum CRP and bicarbonate levels are independent associations with PEW in 11,834 adult (age > 20 yrs) participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: PEW syndrome was defined as the presence of at least one criterion in two out of three categories: serum chemistry (albumin < 3.25 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 20 kg/m² or unintentional wt loss > 10% over 1 yr), and muscle mass (body fat % < 10% or MAMC < 10% of 50th percentile of reference population). Using eGFR 60 to 89 ml/min/1.73 m² as the reference, the odds of PEW in ≥ 40, 45-49 and ≥ 45 ml/min/1.73 m² groups were examined in logistic regression models using svy suite in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. The prevalence of PEW syndrome had a U shaped association with the level of kidney function.

Table: PEW syndrome OR (95% CI)

Awareness and Perceived Risk of CKD Among African American Patients with CKD

L. Ebony Boulware,1 Patti Ephraim,2 Lisa A. Cooper,2 L. Ebony Boulware.2 Johns Hopkins Univ;2 Duke Univ.

Background: African Americans (AAs) are disproportionately affected by CKD with greater prevalence of advanced disease and poorer control of CKD risk factors. Patients’ awareness of CKD may facilitate engagement in self-management behaviors to modify CKD risks.

Methods: As part of a baseline assessment for a randomized controlled trial, we characterized CKD awareness and perceived risk of CKD among AAs with uncontrolled hypertension and CKD (eGFR 15-60 ml/min/1.73m2 or UACR≥30mg/g). We assessed patients’ self-reported CKD awareness (“Do you have a kidney problem or chronic kidney disease?”, yes or no) and degree of perceived likelihood (“How likely do you think it is that you could develop kidney problems or kidney failure in the next 10 years?”, not likely versus slightly, moderately, or very likely risk) and perceived concern of developing CKD (“How concerned are you about developing kidney problems in the next 10 years?”, very concerned to not concerned). We constructed multivariable models to assess patient characteristics independently associated with patients’ CKD awareness and perceived CKD risks.

Results: Among 52 AA patients with CKD, the mean age was 58 years, 67% were female, 67% had diabetes, 15% had coronary artery disease, 40% had eGFR<60 and 60% had albuminuria alone. The majority (n=37, 71%) of patients were not aware of their CKD. Among these, 27% (n=10) considered themselves unlikely to develop CKD and 19% (n=7) were not concerned about developing CKD. CKD awareness was greater among patients ≥ age 60 (vs. <60) [0.3 (0.1-0.8)] or with higher eGFR [0.96 (0.95-0.98), per ml/min/1.73m2] were less common [Odds Ratio (95% CI) in visits of patients ≥ age 60 (vs. <60) [0.3 (0.2-0.9)] or with higher eGFR [0.96 (0.92-1.0)]. PCPs discussed CKD in 47% of visits and discussions more frequently occurred among patients ≥ age 60 [0.1 (0.2-0.9)] or with higher eGFR [0.96 (0.92-1.0)]. Efforts to improve the occurrence of CKD discussions among patients ≥ age 60 and PCPs discussed CKD in fewer than half of routine primary care visits. Efforts to improve the occurrence of CKD discussions during routine primary care encounters are needed.

Primary Care Utilization Is Associated with Reduced Mortality Among Older Adults With CKD

Raquel C. Gregg,1 Hsien-Yen Chang,2 Gerard Fenton Anderson,1 Bernard G. Jaar,1 Craig Pollack,1 Nae-Yuh Wang,1 Lawrence J. Appel,1 L. Ebony Boulware.2 Johns Hopkins Univ;2 Duke Univ.

Background: Routine primary care visits provide opportunities to identify and manage patients’ CKD risk factors and to provide preventative care. It is unclear how primary care utilization impacts clinical outcomes among older adults with CKD.

Methods: We quantified the association between primary care utilization and ESRD incidence or mortality among older US adults with CKD (in 2005-2006) using Medicare claims. We assessed (in 2006) patients’ primary care utilization (no visit at least one, other care utilization [neurology care [no visit at least one], the total number of annual evaluation and management (E & M) visits with any type of provider), and patients’ comorbid conditions and sociodemographics. We used standard and usual care specific (accounting for competing risk of death) Cox proportional hazard models overall and stratified by age (65-74, 75-84, or ≥ 85 years) to estimate hazard ratios (HRs) for ESRD or mortality.

Results: Among 106,765 patients, most (79%) had at least one primary care visit in 2006, and 21% had at least one nephrology visit. The median number of ambulatory & EBM visits was 10. Compared to patients with no primary care visits, patients with at least one visit were younger [78 vs. 80 mean years, p<0.001], less likely African American [10 vs. 14%, p<0.001], and had a greater prevalence of diabetes (46 vs. 42%, p<0.001), hypertension (88 vs. 78%, p<0.001), or coronary artery disease (74 vs. 72%, p<0.001). Over 4 years of follow-up, 4,264 patients developed ESRD and 45,059 died. Primary care utilization was not associated with ESRD incidence. However, compared to patients with no primary care visits, patients with at least one visit had a lower risk of death [HR (95%CI): 0.73 (0.72-0.75)] overall and in age stratified models.

Conclusions: Primary care utilization was not associated with lower ESRD risk, but it was associated with a lower risk of death among older adults with CKD. Efforts to improve the engagement of primary care providers in the care of patients with CKD represent an important strategy to improve the health of this high risk population.

Routine Use of Health Care Among High-Risk African Americans at Risk of CKD

Clarissa Jonas Diamantidis,1 Anupan Anjany Bhavsar,2 Julia J. Schiaccia,1 Clementina A. Davenport,1 Rasheeda K. Hall,1 Crystal C. Tyson,1 Mario Sims,1 Tara Smith Strigo,1 Neil R. Powell,2 L. Ebony Boulware,2 Medicine, Duke Univ;4 Durham, NC; Medicine, Univ of California, San Francisco, CA; Medicine, Univ of Mississippi Medical Center, Jackson, MS.

Background: Engagement in routine health care (RHC) is a key strategy to decrease health inequalities among African Americans (AAs) at high risk of developing CKD or CKD complications. We examined demographic, attitudinal and socio-cultural factors associated with RHC among high-risk AAs at risk of CKD incidence or progression.

Methods: We quantified the prevalence of RHC (physical exam <1 year prior) use among AA Jackson Heart Study (JHS) baseline participants (from 2000-2004) with hypertension (HTN) or diabetes. We identified demographic, attitudinal (e.g., perceived discrimination, anger and hostility, stress, trust in health providers) and educational (i.e., CKD awareness) factors independently associated with RHC use. Those missing demographic or attitudinal data were excluded.

Results: Of 5301 JHS participants, 1152 met inclusion criteria. Most (n=909, 79%) reported RHC use. Rates of RHC were similar in those with and without CKD (22% vs. 23%). Participants not using RHC (vs. using) were more likely to be < 55 years of age (45% vs. 39%), male (43% vs. 39%), without HTN (9% vs. 5%), tobacco users (38% vs. 29%), and uninsured (14% vs. 9%), all p<0.05. In multivariable models, not using RHC was associated with age <55 (OR 1.75 [95% CI 1.25-2.5]), male sex (OR 1.55 [1.12-2.16]), Hispanic (OR 1.63 [1.12-2.34]), no HTN (OR 2.14 [1.34-3.41]), lower provider trust (OR 3.27 [1.61-6.65]) and less anger and hostility (OR 1.53, [1.1-2.1]).

Conclusions: Among high-risk AAs in the JHS, younger participants and males were less likely to use RHC. Those with low trust were also less likely to use RHC. Efforts to address health risks among high-risk AAs should target those using less RHC and consider attitudinal barriers to RHC.

Development of a Question Prompt Sheet for Patients with Chronic Kidney Disease

Swati Lodha,1 Michael J. Fischer,2 Howard S. Gordon,2 Anuradha Wadhwa,2 Subhash Popli,3 Elissa J. Gordon,2 Jesse Brown VAMC and Univ of Illinois, Chicago, IL;1 Hines VA Hospital, Hines, IL;2 Northwestern Univ, Chicago, IL.

Background: Patients with chronic kidney disease (CKD) commonly have unmet information needs. Greater patient participation in healthcare discussions can address these needs, and is associated with improved health outcomes. A question prompt sheet (QPS), a list of questions to prompt discussion, has been shown to increase patient participation in other disease discussions; however, no QPS has been developed for CKD patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

787A
Methods: We conducted a 2-phase cross-sectional study involving semi-structured telephone interviews to assess CKD-QPS targeted to patients with moderate CKD. Patients with an estimated glomerular filtration rate <60ml/min/1.73m², on dialysis, or with a transplant were recruited from a single VA nephrology clinic. Phase 1 interviews included 17 open-ended questions assessing patients' CKD information needs. Responses were quality-assured and translated to an initial 67-items QPS. Phase 2 participants reviewed a pre-nulled QPS to rate the importance of asking each question on a 5-point Likert scale, provide open-ended feedback, and rate their willingness to use a CKD-QPS. Question item responses were analyzed to refine and reduce QPS questions.

Conclusion: Patients have unmet information needs and wish to use a CKD-QPS. Further research is needed to assess whether our CKD-QPS effectively addresses patients' information needs, enhances doctor-patient communication, and improves health outcomes.

Medication Burden and Safety in Veterans with Chronic Kidney Disease

Swati Ledeer,1,2 Michael J. Fischer,3 Zhiping Huo,2 Katie Suda,2 Kevin Stroup.2 1Jesse Brown VAMC and Univ of Illinois Hospital, Chicago, IL; 2Hines VA Hospital, Hines, IL.

Background: Veterans are at exceptionally high risk for chronic kidney disease (CKD) and other chronic health conditions. Pharmacologic treatments are a core aspect of CKD disease management. We characterized medication burden and safety and their relationship to CKD severity among elderly Veterans.

Methods: Using national VA databases, we included all female and a random 10% sample of male VA healthcare users who were >65 years old. We characterized the average number of medications, frequency of contraindicated medications, and occurrence of concern drug-drug interactions. CKD was defined by estimated glomerular filtration rate (eGFR) in 2008 and classified according to conventional eGFR-based severity groups. A non-CKD comparison was used (eGFR >60 ml/min/1.73m²).

Results: Among a final cohort of 96,317 Veterans, 47% had CKD (mean age=79.8, male=81%, non-black=93%, hypertension=90%, diabetes=33%). Mean medications increased with CKD severity: 8.5(eGFR >60), 9.6 (eGFR 30-59.9), 11.7 (eGFR15-29), 12.5 (eGFR <15). After adjusting for demographic characteristics, CKD stage 3, 4, and 5 took 1.3, 3, and 3.6 more medications, respectively, compared to the non-CKD group (p-value<0.0001).

Conclusions: Considerations were often prescribed to patients with an eGFR<60ml/min/1.73m² and included bisphosphonates (5%) and nonsteroidal anti-inflammatory drugs (4%). Concerning drug-drug interactions with an eGFR<60ml/min/1.73m² included: sedatives-opioids (3.8%), ace inhibitor-angiotensin receptor blocker (3.4%), and statins/hitraminotensin receptor blocker (1.6%).

SA-PO701

I illicit Drug Use and Chronic Kidney Disease in an Urban Population

Tessa Kimberly Novick,1 Anika Alvanza,1 Yang Liu,1 Brian A. Zonderman,2 Deidra C. Crews.1 1Johns Hopkins Univ, Baltimore, MD; 2National Inst on Aging, NIH, Baltimore, MD.

Background: Opioid and cocaine use have been associated with risk of ESRD in retrospective studies, however, the association of illicit drug use with chronic kidney disease (CKD) has not been well-examined in prospective studies. Our objective was to determine the association of illicit drug use with reduced kidney function, albuminuria and early kidney function decline (KFD) among a cohort of urban-dwelling adults.

Methods: Our study included 2,286 Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study participants who are community-dwelling African American and white adults from 12 neighborhoods in Baltimore MD. We used logistic regression to examine whether opioid or cocaine use (defined as ≥ 2 lifetime uses of either drug) was associated with baseline reduced eGFR (<60 ml/min/1.73m²) by CKD-EPI, baseline albuminuria (albumin-to-creatinine ratio >30mg/g) or rapid KFD (eGFR decline of ≥5% per year over a median of 4.7 years of follow up).

Results: Participants' mean age was 48 years, 57% were African American, 15% reported opioid use, and 22% reported cocaine use. Those reporting illicit drug use (opiod or cocaine) were more likely to be male, African American, living in poverty and/or uninsured, and to have a personal history of drug use, problem drinking, and hepatitis C. In adjusted models, illicit drug use was associated with baseline reduced eGFR (<60 ml/min/1.73m²) by CKD-EPI, baseline albuminuria (albumin-to-creatinine ratio >30mg/g) and rapid KFD (eGFR decline of ≥5% per year over a median of 4.7 years of follow up).

Conclusions: Illicit drug use was associated with prevalent reduced eGFR and albuminuria, but not rapid KFD. Illicit drug use may be an important risk factor for CKD in urban populations.

A Tailored, Interactive Mobile Health Communication Application for Patients with Chronic Kidney Disease: Development and Feasibility Assessment

Yali Cao,1 Nephrology, China-Japan Friendship Hospital, Beijing, China.

Background: Chronic kidney disease (CKD) is an increasingly common chronic condition whose prognosis can be improved by patient involvement and self-management. Patient involvement can be fostered by web-based Interactive Mobile Health Communication Applications (IMHCAs) combining health information with decision support, social support and/or behavior change support. Tailoring content and tone of IMHCAs to the individual patient’s needs might improve their effectiveness.

Methods: A tailored, IMHCAs was developed by collaborative profession (nephrologist, nurse, research fellow, web developer). The effectiveness and usage of the tailored IMHCA was tested against the control arm without access to this IMHA in a small-scale single-blinded randomized trial. The content covers information on CKD, its complications and sequelae, and its treatment options including health behavior and dietary guidance. In the intervention group the content is delivered in dialogue format, tailored to relevant patient characteristics (the stage of CKD and the Etiology). Eighty patients (40 patients at each arm) with stage 3-5 CKD were enrolled in the study. The data were collected directly after the first visit, and at 3-month follow-up.

Results: There were no difference between the two groups as to the age, gender, CKD stage and blood pressure. Three months after system use, participants using the tailored system displayed significantly more knowledge (P=0.001), better blood pressure compliance rate (P=0.02) and improved dietary behavior, mainly regarding low protein and enough calories (P=0.003).

Conclusions: This is the first tailored IMHCAs in China. Our data demonstrated that implementation of IMHCAs into standard practice is feasible. Suggested developments will augment reported strengths to inform ongoing testing in the wider China network of units.

Evaluation of Clinical Pharmacy Services in the Management of Kidney Disease

Caralatha K. Yon,1 Chai L. Low,2 Pharmacy, Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Chronic kidney disease (CKD) and end stage renal disease (ESRD) place a significant burden on healthcare systems and is the focus of national health initiatives. Management of CKD requires a multidisciplinary approach to maximize outcomes. Studies support the impact of clinical pharmacists (CP) in medication management, but studies demonstrating the significance of a CP as part of a multidisciplinary approach to management of AKI and CKD/ESRD are lacking. This study evaluates the effectiveness of pharmacy services in the setting of a multidisciplinary approach to the management of AKI and CKD/ESRD.

Methods: Interventions by a CP in the inpatient setting were collected from 12/1/2010 to 11/1/2011 as part of Nephrol Consults. Interventions were categorized as: drug interaction, dose/frequency adjustment, untreated diagnosis, adverse reactions, duplication of therapy, and other. Cost avoidance from these interventions were calculated. Outpatient pharmacy patient encounters were monitored from 1/1/2008 to 12/31/2014 as patient visits or interventions in hemodialysis (HD), peritoneal dialysis (PD), erythropoietin stimulating agent (ESA) clinic, and renal access clinic. CPs were involved in the management of anemia, hyperparathyroidism, mineral bone disease, transplant, dialysis related infections, pharmacokinetic drug monitoring, medication reconciliation and patient counseling.

Results: Most of the 440 interventional interventions were dose adjustments for renal function and medication therapy for untreated diagnoses during AKI. Inpatient interventions by a CP resulted in $706,911 in cost avoidance. HD and PD encounters by a CP increased from 241 in 2008 to over 1,400 since 2011. Patient visits in the ESA/anaemia clinic increased from 185 in 2008 to near 300 in 2014. Encounters in the renal access clinic increased from 19 in 2008 to near 300 in 2014.

Conclusions: The expansion of pharmacy services in nephrology at Veterans Affairs San Diego Healthcare System has resulted in the improvement in the quality of care provided to patients with AKI, CKD or ESRD with significant cost avoidance. Clinical pharmacists play a significant role in the multidisciplinary approach to the management of CKD/ESRD.
SA-PO704
Views and Practice Patterns of Dialysis Medical Directors Towards End-of-Life Decision Making for Patients with End-Stage Renal Disease
Enrica Fung,1 Nathan Samuel Slesnick,2 Manjula Kurella Tamura,1,13 Brigitte Schiller.1 1Stanford Univ, Palo Alto, CA; 2Satellite Healthcare, San Jose, CA; 1Geriatric Research and Education Clinical Center, Veterans Affairs, Palo Alto, CA.

Background: Nephrologists frequently engage in end-of-life decision making for patients with end-stage renal disease (ESRD). Patients with ESRD report infrequent end-of-life discussions and nephrology trainees report feeling unprepared for end-of-life decision making, but the views of dialysis medical directors have not been studied. Our objective is to understand dialysis medical directors’ views and practice patterns on end-of-life decision making for patients with ESRD.

Methods: We administered questionnaires to dialysis medical directors during medical director meetings of three different dialysis organizations in 2013. Survey questions corresponded to recommendations from the Renal Physicians Association clinical practice guidelines on initiation and withdrawal of dialysis.

Results: There were 121 medical director respondents from 28 states. The majority of respondents felt “very prepared” (66%) or “somewhat prepared” (29%) to participate in end-of-life decisions and most (80%) endorsed a model of shared decision-making. If asked to do so, 70% of the respondents provided prognostic information “often” or “nearly always”. For patients with a poor prognosis, 36% of respondents would offer a time-limited trial of dialysis “often” or “nearly always”, while 56% of respondents would suggest withdrawal from dialysis “often” or “nearly always” for those with a poor prognosis currently receiving dialysis therapy. Patient resistance and fear of taking away hope were the most commonly cited barriers to end-of-life discussions.

Conclusions: Views and reported practice patterns of medical directors are consistent with clinical practice guidelines for end-of-life decision making for patients with ESRD but inconsistent with patient perceptions.

SA-PO706
Impact of Evidence-Based Clinical Care on Major Adverse Clinical Events in Patients with Clinically Significant Proteinuria: A Population-Based Retrospective Cohort Study
Julius Oluoch Okel1, Bilal Qarni,1 Timothy Olugegun Olarewaju,2 Aminu K. Bello.1 1Univ of Alberta; 2Univ of Ilorin, Nigeria.

Background: Proteinuria is an important prognostic marker for cardiovascular (CV) and renal events. Most studies of quality of care (QoC) in chronic kidney disease (CKD) have evaluated other markers for risk stratification and outcomes. We hypothesized that in proteinuric CKD, markers of good quality care will be associated with lower risk of adverse clinical outcomes (all-cause mortality, all-cause hospitalization, CV and renal outcomes).

Methods: We used a population-based cohort of patients with significant proteinuria (albumin/creatinine ratio (ACR) ≥60 mg/mmol, protein/creatinine ratio ≤100 mg/mmol or protein ≥3 on dipstick) to evaluate current patterns of evidence-based care and association with outcomes. Markers of good quality care were defined as nephrology referral, relevant laboratory testing and appropriate medication use (ACEI/ARBs; statins).

Results: Of the 71, 660 with at least 1 or 2 proteinuria measurements, 16,204 (22.6%) had significant proteinuria. At follow-up, receipt of good quality care (1) timely referral, 2)HbA1c testing, 3)use of ACEI/ARBs and 4) use of statins) was associated with reduced risk of mortality: 0.67 (0.59-0.75), 0.52 (0.46-0.59), 0.68 (0.60-0.74), and 0.63 (0.57-0.69), and all-cause hospitalization: 0.85 (0.69-0.93), 0.65 (0.59-0.72), 0.93 (0.87-0.99), and 0.82 (0.77-0.88) respectively. There were no statistically significant associations with the risk of CV and renal events.

Conclusions: This study examined the link between evidence-based treatment and clinical outcomes in an especially high-risk population with CKD. Good quality care impacts mortality risk and hospitalization rates and reduced risk of hospitalization. The impact of QoC on renal and cardiovascular events is less clear. The findings would justify future interventions to increase uptake of such treatments in patients with proteinuric CKD.

