C. A. Celikel5, D. G. Duman5 and to get idea for the regenerative capacity in the injured liver. Splenocytes were of the rats. MSCs were labeled with GFP to check the localization of stem cells and given MSCs (Healthy buffer saline (PBS) (CBDL

THE AMELIORATION OF THE LIVER FIBROSIS AFTER P0002 NATURAL KILLER CELLS MAY BE THE KEY FACTOR FOR

soids remain in a contractile state in cirrhotic livers, thereby contributing to cirrhosis revealed alterations of the NO-cGMP pathway, characterized by expression of endothelial and inducible NO synthase (eNOS and iNOS), phosphodiesterase 5 (PDE5), soluble guanylate cyclase subunit a1 and b1 (sGCa1 and sGCb1) was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-aminotransferase (ALT, AST), alkaline phosphatase (AP), albumin and bilirubin). The degree of fibrosis was estimated by histological criteria (i.e. Desmet score). PDE5-expression was determined by immunohistochemistry. Kruskal-Wallis test was used for statistical analysis of group differences.

**Results:** 43% (6/14) of TAA-treated rats developed liver fibrosis (Desmet score of 1–3) while 57% (8/14) developed liver cirrhosis (Desmet score of 4). No major differences in ALT, ASAT, and AP serum concentrations were observed in either group. However, bilirubin was significantly elevated in TAA-treated rats, while albumin concentrations were significantly reduced. Gene expression analysis revealed significantly increased expression of eNOS (1.5fold), PDE5 (7.7fold), and sGCb1 (2.1fold) in fibrotic livers compared to controls. cGMP concentrations in fibrotic animals were slightly decreased (-34%). Significantly higher (7.7fold), and sGCb1 (2.1fold) in fibrotic livers compared to controls. cGMP levels in supernatants of cultured lymphocytes, we found that CBDL + PBS group had significantly higher IL-1a, TNF-α and IFN-γ levels than healthy MSCs. Treatment of those rats with MSCs tended to decrease IL-1a, TNF-α and IFN-γ levels compared to CBDL + PBS group. The NK distribution was evaluated both in portal and parenchymal areas of liver. We have found that in the whole liver the NK cells were depressed significantly in CBDL + PBS group compared to healthy + MSC group and furthermore in the CBDL + MSC group, NK cells were significantly increased compared to CBDL + PBS group.

**Conclusion:** Our findings suggest bone marrow MSCs may be effective in alleviating the hepatic injury by suppressing the T cell proliferation, increasing the circulating peripheral NK cell population and CD4+ CD25+ and suppressing the proinflammatory cytokines in rats. Beneficial effects of MSC treatment is accompanied with significantly alleviated hepatic fibrosis and the significant NK recruitment to liver parenchyma. Thus, MSC injection treatment may appear promising in liver injury and future clinical therapies are warranted.

**P0003 SERPINB3 INVOLVEMENT IN THE STIMULATION OF MACROPHAGE ACTIVATION MARKER SCD163 IN HCV INFECTED PATIENTS**

**Introduction:** In chronic HCV infection disease progression is maintained by simultaneous neoinflammation and fibrosis in the liver. Upon macrophage activation, the soluble marker CD163 (sCD163) is released in serum and its levels correlate with fibrosis and NASH in the liver. The serin protease inhibitor SerpinB3 (or SCCA1), has been shown to be involved in liver fibrogenesis and the circulating SCCA-IgM complex has been depicted as a marker of liver disease progression and of NASH in patients with chronic hepatitis C. Preliminary data suggest that SerpinB3 activates primary monocytes through the Wnt canonical pathway. The purpose of this study was to evaluate the relationship between SCCA-IgM and sCD163 in serum and the possibility that SerpinB3 on sCD163 and on pro-inflammatory cytokines expression, in primary monocytes. Primary monocytes were isolated from healthy donors, treated with recombinant SerpinB3 (200ng/ml) and supernatants analyzed after 2 and 7 days. Expression of sCD163 secreted in the supernatant was evaluated by ELISA. In primary monocytes monocytes mRNA expression of IL-12, CXCL10- and TNF-alpha were also analyzed by PCR at different time points.

**Results:** In patients with chronic hepatitis C sCD163 was found correlated with inflammatory and metabolic alterations (AST, ALT, GGT, HOMA-IR, triglycerides), and was significantly elevated in patients with cirrhosis. Advanced histological fibrosis stage (F1-F2 vs. F3-F4 nec. Metavir: p < 0.04). Patients with levels of SCCA-IgM > 200 AU/ml had the highest serum levels of sCD163 (p < 0.05). In primary monocytes stimulated with recombinant SerpinB3 “in vitro”, sCD163 expression increased of 2.5 times and this finding was parallel to an up-regulation of the inflammatory cytokines IL-12, CXCL10- and TNF-alpha.
Conclusion: In chronic hepatitis C SerpinB3 is involved in monocyte activation, leading to the release of cD163. These results support the role of these two molecules in serum of patients with more severe liver fibrosis and metabolic alterations.

P0004 THE PROTECTIVE EFFECTS OF GROUP 3 INNATE LYMPHOCYTES ON HEPATITIS B VIRUS RELATED LIVER FIBROSIS COULD BE IMPAIRED BY TH17 CELLS

S. Wang, W. Ma, L. Cheng, W. Jiang
Gastroenterology, Zhongshan Hospital Fudan University, Shanghai, China

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) related liver fibrosis. Group 3 innate lymphoid cells (ILC3s), which share similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s (Lin^-CD127^-CD117^-CD274^) and Th17 cells (CD4^IL-17^) were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s co-cultured with hepatic stellate cells (HSCs)-LX2 in contact and non-contact manners. Then Th17 cells, which were induced from naive CD4^T cells in vitro, were transferred into Rag1^-^ mice with carbon tetrachloride (CCL4) related liver fibrosis. In addition, ILC3s in Rag1^-^ mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-α, IFN-γ decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCL4 administration, even at week 6. Transferring Th17 cells into Rag1^-^- mice with CCL4 related liver fibrosis made the ILC3s in spleens and livers decreased significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipients further decreased liver inflammation and reverse liver fibrosis.

Conclusion: Our study has uncovered the protective role of ILC3s in liver fibrosis, which is through secrete IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

2The General Hospital of the Chinese People’s Liberation Army, Beijing, China
3Gastroenterology And Hepatology, The General Hospital of the Chinese People’s Liberation Army, Beijing, China

Introduction: Internal biliary drainage has been proved better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstruction, but the relevant mechanisms are still unclear. The expression of intestinal FXR and TLR4, TGR5 and NOD2. Sixty male adult Kunming mice were randomly assigned to four groups: SH (sham operation), OJ (obstructive jaundice), ID (internal drainage), ED (external drainage) (n = 15 in each group). On the 7th day from the first operation, the OJ and SH mice were executed and specimens of blood and ileal tissue of groups were collected. ED and ID were operated on day 8 for biliary drainage procedure. Blood was drawn from heart for liver function test. The expression of FXR and TLR4, TGR5 and NOD2 in intestinal mucosa.

Results: We have successfully established the animal models. The histopathological examination revealed notable inflammatory infiltration and hyperplasia disruption at terminal ileum in OJ mice; significant alleviation of above injuries by ID while little improvement by ED. FXR and TLR4. After biliary obstruction, the expression of protein and mRNA of FXR were significantly increased, while the mRNA of both FXR and TLR4 were increased. After ID, the expression of protein and mRNA of FXR were significantly decreased compared with OJ group’s but were still higher than that in SH group and were better than ED group’s. And the expression of protein and mRNA of TLR4 were significantly increased compared with OJ group’s (P < 0.001), but were still lower than that in SH group and were better than ED group’s. The trend of TLR4 expression was almost the same between vehicle group and no gavage group. After gavage with FXR agonist, the differences of TLR4 expression of four groups disappeared (P > 0.05). TGR5-NOD2: IHC and WB suggested that after OJ surgery, the protein expression of both TGR5 and NOD2 increased obviously compared to that of SH mice; then the level of TGR5 and NOD2 protein fell down remarkably after ID surgery close to SH level while in ED group there was only a slightly reduction form OJ level and still with a high expression of TGR5 and NOD2 protein. Detection of RT-PCR found that TGR5 mRNA and NOD2 mRNA level in OJ group increased several times as that of SH group; after ID surgery, the expression of TGR5 mRNA significantly reduced, NOD2 mRNA level also fell down consistently, but the effect was not observed in ED mice.

Conclusion: The expression of intestinal FXR and TLR4, TGR5 and NOD2 could be one of the critical mechanisms why internal drainage is better than external drainage in restore intestinal barrier function of obstructive jaundice mice.

Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestatic injury and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncogenic microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, mice were sacrificed and small intestines in lumina were carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing – metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF-α and IL-1-β mRNA levels increased in the small intestine of BDL mice, compared with WT. TLR-4 and TGF-β expression was increased in both sham- and BDL-mir-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Strikingly, mir-21 KO reverted mRNA of tight junction proteins to control levels. BDL mir-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, mir-21 KO not only show a decreased small intestine permeability though a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased expression of key markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. Akkermansia muciniphila mediated liver injury is associated with different microbial communities. Accumulating evidence indicates that gut microbiota participates in systemic inflammation and hepatocellular carcinoma (HCC). However, the application of Sorafenib in therapy has faced increasing challenges due to drug resistance. Drug resistance is known to be associated with cancer stem cells (CSC). The transcription factor ZBP-89 expression were statistically associated with better survival of HCC patients. Unfortunately, the mechanism of ZBP-89 in modulating sensitivity of Sorafenib in CSC remains unknown.

Aims & Methods: In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of Huh7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTT assay. Then we examined the expression patterns of Notch1 and liver CSC markers in Huh7 and Hep3B CSC after the treatment with Sorafenib. MTT assay was also used to measure the effect of ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. The levels of ZBP-89 and CD44 were measured using q-PCR in human HCC tissue samples. The regulatory effects of ZBP-89 on CSC phenotype were explored by various methods including q-PCR, immunoblotting, tumor sphere formation assay, soft agar formation assay and colony formation assay. Gene expression and protein interaction in stemness signaling pathways were analyzed.