SA-PO707
APOL1 Risk Alleles and Risks of Cardiovascular Disease in Children with Focal Segmental Glomerulosclerosis (FSGS) Robert Woroniecki,1 Derek Ng,2 Sophie Limou,3 Cheryl Ann Winkler,4 Kimberly J. Reidy,3 Mark Mitsnefes,4 Craig S. Wong,2 Bradley Warady,5 Susan L. Furst,3 Jeffrey B. Kopp,3 Frederick J. Kaskel.1 1Stony Brook Children’s Hospital, Stony Brook, NY; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, NY; 3NCI NIH, FNL, Frederick, MD; 4instein/Children’s Hospital at Montefiore, Bronx, NY; 5Cincinnati Children’s Hospital, Cincinnati, OH; 6Univ of New Mexico, Albuquerque, NM; 7Children’s Mercy Hospital, Kansas City, MO; 8Univ of Pennsylvania, Philadelphia, PA; 9NIDDK, NIH, Bethesda, MD.

Background: APOL1 renal risk alleles are a major cause of glomerular disease in African Americans (AA). It is controversial as to whether individuals with high risk (HR) APOL1 genotypes (2 risk alleles) are at risk for atherosclerotic heart disease, and association with left ventricular hypertrophy (LVH) has not been explored. It is unclear whether children with focal segmental glomerulosclerosis (FSGS) and HR APOL1 are at increased cardiovascular risk.

Methods: Self-identified AA children with FSGS in CKID study cohort were genotyped for APOL1 renal risk variants: G1 (rs73885315, S342G) and G2 (rs71785313, Y388E-389 deletion), and compared to non-AA children with FSGS, none with HR.

Results: Of the 71, 660 with at least 1 or 2 proteinuria measurements, 16,204 (22.6%) had significant proteinuria. At follow-up, receipt of good quality care (1) timely referral, 2)HbA1c testing, 3)use of ACEI/ARBs and 4) use of statins) was associated with reduced risk of mortality: 0.67 (0.59-0.75), 0.52 (0.46-0.59), 0.68 (0.60-0.74), and 0.63 (0.57-0.69), and all-cause hospitalization: 0.85 (0.69-0.93), 0.65 (0.59-0.72), 0.93 (0.87-0.99), and 0.82 (0.77-0.88) respectively. There were no statistically significant associations with the risk of CV and renal events.

Conclusions: This study examined the link between evidence-based treatment and clinical outcomes in an especially high-risk population with CKD. Good quality care impacts mortality risk and hospitalization rates and reduced risk of hospitalization. The impact of QoC on renal and cardiovascular events is less clear. The findings would justify future interventions to increase uptake of such treatments in patients with proteinuric CKD.

SA-PO708
Trends in Burden of Out-of-Pocket Expenses in United States Adults with Kidney Disease from 2002-2011 Mukeoso N. Ozigi1, Kinfe Gebreziabher Bishu2, Clara E. Dismuke2, Leonard Egged.2 1Nephrology, MUSC; 2Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.

Background: High out-of-pocket (OOP) burden negatively impacts healthcare access and outcomes. Studies examining high OOP burden in the general population exists however no studies has examined OOP healthcare burden in people with kidney disease (KD). This study examined trends in high OOP healthcare in people with KD while concurrently evaluating the impact of insurance status and income category on high OOP burden.

Methods: We analyzed 2,966 adults aged 18-64 years with kidney disease using the Medical Expenditure Panel Survey-MEPS. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and.

The top 5% of patients accounted for 80.4% of ED visits, and 7 patients utilized the ED over 100 times in their first ESRD year. Nearly half (46%) of ED visits were coded as a Severity Level 5, with 9.6% coded as Critical Care emergencies. 15.4% of ESRD patients over 100 times in their first ESRD year. Nearly half (46.0%) of ED visits were coded as a Severity Level 5, with 9.6% coded as Critical Care emergencies. 15.4% of ESRD patients over 100 times in their first ESRD year.
- other diseases of kidney and ureters. OOP burden was calculated by dividing total family OOP spending by the family's self-reported pretax income for that year. A person with KD is considered to have high OOP burden if the family total OOP spending on healthcare exceeds 10% of the family income. We used t-test to examine the mean changes from the bench mark year (2002/2003) to the subsequent time periods. The proportion of people with high OOP fell by 10 percentage points from 2002/2003 to 2010/2010. The proportion of poor/near poor people and uninsured with high OOP was as high as 52% and 30% respectively in 2002/2003 but fell to about 25% and 27% respectively in 2010/2011.

Conclusions: Trends in high OOP burden in people with KD has decreased over time however people with kidney disease in the US still experience high OOP burden. Policies to reduce high OOP in people with KD could significantly impact KD outcomes.

**SA-PO709**

**Health Disparities and Increased Risk of Developing End Stage Renal Disease in Patients with Chronic Kidney Disease**

Alejandro Perez, Ritika Sharma, Candace D. Grant, Ronak Patel, Monika Wadhwani, Vladimir Liberman, Shanza Mujeeb, Sairah Sharif, Shayan Shirazian, Nobuyuki (Bill) Miyawaki, Joseph Mattana. Medicine, Winthrop-Univ Hospital, Mineola, NY.

Background: Health disparities occur in groups of people that experience suboptimal health care based on their social, economic, and/or environmental disadvantage. Identifying how these disparities affect the risk of chronic kidney disease (CKD) progression to end stage renal disease (ESRD) can hopefully lead to a reduction in these health inequities and improve clinical outcomes for all CKD patients. We examined health disparities and the risk of ESRD using patient-specific and community-specific variables.

Methods: We studied a cross-section of 623 patients with stage 3 and 4 CKD and estimated their 2- and 5-year risk of ESRD using the method of Tangri et al. (JAMA 2011; 305:1553–1559). The U.S. Census Bureau Community Survey was used to obtain patient zip code-specific data including percent foreign born, percent below the poverty level, median household income, and percentage graduating high school. We did a multivariable generalized linear analysis on the outcome variables of the 2 and 5 year risk of ESRD.

Results: Lower household income was associated with a higher risk of ESRD at 2 and 5 years (p=0.05). There was a trend towards a higher risk of ESRD amongst patients from zip codes with higher poverty rates and lower education levels. Being single, including by divorce and separation but not by being widowed, was associated with a significantly higher risk of ESRD. We also found that patients on Medicaid and patients with private insurance or self pay had a significantly higher risk of ESRD compared to those on Medicare.

Conclusions: Our findings suggest that there are substantial health disparities related to CKD and the risk of ESRD. Some of these disparities are patient-specific but others appear to be related to the community where they reside. This suggests that evaluation of patient-specific as well as community-specific variables might help to better individualize CKD care and improve our ability to identify and treat the patient at increased risk of developing ESRD.

**SA-PO710**

**Impact of Timely AV Fistula Placement on Resource Utilization After Initiation of Dialysis**

Edwin J. Anand,1 Kabir Jalal,1 Laura L. Argauer,1 Brian M. Murray,1 Pradeep Arora,1 Rocco C. Venuto,1 Medicine, SUNY at Buffalo, Buffalo, NY; 2Computer Task Group, Buffalo, NY; 3Epidemiology, SUNY at Buffalo, Buffalo, NY; 4Medicine, VA Medical Center, Buffalo, NY.

Background: Maintenance dialysis is ideally initiated in the outpatient setting with a fistula. However, up to 40% of dialysis initiated at the hospital. AAV fistula placement greater than 90 days prior to starting dialysis was associated with an increased risk of hospitalization and mortality. Patients with AV fistula placed within 28 days of hospital admission had a 45% lower risk of death compared to those with AV fistula placed after 30 days of hospital admission. We postulate that timely access creation should reduce hospitalization and costs.

Methods: In a retrospective study of adult patients starting HD at the university hospital and 3 VA hospitals, we identified patients who initiated HD within 30 days of discharge for any reason. We calculated the proportion of patients with timely fistula placement and compared resource utilization in the 12 months following dialysis initiation between patients who started dialysis in an inpatient setting versus sub-optimally.

Results: 422 patients were started on dialysis in the above period. 257 patients (61%) had a crash start of dialysis. 86 patients (20%) had a fistula prior to dialysis. Compared to patients who did not crash, patients who crashed were older (p <0.0001), had a higher hospitalization rate in the one year period (p=0.0089). Multivariate analysis confirmed that patients who crashed had a significantly higher hospitalization rate in the one year following dialysis (p=0.0067). Patients with a fistula in place prior to dialysis experienced fewer hospitalizations (p=0.0377). Cost in the first year was also higher in patients who had a ‘crash’ without a fistula (p=0.0181). The cost advantage of having a fistula decreased with increasing age (p=0.0462).

Conclusions: Dialysis ‘crash’ results in increased morbidity and resource utilization. Coordination of care and timely access creation should reduce hospitalization and costs.
Conclusions: Our study showed effectiveness of targeted interactive workshops to improve the recognition of CKD and its complications. Intelectualizing the taught concepts by residents did not translate to improved patient care. Declining retention of core concepts at 12-week testing indicates the need for ongoing reinforcement sessions. Continued education including online resources utilization is warranted to be opposed to annual core-lectures provided by most training programs.

SA-PO713
Evaluating Progress of Healthy People 2020 Chronic Kidney Disease Objectives: Are We There Yet? Asel Ryskulova,1 Lawrence Agodoo,2 Paul W. Eggers,2 Kevin C. Abbott.1 1NCHS, CDC, 2NIDDK, NIH.

Background: Chronic Kidney Disease (CKD) is a significant public health problem in the U.S. and a major source of disability, poor quality of life, and premature death for those afflicted. CKD and End-Stage Renal Disease (ESRD), the final stage of the CKD, exact a high economic price. In 2012 ESRD costs exceeded $49 billion dollars including 34 billion (about 20%) of total Medicare expenditures. An estimated 11.5% of adults ages 20 or older had physiological evidence of CKD determined from data collected through the 2001-06 National Health and Nutrition Examination Survey (NHANES). Each year in the United States, more than 115,000 people are diagnosed with ESRD.

Methods: Reflecting the importance of CKD, 24 CKD objectives were included in the Healthy People 2020 (HP2020) national health goals to reduce new cases of CKD and related complications, disability, death, and economic costs. CKD objectives are focused on improving cardiovascular care in patients with CKD; increasing the proportion of patients with CKD and diabetes who received recommended evaluation and treatment; reducing death rate and percentage of U.S. population with CKD; and increasing CKD awareness in persons with impaired renal function. All CKD objectives are measurable, having at least one data point from national data systems including the NHANES, National Death Index, and U.S. Renal Data System.

Results: In 2015, 14 objectives had met their target (n=9) or showed improvement (n=5). Six objectives showed little or no significant change. Two objectives: increase the proportion of persons with diabetes and CKD who received recommended medical treatment with angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, and increase the proportion of patients receiving a kidney transplant within 3 years of ESRD, moved away from the target. The remaining 2 objectives were not evaluated as they were informational with no target set. Disparities persisted by sex, race/ethnicity, and SES status.

Conclusions: The presentation will cover the most recent national and state data for selected CKD objectives and provide an overview of the HP2020 and data search using the HP2020 website.

SA-PO714
Telenephrology for the Remote Management of Chronic Kidney Disease (CKD): A Retrospective Cohort Study Rajeev Rohatgi,1 Judy K. Tan,2 Anita Mehrotra,3 Medicine, James J. Peters VAMC, Bronx, NY; 1Medicine, Icahn School of Medicine, New York, NY.

Background: Veterans with CKD who live in the Hudson Valley Veterans Affairs Medical Center (HVVAMC) catchment area travel to the Bronx VAMC for nephrology care. Analysis of the no-show and cancellation frequencies for these renal appointments was driven by a greater frequency of cancelled visits in the Bronx VA (27.9%) vs. appointments was greater in the telenephrology (70.8%) vs. Bronx VA cohort (61.8%). In-person renal care. In a retrospective observational study, the clinical outcomes of CKD patients visit their local VA and are evaluated remotely via videoconference by a Bronx VA nephrologist, would exhibit comparable clinical outcomes and visit compliance as in-person renal care. In a retrospective observational study, the clinical outcomes of CKD patients enrolled in telenephrology (n=117) and the Bronx VA nephrology clinic (n=121) from 2008-14 were compared.

Results: Characteristics of the groups were similar (initial creatinine [Cr], eGFR, distribution of CKD stage, urine protein) except for race and probable cause of CKD. Prior to the telenephrology service, 53.1% of scheduled visits of HVV AMC patients to the Bronx VA cohort were either cancelled or “no-shows” and this was reduced to nearly half (29.2%) after instituting telenephrology (p<0.001). Moreover, the frequency of attending appointments was greater in the telenephrology (70.8%) vs. Bronx VA cohort (61.8%) which was driven by a greater frequency of cancelled visits in the Bronx VA (27.9%) vs. the telenephrology group (15.8%). The incidence of a composite outcome of doubling of Cr, ESRD and/or death was similar between both groups (Figure 1). The change in blood pressure and eGFR from baseline to 1 year was also similar.

Conclusions: Telenephrology is not inferior to in-person care for the management of CKD and may be superior for visit compliance. Application of this technology is a promising method to deliver care to CKD patients.

SA-PO715
Engaging Urban African Americans at Risk for CKD in Discussions About Their Diet Deidra C. Cressey,1 Debra L. Roter,1 Raquel C. Greer,1 Yang Liu,1 Patti Ephraim,1 Jessica M. Ameling,1 Kimberly Gadzune,1 Lisa A. Cooper,1 L Ebony Boulware.2,1 Johns Hopkins U., Baltimore, MD; 1Duke U., Durham, NC.

Background: Patient-physician discussions about diet are recommended in primary care to decrease patients’ health risks, including CKD. However, little is known about the frequency of diet discussions or factors influencing them among African Americans (AAs) at increased CKD risk.

Methods: In a randomized trial of urban AAs with uncontrolled hypertension, we audio-recorded patients’ routine visits with their primary care physicians (PCPs) at the first visit following enrollment. We transcribed audio recordings, and quantified the frequency of patient-physician discussions about diet during visits. We marked transcripts for discussions of dietary terms (e.g. sodium, weight, sweets). We also assessed patterns of physician-physician communication, including patient centeredness (degree to which the discussion focused on the patient’s psychosocial and lifestyle context), during each encounter using the Roter Interaction Analysis System. We identified factors independently associated with discussions of diet using logistic regression.

Results: Among 127 participants, mean age was 58 years and 70% were female. Average PCP visit lasted 25 minutes. Diet was discussed in 73% of visits, but only included discussion of the Dietary Approaches to Stop Hypertension (DASH) diet in 12%, weight/obesity in 36%, and cholesterol in 39% of visits. Independent predictors of diet discussions (odds ratio, 95% confidence interval) were patient centeredness score ratio (7.5, 1.3-41.9), annual income (3.8, 1.4-10.5) comparing ≤10k vs <10k), and visit length (1.07, 1.02-1.1 for each minute increment). Patient age, gender, literacy, comorbid disease burden, obesity, diabetes nor CKD status predicted discussions.

Conclusions: Discussions of diet in primary care were frequent, and they were more likely to occur when visits were longer, were centered on patient priorities, and were attended by patients with incomes ≤10k. Diet discussions focused on various topics, but infrequently on the recommended DASH diet or other key aspects of dietary modification. Improvements in the content of diet discussions among African Americans at risk for CKD may be needed.

SA-PO716

Background: The Miami VA Healthcare System serves veterans in three South Florida counties: Miami-Dade, Broward and Monroe, with an estimated veteran population of 175,000. To overcome geographical barriers and facilitate the access to nephrology evaluations, we implemented Provider-Patient Tele-Nephrology using secured videoconferencing.

Methods: A retrospective and descriptive study design was used to evaluate the effect of the Tele-Nephrology clinic intervention. Multiple clinical indicators were included in the analysis: blood pressure control, stabilization of the renal function and electrolyte/metabolic control. 101 patients that were evaluated in the clinic between 2013-2015 were included and the indicators were collected retrospectively.

Results: 101 patients were included, 95.5% male (n=96) and 5% female (n=5). The mean age was 65.9 years, 50 patients had Chronic Kidney Disease (CKD) stage III (59.5%), 14 patients had CKD stage IV (13.9%), 8 patients had CKD stage V (7.9%). A one-way analysis of variance analysis (ANOVA) between subjects was conducted and showed that the effect

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
The potassium showed a significant improvement in this sample (P-value: 0.0076). Phosphorous and bicarbonate did not show a statistically significant improvement (P-value 0.79 and 0.91).

Conclusions: With the tele-nephrology clinic intervention we were able to effectively improve blood pressure and stabilize renal function in patients with kidney disease who reside in underserved areas.

SA-PO717
Impact of Exercise Counseling on Physical Function in Chronic Kidney Disease
Clara Bohm,1 Mara McAdams-DeMarco,2 Navdeep Tangri,1 Brett M. Hiebert,1 Leroy J. Storsley,1 Lawrence J. Cheskin,3 Claudio Rigatto.1 (Univ of Manitoba; 1Johs Hopkins Univ.

Background: Few studies have investigated the effect of exercise counseling on physical function (PF) in chronic kidney disease (CKD). Using retrospective, quasi-experimental pretest-posttest non-equivalent control group design, this study investigated the effect of attending a real-world exercise counseling clinic (ECC) on PF in individuals with CKD.

Methods: Individuals with any stage of CKD registered with the Manitoba Renal Program from Jan. 1, 2011 to Dec 1, 2014 were eligible for inclusion. The exposed group (EC) included individuals who attended ECC. The control group (CG) included individuals who did not attend ECC, but participated in an observational frailty study. Primary Outcome: Change in Short Physical Performance Battery score (SPPB) at 1 year. Ranging from 0-12, lower SPPB represents worse PF. Secondary Outcomes: Change in health-related quality of life (HRQOL) at 1 year using EQ5D-3L. Change in physical activity (PA) at 1 year using HAP and PASE. Analysis: Mann Whitney U, Independent T and Chi-square tests used for group comparisons.

Results: Of 194 individuals in EC and 216 in CG eligible for 1-year follow-up, 73 (37%) in EC and 72 (33%) in CG were assessed. At baseline, mean age was lower in EC (60 years) as compared to CG (68 years); p=0.01. Median SPPB scores at baseline and follow-up were significantly different between groups, but change in SPPB over time was not.

Subgroup analysis of individuals with eGFR < 30 ml/min or on dialysis reduced the differences in age and SPPB between groups, but demonstrated no significant difference to change in SPPB over time. HRQOL did not change significantly between groups. Proportion of individuals with improved PA over 1-year was 36% and 38% in EC and CG, respectively (p=0.82).

Conclusions: In this study, an exercise counseling clinic had no significant effect physical function as measured by SPPB at 1-year, suggesting that exercise counseling alone is inadequate to improve physical function in CKD.

SA-PO718
Ideal and Actual Support of Renal Replacement Therapy Modality Selection Patients with Chronic Kidney Disease: A Nationwide Survey in Japan
Shiho Kosaka,1 Shinichi Nishi,2 Yugo Shibagaki,3 Junichi Hoshino,4 Kazuo Takahashi,5 Yukiko Katagiri,6 Chika Murayama,1 Yuka Funakia.1 (1Sophia Univ; Tokyo, Japan; 2Kobe Univ Graduate School of Medicine, Kobe, Japan; 3St. Marianna Univ Hospital, Kawasaki, Japan; 4Toranomon Hospital, Tokyo, Japan; 5Fujita Health Univ School of Medicine, Toyoake, Japan.

Background: Optimal renal replacement therapy (RRT) selection supports for chronic kidney disease (CKD) patients are essential to improve post-therapy outcomes. We aimed to investigate how and when modality selection supports for patients with CKD are used by nephrologists in Japan, through a nationwide questionnaire survey of nephrologists.

Methods: A questionnaire was mailed to 1903 board-certified nephrologists of Japanese Society of Nephrology. Questionnaireitems targeting support for modality selection examined the following points: establishment of an RRT modality selection (RRT-MS) clinic, ideal and actual disease stage at which RRT-MS explanation is discussed, timing of RRT initiation, and type of specialist discussing RRT-MS with patients.

Results: The valid response rate was 12.3% (234/1903). Ninety-four out of 234 responding nephrologists (40.9%) had clinics dedicated to RRT-MS. Modality selection was most frequently discussed at CKD stage 4 (55.0%), stage 3b (22.8%), and stage 3a (13.4%). Nephrologists considered stage 3b (32.5%), stage 3a (19.5%), most ideal for discussing RRT-MS; a significant difference was therefore found between ideal and actual timing of RRT-MS discussion. Timing (by eGFR) of access placement of hemodialysis (HD) and peritoneal dialysis (PD) was significantly earlier in patients of RRT-MS clinics than in those of conventional clinics (HD, 12.3/14.1; PD, 12.6/14.9 ml/min/1.73 m²). Regarding types of specialists, nurses most frequently supported patients in RRT-MS (67.1%), however, this may be partly explained by the fact that nephrologists are required to commit more specialists to supporting patients for RRT-MS.