Results: We found that sphere-forming HCC cells had significant higher resistance to Sorafenib, compared with their parental cells. The expression of Notch1 and EpCAM was increased along with the treatment of low dose of Sorafenib, suggesting that the activation of Notch1 pathway was associated with the drug resistance in liver CSC. Studies further indicated that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib in sphere-forming HCC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor sphere formation was impaired upon transducible overexpression of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed investigation against control cells showed that overexpression of ZBP-89 resulted in reduced expression of CSC markers EpCAM, CD133, Sox2 and c-myc at both mRNA and protein levels. In addition, the overexpression of ZBP-89 or silencing of Notch1 reduced the number of colonies formed by sphere-forming HCC cells, demonstrating opposite effects of these two proteins. Mechanistic studies revealed that ZBP-89 was able to repress the expression of Notch1 and reported target genes including HES1, HES6, HEY1 and NRRARP. Amino acids Δ6–180 of ZBP-89 could directly bind to the activated Notch1 in the nucleus, resulting in a negative regulation of CSCs and overcome of Sorafenib resistance.

Conclusion: Sphere-forming HCC cells, which contained high levels of Notch1 and EpCAM, were resistant to Sorafenib. The overexpression of ZBP-89 was found to result in the loss of CSC phenotype and improve the sensitivity to Sorafenib in CSC through its interaction with activated Notch1. In conclusion, we believe that targeting ZBP-89 is likely to be a new therapeutic strategy to overcome resistance to Sorafenib in HCC.

Introduction: Accumulating evidence indicates that gut microbiota participates in the pathogenesis and progression of liver diseases. The severity of immune-mediated liver injury is associated with different microbial communities. Akkermansia muciniphila can regulate immunologic and metabolic functions. However, little is known about its effects on gut microbiota structure and function.

Aims & Methods: This study investigated the effect of A. muciniphila on immune-mediated hepatitis and potential underlying mechanisms. Twenty-two C57BL/6 mice were assigned to three groups (N=7–8 per group) and continuously administered A. muciniphila MucT (ATTC BAA-835) by oral gavage for 10 days. Mouse feces were collected for gut microbiota analysis on the eleventh day, and acute hepatitis was induced by Concanaavalin A (Con A, 15 mg/kg) injection through the tail vein. Samples (blood, liver, ileum, colon) were assessed for liver inflammation, immunohistochemical and liver barrier function.

Results: We found that oral administration of A. muciniphila (Akk) decreased serum ALT and AST and alleviated liver histopathological damage induced by Con A. Serum levels of pro-inflammatory cytokines (IL-2, IFN-γ, IL-12p70, TNF-α, MIP-1α, β) were significantly increased in the control group that received the vehicle alone. Meanwhile, liver tissue injury-related factors (IL-12p40, IFN-γ, DR5) were negatively associated with specific genera (Ruminococcaceae_UCG-009, Lachnospiraceae_UCG-001, Akkermansia), which were enriched in mice pretreated with Akk.

Conclusion: Our results suggested that A. muciniphila MucT (ATTC BAA-835) had beneficial effects on immune-mediated liver injury by alleviating inflammation and hepatocellular death. These effects may be driven by the protective profile of the intestinal community induced by the bacteria. The results provide a new perspective on the immune function of gut microbiota in host diseases.

Our study indicated that the change of the gut microbiota and pathobiology was significantly decreased in the three NAFLD models than the Control, and was identified as the biomarker of NAFLD in LEfSe analysis. More biomarkers at genus level (Lachnospira, S24-7, etc.) were identified in pairwise comparison of one mouse model with the Control.

**Conclusion:** In summary, the composition of gut microbiota varied remarkably between mice administrated different experimental diets to induce non-alcoholic fatty liver disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

**Disclosure of Interest:** 
All authors have declared no conflicts of interest.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) has become the most common liver disease worldwide, and is thought to be strongly associated with gut microbiota. Several diet models were therefore built in mice to try to clarify the molecular mechanisms. However, how and to what extent these diet models alter the composition of the gut microbiota and pathology connection were suggested in acknowledgment of the decrease of F.P in the NAFLD patients. The decreased abundance of F.B in NASH with severe fibrosis, elevated blood-endotoxin in NAFLD with severe fibrosis patients suggests a role for ET in the pathogenesis of fibrosis. Moreover, we need to investigate that the mechanism of fibrotic progression via the endotoxin in NAFLD may relate to the presence or not of liver steatosis.

**Results:** Among those taxa with greater than 1% representation in any of the disease groups, it was significantly decrease in Bacteroidetes at phylum level in NAFLD compared with HC. At genus level, Faecalibacterium prausnitzii (F.P) was significantly decreased in NAFLD compared with HC. F.P is significantly decreased in NAFLD with severe fibrosis compared with those with mild fibrosis patients. In addition, endotoxin levels were increased in NAFLD with severe fibrosis than those with mild fibrosis. Furthermore, occupation ratio of F.P was 0.6% in patients with blood ET level (R=0.32). Additionally, it showed a significant correlation among three items of F.B, EAA and LMR (F.B vs EAA: P < 0.0001, LMR vs EAA: P < 0.0001, LMR vs F.B: P < 0.0025).

**Conclusion:** Our study indicated that the change of the gut microbiota and pathobiology connection were suggested in acknowledgment of the decrease of F.P in the NAFLD patients. The decreased abundance of F.B in NASH with severe fibrosis, elevated blood-endotoxin in NAFLD with severe fibrosis patients suggests a role for ET in the pathogenesis of fibrosis. Moreover, we need to investigate that the mechanism of fibrotic progression via the endotoxin in NAFLD may relate strongly gut-permeability. We postulate that the distinct composition of the gut microbiota among NAFLD and HC could offer a target for intervention or a marker for disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

patients with HFE mutations and (transferrin saturation index (TSI) values above 40). But we did not have C282Y/C282Y participants in the series.

Aims & Methods: To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque Country. Prospective study of 312 consecutive patients with HF. Group A (C282Y/C282Y), Group B (C282Y/C282Y, C282Y/H63D, H63D/H63D, and TSI > 45 %; Group C: no predisposing mutations for HH and TSI > 45 %; Group D: PM and normal TSI). In the Basque Country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

Results: In all the patients HF study was available: C282Y/C282Y 14 (4.49%); C282Y/C282Y, C282Y/H63D 47 (15.06%); H63D/H63D 99 (31.72%); wt/wt 98 (31.41%); C282Y/S65C 10 (3.22%); H63D/S65C 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MR. Mean age: 55 ± 13.5, 272 men and 40 women. Group A: 54; Group B: 32 Group C: 160; Group D: 54. The mean LIC in group A: 70.53 ± 56.67, group B: 37.21 ± 27.89, group C: 70.53 ± 56.67, group D: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences (p ≤ 0.0000).

Conclusion: The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Alternately activated anti-inflammatory macrophage (also termed M2a Kupffer cell) is important for prevention of the development of steatosis and liver injury in non-alcoholic fatty liver disease (NAFLD). Our previous studies demonstrated that interleukin-25 (IL-25) expressed in NAFLD mice and exogenous IL-25 protected against NAFLD by inducing M2a Kupffer cells.

Aims & Methods: We aimed to explore the intracellular signaling pathways of IL-25 to regulate macrophage polarization and direct effects of IL-25 on Kupffer cells. Mouse model of NAFLD was induced by feeding a high-fat diet (HFD); In vitro expansion of mouse Kupffer cells. IL-10 and IL-25 were used to induce M2a Kupffer cells; specific siRNAs were used to knockdown IL-25 receptor mRNA for assessing the direct and specific effect of IL-25 on Kupffer cells. IL-25 induced M2a Kupffer cells were back transfusion into the abdomen of NAFLD mouse to assess the efficacy; Dual-luciferase reporter assays and Chromatin immunoprecipitation assays were used to determine the transcription factor of IL-25 promoter.

Results: Exogenous IL-25 induced expression of type 2 cytokine and alternative activation of Kupffer cell in vivo. It could also promote hepatic macrophages to differentiate into M2a Kupffer cells in vitro. Interestingly, IL-25 recovered the expression of IL-25 mRNA in the liver of NAFLD mice. Furthermore, IL-25 could induce the expression of IL-25 in cultured hepatocytes by activation of STAT6, rather than MZF1, API or NF-κB. STAT6 was sufficient and necessary for IL-25 expression. Deletion and site-directed mutagenesis of the IL-25 promoter revealed that IL-25 transcriptional activation depended primarily on a putative STAT-binding sequence between nucleotides ~682–~674 upstream of the start site. STAT6 binding to this sequence increased in response to IL-25 treatment in vivo and in vitro. Finally, IL-25 induced M2a Kupffer cells could ameliorate HFD-induced hepatic steatosis by reducing M1 Kupffer cells.

Conclusion: Our results elucidate the molecular mechanisms of IL-25 during amelioration of hepatic steatosis and provide the scientific basis of direct IL-25 treatment or macrophage transfusion therapy for NAFLD.

2Cardiology, Orudias University, Constanta/Romania
3Internal Medicine, Orudias University, Constanta/Romania

Contact Email Address: asuceveanu@yahoo.com

Introduction: NASHi is considered an important risk factor for liver fibrosis. Although literature data indicates that statins may be beneficial when given for NASHi treatment, recent reports are controversial.1

Aims & Methods: To evaluate if statins independently influence the evolution of fibrosis accompanying NASHi using the scales of FibroMax. 120 patients with NASHi and metabolic syndrome were followed-up for a period of 3 years. We excluded patients taking a serie of drugs, with genetic metabolic disorders or impaired intestinal absorption (celiac disease) or alcoholics. Steatosis, fibrosis

References:
and NASH were quantified by using the FibroMax scales at baseline and after three years of statin treatment. Patients were randomized in two groups: the active group of 60 patients receiving low-dose hydrophilic statin (rosuvastatin 5 mg/day) and the witness group of 60 patients, matched by age, gender and sex, receiving placebo.

Results: 97% of subjects fulfilled the follow-up period. The FibroMax staging at baseline showed the following results in the active group: S1–29%, S2–41% and S3–30%; F1–50%, F2–30%, F3–13% and F4–7% of patients, respectively N1–31% and N2–69%. The staging according to FibroTest, SteatoTest and NashTest was similar in placebo group. After 2 years of low-dose hydrophilic statin, the mean ALT level from active group decreased from 72.22 IU/L to 32.80 IU/L, p < 0.05 (s); in the witness group no significant ALT decrease was noticed (69.341 IU/L to 58.17 IU/L, p > 0.5). The FibroMax showed an improvement in steatosis, and fibrosis in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–28%, F3–2%; F4–0% of patients. Nineteen positive evolution of steatosis and steatofibrosis was observed with placebo (N0–36%, N1–40% respectively N2–26%, p > 0.001, s). After adjusting for age, BMI, diabetes, LDL-cholesterol and triglyceride levels, statin therapy showed a significant correlation with the steatosis, fibrosis and NASH stages improvement in the active group (p = 0.02, r = 0.27, respectively r = 0.95, p < 0.005).

Conclusion: While statins proved to be safe and efficient for the treatment of NASH in our series, larger cohort studies are needed to further demonstrate this potential positive effect on liver fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

Aims & Methods: We aimed to study the relationship between CRP and homocysteine (HC) levels with pathological changes in the liver, determined with the non-invasive bioprognostic test Steatoscreen in patients with AO. The study involved patients aged 18 to 59 years with joints with a waist circumference > 80 cm for women, over 94 cm for men. All patients underwent a bioprognostic test Steatoscreen. Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all patients, the levels of CRP and GC were studied. Results: In 3 groups of patients with the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all patients, the levels of CRP and GC were studied. Conclusion: NAFLD in patients with AO is characterized by the development of carotid metabolic disorder associated with atherosclerosis and atherothrombosis. This fact can influence the risk of developing the pathology of not only the liver, but also atherosclerosis and proves the need for a more thorough examination of patients with AO and NAFLD for the purpose of early detection and correction of existing metabolic disorders.

Introduction: In the last decade, the notion of non-alcoholic fatty liver disease (NAFLD) has undergone noticeable changes. It is shown that in the liver with fatty hepatitis, insulin and glucose utilization is disrupted, conditions are created for the synthesis of atherogenic fractions of cholesterol and triglycerides. This contributes to the development of violations of carbohydrate and lipid metabolism, the early appearance of atherosclerosis and associated vascular complications. Thus, NAFLD can be considered as an independent, additional risk factor for atherosclerosis. Obviously, it was important to clarify the nature of the relationship between NAFLD and the early manifestations of atherosclerotic vascular wall lesions are relevant.

Aims & Methods: Study of changes in the vascular wall of the common carotid artery (IMT CCA) and in patients with abdominal obesity (AO) and different forms of nonalcoholic fatty liver disease (NAFLD). The study involved 60 patients with AO between the ages of 18 to 59 years (waist circumference > 80 cm in women and > 94 cm in men) and NAFLD, in the presence of clinical manifestations, provided written informed consent to participate in the study. All patients underwent an ultrasound examination of the abdominal cavity to determine the size of the liver and signs of steatosis. The level of severity of pathological changes in the liver tissue (fibrosis, steatosis, and steato-fibrosis) was assessed by non-invasive diagnostic method Steatoscreen. (Biopredictive laboratory, France). Measurement of the CCA IMT was performed according to standard procedures on the machine Voluson 730 Expert, equipped with a linear transducer phased array with a frequency of 7.5 MHz. The presence of early signs of atherosclerosis was defined as a local thickening of the IMT CCA more than 0.9 mm in any point of the carotid artery (CCA IMT max). Depending on the severity of pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In the future, comparative and correlation analysis of the data was carried out.

Results: Signs of early atherosclerosis, in the form of the IMT CCA > 0.9 mm in any point of the carotid artery (CCA IMT max). Depending on the severity of pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In the future, comparative and correlation analysis of the data was carried out.

Introduction: Insulin resistance is the main pathogenic determinant of both NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver. Overexpression of hepassocin (HPS) increased hepatic lipid accumulation and NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-induced hepatic steatosis and decreased NAS in mice.

Aims & Methods: The aim of this study was to explore the relationship between hepassocin and diabetic patients with or without NAFLD. The study included 80 patients that were divided into 4 groups: Group I: included 20 patients who were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who were diagnosed as non-alcoholic fatty liver disease, Group III: included 20 patients who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV (control group): included 20 healthy person who were matched in age and sex with patients group.

Results: There was stastically significant decrease in mean value of serum hepassocin of group I and IV on comparing with group H and group III. For group II there was stastically significant increase in mean value of serum hepassocin on comparing with other groups. There was a significant serum hepassocin up regulation in patients with type 2 diabetes and non alcoholic fatty liver decreased patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes mellitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0022 DIAGNOSTIC ACCURACY OF SHEAR WAVE ULTRASOUND ELASTOGRAPHY FOR EARLY DETECTION OF NON ALCOHOLIC STEATOHEPATITIS AMONG PATIENTS WITH TYPE 2 DIABETES MELLITUS

A. Gameel, E. M. Elhadidy, A. A. Mousa, M. M. Elrakhawy

Contact E-mail Address: asnaagameel15@gmail.com

Introduction: Non alcoholic fatty liver disease (NAFLD) is a broad term describing simple steatosis, non alcoholic steatohepatitis (NASH), NASH cirrhosis and NASH-induced hepatocellular carcinoma (1). Incidence increased in patients with type 2 diabetes mellitus (DM) (2). Different diagnostic modalities have great limitations in differentiating simple steatosis from steatohepatitis (3). Liver biopsy remains the gold standard for diagnosis of NASH, however, it is invasive with potential severe complications (4). Several ultrasound elastography techniques have been described including transient elastography, acoustic radiation force impulse elastography and shear wave elastography(5). Shear wave elastography shows a stepwise increase of liver stiffness as the severity of liver inflammation increases(6).

Aims & Methods: We aimed to evaluate the accuracy of shear wave ultrasound elastography in differentiating simple steatosis from steatohepatitis in patients with type 2 DM. This was a prospective study including 60 patients 30 males and 30 females who visited our outpatient clinic or inpatient department at Specialized Medical Hospital. These patients were diabetic aged more than 30 years old with ultrasound showing fatty liver. Significant alcohol consumption, drugs causing steatosis and hepatic diseases were excluded by history, laboratory investigations and liver biopsy. All patients underwent full detailed history, examination, laboratory investigations (complete blood count, liver functions, kidney functions, random blood sugar, lipid profile, serology for hepatitis B and C viruses). Shear wave elastography was performed to all patients and stiffness of the liver was measured from different areas in kilopascal (kPa) then average stiffness by elastography was calculated. Liver biopsy was done and histopathological examination by Hematoxilin, Eosin and Masson Trichrome stains, then NAFLD activity score (NAS) was calculated.

Results: Correlation between results of stiffness by elastography and NAS by biopsy revealed that: There was a significant positive association between average stiffness by elastography and definitive NAS (NAS 5 and 6) in patients with type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differentiate simple steatosis from steatohepatitis (Area Under Curve 0.936, sensitivity 90%, specificity 90%, positive predictive value 81%, negative predictive value 49%).

Conclusion: Shear wave ultrasound elastography is a promising non invasive technique to differentiate simple steatosis from steatohepatitis in patients with type 2 DM.

P0024 A NOVEL TOOL FOR THE NON-INVASIVE QUANTITATIVE ASSESSMENT OF HEPATIC STEATOSIS USING B-MODE IMAGE-GUIDED ULTRASOUND ATTENUATION IMAGING: A PROSPECTIVE STUDY

Division Of Hepatology, Department Of Internal Medicine, Iwate Medical University, Morioka, Japan

Contact E-mail Address: kenoy026@yahoo.co.jp

Introduction: Nonalcoholic fatty liver disease is a main cause of chronic liver disease worldwide. A quantitative, non-invasive assessment of hepatic steatosis is desirable. Throughout the path of ultrasound (US), attenuation by liver parenchyma is uneven. This is the basis of the controlled attenuation parameter (CAP). However, further accumulation of data is needed to assess the role of CAP in the diagnosis of steatosis.

The aims of this study were to determine the diagnostic performance of B-mode image-guided ultrasound attenuation imaging and quantitative assessment of hepatic steatosis by a liver biopsy (LB, reference standard).

Method: We compared with the liver-to-spleen ratio (L/S ratio) from computed tomography (CT) and CAP.

Aims & Methods: We prospectively analyzed 112 consecutive patients with chronic liver disease who underwent ultrasound attenuation imaging. CT, and liver biopsy. Ultrasound attenuation imaging was performed using the LOGIQ E9 scanner (GE Healthcare) with a C1-6D convex array probe (frequency, 4 MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured from the uniform phantom (known attenuation, 0.5 dB/cm/MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured from the uniform phantom (known attenuation, 0.5 dB/cm/MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured from the uniform phantom (known attenuation, 0.5 dB/cm/MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured from the uniform phantom (known attenuation, 0.5 dB/cm/MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured from the uniform phantom (known attenuation, 0.5 dB/cm/MHz).

Results: Patients (51% men; 42% had nonalcoholic fatty liver disease, 58% had hepatitis C virus) had a median body mass index of 26 kg/m2. Median AC values for grades S0 (n = 38), S1 (n = 47), S2 (n = 18), and S3 (n = 9) were 0.49, 0.55, 0.66, and 0.72, respectively, demonstrating a stepwise increase with increasing steatosis severity (P < 0.0001). AC was significantly correlated with the steatosis percentage (r = 0.800, P < 0.0001), L/S ratio (r = −0.670, P < 0.0001), and CAP (r = 0.639, P < 0.0001). AUCs of AC vs. the L/S ratio for identifying grades ≥S1, ≥S2, and ≥S3 were 0.919 vs. 0.855, 0.957 vs. 0.902, and 0.960 vs. 0.919, respectively, showing significantly better results than those for the L/S ratio and CAP. For the sensitivity and specificity of AC ≥58.5%, cut-off values were 0.53 dB/cm/MHz for ≥S1, 0.60 dB/cm/MHz for ≥S2, and 0.64 dB/cm/MHz for ≥S3. Steatosis was the only factor independently associated with AC values.