Conclusions: A gap between ideal and actual timing of discussion of RRT-MS with patients in Japan was identified. To promote appropriate timing of RRT-MS among CKD patients, early and multidisciplinary support systems should be structured.

SA-PO719
Primary Care Physicians’ Perceived Barriers and Facilitators to Care of Older Adults with Kidney Failure Not on Dialysis
Helen Tam-Tham, Brenda Hemmelgarn, Chandra Mary Thomas, Karen Fruetel, Robert R. Quinn, Kathryn M. King-Shier. (Univ of Calgary, AB, Canada.

Background: Primary care physicians are important care providers for older adults with kidney failure, but how they perceive and practice conservative (non-dialysis) care has not been studied. We undertook a qualitative study to describe barriers, facilitators, and possible enhancements of conservative care in the community for these older adults.

Methods: Semi-structured telephone interviews were conducted with primary care physicians from southern Alberta, Canada. Participants were identified by a snowball sampling strategy and purposively sampled based on sex, age, and rural/urban location of clinical practice. All participants managed at least 1 patient ≥75 years with kidney failure (eGFR <15 ml/min/1.73m² for at least 3 months, not on dialysis) over the past year. Transcripts were analyzed thematically by conventional content analysis.

Results: Twenty-seven primary care physicians participated in this study (55.6% of participants were male, 55.6% of participants were aged 40 to 60 years, and 51.9% of participants practiced in the primary care setting for greater than 20 years). Perceived barriers to conservative care included: managing expectations of kidney failure for patients and their families, optimizing management of conservative care, and negotiating provider roles and responsibilities of co-management. Facilitators for care included: establishing patient and their family’s expectations of care early, preserving continuity of care, and utilizing a multidisciplinary team approach. Primary care physicians also identified suggestions for enhancement of conservative care in the community, including direct telephone access by primary care physicians to conservative care clinicians, treatment decision aids for patients and their families, and a conservative care clinical pathway for primary care providers.

Conclusions: We found important barriers and facilitators to conservative care by primary care physicians in the community. Further investigation of potential strategies that remove barriers and enable facilitators is required to improve the quality of conservative care in the community.

Asking Patients If They Are Aware of Their Chronic Kidney Disease: Does the Question Matter? Delphine S. Tiou, Yunnuo Zhu, Alexandra Velasquez, Juan Maciel Espinoza, Celia Mendez, Tanushree Banerjee, Chi-yuan Hsu, Neil R. Powe. Univ of California San Francisco.

Background: Awareness of chronic kidney disease (CKD) is low, even among patients with advanced disease. Increasing awareness to 11.7% is a Healthy People 2020 goal. The National Health and Nutrition Examination Survey (NHANES) measures CKD awareness using the question “Have you ever been told by a doctor or other health professional that you had weak or failing kidneys (excluding kidney stones, bladder infections, or incontinence)?” The framing of this question may influence responses. We sought to compare its sensitivity/ specificity to different questions as well as to awareness of other chronic conditions.

Methods: We administered a questionnaire to 220 English, Spanish and Cantonese-speaking adults who received primary care in a public healthcare delivery system. We obtained demographic data, screened for health literacy and ascertained patient awareness about chronic health conditions, including CKD, diabetes, hypertension and hyperlipidemia. CKD awareness was measured using the NHANES question and additional ones, asking if patients had been told about “kidney disease”, “protein in the urine”, “kidney damage”, or “kidney disease”. Health conditions were verified by medical record review.

Results: In our diverse study population (9.6% White, 40.5% Black, 36.4% Hispanic, 12.0% Asian), mean age was 58, mean eGFR was 47 ml/min/1.73m² and 47% had low health literacy. Sensitivities of each CKD awareness question were: 26.7% for “kidney damage”, 28.0% for “kidney disease”, 33.5% weak or failing kidneys (NAHNES), 36.2% for “protein in the urine” and 40.6% for “kidney problem”. Specificities ranged from 88.2% to 97.9%. Combining all 5 questions yielded a sensitivity of 61.1% and a specificity of 79.6%. This was comparable to awareness of hyperlipidemia (68.8%) but was lower than awareness for hypertension and diabetes (89.6% and 94.3% respectively). Sensitivities were lower in patients with low health literacy.

Conclusions: CKD awareness is low compared to other chronic diseases. Nevertheless, by using more sensitive combinations of questions to ascertain CKD awareness, we have likely reached the Healthy People 2020 goal.

SA-PO721

The Effects of Age and Symptoms on Recommendations to Initiate Dialysis Michael Walsh, Rajnish Mehrotra, Carmel M. Hawley, Marcello Tonelli, Clare I. Castledine, Stephen P. McDonald, Peter Margetts, Darin Treleaven, Vicki Levidiotis, K. Scott Brimble. McMaster Univ.

Background: The extent to which patient characteristics influence Nephrologists’ recommendations regarding initiation is unclear. We conducted an international survey to examine the effect of country on recommendations to initiate dialysis.

Methods: Nephrologists from Australia, Canada, New Zealand, the UK and the US were surveyed by email. The survey included clinical vignettes that varied patient characteristics. The framing of this question may influence responses. We sought to compare its sensitivity/ specificity to different questions as well as to awareness of other chronic conditions.

Results: For a given level of GFR, only nephrologists from Canada (p=0.001) and the US (p=0.001) were more likely to recommend dialysis for patients 50 than those aged 45. Conversely, nephrologists from Australia (p=0.001), New Zealand (p=0.001) and the UK (p=0.003) were less likely to recommend dialysis for patients aged 90 than those age 45. All nephrologists were more likely to recommend dialysis as symptoms increased but this association was less pronounced in the US and Australia (p<0.001 for interaction). Patient comorbidities, nephrologists’ years in practice, and practice type were not associated with recommendations.

Conclusions: For patients at a given eGFR, other characteristics such as age and symptom burden influence nephrologists’ recommendations to initiate dialysis but the extent of this influence differed substantially between nephrologists in different countries. Further research is required to understand the effect of these differences on patients and health systems.

SA-PO722

The Association of Community Health Indicators with Late Nephrology Referral in Patients Reaching End-Stage Renal Disease in the U.S. Jung-In Shin, Mari Paltta, Micah R. Chan, Brad C. Astor. Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Late nephrology referral in patients reaching end-stage renal disease (ESRD) is associated with inadequate preparation for dialysis and poorer clinical outcomes after renal replacement therapy (RRT). Previous studies have focused on individual-level factors to identify patients at higher risk of late nephrology referral. Environmental and socioeconomic conditions of communities in which patients live may also impact nephrology referral patterns.

Methods: We assessed the association of community health indicators with late nephrology referral in 587,574 patients reaching ESRD, using the data from United States Renal Data System (USRDS) from 2005-2012. An overall community health risk score was calculated using 35 community-level factors based on 1) health outcomes, 2) health behaviors, 3) access and quality of care, 4) socioeconomic factors, and 5) physical environment, using County Health Rankings data from University of Wisconsin Population Health Institute. Late nephrology referral was defined as the first encounter with a nephrologist occurring > 6 months before RRT initiation. Multilevel logistic regression models adjusted for individual characteristics, including demographics, cause of ESRD, body mass index, comorbidities, and insurance and employment status.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

793A
Results: The prevalence of late nephrology referral was 47.8%. A significant dose-response relationship of community risk score with late nephrology referral was found, with an adjusted odds ratio of 1.52 (95% CI: 1.36-1.71) for the highest versus lowest risk communities.

Conclusions: Higher community risk is significantly associated with late nephrology referral, independent of individual-level factors. Community risk may be an important consideration for developing interventions to improve access to pre-ESRD nephrology care.

SA-PO724

Chronic Kidney Disease (CKD) Patients’ Understanding of Renal Replacement Therapy (RRT) Options: Early Findings from the U.S. CKD Outcomes and Practice Patterns Study (CKDotts) Laura H. Mariani,1,2 Charlotte Tu,1 Brian Bieber,1 Elodie Speyer,1 Jarcy Zee,1 Hal Morgenstern,2 Benedicte Stengel,1 Bruce M. Robinson,1 Francesca Tentori,1,4 Arbor Research Collaborative for Health, Ann Arbor, MI; 2Univ of Michigan, Ann Arbor; MI; 1Inserm UMR1018, France; 4Vanderbilt Univ, Nashville, TN.

Background: Current KDIGO guidelines indicate that kidney failure patients should receive information on all RRT modalities, including conservative management. Even when education is provided, patients’ understanding of such a complex topic may be limited. We report the perspective of US participants in the first year of CKDotts.

Methods: CKDotts is a new international prospective cohort study that enrolls adult advanced CKD patients in national samples of nephrology clinics in the US, Brazil, France, and Germany and follows patients through the dialysis transition period. As of early 2015, 245 US participants with eGFR<50 mL/min/1.73m2 completed a self-administered questionnaire including their understanding of, education on, and preferences for RRT options.

Results: The median age of patients was 71; 43% were male and 57% had diabetes. 66% of patients reported they received no education about treatment options for kidney failure; 20% said they received one-on-one education; and 14% participated in a class. 34% recalled that in-center hemodialysis (HD) was discussed as a treatment option, and less than 25% recalled their doctor discussing peritoneal dialysis, home HD, conservative management, or transplantation. 58% of participants reported they did not know if transplantation was an option for them. Nearly 3 out of 5 participants did not know what RRT option they would choose if their kidneys failed.

Conclusions: Understanding of RRT options was poor among CKDotts participants in the US. Though the responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fail to adequately communicate key messages on RRT.

SA-PO723

Assessment of Quality of Care Received by Patients with Predialytic Chronic Kidney Disease Seen at a Philippine General Medicine Out-Patient Clinic – Experience at a Government Training Hospital Rizza Ann B. Liao, Section of Nephrology, Univ of the Philippines-Philippine General Hospital, Manila, Philippines.

Background: In a country with limited access to dialysis and transplantation such as the Philippines, it is imperative to recognize patients with early stage CKD and aggressively intervene in a timely fashion to prevent ESRD and death. The objective of this study is to evaluate the quality of care (QoC) of patients with predialytic CKD seen at a general medicine clinic.

Methods: This was a retrospective study which reviewed the medical records of 276 patients with CKD Stages 3-4 who have at least 1 year of consult. Patients who were admitted for critical illness, and are on dialysis were excluded. For each QoC parameter, percentage of patients who received the appropriate care were reported. For the QoC correlates, Mann-Whitney U Test, Kruskal-Wallis Test or regression analysis was done.

Results: The mean QoC score for this study is 58.36% (± 23.7%) and the average annual GFR decline is 3.92 mL/min/1.73m².

Conclusions: Approximately 1 in 3 adults with CKD is at high risk of developing cardiovascular disease (CVD). Recent lipid management guidelines agree that statins alone should be used for CVD prevention via lipid lowering. However, lack of congruent recommendations for statin use in adults with CKD may lead to low utilization of statins in this population at high risk for CVD.

Methods: Outpatient visit data during years 2006 to 2010 were obtained from the National Ambulatory Medical Care Survey to determine the frequency of statin prescriptions among outpatient visits for adults age ≥25 years with non-dialysis stage 1-5 CKD based on ICD-9 codes. Drug type (particular statin or other cholesterol lowering drugs type) was determined by the generic code recorded in the survey data. The analysis accounted for the complex survey design and utilized the sampling weight, cluster and strata statements so that results are generalizable to US outpatient ambulatory visits during years 2006-2010.

Results: A total of 2262 visits were included with patients being 48% white, 54% male and mean age of 69.6 years. 52% visits were covered by Medicare. Overall, 43% and 31.5% of visits for non dialysis CKD stage 3-5 and stages 1-2, respectively, included a statin prescription with simvastatin being the most commonly prescribed statin. Table 1 shows the prevalence of statin prescription in all patients with non-dialysis dependent CKD by provider type for the outpatient visit.

794A
Conclusions: These results suggest that the rate of prescription of statins in CKD patients is suboptimal and differs by the provider group for the patient with CKD. Lack of CV prevention may impact overall CV risk in patients with dialysis-dependent CKD.

SA-PO726

Patients’ Knowledge of Their Chronic Kidney Disease Stage and Education About Kidney Failure Prevention – The CKD-REIN Cohort

Benedicte Stengel,1 Celine Lange,2 Brianzonger,2 Luc Frimat,3 Denis Fouque,4 Maurice Laville,5 Christian Jacquet,5 Michael B. Robinson,2 Ziad Massly,1 Christian Combe.1 1Inserm U1018-CESP USV, Villejuif; 2Agence Biomedecine; 3CHU Nancy; 4CHU Lyon; 5Arbor Research Collaborative for Health, Ann Arbor; 6A4-Pal 2 APHP; 7CHU Bordeaux, France.

Background: Patient knowledge about their CKD stage and how to prevent kidney failure is important to reduce ERIS risk through better adherence to treatment and lifestyle changes. We report primary findings about CKD knowledge among patients seen by nephrologists in France.

Methods: We used baseline data from the CKD-REIN study, a prospective cohort of patients with CKD stage 3 and 4 in a national sample of 40 nephrology clinics. Information was collected from patient interview and self-administered questionnaire. Comparisons between stages were adjusted for age and gender.

Results: Median age was 68(60-76) and 56% were men. About 80% reported knowledge that their kidney function was low. Patients were more likely to know their creatinine level (~40%) than GFR or CKD stage. For each question, knowledge increased slightly from stage 3 to stage 4. Education about how to prevent kidney failure was uncommon (~10%).

Conclusions: Most CKD patients seen by nephrologists are aware that they have low kidney function, but their knowledge of disease severity is low. Very few received education about prevention of kidney failure. While the precise impact of these gaps in knowledge on CKD outcomes requires further investigation, the findings highlight the need to more effectively educate CKD patients about its potentially serious consequences.

SA-PO727

The Cost-Effectiveness of Primary Screening for Chronic Kidney Disease in Rural and Remote First Nations

Matthew T. James,1 Flora B. Conner,2 Luke James,3 1,2Health Sciences, Univ of Manitoba, Winnipeg, MB; 3Biomedecine, Massy, France.

Background: Chronic kidney disease (CKD) is a risk factor for cardiovascular disease, early mortality, and kidney failure. We have shown that the burden of CKD in First Nations (FN) populations in Manitoba is similar to that in diabetic and hypertensive populations. The cost-effectiveness of screening for CKD and subsequent treatment in FN or other high-risk indigenous populations has not yet been described.

Methods: We constructed a Markov model comparing screening in adult FN (age 18+) for CKD by both proteinuria and estimated glomerular filtration rate (eGFR) to usual care from the perspective of the publicly funded Canadian health care payer. Patients were assigned an initial risk classification based on urine albumin-to-creatinine ratio and eGFR using the Kidney Disease Improving Global Outcomes (KDIGO) heat map. We obtained screening tests results on 1346 adult participants from the First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) initiative. Our analysis was further stratified into communities accessible by road and communities accessed by air travel. Our primary outcome of interest was the incremental cost per quality-adjusted life-year (QALY).

Results: Overall crude prevalence of CKD in FN was 26.7%. Screening for CKD was associated with an ICER of $33,500/QALY in comparison to usual care. Restricting the model to screening in the remotest air access communities (prevalence of CKD 36.0%), this ratio fell to an ICER of $16,180/QALY. In less remote road access communities (CKD prevalence of 18.4%), the ICER was $63,780/QALY. Primary model drivers included the cost of dialysis, assumed treatment effectiveness, and rates of progression towards kidney failure.

Conclusions: Targeted screening for CKD in rural and remote First Nations is likely cost-effective (< $50,000/QALY). These findings may be translatable to other high-risk indigenous groups with elevated rates of CKD and kidney failure and warrant further research.

SA-PO728

Getting a Diagnosis of Chronic Kidney Disease: Despite Fears, Patients Want to Know Early

Julia A. Wright Nunes,1 Meghan Roney,2 Eve Kerr,3 Akinolu O. Ojo,1 Angela Fagerlin.1,2,3 1Internal Medicine, Univ of Michigan, Ann Arbor; 2Center for Bioethics and Social Sciences in Medicine, Univ of Michigan, Ann Arbor; 3Center for Clinical Management Research, VA Ann Arbor Healthcare System, Ann Arbor, MI.

Background: Little is known about patient perspectives related to getting a diagnosis of chronic kidney disease (CKD). This information could help providers optimize diagnosis messaging at the point of care.

Methods: Using root/cause analysis and quality function deployment we conducted semi-structured patient interviews. Adult patients with established non-dialysis CKD were interviewed between January-October 2014. Interviews were audiorecorded and transcribed. Content analysis was done with Dedoose, a qualitative software package.

Results: 49 patients completed interviews. Mean (SD) age was 63 (14) years, 50% were male, 80% were Caucasian and 84% had CKD Stage 3-5. Key themes emerged from a total of 786 statements: 1) Reaction to diagnosis (160 statements) 2) Barriers to accepting diagnosis (61 statements) and 3) Expectations of diagnosis communication (122 statements). 45% of patients felt fearful after getting a CKD diagnosis - most often related to perceived threats of future dialysis and death. Barriers to diagnosis acceptance included disbelief because of lack of symptoms and lack of prior familiarity with CKD. Despite fear and denial the majority of patients (63%) desired early diagnosis communication by their providers, i.e. at earliest stages of identification. Consistent terminology and disease explanations by providers across the care continuum were perceived as critical to effective communication and diagnosis delivery, yet patients expressed frustration at inconsistent terminology/explanations.

Conclusions: Our findings emphasize that patients learning of a CKD diagnosis can experience fear, but they also prefer early communication of diagnosis. More work is needed to set uniform diagnosis terminology for patients with CKD across the care continuum.

The Impact of Chronic Kidney Disease on Household Income: Does Health Affect Wealth? Rachael L. Morton,1 Alan Cass,2 Borislava N. Mihaylova,2 1Univ Sydney, Australia; 2Charles Darwin Univ, Australia; 3Univ Oxford, United Kingdom; 4On behalf of SHARP Collaborators.

Background: The impact of progressive chronic kidney disease (CKD) on household income is unclear. We sought to determine whether CKD severity and non-fatal adverse events were associated with a fall into poverty.

Methods: Prospective cohort study among participants with moderate-to-severe CKD randomized into the Study of Heart and Renal Protection (SHARP) with information on household income at study entry and study end (median follow-up 5 years). Household income recorded as: High (> twice the participating country median); Medium-high (> the median, but < twice the median); Medium-low (< the median, but > half the median); Low (< half the median income, i.e. poverty). Logistic regression models with socio-demographic factors, smoking, prior diseases, severity of CKD, income category at entry and incident non-fatal events (myocardial infarction, stroke, incident cancer, initiation of dialysis, kidney transplantation) were used to determine a fall into poverty, defined as a move into the lowest household income category.

Results: 2914 SHARP participants were included in the analysis; 933 of these were in poverty at screening and a further 436 (22% of the remaining) moved into poverty by study end. In addition to black ethnicity, low educational attainment, single adult household and low income category at baseline, CKD severity was a significant predictor of a fall into poverty.

Conclusions: Those who received kidney transplant were less likely to fall into poverty (OR 0.48, 95%CI 0.31-0.72). Non-fatal adverse events were not significantly associated with a fall into poverty.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
Conclusions: Patients in advanced stages of CKD are at an increased risk of falling into financial hardship. Kidney transplantation may have a role in reducing the risks of household poverty due to CKD.

Healthcare Expenditures for Non-Diabetes Dialyzed Kidney Disease Compared to Other Chronic Diseases

Christina Small,1 Holly J. Kramer,1 Karen A. Griffin,1 David J. Leehey,1 Vinod K. Bansal,1 Kavitha Vellanki,1 Talar Markossian.1 1Loyola Univ Chicago; 2Hines VA Medical Center.

Background: There is a paucity of literature comparing the expenditures of kidney disease with other common costly chronic diseases in the United States. Our study compares the U.S. healthcare expenditures of non-dialysis dependent kidney diseases to several other common conditions.

Methods: This study used the 2012 Medical Conditions and Consolidated Data files from the Medical Expenditure Panel Survey administered by the Agency for Healthcare Research and Quality. Analyses included adults aged 21 years with one of the following conditions: kidney disease, stroke, cancer, or a combination of the three (multicronic). Non-dialysis dependent kidney disease included any ICD9 code for kidney related conditions while chronic kidney disease (CKD) included only ICD9 code “585.” Analyses of calculated healthcare expenditures accounted for the complex survey design and incorporated the sampling weights so that estimates represent healthcare expenditures for the 2012 adult U.S. population (~313.4 million). Out of pocket healthcare expenditure burden was defined as the ratio of out of pocket healthcare expenditure to total person-level income for the year 2012.