Conclusion: Ultrasound attenuation imaging had a high diagnostic accuracy for detecting hepatic steatosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Serum ferritin concentration shows a poor outcome of patients with alcoholic liver cirrhosis (ALC). However, according to recent research, the protein expression is not limited to the cells of nervous system as it was believed, but since it is highly expressed in various tissues, such as vascular remodeling, inflammation and oxidation. The function and expression of the protein in liver disease is still not clear.

Aims & Methods: In this study we aimed to evaluate plasma levels of RTN4 protein in cirrhotic patients and associate them with clinical parameters and portal hypertension.

The study included 72 patients with ALC. The control group was formed by laboratory tests, clinical features, radiological imaging, and percutaneous or tranjugular liver biopsy. Alcoholic liver cirrhosis was confirmed when all authors have declared no conflicts of interest.

Results: Plasma levels of RTN4 were determined by enzyme-linked immunosorbent assay (ELISA). The study included 72 patients with ALC. The control group was formed by laboratory tests, clinical features, radiological imaging, and percutaneous or tranjugular liver biopsy. Alcoholic liver cirrhosis was confirmed when patients were classified as SPH (p < 0.0001). Using a RTN 4 cut-off value of 1.7 ng/ml, the AUC for predicting early mortality in patients with cirrhosis (AUC 0.838, p < 0.0001).

Conclusion: Serum ferritin level above 400 ng/l, elevated liver enzymes and bilirubin concentration shows a poor outcome of patients with ALC (p < 0.0001). An RTN4 protein level is a specific predictor for predicting early mortality in ALC.

Disclosur of Interest: All authors have declared no conflicts of interest.

Introduction: Peritoneal carcinomatosis (PCA) has a prognostic role in patients with gastrointestinal cancers. Despite the low sensitivity, cytology remains the gold standard in diagnostic differentiation of PCA to peritonitis (for example spontaneous bacterial peritonitis, SBP) or uncomplicated ascites due to portal hypertension. RTN4 correlates with liver function (CD34+) of the vascular compartment for translocating bacteria. For this purpose two different models of experimental portal hypertension, namely partial portal vein ligation (PPVL) and bile duct ligation (BDL) were used in mice under standardized gnotobiotic conditions (sdDM2). A novel in vivo confocal endomicroscopy technique was established in order to evaluate the expression of PV1 in intestinal vessels (CD34+ of BDL but not PPVL). Portal hypertension per se has an impact on the GVB increasing FITC-70kDa-dextran leakage from intestinal capillaries to the lamina propria in both BDL and PPVL. However, the IF showed only in BDL an increased PV-1 expression indicative of a wider opening of the intestinal diaphragms than in PPVL. Therefore, different mechanisms appear to be involved in alterations of the gut-vascular barrier in pre-hepatic portal hypertension and biliary cirrhosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal permeability.

Aims & Methods: A clear role of intestinal vascular leakage for luminal intestinal bacteria is yet to be defined but we hypothesize that the recently described gut vascular barrier (GVB) is impaired in experimental portal hypertension leading to protein loss and increased accessibility of the vascular compartment for translocating bacteria. For this purpose two different models of experimental portal hypertension were selected for the proof-of-principle analysis (miR-21 and miR-16) were performed for GVB analysis.

Conclusion: Confocal endomicroscopic data revealed an earlier and significantly increased leakage of 70kDA through the intestinal vasculature in both BDL and PPVL mice. FITC-70kDa-dextran did only leak in BDL and PPVL but not in control (sham operated) mice. Interestingly GVB stains showed increased expression of PV1 in intestinal vessels (CD34+) of BDL but not PPVL.

Disclosure of Interest: All authors have declared no conflicts of interest.

P-AKT protein expression was detected in the spleen of TAA group compared to control.

P0029 INHIBITION OF CYCOOXYGENASE-2 AMELIORATES SPLENOMEGALY IN CIRRHOTIC RATS
Gastroenterology, West China Hospital, Sichuan University, Chengdu/China
Contact E-mail Address: 812903560@qq.com

Introduction: Splenomegaly is a common finding in liver cirrhosis. However, the precise underlying mechanisms behind this phenomenon have not been elucidated, and its effective therapies are limited.

Aims & Methods: We aimed to investigate whether cyclooxygenase-2 (COX-2) is involved as a contributing factor in the pathological process of splenomegaly in cirrhotic rats. Thirty-six male Sprague-Dawley rats were randomized into three groups with 12 rats in each group. The control group received intraperitoneal injection of normal saline (1 ml, twice a week); the TAA group received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA + celecoxib group received TAA intraperitoneally and celecoxib via gastric gavage (20 mg/kg/day). The portal pressure was measured by portal venous catheterization. Sections from paraffin-embedded spleens were stained with hematoxylin and eosin and Sirius Red, and immunostained with VEGF and CD31. The protein expressions of COX-2, VEGF, PI3K, p-AKT, and AKT in the spleen were assessed by Western blot. The enzyme-linked immunosorbent assay was performed to evaluate the expression of TNF-a and IL-1b in the spleen.

Results: The ratio of splenic weight to body weight increased by 73.9% in TAA group, while in rats treated with celecoxib, the ratio was significantly reduced. While determined by H&E staining, areas of splenic white pulp in the TAA group enlarged by 27.9%. Yet, compared with that in TAA group, celecoxib obviously decreased the area of spleen with white pulp by 27.6%. Besides, the portal pressure elevated by 79.1% in the TAA group; while significant reduction of the portal pressure was observed in the TAA + celecoxib group by (28.8%). In addition, a considerable amount of collagen was visualized with Sirius Red staining in the spleen of TAA group. The increased spleen weight was found in TAA + celecoxib group. Increased COX-2 protein was detected in the spleen of the TAA group compared with that in the control group. However, the expression of proangiogenic factor VEGF and the novascular marker CD31 increased in TAA group by Western blot and immunohistochemistry, which indicated a role of angiogenesis in the pathophysiology of splenomegaly. Furthermore, up-regulation of PI3K and p-AKT protein expression was detected in the spleen of TAA group compared
P0030 EPITHELIAL BARRIER DESTABILIZATION AND REGULATION OF PS3 – A POSSIBLE BACTERIAL DEFENSE MECHANISM IN SPONTANEOUS BACTERIAL PERITONITIS?

Introduction: Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with Escherichia coli (E. coli), Klebsiella pneumoniae being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiosis.

Aims & Methods: With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SBP were explored. These insights might lead to an initiation of antibiosis on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with E. coli with different MOI (MOI 0, 1, 5 and 10) for 2 to 4 hours post confluence. Experiments with heat inactivated E. coli were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Ocluladin, E-cadherin and the p53 family including p53 and p73.

Results: E. coli stimulation of HCT-116 cells resulted in a strong decrease of Ocluladin, E-cadherin and the p53 family including p53 and p73.

Conclusion: By using an in vitro model, we demonstrate destabilizing effects of E. coli on intestinal cells junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent a mechanism to protect bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0031 INTESTINAL EPITHELIAL BARRIER IN EXPERIMENTAL LIVER CIRRHOSIS - A ROLE FOR BILE SALTS IN THE MUCUS LAYER

M. Sorribas Olivera1, Y. Nose1, A. Albillos2, R. Wiest3

Introduction: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiologic hallmark for spontaneous bacterial infections increasing mortality sever-fold. Factors known to contribute to PBT in LC are among others an increased intestinal epithelial permeability.

Aims & Methods: Since mucus represents one of the major components of this barrier we hypothesize that i) gut mucus is altered in LC and ii) bile could be a modulator of its production. Two different models of experimental LC – namely bile duct ligation (BDL) and the chronic treatment with carbon tetrachloride (CCL4) – as well as partial portal vein ligation (PPVL) and sham-operated mice were used. Finally the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) and the FXR antagonist CDCA were used. Mucus thickness measurement on gut explants and PAS (Periodic acid–Schiff) staining to visualize and count goblet cells (GC) were utilized.

Results: We have observed a significant reduction in mucus thickness in ileum and colon (OCA: CCL4: BDL: PPVL: Control: 154.38±12.51 μm/ C60.74±0.6 μm in proximal colon) and goblet cell numbers in ileum (Control 0.47 GC/100 μm of villus±0.07 vs BDL 0.29 GC/100 μm of villus±0.04) of mice following BDL but not PPVL (Control 0.27 GC/100 μm of villus±0.11 vs BDL: 0.08±0.01). However, the treatment with obeticholic acid strongly decreased the protein expression of VEGF, CD31, P3K and AKT in the spleen of cirrhotic rats.

Conclusion: The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by celecoxib could ameliorate portal hypertension and splenomegaly.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0032 CAPSAICIN AND SULFORAFANE PREVENT THE ADVANCEMENT OF LIVER FIBROSIS IN AN EXPERIMENTAL MODEL OF LIVER CIRRHOSIS

P0033 DIAGNOSIS OF GASTRIC VARIATES BY ENDOCOSCOPIC ULTRASONOGRAPHY USING COLOR DOPPLER

T. Sato

Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenterology, Sapporo/Japan

Contact E-mail Address: taka.sato@ja-hokkaidokououseiren.or.jp

Introduction: Gastric variceal bleeding is common complication, and it is associated with higher morbidity and mortality rates than hemorrhage from esophageal varices. Oesophageogastroduodenoscopy is usually the initial investigation in order to detect and treat portal hypertension for the purpose of the distinction between gastric varices and gastric folds. The aim of this study was to investigate endoscopic color Doppler ultrasonography (ECDUS) findings of gastric varices.