Results: The mean age for non-diabetes dependent kidney disease and CKD was 56.5 and 65.9 years, respectively. Table 1 shows the median total and out of pocket healthcare expenditures values and mean out of pocket healthcare expenditure burden for kidney disease, CKD and other chronic conditions.

</table>

Conclusions: Healthcare expenditures including out of pocket costs are higher for non-dialysis dependent CKD compared to other chronic medical conditions. Policy efforts should focus on reducing the healthcare cost burden for patients with kidney disease.

SA-PO731

Smartphone-Based Self-Management System for Chronic Kidney Disease: Results from a Single Centre Prospective Trial

Stephanie C. Logan,1 Joseph A. Cafazzo,1 Vinod K. Bansal,1 Mary Moaveni,2 Arlene C. Gerson,1 Kavitha Vellanki,1 Talar Markossian.1 1Loyola Univ Chicago; 2Hines VA Medical Center.

Background: Following user-centric design principles we developed a smartphone-based self-management support system for patients with advanced CKD. The patient interface focuses on 4 behavioral elements over which they have direct control: monitoring BP at home, self-assessment of symptoms, managing medications and tracking laboratory results. The main objectives of this 6-month prospective study were to determine acceptability, measured by system adoption and adherence, and assess effectiveness by measuring pre and post changes in BP, medications, labs and self-management behaviors.

Methods: We tested the mobile app system in 10 renal clinics at a single academic center in Toronto. The 47 enrolled patients were instructed at a regular clinic visit on the use of the mobile app. The clinical team independently received information on the mobile app system’s operation.

Results: 61% of participants were non-smartphone owners. All had more than one chronic condition and on average were on 10 to 15 medications. Most were over the age of 50 with the greatest representation in the age group 55-64 ~80% of the users achieved more than the recommended 80% adherence rate to mobile app use.27% with normal clinic BP at home, self-assessment of symptoms, managing medications and tracking laboratory results. For unadjusted analyses, test scores of the subjects with BPV in the upper tertile were compared to that of subjects in the lower tertile. Multiple linear regressions were used to evaluate the relation between BPV and NCT scores, adjusting for BP index, sex, age, maternal education, race, BMI %ile, estimated GFR, % of life with CKD, nephrotic proteinuria, and low birth weight.

Results: Depending on the task, 121-511 subjects had both BP and NCT results available. In unadjusted analyses, subjects with increased visit-to-visit systolic BPV scored lower on Verbal Category Switching (3rd vs 1st tertile of BPV-SD, 8.4 ± 2.7 vs 9.8 ± 3.0, p = 0.006; of ARV, 8.6 ± 3.0 vs 9.7 ± 2.5, p = 0.009). There was no effect of increased visit-to-visit BP or ambulatory BPV on any other task. In adjusted analyses, increased visit-to-visit systolic BPV remained significantly associated with lower Verbal Category Switching scores for BPV-SD (β=-0.28, 95% CI: -1.34, -0.15) and there was a trend for ARV (β = 0.7, 95% CI: -1.16, 0.03).

Conclusions: Increased visit-to-visit systolic BPV was independently associated with decreased Verbal Category Switching scores in children with CKD. These results suggest that children with CKD may have difficulties with set shifting that are related, in part, to increased BPV. Further study is needed to determine the significance of this isolated result.

Rapid Post-Transplant Improvement of HRQOL in Older Kidney Recipients

Kristian Heldal,1 Kjersti Lenning,2 Tom Bernklau,2 Nanna von der Lippe,2 Anna Reisaeter,1 Anders Hartmann,2 Marit helen Andersen,1 Karsten Midveldt,1 1Clinic of Internal Medicine, Telemark Hospital, Skien, Norway; 2Inst of Clinical Medicine, Faculty of Medicine, Univ of Oslo, Oslo, Norway; 3Clinic of Surgery, Surgery and Transplantation, Oslo Univ Hospital, Rikshospitalet, Oslo, Norway; 4Research Unit, Telemark Hospital, Skien, Norway.

Background: It is widely accepted that health-related quality of life (HRQOL) is significantly compromised in patients with ESRD. In adults, kidney transplantation (KTx) is known to improve HRQOL. In older recipients there is a lack of studies measuring the effect of KTx on HRQOL. The aim of this study was to measure HRQOL longitudinally in enlisted patients >65 years of age, from pre-transplant and until 6 months after KTx. Methods: Patients >65 years listed for transplantation at our centre were asked to complete the SF36 questionnaire at enlisting and thereafter every 6 months until KTx. Post transplant, the patients received a new SF36 form after 10 weeks and 6 months. Results: A total of 180 patients have been included from Jan 2013. Mean age at enlisting was 70.6 years (65.0-81.8) and 68% were male. By the end of May 2015, 100 patients were transplanted and 59 of them had completed both pre- and post-transplant questionnaires. Mean time from completing the first pre-tx questionnaire to transplantation was five months. When comparing the scores for the last SF36 pre-tx with 6 months post-tx, there was a statistically significant increase of the mean scores for GH (53.71), PF (68.74), BP (64.78), VT (53.71) and MH (79.85). This was also a tendency towards improved scores for RP and RE, while the SF score was unchanged.

Conclusions: Our preliminary findings indicate that older patients report a significant improved HRQOL measured by SF36 already 10 weeks after KTx and the status remains stable after 6 months. Longer follow-up is warranted.

SA-PO735

L-Carnitine Improves Cognitive and Renal Functions in a Rat Model of Chronic Kidney Disease

Zaher Anis Armaly,1 Adel Rafik Jabbour,2 Avi Avital.3 1Dept of Nephrology, Bar Ilan Univ, E.M.M.S. Hospital, Nazareth, Israel; 2Dept of Neurochemistry Laboratory, E.M.M.S. Hospital, Nazareth, Israel; 3Behavioral Neuroscience Lab, Dept of Physiology, Rappaport Faculty of Medicine, Technion and The Emek Medical Center, Haifa, Israel.

Background: Over the past decade, the prevalence of chronic kidney disease (CKD) has reached epidemic proportions. L-Carnitine, considered as the “gatekeeper” responsible for admitting long chain fatty acids into mitochondria, L-Carnitine synthesis and turnover has reached epidemic proportions. L-Carnitine, considered as the “gatekeeper” responsible for admitting long chain fatty acids into mitochondria and for transporting fatty acids from the cytosol into the mitochondrial matrix, has a wide range of beneficial effects and offers protection against both kidney disease and renal failure.

Methods: Animals were subjected to right unilateral nephrectomy combined with 2/3 left kidney ligation. Sham operated rats served as controls. Following 14-days recovery period, animals were randomly assigned into two treatment conditions: treatment with saline (sham n=7; CKD n=9) or L-Carnitine (250 mg/kg) (sham n=7; CKD n=9) by daily intraperitoneal injections, for 8 consecutive weeks. Then all rats were sacrificed, blood was collected, and the kidneys were collected, for biochemical and histological analyses, respectively. Two way shuttle avoidance test was used to assess the effects of L-Carnitine and L-Carnitine treatment on cognitive-related behavior.

Results: We found that all CKD animals exhibited renal dysfunction, as indicated by elevated Scr, BUN, and histopathological abnormalities. L-Carnitine treatment of CKD rats significantly reduced Scr and BUN, attenuated renal hypertrophy and decreased renal tissue damage. In addition, in the two way shuttle avoidance learning, CKD animals showed cognitive impairment which recovered by the administration of L-Carnitine.

Conclusions: Administration of L-Carnitine in a rat model of CKD, significantly improved cognitive and renal functions.

SA-PO736

Being a Relative to Patients with Chronic Kidney Disease – Experiences of Participation in Care and Treatment

Hanne Angholm,1 Jette Kristiansen,2 Mona Kyndi Pedersen.3 1Dept of Nephrology, Aalborg Univ Hospital, Aalborg, Denmark; 2Univ College of Northern Denmark, Aalborg, Denmark; 3Clinic for Internal Medicine, Aalborg Univ Hospital, Aalborg, Denmark.

Background: Studies concerning the lives of patients with chronic kidney disease have focused on the patients, and not the relatives. However, relatives share and are affected by the same consequences as the patient with regard to changes in everyday life, roles in the family and mutual relationship. The purpose of the study was to gain insight into and understanding of the needs of the relatives of patients with chronic kidney disease with regard to their ability to provide support in everyday life, and the expectations of the relatives of participation in care and treatment.

Methods: A qualitative study based on four focus group interviews with four to eight relatives in each group (in total 27 relatives). The groups were formed according to the age and gender of the relatives as well as their relation to the adult patient with chronic kidney disease.

Results: The study demonstrated how relatives provide substantial support to the patient both in everyday life and in care and treatment. In relation to the patient, it was a constant challenge for relatives to find the balance between supporting and taking over. They expressed a need for recognition by both the close relations and the health care professionals as well as a need for sharing their experiences with other relatives in the same situation. The analysis identified six themes: 1. Different needs and possibilities for support and participation. 2. Finding balance between disease and everyday life. 3. Emotional pressure. 4. The importance of recognition. 5. Need for regaining energy, and 6. Collaborating with health care professionals.

Conclusions: When collaborating with the relatives with regard to care for patients with chronic kidney disease, the health care professionals should actively recognize the patient support that the relatives already provide in everyday life. Initiatives of participation in care and treatment should be based on collaboration and the needs, expectations and possibilities of both the patient and the relatives.

SA-PO737

CKD(3-5) Affects Endurance, Strength, Balance and Fine Motor Skills which Are Not Detectable by Questionnaire

Naoimi D. Clyne,1 Matthias Hellberg,1 Peter Hoglund.2 1Clinical Sciences Lund, Nephrology, Lund Univ, Lund, Sweden; 2Laboratory Medicine, Clinical Pharmacology, Lund Univ, Lund, Sweden.

Background: Physical functions are impaired in dialysis patients. It is unclear which functions are affected and how they decline in the course of CKD. This study investigated the effects of declining GFR (CKD 3-5) on measured physical functions, self perceived physical functioning and well being.

Methods: In this cross sectional analysis 101 patients (40 women, 61 men; mean age: 67±13 years, median GFR: 21 (9-41) ml/min/1.73m²) were tested with 6 Minutes Walk (6-MWT), Isometric Quadriceps Strength (IQS), Functional Reach (FR) and Picking-up (PUT). Self perceived physical functioning and well-being were assessed by KDQOL-SF™. GFR was measured with iothalamate clearance and comorbidity by Davies' index. Multivariable linear regression analyses were employed including the following explanatory variables: GFR, age, sex, comorbidity and the interaction between sex and age.

Results: Significant associations were found between decline in GFR and endurance (6-MWT; p=0.039), strength (IQS; p=0.035), balance (FR; p=0.024) and fine motor skills (PUT; p=0.015) as well as by the patients' perceived domains in the KDQOL-SF™ of effects- and burden of kidney disease and social support (p=0.006) after having taken the explanatory variables into account. There were significant associations between the KDQOL-SF™ domains role physical and emotional well-being and 6-MWT (p=0.018; p=0.018, respectively) and IQS (p=0.005; p=0.045, respectively), but these were dependent on age, sex and comorbidity but not driven by GFR.

Conclusions: Physical functions comprising endurance, strength, balance and fine motor skills were impaired relatively early in the course of CKD (3b-5), seemed to progress with declining GFR and could be detected by easy to perform physical function tests. The relationship between self perceived physical functioning and well being, respectively, with measured endurance and strength, respectively, were driven by age, sex and comorbidity but not by decline in GFR. The only domains that discriminated for GFR associated influence were effects- and burden of kidney disease and social support.

SA-PO738

The Prevalence of Cognitive Impairment in Chinese Peritoneal Dialysis Patients

Chi-hon Leung, Cheuk-Chun Szeto. Dept of Medicine and Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.

Background: Cognitive impairment is common amongst patients with chronic kidney disease and may be associated with excessive morbidity in dialysis patients. This study determines the prevalence and risk factors of cognitive impairment in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalence PD patients (103 males). Cognitive impairment was screened by the 10-item Abbreviated Mental Test (AMT) questionnaire. We also determined patients’ comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7±11.7 years; vintage of dialysis 42.5±44.1 months. Average AMT score was 9.3 ± 1.3. The AMT score is closely associated with age (r =
Neurocognitive Functioning and Association with Clinical Outcomes in Adults with End-Stage Kidney Disease: The COGNITIVE-HD Study

Giovanni F.M. Strippoli

Background: Cognitive impairment and neurocognitive disorder have been associated with increased mortality in the general population. Whether dialysis patients have specific patterns of cognitive dysfunction, or whether cognitive function is associated with activities of daily living and durability of dialysis treatment remain poorly understood.

Methods: The COGNITIVE-HD study will provide detailed neuropsychological assessments of cognitive function among hemodialysis patients to characterize age- and education-adjusted prevalence and patterns of cognitive impairment and the associations with physical and social functioning and clinical outcomes including cardiovascular events at 12 months. The COGNITIVE-HD study is a prospective, longitudinal, population study of 751 adults conducted in 20 dialysis centers in Italy. A detailed battery of comprehensive testing for executive function, visuospatial function, language, learning and memory, personality traits, and complex attention has been carried out by a trained psychologist at baseline to assess for presence of cognitive impairment and to evaluate the pattern of cognitive deficits, and any association between cognitive impairment and activities of daily living.

Results: Preliminary analyses have been conducted on the Mini Mental State Examination (MMSE) evaluation of cognitive function among 702 participants (mean age 68.2 years, 60% men). 50% had normal cognitive function (MMSE score 27-30), 14% had mild impairment (score 21-26), 14% had moderate impairment (score 18-20), and 22% had mild cognitive impairment (score 20-26). 18% patients had MMSE results compatible with dementia (score <24), of whom 51%, 48% and 1% had mild, moderate and severe impairment respectively.

Conclusions: The COGNITIVE-HD is a population-based study of cognitive function involving dialysis patients that has the potential to inform candidate interventions for treatment trials of cognitive impairment in the setting of advanced kidney disease. 2*List of study investigators: S Palmieri, M Rusopo, A Iurillo, V Saglimbene, P Natale, O Barulli, L Leslie, 2 GRECC, VA Maryland Healthcare System; 1 Univ of Bari; 4 Univ of Sydney.

Neurocognitive Function and Psychiatric Disorder in Children with Chronic Kidney Disease from the KNOW-Ped CKD Cohort Study (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease)

Kyoung Hee Han, 1 Eujin Park, 3 Yo Han Ahn, 2 Seong Heon Kim, 4 Joo Hoon Lee, 2 Young Soo Park, 4 Hee Gyung Kang, 1 Hae Il Cheong, 1 Curie Ahn, 1 H-Soo Ha. 1 Dept of Pediatrics, Jeju National Univ School of Medicine, Jeju, Republic of Korea; 2 Dept of Pediatrics, Seoul National Univ Children’s Hospital, Seoul, Republic of Korea; 3 Dept of Pediatrics, Pusan National Univ Children’s Hospital, Yangsan, Republic of Korea; 4 Dept of Pediatrics, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; 5 Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.

Background: We determined whether pediatric chronic kidney disease (CKD) is associated with neurocognitive impairment and psychiatric disorder from the KNOW-PedCKD cohort study in Korea.

Methods: A total of 322 children (M:F 218:104) enrolled from seven major pediatric nephrology centers of Korea from July 2010 to December 2013 were the subject of this study. Neurocognitive function and psychiatric status of pediatric CKD patients were evaluated using Wechsler intelligence scale for children, Child Behavior Checklist, ADHD Rating Scale-IV, State-Trait Anxiety Inventory, Child Depression Inventory and Parental bonding instrument-Korean version.

Results: Verbal, performance and full scale IQ were lower in younger age and congenital anomalies of the kidney and urinary tract as a cause of CKD. More than 10 percent of school-age children with CKD presented significant emotional distress including somatization (15%), attention problems (15%) and anxiety (12%). Impact of progression of CKD on their neurocognitive function and psychiatric status will be investigated in KNOW-PedCKD cohort study in Korea.

Conclusions: In young patients with CKD and those with multiple congenital problems in addition to CKD suffer from low intelligence and psychiatric disorder. Pediatric CKD patients with low intelligence and psychiatric disorder need close attention and developmental training techniques. 2Acknowledgement. This work was supported by the Research Program funded by the Korea Centers for Disease Control and Prevention (2013E3301600, 2013E33081601).

Funding: Government Support - Non-U.S.
This association is possibly mediated by distress caused by CKD. 

Awareness of kidney disease is significantly associated with subthreshold depressive symptoms. Significance was defined as \( p \leq 0.05 \).

Conclusions: Awareness of kidney disease is significantly associated with subthreshold depressive symptoms. This association is possibly mediated by distress caused by CKD.

SA-PO743

Vitamin D Deficiency Is Significantly Associated with Depression in Chronic Kidney Disease Patients

Jung Hyun Jhee, Su A Lee, Hyung Jung Oh, Jung Tak Park, Seung Hyook Han, Shin-Wook Kang, Tae-Hyun Yoo. Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Recent studies have reported significant associations between vitamin D deficiency and depression in the general population. Although both vitamin D deficiency and depression are common features in chronic kidney disease (CKD) patients, the association between these two prevalent factors in this patient population remains poorly elucidated. Therefore, the association between vitamin D deficiency and depression in CKD patients was investigated.

Methods: The data from the Korean National Health and Nutritional Examination Survey between 2010 and 2012 were used. A total of 495 patients with estimated glomerular filtration rate \( \geq 60 \) mL/min/1.73m\(^2\) were enrolled. Vitamin D deficiency was defined as 25-hydroxyvitamin D3 \( [25(OH)D3] \) levels \( \leq 10 \) ng/mL. Patients were dichotomized by the presence of vitamin D deficiency. Depression was determined by the EuroQOL-5D (EQ5D) questionnaire.

Conclusions: Depression was highly prevalent in CKD patients. Vitamin D deficiency was a significantly independent predictor of depression in CKD patients. Therefore, vitamin D levels might be helpful to predict depression in these patients.

SA-PO744

Comparison of Prevalence and Predictors of Fatigue in Advanced Chronic Kidney Disease and Cancer Patients

Naimah Jamb, Sanah Parvez, Khaled Abdel-Kadeb, Mark L. Urnrah, Jennifer L. Steel. 1 Univ of Pittsburgh; 2 Univ of New Mexico; 3 Vanderbilt Univ.

Background: Although >50% of patients with advanced CKD report fatigue, its prevalence, predictors and consequences are under-appreciated by renal providers. We compared the symptom burden among CKD/ESRD patients to those with advanced hepatobiliary cancer (CA).

Methods: In 237 patients with advanced kidney disease (35% CKD stage 4-5, 65% ESRD) and 606 with advanced CA, patient-reported symptoms and health-related quality of life (HRQL) were assessed using validated fatigue, pain, sleep quality, depression and HRQL questionnaires. Chi-square and unpaired t-tests defined significant differences between outcome groups. Multivariable logistic regression defined variables independently associated with fatigue, pain, sleep quality, depression and 3.3% had severe depressive symptoms. Multivariable predictors of fatigue were hypotension, sleep disturbance, psychological distress, labs indicative of kidney disease, income, single marital status, Mexican and Black race, diabetes, elevated diastolic blood pressure, smoking, cardiovascular comorbidity and awareness of kidney disease. 6.4% of subjects were aware they had CKD. CKD awareness was significantly associated with subthreshold depressive symptoms but not severe depressive symptoms in univariable analysis (OR 1.76, CI 1.10-2.80). In multivariable analysis, the association between awareness of CKD and subthreshold depressive symptoms remained significant (p=0.05). There was a significant interaction between awareness and stage 1 CKD on subthreshold depressive symptoms (OR 2.25, CI 2.24-30.63), and between awareness and gender on subthreshold depressive symptoms (OR 2.19, CI 1.09-4.38).

Conclusions: Awareness of kidney disease is significantly associated with subthreshold depressive symptoms. This association is possibly mediated by distress caused by CKD diagnosis. Increased psychosocial support, especially in early stages of CKD, may be warranted.

SA-PO745

Urinary Incontinence Is Common Among Adults with Chronic Kidney Disease (CKD) and May Impact Patient Compliance with Diuretics

Background: Urgency urinary incontinence (UUI) is a stigmatized condition that may be common among adults with CKD due to the older age and high prevalence of comorbidities (obesity and diabetes) that increase risk for UUI in this population. Diuretics, which are commonly used for hypertension management, may exacerbate UUI symptoms. However, the impact of UUI on diuretic compliance has not been previously assessed in adults with CKD.