Aims & Methods: Two hundred-fifteen patients with gastric varices were evaluated with ECDUS. To begin with, identification of gastric varices was performed with B-mode scanning and then, color flow mapping was done. On B-mode scanning, submucosal gastric varices, and para-gastric collateral veins were obtained as hypoechoic vessels within gastric wall or in the tissue and spaces exterior to the adventitia of gastric wall. ECDUS provides a color display of blood flow and evaluates the flow pattern using fast Fourier transform (FFT) analysis. FFT analysis can indicate the flow pattern and calculate the velocity of blood flow. We monitored the color flow images of gastric varices, and para-gastric or per-gastric collateral veins. Endoscopic findings of gastric varices were evaluated according to the grading system outlined in The General Rules for

Results: The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2 ± 6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7 ± 6.2 cm/s (n = 52), while the mean velocity of enlarged tortuous (F2) type gastric varices was 16.7 ± 5.0 cm/s (n = 163). The velocities of F3 type gastric varices were significantly higher than those of F2 type (P < 0.0001). Next, we evaluated the wall thickness to submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6 ± 0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2 ± 0.2 mm (n = 42), while the mean thickness of RC or erosion negative varices was 1.7 ± 0.3 mm (n = 173). The thickness of RC or erosion positive varices was significantly thicker than that of the negative cases (P < 0.0001). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow up (bleeding cases, n = 10), and mean thickness of these bleeding cases were 1.2 ± 0.2 mm.

Conclusion: ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0034 PORTAL HYPERTENSION COLOPATHY BUT NOT ILEOPATHY IS COMMON IN EGYPTIANS WITH LIVER CIRRHOSIS

A. Farag1, M. Wi fi2, M. Fawzi1, A. Nageeb1, M. Alborzi1

Introduction: Liver cirrhosis and portal hypertension are associated with esophageal varices, gastric varices, small and large intestinal enteropathies.

Aims & Methods: We aimed to study the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. The severity of cirrhosis was classified by the Child-Pugh score. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hypertension complications. Esophageal varices were graded as small, moderate and big varices. Portal hypertensive gastroplasty was classified as absent or present, and if present, it was sub-classified as mild or severe. Coloscopy was done up to terminal ileum in all patients.

Results: Our study included sixty chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis (53.33% females) their mean age (±SD) was 54.75 (±13.13) years. Child-Pugh class was A for 2 (3.4%), B for 33 (55.9%) and C for 24 (40.7%). 53 (88.3%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-band ligation and 5 obliterated varices). Gastric varices were present in 3 patients (5%). Portal hypertensive gastroplasty was noted in 43 patients (71.6 %) and was mild in 38 and severe in 5 patients. Colonoscopy finding up to the terminal ileum revealed that portal hypertensive colopathy was present in 16 patients (26.7%). Portal hypertensive ileopathy was noted only in one case (1.7%). No colonic or ileal varices were noted.

Conclusion: Portal hypertensive colopathy but not ileopathy is common in Egyptians with liver cirrhosis. Ileal varices and ileopathy are not common in patients with liver cirrhosis and PH.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0035 PREDICTIVE FACTORS FOR THE DEVELOPMENT OF ACUTE-ON-CHRONIC LIVER FAILURE IN PATIENTS WITH GASTROINTESTINAL BLEEDING

C. Ciocecaru1, S. Chiriac2, A. Trifan2, C. Stanciu3
1Gastroenterology, "Grigore T. Popa" University of Medicine and Pharmacy Iasi, Iasi/Romania;

Contact E-mail Address: stefannchiriac@yahoo.com

Introduction: Acute-on-chronic liver failure (ACLF) is a specific clinical form of liver failure in patients with liver cirrhosis, referred as acute deterioration of liver function associated with an acute specific complication of liver cirrhosis. ACLF is defined by the presence of renal failure or 2 or organ failures according to the European Association for the Study of the Liver-International Chronic Liver Failure consortium: 1) circulatory- need for vasopressor support; 2) renal- serum creatinine value ≥ 2 mg/dL; 3) cerebral- Grade III or IV hepatic encephalopathy; 4) respiratory- SpO₂-FI O₂ ≤ 214.

Aims & Methods: We aimed to identify predictive factors for ACLF development in cirrhotic patients admitted for variceal gastrointestinal bleeding. All patients admitted in the study were registered in the Institution Transplantation, Transfusion, and Hepatology Iasi (consisting of 8 secondary hepatology centers) between January and December 2016 were evaluated for ACLF (we excluded from the study the patients presenting ACLF diagnosis criteria on admission). We compared cirrhosis patients who developed ACLF after 12 hours of admission with those who did not.

Results: 99 cirrhotic patients with gastrointestinal bleeding were evaluated. 45.5% of patients admitted with variceal bleeding developed ACLF. Demographic data were similar in patients with ACLF vs. no ACLF in age (54.2 ± 7.3 vs. 56.6 ± 9.5 years), male sex (54 vs. 45), and diabetes (56 vs. 43) and significant difference was found in alcohol consumption (72 vs. 27). In patients with ACLF, the grade 1 was the most frequent (56.3%); grade 2 (33.3%) and 3 (10.4%) of ACLF were more rare and no significant differences between the ACLF subgroups was observed. The patients with ACLF were more likely to be admitted with infections and alcohol consumption, when compared to patients without ACLF, Independent predictors for ACLF development included a high admission MELD (p < 0.05), presence of infection and alcohol abuse (p < 0.001), hospitalization in the last 6 months (p < 0.05). Inhospital and 30-day mortality were significantly higher in patients with ACLF (p < 0.0001).

Conclusion: Patients admitted with variceal bleeding, with alcohol consumption, high MELD on admission, previous admission in < 6 months are more likely to develop ACLF and need to be monitored closely for the development of ACLF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0036 HAEMOSTASIS IN PORTAL VEIN IN CIRRHOSIS: ROLE OF LOCAL ENDOTHELIAL DAMAGE

Introduction: Cirrhosis is characterized by both bleeding and thrombotic complications due to underlying procoagulative haemostatic imbalance [1]. Among thrombotic events, portal vein thrombosis (PVT) is the most common with annual incidence ranging between 4.6% and 12.8% [2, 3]. Demonstrated associated risk factors are severity of portal hypertension and slowed portal flow [4]. However, data regarding haemostasis in the portal venous system of cirrhotics is lacking.

Aims & Methods: To evaluate peripheral and portal venous haemocoagulative state in patients with cirrhosis in comparison with controls, through thrombin generation test (TGT), rotational-thromboelastometry (ROTEM) along with evaluation of endothelial dysfunction by quantification of circulating endothelial microparticles (MP). Correlate these results with activity levels of local pro and anticoagulant factors. Compare peripheral and portal venous districts in cirrhosis in terms of haemostatic balance. We consecutively enrolled adult patients with cirrhosis due to liver cirrhosis undergoing liver transplantation (LT) or transjugular intra-hepatic portosystemic shunt (TIPS). Patients without liver disease awaiting liver surgery or deceased liver donors were enrolled as controls. The following laboratory tests were performed on citrated peripheral and portal venous blood samples: TGT with and without thrombinomoid (TM), ROTEM, dosage of main pro and anticoagulants factors activity and analysis of circulating endothelial MP.

Results: 25 cirrhotics (15 LT and 10 TIPS) and 6 controls (2 undergoing hepatic resection for benign liver lesions and 4 liver donors) were enrolled. Peripheral blood in cirrhotics showed resistance to activation of PC-pathway at TGT (ETP with without TM 0.89 (0.78–0.92) vs 0.6 (0.3–0.74), p < 0.001), lower clot stability at ROTEM (MCF-NATEM mm: 46 (39–51) vs 62 (49–66), p = 0.042), and significant increase of endothelial-MP (CD62EPM/L: 1391 (651–2301) vs 582 (380–1161), p = 0.046), indicative of higher endothelial damage compared to controls. Similar results were obtained comparing portal blood of cirrhotics and controls (ETP with/without TM 0.89 (0.78–0.92) vs 0.63 (0.33–0.75), p = 0.001; MCF-NATEM mm: 46 (39–51) vs 62 (49–66), p = 0.056; CD62EPM/L: 1606.5 (680–1885) vs 529.5 (266–781), p = 0.009). There was a significant correlation between diminished levels of PC, PS, AT, FII and either TGT or ROTEM parameters. Comparing portal and peripheral blood of cirrhotics, we detected endogenous heparinoids in portal (α-antemel 51 (46–57) vs
**P0037 RIFAXIMINA IS ASSOCIATED WITH REDUCTIONS IN EMERGENCY DEPARTMENT RESOURCE USE IN UK PATIENTS WITH HEPATIC ENCEPHALOPATHY: REAL-WORLD EVIDENCE FROM THE IMPRESS STUDY**

**Introduction:** In clinical trials rifaximin (RFX) has been shown to reduce recurrence of episodes of overt hepatic encephalopathy (HE) and HE-related hospitalisations. UK real-world data confirmed reductions in hospital admissions and length of stay with RFX use, however, data on use of emergency department (ED; A&E in UK) resources are still scarce. This study assessed the impact of RFX on utilisation of ED resources.

**Aims & Methods:** Patients from 11 UK hospitals who were prescribed RFX for HE between July 2008 and May 2014 were included in this retrospective observational study. Patient records were reviewed; details of demographic and clinical characteristics, and all-cause ED attendances and admissions were collected in the 6 and 12 months pre- and post-RFX initiation. The analysis included only patients who were alive at the end of the study periods.

**Results:** Of the 145 patients included, 114 (79%) were alive at 6 months and 102 (70%) at 12 months post-RFX initiation. At RFX start, mean age was 61 years, 63% were male; 67% had alcohol-related liver disease; for patients with available MELD score (70%), the mean was 16; 78% were on lactulose. Use of ED resources in the 6 and 12 months pre- and post-RFX initiation is shown in Table 1. Six patients developed adverse events, none serious.

**Conclusion:** In UK clinical practice, treatment with RFX for HE is well-tolerated and associated with significant reductions in ED attendances, with or without admission, both within 6 and 12 months of RFX initiation.

HEPTEM 57 (50–59), p = 0.05). This finding, together with a decreased concentration of endothelial-MP carrying TM (TM-MP/L: 232 (190–287) vs 377 (218–493), p = 0.002) and endothelial-PC receptor (EPCR/C65E-MP/L: 16 (14–25) vs 37 (24–70), p < 0.001), demonstrated a local greater endothelial damage in cirrhotics.