Methods: This pilot study recruited 89 adults with no-dialysis dependent stage 3-5 CKD who are prescribed diuretics for hypertension management. All participants provided written informed consent. Study participants completed the Morrisky Medication Adherence Scale (MMAS), a validated questionnaire for hypertension medication compliance with scores ranging from 0 (poor adherence) to 11 (excellent adherence). Participants were asked “Do you ever avoid taking the diuretic (water pill) because it increases the urge to urinate occasionally makes you urinate before reaching the toilet?” Information on UUI prevalence and nocturia was collected using standardized, validated questions for urinary symptoms.

Results: The mean age of the participants was 71 years, 54% were male and 71% were white. Overall, UUI was present in 44%, and 93% reported nocturia (waking at night to urinate) and 33% reported severe nocturia (waking 3 or more times to urinate). Overall 77% reported ever not taking their diuretic due to urinary urgency and this was significantly more frequent among those with UUI vs. those without UUI (32% vs. 6%; \( p = 0.002 \)). Compared to patients who do not avoid diuretics, patients who reported ever avoiding diuretics had a significantly higher median values of medication adherence scores (7.0 vs. 10.0; \( p = 0.001 \)) and were less likely to have a blood pressure < 140/90 mmHg at the clinic visit (53% vs. 72%; \( p < 0.05 \)).

Conclusions: UUI is common among older adults with CKD and may negatively impact compliance with diuretics and blood pressure management.

SA-PO746

Validation of a Patient-Perceived Symptom Score for Chronic Kidney Disease

Stephanie A. Brown, Freya Tyrer, Amy L. Clarke, Andrew G. Lloyd-Davies, Andrew G. Stein, Carolyn Tarrant, Alice C. Smith. 1 Leicester Kidney Exercise Team, Univ of Leicester, Leicester, United Kingdom; 2 Dept of Health Sciences, Univ of Leicester, United Kingdom; 3 Univ Hospitals of Coventry and Warwickshire, United Kingdom.

Background: Chronic Kidney Disease (CKD) is associated with a range of symptoms, even at relatively early stages. There is increasing recognition of the importance of the patient symptom experience for clinical management and quality of life, but validated symptom scores are lacking. We have refined and validated an existing draft CKD symptom questionnaire listing 11 common renal symptoms plus lines for additional symptoms not included in the list.

Methods: Validation was undertaken in 4 phases. In Phase 1, 219 patients with CKD1-5 not requiring renal replacement completed the draft questionnaire to identify the most common symptoms in this population. Phase 2 explored cognitive validity via semi-structured interviews with 11 patients, after which the draft questionnaire was refined. Phase 3 was a focus group with 5 patients, to review and further refine the updated questionnaire. Phase 4 was content validity testing: the questionnaire was sent to 16 external expert clinicians for assessment of relevance, clarity and comprehensiveness.
SA-PO747
Impact of Psychosocial Factors in Advanced Chronic Kidney Disease on Wait-Listing for Transplantation

Background: Transplantation (Tx) is generally regarded as the best option for renal replacement therapy. However, few patients with CKD are listed for Tx when eligible. We examined the association between psychosocial factors in patients with advanced CKD and wait-listing for kidney Tx.

Methods: The study population includes 803 individuals with an eGFR of less than or equal to 20mL/min/1.73m2 (advanced CKD) in the Chronic Renal Insufficiency Cohort study. The primary predictors were health related quality of life (HRQOL) and depressive symptoms assessed within 24 months prior to reaching the eGFR inclusion criteria using the Kidney Disease QOL (KDQOL)-56 survey and the Beck Depression Inventory (BDI), respectively. The primary composite outcome was wait-listing or transplantation (WLT). Cox proportional hazards models were used to examine the association between low HRQOL (%SD below the cohort mean) and BDI (%ILI with WLT).

Results: Of the 803 subjects, 380 (47%) were wait-listed including 120 that proceeded to Tx. Compared to individuals who were not WLT, those in the WLT group were more likely to be younger, male, have no history of cardiovascular disease, and have proteinuria >300mg/day (p<0.01). After adjustment for demographic and clinical variables, a low Mental Component Summary (MCS) score was associated with a lower likelihood of WLT (Table). There was no association between the BDI or other QOL measures with WLT.

Conclusions: Lower MCS scores were associated with lower likelihood of WLT. Further work is needed to evaluate the impact of poor mental QOL in advanced CKD and how it might influence wait-listing.

SA-PO748
Perspectives on Pregnancy in Women with Chronic Kidney Disease
Allison Tong,1 Mark A. Brown,2 Wolfgang C. Winkelmayer,1 Jonathan C. Craig,3 Shilpa Jesudason.4 1The Univ of Sydney; 2St. George Hospital; 3Baylor College of Medicine; 4Royal Adelaide Hospital.

Background: Women with chronic kidney disease (CKD) often have difficulty achieving pregnancy, and are at increased risk of adverse pregnancy outcomes. Given the medical, ethical and emotional complexities of pregnancy in CKD, the clinical approach should involve explicit consideration of women’s values; of which there are sparse data.

Methods: Six ethics themes were identified: bodily autonomy (conscious of fragility, nocturnal self, critical timing, suspended in limbo); devastating loss (denied motherhood, disempowered by medical catastrophizing, resolving grief, barriers to parenthood alternatives, social jealous); intragenic guilt (disappointing partners, fear of genetic transmission, respecting donor sacrifice, medical judgment); rationalizing consequential risks (choosing survival avoiding fetal harm, responding to family protectiveness, compromising health, decisional ownership, unjustifiable gamble); strengthening resolve (hope and opportunity, medical acountability to the patient and next of kin, determinant, reorienting focus (valuing life, gratitude in hindsight).

Conclusions: Decisions surrounding pregnancy in the context of chronic kidney disease require women to confront uncertainties about their own survival, disease progression, and their ability to serve as a family and kidney donor, the outcomes of their offspring, and genetic transmission. Communicating the medical risks of pregnancy to women with chronic kidney disease must be carefully balanced with their values of autonomy, hope, security and family. Informed and shared decision making that is sensitive to women’s priorities as identified in this study can contribute to improved pregnancy, health and psychosocial outcomes in this vulnerable population.

Nrf2 Activator, Resveratrol, Ameliorates Aging-Related Progressive Renal Injury in Nrf1-/- Mice
Wong Kim,1 Jung Ja,1 Zhen Yan,2 Ji Hee Lim, Min Young Kim, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong Soo Kim, Younsik Chang, Bum Soon Choi. 1Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.

Background: The senescence markers of kidney injury in mice are shown to cause many changes in the energy metabolism. Two important issues in aging kidney are mitochondrial dysfunction and oxidative stress. Nrf2 activator, Resveratrol may prevent inflammation and oxidative stress by activating SIRT1 and Nrf2. We examined that Resveratrol can potentially ameliorates the cellular condition, such as renal injury due to cell oxidative stress and mitochondria dysfunction caused by aging.

Methods: Male 19-month-old C57BL/6 mice were used in this study. Resveratrol (0.04%) was provided to old mice for 6month. We compared histological change, oxidative stress, and aging-related protein expression in the kidneys between Resveratrol treated old-mice group (RSV) and vehicle old-mice group (VH).

Results: In our study, expression of Nrf2 in nuclear (+1 ± 0.04 fold vs. ± 2 ± 0.4 fold; p < 0.01 vs. VH) was increased in RSV. Expression of SIRT1 (+1 ± 0.11 fold vs. ± 1.3 ± 0.11 fold; p < 0.05 vs. VH) was increased in RSV. p-AMPK/Total AMPK ratio expression (+1 ± 0.1 fold vs. ± 1.79 ± 0.2 fold; p = 0.01 vs. VH) was increased in RSV compared with VH. RSV group displayed decreased albuminuria and Creatinine clearance increased with RSV. There were decreases in mesangial volume, tubulointerstitial fibrosis and collagen IV in RSV. Immunohistochemistry of F4/80 expression in glomerulus and tubule were decreased in RSV compared with VH. Also, TGF-β was decreased in RSV. Urine isoprostane and 8-OHdG excretion decreased with aging. Antioxidant enzyme, HO-1 (+3 ± 0.8 fold vs. ± 1.6 ± 0.1 fold; ± 0.001 vs. VH) and NQO-1 (± 1 ± 0.06 fold vs. ± 1.3 ± 0.1 fold; p < 0.01 vs. VH) were increased in RSV compared with VH.

Conclusions: These results suggest that activation of Nrf2 may benefit aging-related renal related with SIRT1 and AMPK activation by reducing oxidative stress. Pharmacologically targeting Nrf2 signaling molecules may reduce the pathologic changes of aging in the kidney.

Dual Agonist of Nuclear Hormone Receptor Farnesoid X Receptor and G Protein Coupled Receptor TGR5 Exhibits Calorie Restriction Mimetic Effects in Aging Mice
Naween Wang,1 Evgenia Dobrinskikh,2 Yuhuan Luo,1 Luciano Adorini,3 Moshe Levi.1 1Univ of Colorado Denver; 2Intercept Pharmaceutical Company.

Background: Previous studies have shown that calorie restriction (CR) in mice and rats prevent age-related proteinuria and glomerulosclerosis. We have observed an age-related decrease in renal nuclear hormone receptor farnesoid X receptor (FXR; NR1H4), and G protein-coupled receptor TGR5 (GPR81 or GPR131) expression. In contrast, renal FXR and TGR5 expression are increased by CR in the aging mice. FXR and TGR5 expression are also increased in the long-lived Ames dwarf mouse. The purpose of the present study was to determine if activation of FXR and TGR5 in the kidneys of ad lib fed aging mice have similar effects to CR.

Methods: We studied 5 month old ad lib fed, 24 month old ad lib fed, 22 months old ad lib fed mice treated with the dual FXR/TGR5 agonist INT-767 for 2 months, and compared them to lifelong 24 month old CR mice.

Results: Treatment of 22 month old ad lib fed aging mice with FXR/TGR5 dual agonist INT-767 for 2 months decreases albuminuria, TGF-β expression, and fibronectin accumulation in aging mice. INT-767 stimulates mitochondrial biogenesis, increases mitochondrial DNA content, and mitochondrial transcription factors Nrf1 and Tfm in the aging kidney. INT-767 also increases the expression of SIRT1, PGC-1α, and ERRα mRNA, as well as PGC-1α and SIRT3 protein abundance. INT-767 activation of the mitochondrial NAD-dependent deacetylase SIRT3 restores its targets MCAD and acetyl-CoA to normal levels, which are important for regulation of mitochondrial fatty acid β-oxidation as well as mitochondrial redox status. Furthermore, INT-767 increased expression of NAMPT and Nk1, enzymes involved in synthesis of sirtuins substrate NAD.

Conclusions: Our results therefore indicate that activation of FXR and TGR5 in the aging kidney reverses most of the age-related changes and the effects of FXR and TGR5 are similar to beneficial effects achieved by lifelong CR.

ESRD in Nonagenarians in the United States, 1995 Through 2010
Donald J. Sexton, Scott Reule, Robert N. Foley. Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Patients in their 90’s are increasingly being considered for maintenance dialysis, comprehensive epidemiological data could help with decision making.

Methods: We used US census data and data for patients who initiated maintenance dialysis between 1995 and 2010 (N=1,557,117) to examine trends in ESRD for those aged 90 to 99 years (N=14,289).

Results: The rate of ESRD in 1995-1996 was 0.6 per million per year in those aged 90-99 years respectively. Standardized incidence ratios (SIRs) rose between 1995 and 2010 both overall (SIR 2.8), and in individuals (SIR 2.7, females 2.7 white (3.1) African American (1.93) and other races (2.43). Median survival was 10.7 months. “Unspecified renal failure” was the most common reported cause of ESRD (62.6%), followed by “diabetes mellitus type 2” (15.8%), “ATN without recovery” 3.4%, “GN (not histologically examined)” 3.18%, “renal artery stenosis” 2.44% and other 12.44%. Causes of death included: Cardiac deaths 42.4%, Infection 12.07%, Withdrawal of dialysis/ Uremia 10.16%, Stroke/Intracranial Hemorrhage 3%, Cachexia 2.99%, Cancer 2.45%, Other 12.03% and Unknown 14.89%. Mortality fell over time, AHR (95% CI) 0.79 (0.72, 0.87) in 2009-2010 vs 1995-1996. Factors associated with a higher likelihood of death included: ischemic heart disease (AHR 1.13), AV graft (AHR 1.36 vs AV fistula), or venous catheter for hemodialysis vascular access (AHR 1.7 vs AV fistula), shorter pre-dialysis nephrology care (AHR 1.37), higher eGFR at dialysis initiation (AHR 1.13), serum albumin < 3.5 g/dl (AHR 1.34), cerebrovascular disease (AHR 1.21), peripheral vascular disease (AHR 1.14), cancer (AHR 1.08), inability to ambulate (1.43) or transfer (1.59), “ATN without recovery” as primary cause of ESRD (AHR 1.11 “renal failure not specified”).

Conclusions: ESRD in nonagenarians has risen over the period of observation in the United States. Rising prevalence may be attributable not only to rising incidence but to falling mortality also.

Impact of Geriatric Multi-Morbidity Versus Medical Multi-Morbidity on Quality of Life in Older CKD Patients
Steven L. Seliger,1 Jamie J. Jamison,1 Kieran Reid,1 Leslie I. Katzel,1 Stephen L. Seliger,2 Daniel E. Weiner,1 Roger A. Fielding,2 1Boston Univ, Boston, MA; 2Tufts Univ, Boston, MA; 1Univ of Maryland, Baltimore, MD.

Background: Geriatric conditions are constellations of signs and symptoms not always linked to a disease, such as cognitive impairment and fatigue; geriatric conditions are associated with worse quality of life (QoL). Older adults with CKD are likely to have geriatric multi-morbidity (GM), defined as ≥2 geriatric conditions. Medical multi-morbidity (MM) is also common in this population and affects QoL. We compared the impact of GM to MM on QoL in older CKD patients.

Methods: We used baseline data from an ongoing trial of exercise in persons ≥55 years with stage 3b-4 CKD. For GM, persons were defined with 1) cognitive impairment if Montreal Cognitive Assessment <26; 2) poor physical function if Short Physical Performance Battery ≤7; 3) dizziness as reported by Memorial Symptom Assessment Scale; 4) fatigue if reported ≥‘good bit of time’ to feeling worn out on Short Form-36 (SF-36); and 5) chronic pain if ≥‘moderate’ pain on SF-36. For MM, hypertension, diabetes, CAD, and heart failure were self-reported. Severe depression was defined as Beck Depression Inventory >15. QoL was measured with the SF-36. Linear regression adjusting for age, sex, race, site, BMI, and eGFR was utilized.

Results: Of 72 persons (31% women, mean age 68.6±7.8 years, mean eGFR 33.3±9.8 ml/min/1.73m), 49% (35) had GM and 76% (55) had MM. GM was associated with lower scores in all SF-36 subdomains (all p<0.05). MM was associated with lower scores in two SF-36 subdomains (both p<0.05).

Conclusions: In older adults with CKD, geriatric multi-morbidity is common and likely affects QoL.

A Survey of Provider Knowledge, Attitude, and Practices Surrounding Conservative Management for Patients with Advanced Chronic Kidney Disease
Sarah Purvez,1 Khaled Abdel-Kader,2 V. Shane Pankratz,1 Mi-Kyung Song,1 Mark L. Unruh,1 1Div of Nephrology, Univ of New Mexico; 2Div of Nephrology, Vanderbilt Univ; 1Adult and Geriatric Health Div, School of Nursing, Univ of North Carolina.

Background: Despite the potential benefits of conservative management (CM), discussing CM as a viable treatment option rarely occurs. Several factors might contribute to this but no studies in the U.S. have described them. The purpose of this survey was to describe nephrologists’ (NEPHs) and primary care providers’ (PCPs) knowledge, attitudes, and practices of CM for patients with advanced CKD.

Methods: We developed a survey based on the relevant literature to include items assessing knowledge, attitudes, and self-reported practices of CM for patients with advanced CKD. We then conducted a web-based cross sectional survey between April and May 2015. We used the American Medical Association’s Physician Masterfile to identify NEPH and PCPs practicing in the U.S.

Results: 431 (67.6% NEPHs, 32.4% PCPs) providers completed the survey. The respondents were, on average, white, predominantly male, and in their 30s and 40s. A majority of both PCP (83.5%) and NEPH respondents (78.2%) reported that they were likely to discuss CM with their older advanced CKD patients. Self-reported number of patients managed conservatively was at least >11 patients for 30.6% NEPHs and 49.2% of PCPs. As shown in the figure where a higher percent demonstrates a lower barrier, the major barriers to CM discussions identified by NEPHs and PCPs significantly differed.

There were significant differences in knowledge across the groups with PCPs reporting significantly more uncertainty about survival rates with CM.

Conclusions: Both NEPH and PCP are comfortable with discussing CM with their patients. PCPs have less certainty regarding patient selection for CM and report feeling less informed about outcomes of CM.

Which Therapeutic Project for Elderly Reaching ESRD? Patient’s Characteristics and Outcomes
Coraline Faaf1, Cecile Coudouh2, Cecile M. Vigneau,1 Olivier Moranne,1 1Nephrology, CHU Nice, Nice, France; 2REIN Registry, Agence de Biomédecine, St. Denis La Plaine, France; 3Nephrology, CHU Pontchaillon, Rennes, France.

Background: The KDIGO guidelines recommend referral for planning RRT in people at risk of kidney failure. Treatment without dialysis in ESRD patient is another therapeutic option especially in elderly. The objective of our study is to describe the therapeutic projects declared by nephrologist and associated patient’s characteristics and outcomes in a prospective design.

Methods: 573 patients over 75 y/o (82±5 y/o) with eGFR below 20 (14 ± 4) were included by nephrologists in 2009 and followed 4 yrs (Moranne et al 2012). At baseline, we recorded social, clinical characteristics and therapeutic project declared by nephrologist. The first project was considered at the second visit as Postponed decision about dialysis (STAB), decision to start Dialysis when required (DIAL), Non-dialysis made by nephrologist (NDne) or at patient’s request (NDpt). During follow-up, we evaluated the dialysis start and death before dialysis and compared patient’s characteristics and incidence of these events according to the therapeutic projects.

Results: The therapeutic project was STAB in 234 patients (41%), DIAL in 216 pts (38%), NDne in 66 (12%) and NDpt in 55 (10%). Patients were older in ND group, with more women for NDpt and more comorbidities for NDne (dementia, active malignancy,
SA-PO755
Specific Prognosis Factors of Death and Dialysis Start for Elderly Patients Reaching ESRD in the Prospective PSPA Cohort Study
Coraline Fahn,1 Cécile Couchoud,2 Cécile M. Vigneau,1 Olivier Moranne.1 Nephrology, CHU Nice, Nice, France; Agence de Biomedecine, REIN, St Denis de la Plaine, France; Nephrology, CHU Pontchaillou, Rennes, France.

Background: The death before dialysis start is high in elderly patients reaching ESRD and the treatment without dialysis is another option. We need to better predict the outcomes of this specific population and identify prognosis factors to improve strategies of care.

Objective of our study is the identification of prognosis factors of dialysis start or death before dialysis in a multicenter prospective cohort of elderly reaching ESRD.

Methods: 573 patients over 75 y/o were included by nephrologists. We identified specific factors that could discriminate the risk of starting dialysis or died before dialysis to help organisation of the CKD 5 care in elderly patients.

Results: After 4 yrs follow-up, 274 patients (48%) started dialysis and 223 (39%) died. Compared to patients who reached dialysis, elderly patients without dialysis were independently associated with higher risk of death prior to dialysis are: higher age, male, diabetes, lower eGFR, behavioural disorder, less mobility, cerebrovascular disease, cardiac heart failure, active malignancy and anaemia. The variables associated to higher probability of dialysis start are: lower age, male, lower eGFR, high blood pressure, hyperphosphatemia, higher proteinuria, chronic respiratory disease, cerebrovascular disease and less behavioural disorder or active malignancy.

Conclusions: We observed a higher probability of dialysis start than death before dialysis in this population of elderly patients included by nephrologists. We identified specific factors that could discriminate the risk of starting dialysis or died before dialysis to help organisation of the CKD 5 care in elderly patients.

Indoxyl Sulfate, a Representative Uremic Toxin, Suppresses Myogenic Differentiation: Implication in Uremic Sarcopenia
Chih-Kang Chiang,1,2 Un Jong Ao,1 Yuan-Siao Chen,1 Shing-Hwa Liu.1 Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; Deps of Integrated Diagnostics and Therapeutics and Internal Medicine, College of Medicine, National Taiwan Univ, Taipei, Taiwan.

Background: Sarcopenia (or muscle wasting) is a common feature of the uremic phenotype, and retards the process of muscle proliferation and regeneration in uremic individuals. It might disturb skeletal myoblast differentiation and contribute to sarcopenia. In this study, we hypothesized that indoxyl sulfate (IS), a representative protein-bound uremic toxin, might disturb skeletal myoblast myogenesis and differentiation in uremic sarcopenia.

Methods: The mouse myoblast cell line C2C12 was applied to evaluate myoblast differentiation and signaling. Cell viability evaluated by MTT assay. Cell morphology was observed by microscopy. Hematoxylin and cosin staining morphologically analyzed the multilamellated myoblast formation. The expressions of myogenic differentiation markers were also disturbed by IS treatment.

Results: We first investigated the non-lethal concentration of IS by MTT assay, and found IS level less than 1mM without significant cellular toxicity as compared with control group. In order to development the protocol, we confirmed myoblasts were visibly formed throughout 4 days of differentiation first. IS significantly attenuated the number of myotubes and the percentage of mature myotubes. Furthermore, IS significantly and dose-dependently decreased the expression of MyOD, Myogenin and myosin heavy chain, which is the representative markers of slow and fast myofiber phenotype, both in translational and transcriptional level. The molecular signals of myoblast differentiation were also disturbed by IS treatment.

Conclusions: These findings suggest that IS, a uremic toxin, dysregulates myoblast differentiation in C2C12 cells. This is the first time to provide additional evidence that IS might contribute to the development of sarcopenia in uremic patients. Further exploration would give the light to provide potential therapeutics in uremic sarcopenia.

Attitudes, Experiences and Perspectives of Elderly Kidney Transplant Recipients: Thematic Synthesis of Qualitative Research
Jule Pinter,1 Camilla Sara Hanson,1 Jonathan C. Craig,1 Jeremy R. Chapman,1 Klemens Buddke,2 Fabian Halleck,2 Allison Tong.1 Univ of Sydney; 1Charité - Universitätmedizin Berlin.

Background: Kidney transplantation offers improved survival and quality of life in an increasing number of elderly patients with end-stage kidney disease. However, elderly kidney transplant recipients may face unique challenges due to a higher burden of comorbidity, greater cumulative risk of immunosuppression-related complications, and increasing frailty. We aimed to describe the perspectives of elderly kidney transplant recipients.

Methods: Electronic databases were searched to April 2015. Thematic synthesis was used to analyze the findings.

Results: 41 studies involving more than 120 kidney transplant recipients aged 60 yrs and over were included (29 studies did not specify number of patients aged ≥ 60 yrs). We identified 6 themes. Regaining strength and vitality meant valuing the marked physical and psychosocial improvements in daily functioning and life participation. Extending life was the willingness to accept an organ, including an extended criteria kidney, to prolong survival. Debt of gratitude entailed a need to be consciously appreciative towards their donors knowing they were able to repay their sacrifice. Moral responsibility of maintaining health motivated adherence to medication and lifestyle recommendations out of an ethical duty to protect their gift and prolong graft survival. Disillusionsment with transplant reflected disappointment and exasperation at having to contend with side effects and adverse events such as cancer, and residual physical limitations. Finality of treatment option reflected an acute awareness that their current transplant may be their last and some would not return to dialysis if the transplant failed.

Conclusions: Kidney transplantation reverses deterioration of functioning and well-being that patients experienced whilst on dialysis. However, elderly transplant recipients may have anxieties about debilitating adverse events, comorbidities, and a sense of vulnerability that the current transplant may be their last. Addressing these concerns in the care of elderly kidney transplant recipients may improve treatment outcomes in this growing population.

SA-PO759
New Perspectives on the Evolution of Quality of Life and Depression Among Hemodialysis Patients
Christiane Hegedus Karam, Nadia Guimaraes-Souza, Adriano Luiz Ammirati, Maria C.C. Andréoli, Thais Nemoto Matsu, Fabiana Dias Carneiro, Rosana B. Pinter, Manoel F. Hernandez, Bento C. Santos. Nephrology, Hospital Albert Einstein, São Paulo, Brazil.

Background: Hemodialysis is the most common treatment for patients with chronic kidney disease. Five to 22% of patients have a psychiatric condition. The objective of this study was to evaluate the quality of life perception and depression symptoms in three groups of age (<65, 65-75, ≥ 75 y.o.).
Methods: This was a retrospective observational study. Clinical and social demographic data were collected from clinical records. The Kidney Disease Quality of Life and Beck depression inventory were used to assess quality of life and depression symptoms. Results: 104 patients were included. 68.3% were men, 71.2% married, 91.3% Caucasian and 44.2% were in productive life period. A relation between quality of life score and time in dialysis was observed (p=0.0138, CI -0.0223; 0.0033). Patients younger than 65 y.o. showed more favorable results, such as general health perceptions, emotional well-being, energy/fatigue, pain and dialysis staff encouragement. Patients between 65 to 75 y.o. showed lower energy/fatigue index (11.96; CI -22.95; 1.02) and a reduction of 18.97 points (IC: -33.97; -3.98) for emotional well-being. A 15.04 point (CI -27.21; -2.87) and a 14.78-point (p=0.0118, CI -0.0023; 0.0003) reduction, for patients between 65-75 y.o. and for older than 75 years, respectively, was observed in physical function. Burden of kidney disease had a reduction of 13.29 (-25.40; -1.18) and sexual function reduced 69% (27%; 87%) in 65-75 y.o. patients. Patients older than 75 years had a significant increase in quality of social interaction (17%; CI: 1%;36%) and an increase of 16% (CI 3% -30%) in social support. Depression correlated with time in hemodialysis (p = 0.0007; CI 0.14%; 0.55%). For each month an increase of 0.35% on depression symptoms was found. Conclusions: For patients younger than 65 years hemodialysis treatment represents a rehabilitation possibility. Patients over 75 years had significant increase on social support and social interaction. Patients 65 to 75 y.o. had worse perception of quality of life.

SA-PO760

Fibroblast Growth Factor 23 and the Risk of Infection-Related Hospitalization in Older Adults: The Cardiovascular Health Study

Kristen L. Nowak, Traci M. Bartz, Lorien S. Dalrymple, Joachim H. Ix, Ian H. De Boer, Bryan R. Kestenbaum, Michael Shlipak, Pranav S. Gariemana, Michael Chonchol. Univ of California Davis; Univ of California San Diego; Univ of California Davis; Tufts Medical Center.

Background: Fibroblast growth factor 23 (FGF23) may inhibit 25-hydroxyvitamin-D-1α-hydroxylase (CYP27B1) in monocytes. We hypothesized that higher circulating levels of FGF23 may promote intracrine production of 1,25-dihydroxyvitamin D (1,25(OH)2D-1α-hydroxylase (CYP27B1) in monocytes. We hypothesized that higher circulating FGF23 levels may lead to an increase in serious infection risk because FGF23 decreases the intracrine production of 1,25-dihydroxyvitamin D (1,25(OH)2D), which consequently reduces production of cathelicidins.

Methods: Plasma C-terminal FGF23 concentrations were measured in 3141 participants. Cox proportional-hazards models were used to examine the association between FGF23 levels and the first infection-related hospitalization event in study participants. The group aged >75 years had the highest incidence of death and accumulation of co-morbidities. We aim to develop a risk prediction model to identify the characteristics of this phenotype, which may help in modifying their risk.

Conclusions: The group aged >75 years had the highest incidence of death and accumulation of co-morbidities. We aim to develop a risk prediction model to identify the characteristics of this phenotype, which may help in modifying their risk.

SA-PO762

Muscle Strength Rather Than Muscle Mass Is More Important in Evaluating Physical Function in Elderly Patients with Predialysis Chronic Kidney Disease

Yasuhiro Taki, Koji Hiraki, Keita Uehara, Hiroo Kavarazaki, Tsutomu Sakurada, Yugo Shiba, Naho Sato.

Background: Recently, physical function has been reported to be strongly associated with prognosis of patients with chronic kidney disease (CKD). Sarcopenia is well described in CKD patients on dialysis especially of the elderly and is known to be associated with reduced physical function, but whether this is the case in elderly predialysis CKD is undetermined.

Methods: We enrolled consecutive 85 elderly patients (age over 60) with predialysis CKD (estimated GFR < 60 ml/min/1.73m2) in outpatient nephrology clinic at St Marianna University Hospital. We evaluated kidney functional parameters, muscle mass by bioimpedance, muscle strength by dynamometer (hand grip, knee extension) and 4-meter walking speed in these participants.

Results: Average age was 74 years old, 76% were men, 33% had diabetes mellitus (DM) and average eGFR was 28.6ml/min/1.73m2. Patients were divided into those with eGFR<30 or ≥30. After adjustment for age, gender and history of DM, hand grip strength (p=0.0001; 95%CI: -4.36; -7.85), knee extension strength (p=0.001; 95%CI: -2.28; -8.97) and 4-meter walking speed (p<0.001; 95%CI: -0.03; -0.22) were significantly reduced in those with eGFR<30. However, there was no difference in muscle mass (p=0.23, 95%CI: -0.68; -0.23).

Conclusions: In conclusion, muscle strength and walking speed but not muscle mass measured along with progression of CKD. Thus, it seemed more important to check muscle strength and walking speed rather than muscle mass when evaluating physical function in elderly patients with predialysis CKD.
SA-PO763

Lower Muscle Endurance, Strength and Quality Are Associated with Greater Risk of Functional Limitations in Older Adults with CKD
Baback Roshanravan,1 Kushang V. Patel,1 Linda F. Fried,1 Ian H. De Boer,1 Cassianne Robinson-Cohen,1 Anne B. Newman,2 Bryan R. Kestenbaum,1
1Medicine/Nephrology, Kidney Research Inst - Univ Washington, Seattle, WA; 2Univ of Pittsburgh, Pittsburgh, PA; 3Univ of Washington, Seattle, WA.

Background: Chronic kidney disease is associated with inflammation and insulin resistance, contributing to fatigue and muscle weakness. The association of muscle endurance, strength, and quality with functional limitation among persons with CKD is unknown.

Methods: We studied 186 participants with eGFR<60 at the year 3 Health ABC visit. Participants were excluded if unable to complete >90% of quadriceps isokinetic fatigue testing. Quadriceps endurance was defined by total work using isokinetic dynamometer. Quadriceps strength was measuring by isometric torque. Leg lean mass (legml) was measured using DXA. Muscle quality was defined by specific work (work/legml) and specific torque (torque/legml). Outcome was incident persistent severe lower extremity limitation (PSLL) based on 2 consecutive reports of having a lot of difficulty or inability to walk 1/4 mile or climb 10 steps without resting. We used competing risks regression.

Results: Participants had a mean age 76.2 ±3.3yrs, eGFR<60 of 49.2 ±10. None had mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with a 1.38 fold (95 CI 1.04, 1.85, P=0.028) and 1.43 fold (95 CI 1.01, 2.03 P=0.045) greater risk of PSLL, respectively. Leg lean mass was not associated with PSLL (P=0.12).

Conclusions: Among older adults with CKD free of mobility disability, lower muscle endurance, strength, and quality are independently associated with greater risk of severe lower extremity limitation.

SA-PO765

Determinants of Impaired Cardiorespiratory Fitness in Older Adults with CKD
Stephen L. Seliger,1,2 Jamie Giffuni,3 Roger A. Fielding,3 Eamon F. Fleming,2 Christine Liu,1,4 Leslie I. Katzel,1,2 Kieran Reid,2 Sushrut S. Waikar,4 Andrew M. Well,5 Daniel E. Weiner,1 1Medicine, U Michigan School of Medicine; 2GRECC, VA Maryland Healthcare System; 3Tufts Univ Sch of Medicine; 4Boston Univ Sch of Medicine; 5Emory Univ School of Medicine.

Background: Chronic Kidney Disease (CKD) may be associated with impaired cardiorespiratory fitness (CRF). We examined methods of estimating CRF in CKD and identified factors associated with CRF.

Methods: We measured peak aerobic capacity (VO2peak) using a modified Graded Exercise Treadmill Test (GXT) in 71 older adults with CKD stage 3b-4 in an ongoing exercise clinical trial. GFR was estimated with the CKD-Epi equation. Linear regression was used to examine factors associated with VO2peak. Resting VO2 was measured prior to GXT in seated position. Metabolic Equivalents of Task (MET, oxygen consumption during exercise relative to rest) was estimated at peak exercise based on GXT stage and compared to actual achieved METs.

Results: Mean age was 68.4±7.7 years, with 61% African-Americans, 30% men; mean eGFR was 33±11 ml/min/1.73m2 and mean Hb 12.3±1.6 g/dL. Mean VO2peak was 17.4±5.4 ml/kg/min, which was 31±17 lower than expected based on normative values (p<0.001). In a multivariate model including demographics and co-morbidity, lower hemoglobin - but not GFR - was associated with lower VO2peak (Table). Albuminuria did not correlate with VO2peak.

</table>

**Estimated METs**: Mean achieved METs was 5.6±1.8. Although there was low bias for estimated vs. achieved METs (mean difference, -0.45), precision and accuracy were poor, with only 35% of predicted values within 1 MET of achieved values, and nearly one third of estimated values >30% different from achieved.

Conclusions: Among older adults with CKD stage, CRF as reflected by VO2peak is markedly impaired. Lower hemoglobin, obesity, and prevalent cardiac disease are associated with worse aerobic capacity. The use of estimated METs during treadmill testing poorly estimates actual aerobic capacity.

Efficacy and Safety of Exercise Training in Patients with Predialysis Chronic Kidney Disease
Yuqo Shibagaki,1 Koji Hiraki,2 Takashi Yasuda,1 Kenjiro Kimura,1 1Div of Nephrology and Hypertension, St. Marianna Univ; 2Div of Rehabilitation, St. Marianna Univ.

Background: Efficacy and safety of exercise training has not been well studied in patients with predialysis chronic kidney disease (CKD). Since we have reported in elderly patients with predialysis CKD that there was a significant reduction in muscle strength and short-term exercise did not damage kidney, we conducted a randomized controlled trial to elucidate the long-term efficacy and safety of exercise in this population.

Methods: Study design was a randomized controlled trial. Thirty six male elderly patients with CKD stage 3-4 seen at the outpatient nephrology clinic at St. Marianna University Hospital agreed to participate in the study with written informed consent. We randomly divided them into intervention (I) group and control (C) group. Patients with I group were advised to walk fast for 30 minutes a day or 10,000 foot steps a day and was trained to do muscle training for upper/lower extremities at every clinic visit for 12 months. Participants had a mean age 76.2 ±3.3yrs, eGFR<60 of 49.2 ±10. None had mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with a 1.38 fold (95 CI 1.04, 1.85, P=0.028) and 1.43 fold (95 CI 1.01, 2.03 P=0.045) greater risk of PSLL, respectively. Leg lean mass was not associated with PSLL (P=0.12).

Conclusions: Among older adults with CKD free of mobility disability, lower muscle endurance, strength, and quality are independently associated with greater risk of severe lower extremity limitation.

SA-PO766

Access to Kidney Transplantation and Outcomes of Those Listed for Kidney Transplant in Elderly
Pritika Shrivastava,1 Ankit Sakhija,1 Diane M. Cibrik,2 Abhijit S. Naik,1 1Div of Transplant Nephrology, U Michigan, Ann Arbor, MI.

Background: Data suggests that patients above 70 years of age (>70 y.o.) with ESRD derive a benefit from kidney transplant (KT). We report our single center experience of access to transplant and outcomes for those >70 y.o. listed for KT. We used the number of evaluations in a year and rate of acceptance after evaluation as surrogate markers for KT access in elderly.

Methods: We assessed the rate of acceptance for KT and its trends over the years for those >70 y.o. between 2000-2014. Linear regression was used to assess trends over time. Differences in rates of listing stratified by diabetes status, KT rates among those approved for listing by diabetes status and mortality among those transplanted vs waitlisted was assessed.

Results: Over 15 year period, we evaluated 612 elderly patients (pts). 25.3% of those evaluated were approved to be listed for transplant. There were 9 patients who were evaluated twice of those 5 were approved for listing the second time and two got transplanted. There was 300% increase in annual evaluation of the elderly from year 2000 to 2014 and trend towards increased acceptance rate of those evaluated (slope=0.82, p=0.12).

Conclusions: Lower hemoglobin, obesity, and prevalent cardiac disease are associated with worse aerobic capacity. The use of estimated METs during treadmill testing poorly estimates actual aerobic capacity. The rate of acceptance for KT and its trends over the years for those >70 y.o. between 2000-2014. Linear regression was used to assess trends over time. Differences in rates of listing stratified by diabetes status, KT rates among those approved for listing by diabetes status and mortality among those transplanted vs waitlisted was assessed.
Factors Associated with Early Death After Dialysis Initiation Among Elderly CKD Patients

Methods: We studied 621 CKD patients ≥65 years from an EMR based CKD registry linked to the USRDS data. We retrospectively analyzed factors associated with one year mortality after dialysis initiation including: age, sex, race, presence of diabetes, hypertension, BMI, stroke, CHF, COPD, malignancy, peripheral vascular disease, depression, alcohol use, smoking, presence of AVF, pre-dialysis serum albumin and potassium.

Results: In our study, 224 (36%) patients died within the first year of dialysis initiation. Results from the Cox proportional model showed that older age and CHF were associated with early deaths, while higher albumin, presence of AVF and HTN were associated with a lower hazard of early death.

Conclusions: CHF and older age in the pre-dialysis setting are associated with higher 1-year mortality after dialysis initiation. These prognostic data need to be presented to geriatric CKD patients while discussing renal replacement therapy options.

P-Cystatin C Improves GFR Estimation in Older People

Background: There is a need for validation of commonly used cystatin C and creatinine based formulas for eGFR (estimated glomerular filtration rate) in the older segment of the general population for all levels of kidney function.

Methods: Markers used for eGFR estimation were P-Cystatin C and P-Creatinine. Measured GFR (mGFR) adjusted to body surface area was performed by a single sample iohexol clearance in 112 participants, aged 70-100 years old from the population-based cohort “Good Aging in Skåne”. The participants were selected to cover a wide range of kidney function and to obtain an even distribution regarding sex and age. The timing of the sample depended on eGFR (eGFR >50, 25-50, and >25 at 4, 7, and 24 hours respectively).

Results: There were 57 women and 55 men. Mean age was 82 years and mean GFR 55 ml/min per 1.73m². Results are presented in the table.

Conclusions: All the formulas that include cystatin C performed well in this Swedish cohort with a mean age above 80. This confirms that it is safe to use either of those formulas in our older patients across a wide spectrum of kidney function. However, the formulas based solely on creatinine are not reliable enough below GFR 45. Further sub-analysis can demonstrate detailed performance for males and females respectively, for all CKD-stages and for smaller age-intervals.

Factors Associated with Early Death After Dialysis Initiation Among Elderly CKD Patients

Background: There are limited studies examining prognosis for elderly CKD patients following dialysis initiation. Herein, we evaluated the factors associated with poor one year survival after dialysis initiation among elderly CKD patients at our institution.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

805A
Methods: This is a single-center, retrospective cohort study from January 2009 to December 2014. In total, 90 ESRD patients commencing HD were enrolled. All the patients were aged 65 years or older. Six-month and 3-year survival rates and prognostic factors for mortality were evaluated.

Results: The mean follow-up period was 21.7±18.3 months. The 6-month and 3-year survival rate were 94.0% and 66.9%, respectively. Age, unplanned initiation of HD, presence of heart failure, high value of estimated GFR on starting HD, Charlson comorbidity index (CCI), and Eastern Cooperative Oncology Group Performance status scale (ECOG-PS) were associated with 3-year mortality, whereas only the presence of heart failure and ECOG-PS were significant predictors of 6-month mortality. There was no significant difference in 6-month mortality rate between patients aged ≥80 and <80. On the other hand, 3-year mortality rate of ≥80-year-old patients was significantly higher than that of <80 (≥80: 53.3% vs <80: 14.2%, p = 0.0004).

Conclusions: There is a variation of significance among different prognostic factors according to the duration of life after starting hemodialysis. The presence of heart failure and ECOG-PS predicted short-term mortality among elderly ESRD patients starting HD. These results might help clinical decision making when nephrologists consider commencing HD for elderly ESRD patients.

SA-PO770 Cumulative Cardiovascular Polypharmacy Is Associated with the Risk of Geriatric Acute Kidney Injury Chia-Ter Chao,1 Hung-Bin Tsai,2 1Dept of Medicine, National Taiwan Univ Hospital Jin-Shan Branch, New Taipei City, Taiwan; 2Dept of Traumatology, National Taiwan Univ Hospital, Taipei, Taiwan.

Background: Polypharmacy is common in the elderly due to multiple morbidities. However, the effect of polypharmacy on renal outcomes is rarely recognized. We investigated the effect of cardiovascular polypharmacy on acute kidney injury (AKI) in elderly patients.

Methods: We used the Taiwan National Health Insurance PharmaCloud system to investigate the relationship between cumulative cardiovascular medications in the 3 months prior to admission and risk of AKI in the elderly at admission to general wards. Community-dwelling elderly patients (>60 years) were prospectively enrolled and classified according to the number of pre-admission cardiovascular medications. Cardiovascular polypharmacy was defined as use of 2 or more relevant medications.