**Conclusion:** In cirrhotics, venous hypercoagulability and portal site specific endothelial damage, associated with hampered antithrombotic properties, may be important local risk factors in the pathogenesis of PVT along with the documented venous stasis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0039 SAFETY, EFFICACY AND RISK OF COMPLICATIONS FOR CIRRHOTIC HCV PATIENTS WITH THROMBOCYTOPENIA AND HYPOALBUMINEMIA TREATED WITH OMBITASVIR/R-+DASABUVIR/R+RIBAVIRIN – A REAL-LIFE COHORT

C. Ester1, L. Gheorghe1, S. Iacob1, C. Cijevschi1, A. Trifan1, C. Stanciu1, L. Gheorghe2, N. Dudas2, R. Cipelli3, R. Aspinall4

1Department Of Gastroenterology, Fundeni Clinical Institute, Bucharest/Romania
2Third Medical Clinic, Matei Bals Clinical Institute, Bucharest/Romania
3EMF Craiova, Craiova/Romania
4The IMPRESS Study

Introduction: The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia and hypoalbuminemia were markers for portal hypertension and hepatic synthetic dysfunction, respectively, have been shown to reduce the likelihood of sustained virological response and to increase the rates of serious adverse events.

Aims & Methods: The aim of this study was to evaluate the impact of thrombocytopenia and hypoalbuminemia on treatment outcome and disease complications. We included in this study 855 HCV-infected cirrhotic patients treated with ombitasvir/paritaprevir/r+dasabuvir/r+ribavirin for 12 weeks in 10 university hospitals in Romania. The following groups were studied: 151 patients (17.7%) with albumin <3.5 g/dl, 239 (28%) with thrombocytopenia (a cutoff of 10000/mm3 was used) and 71 patients (8.3%) with both hypoalbuminemia and thrombocytopenia before initiating antiviral treatment. Safety (as AE in >5% and SAE), efficacy (HCV RNA undetectable at week 12 post-therapy and complications) and re-litigation were evaluated using Pearson’s correlation, multivariate analysis and Chi-Square test.

Results: Main patient characteristics were: 100% genotype 1b, a median age of 60 years (46.6% women (54.57%), high rate of previous interferon-based treatment (36.1%). End-of-treatment and sustained virological response rate were both >99% and there was no correlation with the presence of thrombocytopenia or hypoalbuminemia. The rate of adverse events in the whole cohort was 17.5% at 2 weeks reaching 18% at the end of treatment with only 0.8% severe adverse events with no statistical association with the presence of thrombocytopenia and hypoalbuminemia. The multivariate analysis showed significant association of thrombocytopenia (<10000/mm3) with higher (>1) degree of oesophageal varices (p = 0.001), one of upper digestive hemorrhage during treatment (p = 0.011), and prior exposure to interferon based regimens (p = 0.025). Low albumin (<3.5g/dl) also correlated with higher (>1) degree of oesophageal varices (p = 0.001) and onset of upper digestive hemorrhage during treatment (p = 0.002).

Conclusion: The efficacy and safety of the ombitasvir/paritaprevir/r+dasabuvir/r+ribavirin (as recommended by national regulations) was not different in cirrhotic patients with hypoalbuminemia and thrombocytopenia, but complications were higher at the end of therapy due to the absence of interferon and profatic measures should be recommended, especially if previously exposed to interferon containing regimens.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0040 BACTERIAL INFECTION IN PATIENTS WITH DECOMPENSATED CIRRHOSIS - A PREDICTOR OF LONG-TERM MORTALITY INDEPENDENT OF DISEASE SEVERITY

M. Sousa1, S. Fernandes1, J. Silva1, A. Ponte1, J. Rodrigues1, J. C. Silva1, L. Proença1, J. Carvalho1

Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Introduction: Bacterial infections are common in cirrhotic patients and the pro-inflammatory response superimposed on the hemodynamic dysfunction of portal hypertension predisposes to the development of complications. Some authors suggest that the occurrence of infection should be considered a separate clinical event, also altering the natural history of cirrhosis.

Aims & Methods: Retrospective assessment of patients with cirrhosis hospitalized for first episode of decompensation between 2011-2015. The aim was to evaluate the prognostic significance of bacterial infections regardless of the severity of the underlying liver disease.

Results: 115 cirrhotic patients (85% male, mean age 59 years, mean MELD 15, 72% alcoholic cirrhosis) were included with a total of 197 hospitalizations. Hospitals admissions were more frequent due to variceal haemorrhage (42%) and encephalopathy (37%). The incidence of bacterial infection was 23%: respiratory 25%, spontaneous bacterial peritonitis 24% and urinary 31%. Of these, 51% were nosocomial and in 20% an infectious agent was isolated. The survival rates at 30 days, 3 months, 6 months and 1 year were 65%, 55%, 34% and 27% in patients with infection and 97%, 90%, 85% and 78% in those without infection (p < 0.001). In the multivariate analysis, survival was independently associated with MELD (hazard ratio (HR) 1.073, p = 0.012), age (HR 1, 032, p = 0.012) and infection (HR 3, 821, p < 0.001). Bacterial infection remained an independent predictor of mortality, even when excluding patients with in-hospital mortality and long-term follow ups (HR 3, 093, p < 0.001 and HR 2, 015, p < 0.001).

Conclusion: Patients with cirrhosis exposed to a bacterial infection are at increased risk of death. This risk remains in the long term when we exclude patients with in-hospital mortality and at 30 days and regardless of the severity of the underlying disease (MELD).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0041 REAL-WORLD IMPACT OF RIFAXIMIN-A USE IN HEPATIC ENCEPHALOPATHY PATIENTS WITH ADVANCED LIVER DISEASE: A CONTINUED ALCOHOL MISUSE: A POST-HOC ANALYSIS OF THE IMPRESS STUDY

M. Hudson1, P. Di Maggio2, R. Cipelli3, R. Aspinall4

1Freeman Hospital, The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne/United Kingdom
2C. Maggioni, Norgine, Harefield/United Kingdom
3Ph Associates, Marlow/United Kingdom
4Queen Alexandra Hospital, Portsmouth Hospitals NHS Trust, Portsmouth/United Kingdom

Introduction: In the UK multicentre, retrospective, real-world study, IMPRESS, rifaximin-NF (RFX) use in patients with hepatic encephalopathy (HE) significantly reduced hospitalisations and length of stay in the 6 and 12 months post-RFX initiation compared to the respective periods pre-RFX initiation. This post-hoc analysis of the IMPRESS data compared hospital resource use pre- and post-RFX initiation in 2 sub-groups of difficult-to-treat HE patients: those with advanced liver disease or disease with continued alcohol misuse.

Aims & Methods: Medical records of patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were retrospectively reviewed; details of demographic and clinical characteristics, and all-cause hospitalisations were collected in the 6 and 12 months pre- and post-RFX initiation. Patients with baseline MELD score ≥15 or not abstinent at the end of the study period were included in this analysis. Statistical significance of the mean change (standard error of the mean, SEM) was calculated using paired t-test or Wilcoxon test.

Results: Only patients alive at the end of the 6 and 12 months RFX-treatment periods were included: 114 and 102, respectively. Amongst these, 33/114 (29%), for the 6 months) and 26/102 (25%, for the 12 months) had baseline MELD ≥15; mean age, 63 years; 70% were male; 66% had alcohol-related liver disease; mean MELD 24. The mean (SEM) number of bed days/patient reduced from 25 (6.0) in the 6 months pre- to 15 (5.5) in the 6 months post-RFX initiation, and from 36 (9.5) in the 12 months pre- to 20 (7.7) in the 12 months post-RFX initiation (p value not significant). At 6 months post-RFX initiation, 15/114 (13%) patients were still actively drinking. At RFX initiation, mean age was 56 years; 73% were male, mean MELD was 19. Despite this, the mean (SEM) number of bed days/patient decreased from 36 (7.9) in the 6 months pre- to 15 (5.4) in the 6 months post-RFX initiation (p = 0.048), and the mean of hospitalisations/patient fell from 2.8 (0.8) to 1.2 (0.4) (t-test p = 0.059; Wilcoxon test p = 0.029). Too few patients with continued alcohol misuse were alive at 12 months to evaluate. Two patients reported adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE for 6 or 12 months suggested trends in reduced hospital length of stay in patients with advanced liver disease and in those with continued alcohol misuse. However, larger studies are needed to strengthen these findings.