Results: We enrolled 152 patients, 48% with AKI (based upon Kidney Disease Improving Global Outcomes [KDIGO] classification) and 64% with cardiovascular polypharmacy. The incidence of AKI was higher in patients taking more cardiovascular medications (0 drugs: 33%; 1 drug: 50%; 2 drugs: 57%; 3 or more: 66%; p = 0.048). Patients with higher KDIGO grades also took more cardiovascular medications (p = 0.04).

Conclusions: We enrolled 152 patients, 48% with AKI (based upon Kidney Disease Improving Global Outcomes [KDIGO] classification) and 64% with cardiovascular polypharmacy. The incidence of AKI was higher in patients taking more cardiovascular medications (0 drugs: 33%; 1 drug: 50%; 2 drugs: 57%; 3 or more: 66%; p = 0.048). Patients with higher KDIGO grades also took more cardiovascular medications (p = 0.04).

SA-PO771 Low Bicarbonate Associates with Higher Mortality Independent of pH in Healthy Older Individuals: The Health, Aging, and Body Composition Study Kalani L. Raphael,1 Rachel A. Murphy,1 Michael Shilpak,2 Suzanne Satterfield,3 Hunter K. Huston,1 Anthony Sebastian,1 Deborah Sellmeyer,1 Kushang V. Patel,1 Anne B. Newman,1 Mark J. Sarnak,3 Joachim H. Ix,4 Linda E. Fried,4 University of Washington; 5University of California San Francisco; 6University of Tennessee; 7Johns Hopkins Univ; 8Univ of Washington; 9Univ of Pittsburgh; 10Tifts Medical Center; 11Univ of California San Diego.

Background: Low serum [HCO3-] associates with higher mortality in CKD. The purpose of this study is to determine if [HCO3-] associates with all-cause mortality independent of systemic pH in healthy older persons.

Methods: Data were analyzed from the Health, Aging, and Body Composition Study, an observational study of black and white adults aged 70-79 years followed from 1997-2014. Arterialized venous blood gas measurements were obtained in 2,287 participants. Participants were grouped into one of 3 [HCO3-] categories: <23.0 (low), 23.0-27.9 (reference group), and ≥28.0 mEq/L (high). Mortality hazard ratios (HR) in the low and high [HCO3-] groups were compared to the reference group using Cox models adjusted for demographics, eGFR, albuminuria, COPD, smoking, and pH. Multivariable interaction terms tested whether CKD status modified the relationship between [HCO3-] categories and mortality.

Results: The mean age was 78 years, 51% were female, and 38% were black. The mean pH was 7.41, mean [HCO3-] was 25.1 mEq/L, 11% had low and 10% had high [HCO3-]. The mean eGFR was 82.1 ml/min/1.73m2; 12% had CKD. During follow-up (mean 10.3 years), 1,326 (58%) participants died. The adjusted all-cause mortality HR was 1.24 (95% CI, 1.02-1.49) in the low [HCO3-] category and 1.03 (95% CI 0.84-1.26) in the high [HCO3-] category compared to the reference group. CKD status did not modify the association between [HCO3-] and mortality (p=0.74).

Conclusions: Healthy older persons with low [HCO3-] have higher mortality risk than those with normal [HCO3-] independent of pH and potential confounders. High [HCO3-] does not associate with higher mortality. The potential health benefits of normalizing low [HCO3-] in generally healthy older persons should be investigated.

SA-PO772 Low Urinary Creatinine Excretion Is a Valid Surrogate for Frailty in Patients with Advanced Chronic Kidney Disease Harmeke Polinder-Bos,1 Hakon Nacak,1 Friedo W. Dekker,1 Stephan J.L. Bakker,1 Carlo A. Gaalder,1 Ron T. Gansevoort,1 1Internal Medicine, Univ Medical Center Groningen, Groningen, Netherlands; 2Epidemiology, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Muscle wasting is a key component of frailty, which is highly prevalent in advanced stages of chronic kidney disease (CKD). Whether low urinary creatinine excretion (UCrE) is a valid surrogate for frailty is unknown. We studied cross-sectional associations between frailty and a low UCre in patients with CKD stages 4 and 5 (not on dialysis).

Methods: 2748 healthy individuals of the general population were included to define low UCre. Low UCre was defined as height-indexed UCre below the age- and sex-specific 5th percentile. In a CKD population including 320 and 967 participants of the resp. PREPARE-2 and NEOCOSAD studies, associations of frailty, the individual components that define frailty, and frailty-associated variables with low UCre were evaluated using multivariate logistic and linear regression models. Frailty was defined as a composite construct including self-reported poor physical functioning, exhaustion, low physical activity, and underweight.

Results: In the general population with a median age of 46 years, median UCre was 9.8 mmol/day for women and 14.3 mmol/day for men, compared to 7.0 mmol/day and 9.5 mmol/day in CKD patients, respectively. In the CKD patients with a median age of 63 years, low UCre was found in 38%. Frailty, and the individual components that define frailty, were associated with a low UCre, independent of comorbidities (OR frailty = 2.19 [1.28-3.77], p=0.005). Of the frailty-associated variables, lower hemoglobin and albumin levels, and higher parathyroid hormone levels were associated with low UCre. Adjustment for GFR attenuated the associations of frailty, and the individual components that define frailty with low UCre, except for underweight.

Conclusions: Low UCre is a valid surrogate for frailty, independent of comorbidity. Low UCre is strongly determined by a lower kidney function, suggesting that reduced kidney function induces changes in muscle mass and performance leading to frailty.

SA-PO773 Oral Anticoagulation and Kidney Function in Elderly Antonios Dourou,1 Elke Schaeffner,1 Olga Jakob,1 Reinhold Kreutz,1 Natalie Ebert,1 1Clinical Pharmacology, Charité; 2Nephrology, Charité; 3Clinical Epidemiology, Charité.

Background: In the past years new oral anticoagulants (NOACs) were approved expanding our pharmacological arsenal. Data on their utilization in elderly compared to vitamin K antagonists (VKA) are scarce and the impact of kidney function (KF) on NOAC use in a population with declining glomerular filtration rate (GFR) is of great interest. The present study investigates anticoagulant use and KF in people ≥70 years. Medication was assessed through personal interviews and coded using the Anatomical Therapeutic Chemical Classification System. For GFR estimation we used the CKD-EPI equation. Predictor analysis was conducted via logistic regression.

Results: Figure 1 illustrates the percentage of drug use for the three NOACs and phenprocoumon, the most common VKA in Germany, over the course of 4 years.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

**P<0.05, ***P<0.01, ****P<0.001

Conclusions: This study demonstrated high symptom burden, reduced functional status and QOL in dialysis patients. Patients with severe pain, weakness, shortness of breath, nausea, mouth problems, drowsiness, poor mobility and skin changes were more likely associated with higher mortality risk. Symptom identification and management may help predict and improve patient QOL outcomes in dialysis patients.

SA-PO775

Outcomes of Cardiopulmonary Resuscitation in Maintenance Dialysis Patients Based on CPR Characteristics

Haris Farooq Murad, Fahad Saeed. Cleveland Clinic Foundation.

Background: Cardiopulmonary resuscitation (CPR) is associated with high rates of mortality, especially in patients with end stage renal disease (ESRD). Previous studies have reported an in-hospital mortality rate of up to 75% in ESRD patients undergoing CPR. There are no large studies to date on how individual CPR characteristics relate to the long term outcomes in these patients. Herein, we aimed to answer this question.

Methods: By an EMR inquiry, we identified all the adult patients (>18 years) who had underwent CPR from January 2006 to December 2014, and then selected patients who were on maintenance dialysis. We conducted a chart review of CPR characteristics and its association with the hospital discharge survival. We studied following variables: initial rhythm, duration of CPR, in-hospital versus out of hospital CPR and the use of hypothermia protocol.

Results: We studied a total of 497 ESRD who had undergone CPR. Sixty eight percent of our patients had expired in the hospital post-CPR. Pulsless electrical activity (PEA) was the most common initial rhythm (51.4%), followed by ventricular arrhythmias (19.6%) and asystole (19.2%). In-hospital mortality was the highest (76.8%) for patients with asystole. Mortality rates at the time of discharge were 73.3% for PEA and 57.7% for patients with ventricular arrhythmias respectively. Fifty six percent of patients who underwent therapeutic hypothermia died in the hospital as compared to 68.9% of those who did not undergo a cooling protocol. CPR duration of greater than 10 minutes was associated with higher in-hospital mortality (76.1%) as compared to patients who had CPR for less than 10 minutes (40.9%). Patients who had undergone out of hospital CPR (by paramedics or bystanders), 72.2% died before discharge; while 68.9% of patients who underwent CPR in the hospital expired during the same hospitalization. The average length of stay for patients who were alive at discharge was 17 days.

Conclusions: CPR in dialysis patients is associated with high mortality rates. It is possible to predict hospital discharge survival of patients with cardio-pulmonary arrest based on the CPR characteristics.

SA-PO776

End of Life Care Preferences in Maintenance Dialysis Patients

Haris Farooq Murad, Muhammad Adil Sardar, Syed Zamrak Khan, Sara N. Davison, Fahad Saeed. Cleveland Clinic Foundation; Univ of Alberta.

Background: Dialysis patients have an annual mortality rate of 20-25%. A previous Canadian study comprising mainly of Caucasian patients has shown that patients are interested in active involvement in end of life care discussions and majority would want to know their prognosis on dialysis. In this Caucasian predominant cohort, approximately 50% chose to be DNR. It is not known if patients' preferences on end of life care are any different in a racially more diverse cohort of patients in the U.S.
Methods: We collected data on 423 out of 440 dialysis patients from 7 dialysis facilities in the US using paper questionnaires. Results: Our study included 28.1% Caucasian and 66.7% African American patients. Eighty three percent of the patients felt that their QOL was an important determinant in guiding their future care plans, and 72.3% of patients reported that they had to have frequent discussions about QOL with their nephrologist. Only 35.4% of patients actually get information about their health and well-being from their nephrologists. Only 8.6% of patients had a discussion with any Physician, nurse or social worker regarding end of life care during the past 12 months. Notably, 74.2% of our participants reported that they would like to have such discussions with their healthcare provider. Sixty seven percent of the patients wished to be full code. Fifty six percent of the patients preferred to die at home versus 20.4% wanted to die in a hospice facility and 13.4% in a hospital. Only 23.6% of patients knew about palliative care.

Conclusions: There is a need to have more dialogue between patients and their nephrologists regarding end of life care preferences, and it is necessary to develop policies and practices that would help address this need.

SA-PO777

“So I had No Choice”: Perceptions of Dialysis Decision-Making Among Older Adults Keren Ladin,1 Daniel E. Weiner.2 (1Occupational Therapy, Tufts Univ, Medford, MA; 2Medicine, Tufts Univ Medical School, Boston, MA.)

Background: Multiple treatments are available to older patients with advanced chronic kidney disease. However, poor communication about available treatment options may result in a mismatch between patient preferences and treatment choice.

Methods: Semi-structured in-depth interviews were conducted with a purposive sample of 10 patients aged 65 and older at two dialysis clinics in the Greater Boston area. Trained researchers conducted, audiorecorded and transcribed interviews. Applying grounded theory, interviews were and analyzed in an iterative process to identify emergent codes. Codes were discussed using consensus and organized into themes.

Results: Twenty-six patients participated in the interview. Mean age was 77±9 years; 50% were men, 19% African American and 56% diabetic. Median vintage was 28 (17, 39) months. Four major themes with associated subthemes were identified. The first, “Deciding to start dialysis” revealed that only two patients conceptualized dialysis initiation as a choice. Patients were seldom informed of conservative management, and many had unanswered concerns about trade-offs among treatment choices. The second theme, “Experience with dialysis”, included positive and negative physical, emotional, and social consequences of dialysis and logistics of care. While many reported greater than anticipated levels of pain, fatigue, and frustration over transportation costs and time, others reported substantial benefits, including increased longevity and the ability to achieve life goals. The third theme, “Patient Role”, revealed patients tied self-worth to meeting clinical goals. Finally, “End-of-life (EOL) preferences and conversations” revealed that most patients had not discussed EOL with their clinical team and or with loved ones.

Conclusions: Many older patients who treated with dialysis do not perceive that they had a choice when making their dialysis decision. Initiating dialysis may contradict patients’ EOL preferences, and many desire greater information and more discussions with clinicians. Older adults’ preferences and experiences with dialysis vary, underscoring the importance of patient involvement in decision-making.

SA-PO778

Improving Advance Care Planning in Elderly Outpatients with Chronic Kidney Disease: A Quality Improvement Initiative Binh K. Nguyen,1 K. Souris,2 and M. Schell.1 1Section of Palliative Care and Medical Ethics, Univ. of Pennsylvania Medical Center, Pittsburgh, PA; 2Renal-Electrolyte Div, Univ of Pittsburgh Medical Center, Pittsburgh, PA.

Background: Despite a high annual mortality rate in patients with advanced chronic kidney disease (CKD), advance care planning (ACP) is underutilized. A minority of dialysis patients complete advance directives (AD). Timely ACP ensures that patients’ preferences for future care are respected and is associated with less intensive care at end of life. We sought to introduce ACP and increase documentation of AD in older outpatient CKD patients.

Methods: This quality improvement study was conducted over 15 weeks in older outpatients at the University of Pittsburgh Kidney Clinic. The intervention included training and rewarding the CKD nurse educator to introduce and encourage ACP completion. Inclusion criteria were age older than 65 years and referral to the CKD education session. The CKD nurse educator was assigned the role of asking whether each patient had AD and a designated healthcare power of attorney (HPOA). The nurse additionally offered every eligible patient the Five Wishes AD form and documented the AD and HPOA screening information was documented by the nurse educator in 56% and 61.5% patients respectively. One patient had an AD scanned in the electronic records and one patient requested referral to the Renal Supportive Care clinic for continuation of ACP discussions.

Results: Of the 110 patients who underwent CKD education over a period of 15 weeks, 52 (47.2%) were eligible. Thirty-one of 52 (59.6%) patients already had AD and 32 of 52 (61.5%) had a HPOA. Thirteen of 52 (25%) were interested in reviewing the Five Wishes AD form and had already completed an AD. The AD and HPOA screening information was documented by the nurse educator in 56% and 61.5% patients respectively. One patient had an AD scanned in the electronic records and one patient requested referral to the Renal Supportive Care clinic for continuation of ACP discussions.

Conclusions: Only 2 patients had ADs in their charts (1.0%). In adjusted analyses, racial differences in receipt of intensive procedures were most pronounced at older ages (black vs. white aOR [95% CI]; 1.38 [1.33-1.42] in patients < 55 years, 2.48 [2.38-2.59] in patients 85+ years). Based on the Prochaska model we are anticipating that the staff nephrologists change their practice behaviour and begin to ask their hemodialysis patients about ADs and document the discussion? As part of the process to discuss ADs, the unit’s social workers distributed a pamphlet for the patients with simple and explicit definitions and advantages of AD and also provided explanations about the contents of the AD forms. The Staff Nephrologists were educated about the importance and advantages of ADs in their patients and were asked to start discussing the issues with their patients. The Nephrologists will also be educated about how an AD discussion might go and how to document the results of the discussion. In 3 months, a review of the patients’ charts will again look for any documented ADs. We will also study the response of individual dialysis staff and their participation in completing and discussing the ADs. We will assess the potential barriers for not completing ADs by the dialysis unit staff and by patients and attempt to address these barriers.

Conclusions: Expected Outcome: Based on the Prochaska model we are anticipating that the dialysis staff are now in the contemplation stage and we are aiming to observe the progression in their behavior to more advanced stages of behavior and try to find out what are the barriers that prevent the progression.

Will Nephrologists Implement an Advance Directives Program in Their Patients? (Quality Improvement Program) Ali Mohammad Habeeb, Sheldon W. Tobe. Nephrology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Background: Mortality remains high among patients on dialysis. Advanced age and multiple co-morbidities are the major predictors for increasing mortality. ADs extend patient autonomy and are the best tool to inform patients and family about health care decisions when they become unable to make such decisions. Chronic dialysis patients have been shown to want to discuss ADs in the past.

Methods: We reviewed 215 chronic in-center hemodialysis patients at Sunnybrook Health Sciences Centre from March to April 2015 by the dialysis unit social workers for any documents related to ADs (like Living wills, Substitute Decision Maker (SDM) and CPR forms). Only 2 patients had ADs in their charts (1.0%). When this data has been presented to the Nephrologists they agreed that ADs should be discussed with their patients and that this was a quality improvement issue. The Staff Nephrologists change their practice behaviour and begin to ask their hemodialysis patients about ADs and document the discussion? As part of the process to discuss ADs, the unit’s social workers distributed a pamphlet for the patients with simple and explicit definitions and advantages of AD and also provided explanations about the contents of the AD forms. The Staff Nephrologists were educated about the importance and advantages of ADs in their patients and were asked to start discussing the issues with their patients. The Nephrologists will also be educated about how an AD discussion might go and how to document the results of the discussion. In 3 months, a review of the patients’ charts will again look for any documented ADs. We will also study the response of individual dialysis staff and their participation in completing and discussing the ADs. We will assess the potential barriers for not completing ADs by the dialysis unit staff and by patients and attempt to address these barriers.

Conclusions: Expected Outcome: Based on the Prochaska model we are anticipating that the dialysis staff are now in the contemplation stage and we are aiming to observe the progression in their behavior to more advanced stages of behavior and try to find out what are the barriers that prevent the progression.

Current Practice of Advance Care Planning in New Zealand and Australian Renal Centres

Robert L. Morgan,1 2 Lucy Spencer,3 Allison Tong,4 Carol A. Pollock,2 4 Karen M. Detering,5 Josephine M. Clayton,5, 1 The Univ of Sydney, Australia; 2 Royal North Shore Hospital, Australia; 3 HammondCare Palliative Care Service, Australia; 4 Austin Health, Australia; 5 On behalf of Univ of Technology Sydney Collaborators.

Background: Recent guidelines emphasise the need to improve advance care planning (ACP) for patients with chronic kidney disease (CKD). Little is known about current ACP practice in Australian/New Zealand renal centres. We aimed to describe current practice and barriers to ACP from the perspective of renal clinicians.

Methods: A cross-sectional survey was administered online to nephrology nurses, nephrologists, and social workers between June 2014 and January 2015. Surveys covered the topics of experience, skills, comfort and knowledge regarding ACP, workplace policies and procedures concerning ACP, perceived barriers and facilitators to ACP, and perceived need for new CKD-specific ACP programs and materials.

Results: The survey was completed by 487 nephrologists and social workers from all Australian states and territories and New Zealand. 57% indicated that ACP was performed in their workplace on an ad-hoc basis; 22% reported that there was a formal program; 13% reported that ACP hardly ever occurred; and 8% were unsure. 61% reported that ACP was done poorly, 32% well, and 7% were unsure. Perceived barriers to ACP included patient/discomfort (72%), cultural/language barriers (65%), environmental problems such as lack of space (61%) and lack of formal policy/procedures (60%). Whilst discouragement from colleagues or managers was identified as a barrier in only 19% of cases, narrative comments on the survey emphasised the gate-keeping role played by nephrologists.

Conclusions: ACP in Australian/New Zealand renal centres is subject to health system, provider and patient related barriers. Given the volunteer effect associated with online surveys, our study may underestimate the need for ACP support. Targeted interventions are needed to improve ACP in Australian and New Zealand renal centres.

Nephrology Leadership Required to Address Unmet Palliative Care Needs in Dialysis Centers

Alvin H. Moss,1 Stacey Culp,1 Dale Lupu,2 Cheryl Arenella,2 Nancy C. Armitstead,3 1 Medicine, West Virginia Univ School of Medicine, Morgantown, WV; 2 DaVie1 Associates, Silver Spring, VA; 3 Mid-Atlantic Renal Coalition, Richmond, VA.

Background: Because of high symptom burden, numerous comorbidities, and shortened life expectancy, dialysis patients are increasingly recognized as appropriate candidates for early and continuous palliative care.

Methods: In 2013 the Coalition for Supportive Care of Kidney Patients conducted an online survey of dialysis professionals and administrators using ESRD Network and Renal Physicians Association email lists to determine perceptions about how well patient palliative care needs are met. Differences among disciplines were assessed by chi-squared testing and one-way ANOVA.