P0043 A PROPORTIONALY GREATER ELEVATION IN LIVER TRANSPLANT CANDIDACY IN PATIENTS WITH NAFLD AND PORTAL VEIN THROMBOSIS
M. Basaranoglu
Gastroenterology, Bizzamum Valh University, Istanbul/Turkey
Contact E-mail Address: metin_basaranoglu@yahoo.com
Introduction: NASH progresses to cirrhosis and its complications including hepato-cellular carcinoma. It is possible that risk factors for NAFLD-associated cirrhosis differ in Eastern countries from those in the Western world. Thus, we aimed to document the characteristics of patients with NAFLD-associated cirrhosis from Turkey, a European country sharing 97% of its borders with Asia. Relative to other European countries, the Turkish population exhibits a higher rate of obesity that can contribute to that in the Western world.
Aims & Methods: To characterize non-alcoholic fatty liver disease (NAFLD) presentation with esophageal varices. METHODS: We have kept the records of patients at our hepatology unit and affiliated liver center. Data were collected for esophageal varices at the advancing stage of cirrhosis. A cohort of patients with esophageal varices from 2003 to 2014 was reviewed. Eligible patients were ≥18 years of age and have had esophageal varices diagnosed by upper gastrointestinal endoscopy examination. They had regular clinical follow-up and endoscopic examinations at our clinic. Efficacy data were based on the last evaluation. Transplanted cases were excluded. The main inclusion criterion was the presence of esophageal varices with or without gastric varices. Only 258 patients with esophageal determined high-risk varices had reliable data and were included in this study. Each patient was evaluated for fundal varices, PVT, cirrhosis, HCC, and mortality. After the first evaluation, patients were divided into 4 groups: Those with hepatitis B, hepatitis C, NAFLD and others related to autoimmune hepatitis, Wilson Disease, primary biliary cirrhosis, etc.
Results: Primary end-point of the study was to use this cohort of patients with esophageal varices to evaluate the relationship between this disease and several etiologies, including NAFLD, hepatitis B, hepatitis C, or other liver-related diseases. The main objective was to draw this comparison in terms of PVT, HCC, cirrhosis survival and mortality. Of the 258 patients with esophageal varices, NAFLD was observed in 39.0% (101 patients), hepatitis B virus in 29.1% (75 patients) and HCC in 11.2% (29 patients). The mean age of NAFLD was 56.4 ± 16.0 years and 62% of these patients were men. Moreover, 47.5% had PVT, 5.0% had HCC, and 45.5% had fundic varices. The mortality rate was 47.5% during follow-up, but increased to 80% in the presence of HCC. PVT was observed in 47.5% of patients with NAFLD, 29.3% of patients with hepatitis B, 17.2% of patients with hepatitis C, and 23% of patients with other liver-related diseases (P < 0.001). Of the 111 patients (43%) that died during the study period, 72 patients (64.9%) had no PVT (P = 0.057). HCC was: 5.0% in patients with NAFLD, 26.7% in patients with hepatitis B, 34.5% in patients with hepatitis C, and 5.7% in other diseases (P < 0.001). Of the 38 patients with HCC, 13% had PVT. Moreover, HCC increased the mortality rate in almost in all the groups. Of the patients, 50.0% with NAFLD, 33.3% with hepatitis B, 26.3% with hepatitis C, and 58.3% with other diseases were alive at the end of the 5-year period with a significant difference according to the Kaplan-Meier log Rank test (P = 0.04). Risk for mortality, measured by risk ratio (RR), did not change per gender (RR: male/C6 female = 43.3%/42.5%, P > 0.05) or with the occurrence of cirrhosis (RR: 44.8%/28.6%, P > 0.05). However, it changed with the existence of fundic varices (OR = 4.90; 95% CI [2.24–10.71]; P < 0.001) and antibiotic therapy for infection (OR = 2.3, P = 0.009). MELD score greater than 10 (OR 2.9, P = 0.001) were independently associated with mortality. After the first evaluation, patients were divided into 4 groups: Those with hepatitis B, hepatitis C, NAFLD and others related to autoimmune hepatitis, Wilson Disease, primary biliary cirrhosis, etc.
Conclusion: The prevalence of MDR bacterial infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0045 EFFECT OF TREATMENT OF CHRONIC HEPATITIS C WITH SOFOSBUVIR AND DACLATASVIR IN PATIENTS OLDER THAN 60 YEARS
K. Elnozemly1, M. Badr2
1Gastroenterology, National Liver Institute (NLI), Elmenoufia gov/Egypt
2Internal Medicine, Menofya University, Shebin Elkom/Egypt
Contact E-mail Address: dr_kareemn@yahoo.com
Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing the impact of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients.
Aims & Methods: The aim is to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after 3 months of end of treatment.
Results: Old chronic hepatitis C patients who were treated achieved primary virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment) compared to SVR (after 3 months of end of treatment) in about 96% of treated patients. Before treatment, patients with chronic hepatitis C had worse scores especially in work, sleep, rest and recreation and pastimes categories. After treatment, patients who received sofosbuvir/daclatasvir with or without ribavirin had significant improve in work, sleep, rest and recreation and pastimes categories with p-value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and after 3 months of end of treatment.
Conclusion: Treatment of chronic hepatitis C in old-aged patients had a significant improvement in HRQOL.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bacterial infections are a leading cause of mortality in patients with decompensated cirrhosis. Aims & Methods: The objective of this study was to evaluate the prevalence of multiresistant bacterial infections, associated risk factors and their impact on prognosis in hospitalized decompensated liver cirrhosis patients. This was a retrospective case-control study that consecutively evaluated all bacterial infections with confirmed microbiological isolation in patients with decompensated liver cirrhosis admitted to the Gastroenterology ward between January 2009 and May 2016.
Results: There were 308 infections with confirmed microbiological isolates, corresponding to 218 hospitalizations, in a total of 161 patients. The median age of the patients was 63 years (IQR 55–71) and 67% of them were men. Alcoholic liver disease was the major cause of cirrhosis (72%). Among the infections evaluated, 87% were nosocomial and 13% community-acquired. Urinary tract infection was the most common infection (57%). In 27% of patients there were at least two concomitant bacterial infections. Multidrug resistant (MDR) bacteria were isolated in over half of patients. In the multivariate analysis, prophylaxis for spontaneous bacterial peritonitis (OR 2.3, p = 0.009), MELD score greater than 19 at admission (OR 1.7, p = 0.043), hospitalization in an Intensive/Intermediate Care in the previous month (OR 2.8, p = 0.001) and antibiotic therapy for infection in the last 6 months (OR 2.4; p = 0.001) were independently associated with MDR infection. From the variables identified in the multivariate analysis, a predictive model of MDR bacterial infection was created. Assuming a sensitivity of 66% and a specificity of 72%, we considered the cut-off of ≤0.0415 as clinically relevant, regarding likelihood of developing a MDR bacterial infection (AUCROC 0.723; 95% CI [0.667–0.780]). The occurrence of a MDR infection was associated with a longer duration of hospitalization (p = 0.017). In the multivariate analysis there was no independent association between MDR infection and in-hospital mortality and one month after discharge.
Conclusion: The prevalence of MDR bacterial infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.

Introduction: Accurate determination of the degree of hepatic-fibrosis is mandatory not only for the diagnosis and prognosis of disease, but also for deciding on the antiviral treatment. Indeed, many studies have been dedicated to the search of non-invasive fibrosis markers capable of providing an accurate information about hepatic fibrosis stage in patients with chronic hepatitis C (CHC). Direct and indirect markers of hepatic fibrosis are useful for prediction of liver cirrhosis but have limited accuracy for the diagnosis of significant fibrosis. Therefore, the development of more advanced scores combining both direct and indirect markers may improve their diagnostic accuracy.

Aims & Methods: This work is concerned with determining the levels of some of fibrosis markers, which are directly involved in deposition and removal of extra-cellular matrix (ECM), together with other indirect fibrosis markers so as to construct a predictive score capable of identifying the presence of significant fibrosis with a high degree of accuracy. Then, we aimed to estimate its performance against that of the other simple noninvasive tests in chronic hepatitis C patients.

Material and Methods: A total of 148 Egyptian HCV patients were subjected to routine laboratory workup in addition to estimation of serum AFP, hyaluronic acid (HA), platelet-derived growth factor (PDGF), tissue inhibitor of metalloproteinase-1 (TIMP-1) and collagen IV. According to fibroscan, patients were classified into those with non-significant fibrosis (F<2) and significant fibrosis (F2).

Results: Based on univariate analysis, ten variables were significantly higher in patients with significant fibrosis. Patients with F2-F4 had 2.08-fold, 2.14-fold, 1.80-fold and 1.90-fold increase in the concentrations of collagen IV, HA, PDGF and TIMP-1, respectively. Multivariate regression demonstrated that only age, AFP, PDGF, collagen IV and TIMP-1 retained significance. Therefore, a five-marker score named Egypt (EGY) Fibro-mark (FM) was developed. A significant correlation was found between its candidate markers and liver fibrosis progression. AFP was found to have highest correlation (r=0.47, P<0.0001) followed by collagen IV (r=0.46, P<0.0001), age (r=0.43, P<0.0001), TIMP-1 (r=0.40, P<0.0001) and PDGF (r=0.40, P<0.0001). ROC curve was used to estimate and compare the diagnostic accuracy of these candidate variables. As a consequence, these markers were in a decreasing rank: AFP (AUC 0.79), collagen IV (AUC 0.78), age (AUC 0.70), TIMP-1 and PDGF (AUC 0.75). Additionally, Bivariate Spearman’s rank correlation coefficient between EGY-FM and its candidate markers was determined for estimating the impact of each marker on the predictive criteria. The diagnostic value of Egy FM was then assessed by ROC curve showing an AUC of 0.89 for diagnosing significant fibrosis at an optimal cut-off point of 4.05 with 77% sensitivity, 83% specificity and 79% efficiency. Next, the area under the ROC curve (AUC) was used to discriminate and compare the performance characteristics of different non-invasive scores. The AUC was greatest for Fibro-mark (0.89), then BRC (0.83), followed by FRT and King’s score (0.81), APRI (0.80), Fibro-a (0.70) and finally FibroQ (0.63).

Conclusion: Egy Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King’s score, APRI, Fibro-score and FibroQ in this group of Egyptian patients.

P0047 EXTRACELLULAR MATRIX PROTEINS CIRCULATING LEVELS SUBSTANTIATE THE EFFECT OF IL-28B RS12979860 T ALLELE ON FIBROSIS STAGE OF CHRONIC HEPATITIS C TYPE 4

Introduction: In patients with chronic hepatitis C, host genetics influence liver fibrosis, particularly modifiers in genes controlling the inflammatory and immune response pathways. In this context, interleukin 28B (IL-28B) rs12979860 single-nucleotide polymorphisms (SNP) is considered the most important. Controversial data suggests that IL-28B SNP relate to the severity of hepatic histology. Some studies showed that rs12979860 C allele may be associated with greater hepatic inflammation, higher alanine aminotransferase levels and increased risk of worse clinical outcomes, other studies have not found this association. Furthermore, other studies found that the T allele affects the severity of liver fibrosis and had a mean staging score higher than other genotypes. Else, none of the previous studies concerned the association between the IL-28B SNP and signs of fibrosis severity.

Aims & Methods: We aimed to evaluate the cirrhotic development in C/T genotypes using FibroScan, extracellular matrix (ECM) proteins and the model for end-stage liver disease (MELD) in order to resolve conundrum regarding the association between interleukin 28B (IL-28B) rs12979860 and disease severity in chronic hepatitis C (CHC). So we assessed the allelic and genotypic frequencies of IL-28B rs12979860 in 272 HCV-infected Egyptian individuals; investigate serum levels of ECM proteins, including hyaluronic acid (HA), laminin, collagen type IV and the N-terminal pro-peptide of collagen type III (PHINP) as well as its association with liver fibrosis, as assessed by FibroScan, in different IL-28B rs12979860 genotypes; From another view, if C allele has a protective role, we also decided to evaluate the difference in cirrhotic behavior using FibroScan, ECM proteins and the MELD score between C/T IL-28B genotypes and evaluate the diagnostic performance of Fibroscan and these ECM proteins in IL-28B rs12979860 genotypes.