Results: The 487 respondents included 41 nephrologists, 152 nurses/physician assistants, 199 social workers, and 95 dialysis center administrators. There was a significant difference by discipline in reported unmet palliative care needs for symptom management, care coordination, and family bereavement support, with administrators least likely to view each need as unmet (all p < .05). In rating possible barriers to providing high quality palliative care in their centers, mean age 48 years, from renal centers in all Australian states and territories and New Zealand, 57% indicated that ACP was performed in their workplace on an ad-hoc basis; 22% reported that there was a formal program; 13% reported that ACP hardly ever occurred; and 8% were unsure. 61% reported that ACP was done poorly, 32% well, and 7% were unsure. Perceived barriers to ACP included patient/discomfort (72%), cultural/language barriers (65%), environmental problems such as lack of space (61%) and lack of formal policy/procedures (60%). Whilst discouragement from colleagues or managers was identified as a barrier in only 19% of cases, narrative comments on the survey emphasised the gate-keeping role played by nephrologists.

Conclusions: ACP in Australian/New Zealand renal centres is subject to health system, provider and patient related barriers. Given the volunteer effect associated with online surveys, our study may underestimate the need for ACP support. Targeted interventions are needed to improve ACP in Australian and New Zealand renal centres.

Hospice and Race for End-of-Life Care in U.S. Dialysis Patients

Robert N. Foley,1 Scott Reule,1 Donal J. Sexton,1 1 Div of Nephrology, Univ of Minnesota, Minneapolis, MN; 2 Div of Medicine, National Univ of Ireland, Galway.

Background: While hospice use is increasingly used for end-of-life care in dialysis patients, we hypothesized that important racial disparities may be present.

Methods: To address this hypothesis, we examined USRDS files to characterize end-of-life care for deaths occurring between 2006 and 2011.

Results: During this 5-year period, the proportion of deaths in hospice increased from 14.7% to 24.2%; grouped by age at death, the following trends were observed: < 65 years-11.5% to 15.0%; 65 to 79 years-19.1% to 26.1%; 80-89 years-24.9% to 34.3%; > 90 years-25.9% to 39.6%. As shown in the accompanying Table, associations of hospice use among decedents included more recent calendar year, older age and female sex. Hospice use varied substantially with race: compared to whites, adjusted odds ratios of hospice use were 0.56, 0.56 and 0.57, respectively, in patients of African American, Native American and Asian race.

Conclusions: While end-of-life care in hospice settings is growing rapidly in the US, substantial, unexplained racial disparities exist.

Palliative Care Perspectives of Latinos with End-Stage Renal Disease

Lilia Cervantes,1,2 Stuart L. Linas,3,4 Stacy M. Fischer. 1 Dept of Medicine, Univ of Colorado, Denver, CO; 2 Dept of Medicine, Denver Health and Hospital, Denver, CO.

Background: Latinos are the fastest growing minority and have a nearly 2-fold faster progression from chronic kidney disease to end-stage renal disease (ESRD). Despite the high symptom burden and mortality suffered by patients with ESRD, there is limited palliative care research and Latinos are underrepresented in existing palliative care studies.

The purpose of our study is to provide the first description of the Latino palliative care perspective.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We modified Davison’s 2010 End of Life Care Preferences and Needs Survey to include known barriers to palliative care in the Latino community. The survey was translated to 3rd grade Spanish and then back-translated to English.

Results: Participants (n=61) had a mean age of 59 years ± 12, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 months ±44.8. The majority (77%) spoke Spanish and reported limited understanding of hospice and palliative care. We found that 60 (98%) want to be informed about their prognosis and 55 (90%) want to be prepared and plan ahead; however, only 16 (26%) had discussed prognosis and only 10 (16%) had discussed end-of-life care with their nephrologist. The majority of participants stated that it was their doctor’s choice (68.8%) to start dialysis; however, few (14.7%) regret the decision to start dialysis. Participants reported a preference to have advance care planning conversations on a routine basis (86.8%), after starting dialysis but before becoming ill (85.2%), and while receiving dialysis (47.5%) or at home (37.7%). Participants want their family to have a central role in medical decision-making (93.4%) and care giving (95%).

Conclusions: Our findings provide the first description of the palliative care perspectives of a predominantly Mexican Latino population with ESRD. By understanding the palliative care perspectives and barriers experienced by Latino patients with ESRD, we can move toward a value-based and patient-centered model of palliative care.

Symptom Burden Amongst Latinos with End-Stage Renal Disease

Lilia Cervantes,1,2 Stuart L. Linas,3,4 Stacy M. Fischer. 1 Dept of Medicine, Univ of Colorado, Denver, CO; 2 Dept of Medicine, Denver Health and Hospital, Denver, CO.

Background: All patients with end-stage renal disease (ESRD) experience a high symptom burden. Although Latinos represent 19% of the US ESRD community, little research is available on their symptom burden. The purpose of our study was to provide the first description of symptom burden prevalence and severity amongst Latinos with ESRD.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We used Davison’s ESAS-r: Renal tool which measures physical and psychological symptom distress and contains 11 symptom items on a Likert scale of 0-10. Moderate = 4-6 and severe = 7-10. We asked three questions about symptom treatment preferences.

Results: Participants (n=61) had a mean age of 59 ±12 years, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 ±44.8 months. The majority were born in Mexico (90.2%), spoke Spanish only (77%), and had a less than high school education (72.2%). Overall, Latinos experience a substantial symptom burden with a mean of 6.8 ± 2.9 symptoms of which 5.1 ± 2.8 are moderate or severe symptoms. Tiredness
was experienced by 83.5% of patients and reported as moderate or severe by 67.2%. Pain was present in 86.5% and moderate or severe in 49.1%. Depression was reported by 55.7% and anxiety by 49.1% and moderate or severe in 49.2% and 39.3%, respectively. The majority (78.6%) of patients reported lack of well-being and feeling down (70.5%). With respect to medication preferences, our cohort prefers Western Medicine (77.1%) over traditional curanderismo (22.9%) and is agreeable (77.1%) to taking a few more medications if it meant all symptoms could be controlled. Our Latino cohort prefers (88.5%) to have their physical symptoms (e.g. pain, nausea) treated by nephrology staff.

**Conclusions:** Latinos with ESRD suffer from a debilitating symptom burden and over half of the symptoms are amenable to symptoms directed therapy. Our findings support the early identification and treatment of physical symptoms by nephrology staff.

**Care of the ‘Failing HD Patient’: Role of a Supportive Care Register**

Tracy Maryan, Maria Da Silva-Gane, Suresh Mathavakkanam.

**Renal Unit, Lister Hospital, Stevenage, Hertfordshire, United Kingdom.**

**Background:** Older dialysis patients (>70) often have significant comorbidities, that worsen with duration on HD. Continuation of dialysis often occurs at the expense of frequent illness episodes. There is a progressive decline in cognitive and physical function that exacerbates dialysis. We had introduced a Supportive Care Register (SCR) in 2012 to identify ‘failing dialysis patients’ based on their physical performance scores. We attempted to understand whether being on the SCR enabled better patient care when these patients were admitted with inter-current illnesses.

**Methods:** Data was collected from Patient Administration System (PAS) and Renal IT database in a large Tertiary (non-transplanting) Renal Unit serving a catchment population of 1.2 million. Data maintained in the SCR was reviewed. Total number of HD patient admissions to the acute renal service in 2013 were obtained with analysis of demographics, length of stay (LoS) and outcomes at discharge. Patients who were admitted were checked against the SCR entries.

**Results:** 287 out of the 409 total HD patients were admitted (123 F, median age 68 years, 590 episodes) with 137 of these patients being admitted more than once. The LoS was 9 days. 24 patients died in 2013 (28M; 76±16 yr; vintage 60 60; LoS 18±12 p<0.05). 28 patients died in hospital or at home/hospice following withdrawal of dialysis and institution of palliative care. 16 patients had died following severe acute illness. Five patients died at home. 18/28 patients were on the SCR and had discussions relating to ongoing and future dialysis therapy and advanced and preferred place of care planning prior to their last admission in the clinic setting. Seven patients had proceeded to discussions regarding resuscitation.

**Conclusions:** In conclusion, establishment of a SCR for dialysis patients with declining functional capacity and significant comorbidities allows for an early identification of patients at risk of physical and functional decapsulation. Once identified, establishing a dialogue in the OP dialysis setting about future care needs and expectations allows for a more integrated care approach when patients decompenstate to the point of being unable to continue dialysis.

**Funding:** Government Support - Non-U.S.

**SA-PO787**

**A Descriptive Study of Home Palliative Service Utilization and Care Trajectory Among Patients Dying on Dialysis**

Gihad E. Nesrallah, Stephanie Dixon, Marnie MacKinnon, Sarah E. Bota, Jade S. Hayward, Erin Arthurs, Penny G. Blake, Sara N. Davison, Ognjenka Djurdjev, Mohamad A. Karim, Rachel C. Carson, Gaylene M. Hargrove, Dan J. Martinussen, Helen Chiu, Lee Erţ, Ognjenka Djurdjev, Mohamad A. Karim, Rachel C. Carson, Gaylene M. Hargrove, Dan J. Martinussen. 1Dept of Medicine, Faculty of Medicine, UBC; 2BC Provincial Renal Agency; 3Island Health Authority, BC, Canada.

**Background:** End-Stage Renal Disease (ESRD) is associated with poor prognosis. Clinicians must be prepared to address end-of-life issues; hence, identifying patients at higher MR is recommended. We aimed to validate a 6-month MR prediction model for prevalent hemodialysis patients derived by Cohen et al. (2010) in a Canadian cohort and assess its clinical utility.

**Methods:** 375 prevalent dialysis patients in two regions of BC, Canada, were followed for 6 months. Data including serum albumin (ALB), age, peripheral vascular disease and dementia captured when the surprise question (SQ) was asked were used to validate the 6-month MR model. Model performance was evaluated through discrimination, calibration and decision-curve analysis.

**Results:** The observed mortality was 13.3% at 6-months. The model had reasonable discrimination (c-stat=0.70) but poor calibration (slope=0.46 [95% CI: 0.24, 0.69]) in our data. Decision curve showed added value of the model for threshold probabilities of 8%-20% (~12-42% fewer false-positive death), but no more beneficial to “treat-all” for probability ~8% and “treat-none” for probability ~20%.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**SA-PO788**

**Ventilator Dependent Dialysis Patients**

Jack Rubin, Los Angeles.

**Background:** We have started treating ventilator dependent patients at our dialysis unit and wish to share our results.

**Methods:** Chart review was done on all ventilator dependent patients treated at our unit.

**Results:** All data are shown mean ± sd. To date we have treated 19 patients (8F/11M) aged 71 ± 14 years with a mean time on dialysis of 90 ± 102 days. These patients were on dialysis prior to coming to us a mean 741 ± 1046 days. Seven were started within 2 months of their catastrophic event. Mean last available KTV L 1.5 ± 0.3, weight 152 ± 41 pounds, dialysis time 194 ± 21 minutes, bun 90 ± 20, creatinine 4.5 ± 1.5 Hemoglobin 9 ± 0.6, albumin 3 ± 0.5 g%, pre-albumin 18 ± 9 mg%, calcium 9.2 ± 0.6 mg% and phosphorus 3.4 ± 1.3 mg%. Four patients were transferred a mean of 71 ± 54 days because of insurance issues. 7 are on dialysis 97 ± 137 days and 8 have died after 94 ± 95 days on dialysis. There were no apparent differences in the parameters listed above between those transferred for insurance reasons, those who died and those still receiving treatment. 7 patients were non communicative, 7 were diabetic, 2 had a fistula and the rest catheters, 3 had atrial fibrillation and all a history of hypertension and congestive heart failure. Deaths were caused by gastrointestinal bleeding (1) and sepsis (7).

**Conclusions:** These non verbal non communicative patients are receiving aggressive end-of-life care fostered in some cases by unrealistic family expectations and in other instances by state conservators who prefer treatment until death so that outpatient withdrawal of dialysis and comfort care is not a realistic option. There are two groups - vintage patients and new to dialysis patients with a catastrophic event. The goal should be to educate families on the consequences of dialysis for the patient so that they do not start or allow withdrawal of dialysis after a defined trial. Upon taking on treatment of this group of patients the dialysis unit should anticipate a lower star rating in the benchmarks as most are on catheters and are frequently admitted for infection, bedsores or pulmonary complications. To sustain these selected patients requires a dedicated staff of nurses, respiratory technicians and ambulance services.

**SA-PO789**

**External Validation of a Prediction Model for 6-Months Mortality Risk (MR) in Patients on Hemodialysis**

Adeera Levin, 1,2 Brian Forzley, Helen Chiu, Lee Erţ, Gane, Suresh Mathavakkann.

Identifying Advanced Chronic Kidney Disease Patients with Same Survival Under Conservative Care versus Dialysis

C Sabra P, Kovesdy 1, 2, 3, M Molnar, 1 J Jing, 3 M Soohoo, 1 J Lin, 1 E Streja, 1 L Agodoa, 1 K Abbott, 1 P Eggers, 2 K Kalantar-Zadeh, 3 1 Univ of Tennessee Health Science Center, Memphis, TN; 2 VA Medical Center, Memphis, TN; 3 Univ of California, Irvine, CA; 4 NIH/NIDDK, Bethesda, MD.

Background: It is unclear if dialysis offers advantages over conservative care in certain patients with advanced CKD who do not have rapidly deteriorating kidney function.

Methods: From 659,546 US patients with CKD we identified 9,273 who transitioned to dialysis, and 6,136 who reached eGFR<15 ml/min/1.73m^2, but did not start dialysis. We matched these groups for their eGFR slope and for the last eGFR prior to ESRD, and restricted analyses to patients with no rapid pre-ESRD progression (defined as a slope of -5 to <0) and pre-ESRD eGFR of 10 to 14.9. We examined all-cause mortality using time-stratified Cox models (by 1-year increments) to account for non-proportionality of hazards.

Results: Of 1,026 veterans included in the analysis, 651 patients did not, and 375 patients did initiate dialysis. Baseline age, gender, race, eGFR slope and last eGFR, and comorbidities were similar in the dialysis vs. no-dialysis groups. Overall, 624 patients died over a median follow-up of 1.5 years. Patients on dialysis experienced lower mortality in the first year (HR, 95%CI: 0.25, 0.17-0.36, p<0.001) and in year 2 (0.67, 0.52-0.87, p=0.003). Among patients who survived at least 2 years (28% of the original cohort), the risk of death associated with dialysis was 28% higher but not statistically significant (1.28, 0.94-1.75, p=0.12) during the subsequent time period. In this latter group baseline slopes were flatter (-2.1(1.3) vs. -1.9(1.2)), but their other characteristics were similar to the overall cohort.

Conclusions: Among patients with eGFR 10-15 ml/min/1.73m^2 and no rapid loss of kidney function, transition to dialysis was associated with survival advantage over a two year time period. However, in 28% of the patients conservative management was not associated with worse mortality. Better characterization of patients who may benefit from conservative management warrants additional studies.

Enteric Dialysis – Stabilization of the Gut Microbiome using Probiotics and Prebiotics (Gut-Kidney Connection)

N Ranganathan, E A Friedman 2 1 Research and Development, Kibow Biotech Inc, Newtown Square, PA; 2 Downstate Medical Center, State Univ of New York, Brooklyn, NY.

Background: Recent scientific evidence from the human microbiome project has revealed that the trillions of gut microbiome exceed the human microbiome by a factor of 10. There are just 23,000 human genes as against the 3.3 million genes coded by the gut microbiome. This complex microbiome has a major role to play in health and diseases. Scientific evidence has shown that there is an imbalance in the ratio of this complex microbial community leads to dysbiosis in various diseases. The use of beneficial microbes as a dietary supplement or probiotics is generally well recognized towards digestive, gut and immune health. However, novel and niche application of probiotics and prebiotics as a dietary supplement in stabilization of Gut Microbiome towards Chronic Kidney Disease (CKD) is relatively new. Many independent researches in various scientific journals have reflected on various topics such as gut Microbiome, its dysbiosis, impact of the altered intestinal motility in health and diseases including small bowel bacterial overgrowth, newer uremic toxins, adsorbent drugs and several observational small scale clinical studies from Kibow and many others.

Methods: "Renady" a sybiotic dietary supplement was studied in randomized clinical trials in CKD 3 and 4 and ESRD patients. Other oral therapies for removal of uremic toxins include the use of keto acids and charcoal sorbents.

Results: Our studies using Renady for “Enteric Dialysis” showed reduction in levels of various uremic toxins like urea and indoxyl glucuronide. Levels of CRP also decreased with improved quality of life. This demonstrates the potential restoration of the gut microbiome dysbiosis with the use of specific strains of probiotics.

Conclusions: The use of a well-researched, clinically documented and safe probiotic/ prebiotic dietary supplement formulation has the potential to safely perform continuous 24h/7d uremic toxin removal and thus stabilize the gut Microbiome and its dysbiosis. Hence, the concept of “Enteric Dialysis” with continuous removal of uremic toxins may be the future key to providing an alternative HOPE for renal failure population.

Charcoal Hemoperfusion in the Treatment of Pruritus in Cholestatic Liver Disease

Wonngarm Kittanamongkolchai, Ziad El-Zogby, Nelson Leung. Nephrology, Mayo Clinic, Rochester, MN.

Background: Pruritus is a distressing symptom in a considerable proportion of cholestatic patients and few of them do not respond to conventional treatment. Charcoal hemoperfusion (CH) is an extracorporeal technique to eliminatealbumin-bound substances that are accumulated during cholestasis by the passage of blood through a column containing activated charcoal. Several case reports have shown significant reduction of bilirubin in mechanical jaundice and neonatal hemolytic jaundice. However, the published data of CH for the treatment of resistant pruritus in cholestatic patients is scarce.

Methods: Procedure code “Charcoal hemoperfusion” was used to identify patients who received charcoal hemoperfusion at Mayo Clinic, Rochester from 1/1/2000 to 5/1/2015.

Results: Thirteen patients were identified. All patients had failed conservative treatment and 2 of them had not responded to plasmapheresis. A median of 3 (1-9) sessions for a total of 20(1-33) hours were performed. CH resulted in a significant decrease of pruritus in 9 patients (69%). 2 patients did not have significant relief and 2 patients did not pursue further treatments after having adverse reaction during the first session. Median pruritic score significantly decreased from 9/10 (9-10) to 4/10 (0-9) posttreatment (p=0.004). Duration of symptom free period ranged from 8 to 46 days (median 18 days) in 6 patients who returned for follow up. 6 patients (46%) experienced adverse reactions described in Table 1.

Conclusions: Charcoal hemoperfusion is an effective therapy for refractory cholestatic pruritus. However, the improvement is not sustainable and the short benefit should be balanced with the invasive nature of the therapy and the relatively common adverse reactions.

Strict Adherence to Medicaid InterQual® Criteria Increases Adverse Events and Health Care Utilization in Undocumented Dialysis Patients

S Jawad Sher, M Anderson, Ranjan N. Moorthy, Sharon M. Moc, Michael T. Eadon. Medicine, Indiana Univ, Indianapolis, IN.

Background: Current estimates suggest there are 6000 undocumented ESRD patients in the US that may be ineligible for scheduled hemodialysis. To meet emergency Medicaid requirements, hospitals have sought creative ways to treat undocumented patients. We present data from an undocumented cohort as it progressed through a succession of three periods with different dialysis criteria.

Methods: This is an retrospective evaluation of a prospective cohort of 20 undocumented ESRD patients. The patients followed over 3 consecutive periods (P1, P2, P3) each of 2 months duration. In P1, patients received twice weekly dialysis. In P2, patients were dialyzed based on strict emergent InterQual® Criteria. In P3, emergent criteria included long interdialytic interval as an additional justification. Adverse outcomes, utilization, and dialysis adequacy in P2 and P3 were compared to P1.

Results: The mean age of the cohort was 35.9y, 39% were female, 45% were employed, and none were US citizens. Emergent dialysis (P2&P3) was associated with increased biochemically abnormal anemia (mean Hb, mean BUN and serum bicarbonate) as compared to P1 scheduled dialysis (P < 0.05). Emergent dialysis (P2&P3) was associated with an increase in nights hospitalized and ICU days (Fig1). Strict adherence to InterQual® Criteria (P2) was
associated with increased adverse events with a composite OR for intubation, bacteremia, NSTE-IMI, ICU admit, and death of 48 (5.9-301.2) compared to P1. P2 charge estimates increased from P1 ($357,501 v $202,326 per person per year, P=0.001).

Fig. 1 - Hospital utilization per patient per month. * = P < 0.05.

Conclusions: Strict adherence to InterQual® Criteria increases adverse events and healthcare cost per patient. We must determine better alternatives to emergent dialysis which minimize cost, while maintaining dignity, safety, and quality of life.

Factors Associated with Withdrawal of Care (WOC) in Maintenance Dialysis Patients Fahad Saeed, Robert Butler, Jesse D. Schold. Nephrology, Cleveland Clinic.

Background: There is paucity of data on factors leading to WOC in dialysis patients. We studied this question by using the NIS dataset, 2005-2011.