Results: IL-28B rs12979860 CT genotype is the commonest genotype among patients constituting ≈73% of the studied sample. The CC and TT genotypes constituted ≈18% and ≈9% respectively. Liver cirrhosis percentage increased with the increasing number of T alleles as it was 10%, 52% and 96% in CC, CT and TT genotypes, respectively. FibroScan values (kPa) gave a strong positive correlation (r=0.6; P<0.0001) with IL28B polymorphism. Similar to FibroScan, HA, laminin (r=0.5), collagen IV (r=0.4) and PHINP (r=0.4) serum levels showed significant (P<0.0001) positive associations with IL28B polymorphism. There was stepwise increase in the values of fibroscan and ECM proteins from CC to TT genotypes, so that elevated ECM proteins serum levels were associated with the presence of IL-28B T allele. (Table). In comparison with CC genotype, IL-28B rs12979860 T allele had a significant 2.4-fold increase (in case of CT) and 4.7-fold increase (in case of TT) in Fibroscan score (P<0.0001) positive associations with FibroScan, ECM proteins and MELD score. Among cirrhotic patients, liver stiffness was 31.13 ± 2.28 kPa in TT genotype vs 20.96 ± 0.74 kPa in CT genotype, MELD was 9.6 ± 0.73 in TT genotype vs 3.9 ± 0.41 in CT genotype and ECM proteins were significantly (P<0.0001) higher in patients with TT than CT genotype. AUC values for FibroScan, HA, laminin, collagen IV and PHINP serum levels to differentiate CC from other IL-28B genotypes were 0.91, 0.85, 0.84, 0.82 and 0.82, respectively. These values rise to 1.0, 0.97, 0.93, 0.98 and 0.93, respectively, when comparing CC to only TT genotype.
Conclusion: FibroScan and ECM proteins prove to be the IL-28B rs12979860 T allele affects the severity of liver disease. Coexistence of C allele with T allele reduces cirrhosis severity. This study gives a good deduction that carriage of the IL-28B C allele protects from unfavorable outcomes in CHC. This study shed the light on using FibroScan and ECM proteins as good diagnostic options for liver disease severity in IL-28B genotypes.

Introduction: Chronic hepatitis C virus (CHCV) patients with persistently normal transaminases represent a category of patients with mild and slowly progressive disease. Proper management of these patients with direct acting antivirals (DAAs) needs to be investigated in real world treatment settings in Egypt to further validate the accumulating data of the achieved high sustained virologic response (SVR) rates with the use of these drugs in clinical trials.

Aims & Methods: We aimed to report the efficacy of 5 different DAAs regimens for treatment of CHCV genotype 4 patients with persistently normal liver enzymes in real-world Egyptian cohort. Data of CHCV genotype 4 patients with normal liver enzymes who started treatment with different DAAs between September 2014 and September 2016 in a single specialized viral hepatitis treatment center in Egypt were retrieved. Treatment regimens included: Pegylated interferon alpha 2b Sofosbuvir/Ribavirin (PEG/SOF/RBV), Sofosbuvir/Daclatasvir (SOF/DCV), Sofosbuvir/Ribavirin (SOF/RBV), Sofosbuvir/Simeprevir (SOF/SIM). All regimens were given for 12 weeks except SOF/RBV which was given for 24 weeks. HCV RNA was tested at week 4 of treatment, and 12 weeks after treatment cessation to check for SVR 12.

Results: Our cohort included 1149 patients (562 males and 587 females). 158 patients were treatment experienced (13.75%) and 146 patients (12.7%) had liver cirrhosis. Regarding the used treatment regimens; 244 (21%) patients were treated with PEG/SOF/RBV, 382 (33.5%) with SOF/DCV, 152 (13.5%) with SOF/DCV/RBV, 117 (10%) with SOF/RBV and 254 (22%) with SOF/SIM. The overall SVR rate was 97.5% while the SVR rates for different regimens were; 94.7%, 99.7%, 100%, 91.5% and 98% for (PEG/SOF/RBV), (SOF/DCV), (SOF/DCV/RBV), (SOF/RBV) and (SOF/SIM) respectively.

Conclusion: Different DAAs achieved high SVR rates in treating CHCV genotype 4 with normal liver enzymes in a real-world cohort from Egypt. SOF/DCV/RBV combination was the most effective among the studied regimens.

Introduction: Recently, new direct antiviral agents (DAAs) with different mechanisms of action have been developed to provide much more efficacious and better tolerated therapeutic strategies for treatment patients with hepatitis C virus (HCV) infection. Several clinical trials have investigated a 12-week therapy with fixed dose of all-oral three-drug combination of daclatasvir (DCV), a potent pan-genotypic nonstructural protein 5A [NS5A] inhibitor, in 60 mg once daily, asunaprevir (ASV), an NS3 protease inhibitor, in 200 mg twice daily; and beclabuvir (BCV), a non-nucleoside NS5B thumb-1 polymerase inhibitor, in 75 mg twice daily (BCV-TRIO) for treatment of patients with HCV genotype 1 infection.

Aims & Methods: This systematic review and meta-analysis aimed to investigate the efficacy and safety outcomes of the three-drug combination of daclatasvir, asunaprevir, and beclabuvir, in treatment of HCV genotype 1 infection. Eleven electronic search engines/libraries, including PubMed, Scopus, Web of Science, Google Scholar, Virtual Health Library (VHL), WHO Global Health Library (GHL), ClinicalTrials, POPLINE, System for Information on Grey Literature in Europe (SIGLE), Cochrane library, and the New York Academy of Medicine (NYAM), were systematically searched for any clinical trial reporting the efficacy and safety of BCV-TRIO for the treatment of HCV genotype 1 infection. Studies were screened for eligibility and data was extracted by two independent reviewers. A well-sustained virologic response rate (SVR12) and, commonly reported outcomes were pooled as event rate and risk ratio in the comparison meta-analysis (RR). The meta-analysis was conducted using the Comprehensive Meta-analysis (CMA) platform. The protocol was registered in PROSPERO (CRD42017054391).

Results: Among the included five studies, four studies, with low to moderate risk of bias, were included for the meta-analysis (n = 1096). The BCV-TRIO showed a high-response rate in naïve patients (SVR12 rate: 95.5% [95% CI [93.5–96.9]). This total population was sub-grouped to get SVR12 rates: 89.5% [95%CI [85.3–92.4]), 96.2% [95% CI [93.0–98.0]), 93.5% (95%CI [89.2–96.1]), 91.1% (95%CI [87.6–93.7]), 93.9% (95% CI [86.6–97.3]), and 91.9% (95%CI [89–94.0]) for HCV genotype 1a, HCV genotype 1b, IL28B CC genotype, IL28B non-CC genotype, cirrhotic, and non-cirrhotic respectively. The virologic failure occurred only in 40 patients (7%) (95% CI [5.2–9.4]). There was no difference when adding ribavirin to this combination (RR = 0.98, 95% confidence interval (95% CI) [0.90–1.03, P = 0.70], using this regimen on interferon-experienced patients (RR = 1.03, 95% CI [0.98, 1.08], P = 0.30), or changing the dose of BCV from 75 mg to 150 mg regardless the genotype 1 subtypes or IL28B genotype. Similarly, the minimal failure of treatment showed no difference regarding the main two comparisons regardless the cause of this failure. Increasing the dose or the duration did not show a significant increase in the efficacy. The rates of serious adverse events (AEs) occurrence were; (3.4%, 95%CI [2.3–5.1]), (6.5%, 95%CI [3.2–12.7]), (2.3%, 95% [0.6–8.8]), and (2.9%, 95%CI [0.2–33.6]) for BCV-TRIO (BCV-TRIO + RBV) for 12 weeks, (DCV + ASV + BCV-150 mg) for 12 weeks, and both (BCV-TRIO) and (DCV + ASV + BCV-150 mg) for 24 weeks respectively. For BCV-TRIO, the most frequent AEs were headache, diarrhoea, fatigue, and nausea with rates; (21.2%, 95% CI [18.4–24.2]), (14.3%, 95%CI [12.0–16.9]), (13.8%, 95%CI [11.2–16.3]), and (13.4%, 95%CI [10.9–16.4]) respectively.

Conclusion: This study reported a high SVR, minimal treatment failure rate, and few AEs with fixed-dose three drug combination of daclatasvir, asunaprevir, and beclabuvir for 12-week duration in HCV genotype 1-infected patients, without adding ribavirin, prior interferon-based therapy, restriction on noncirrhotic patients, restriction on certain IL28B genotype, restriction on baseline resistance-associated variants, or expansion the duration of the treatment to 24 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.
GENETIC EPIDEMIOLOGY OF HCV INFECTION IN UPPER & LOWER EGYPT: A MULTICENTRE FAMILY-BASED STUDY

M. El-Bendary1, M. Neamatallah1, E. Kameel1, H. Elalfy1, T. Besher1, M. El-Muhandis1, A. A. Elmorsy1, M. El-Setouhy2, Y. Eladl2, G. Esmat1

Introduction: Egypt has the highest prevalence of HCV worldwide. Prevalence of HCV was reported to be 13.9% among healthy populations. Adults have higher HCV prevalence (15.7%) than children (4.0%). Geographically, HCV is highly prevalent in the Nile delta (15.8%) than in Upper Egypt (9.0%). The household contacts of HCV seropositive patients had been shown to have a high risk of HCV infection.

Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt.

The multicentre hospital case control based study was conducted in 4894 Egyptian individuals enrolled to the hospitals from different Egyptian population in Upper & Lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates). The index HCV patients were 1106 cases whereas the families or close household contacts of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders first and second degree consanguinity, living and sharing usual lifestyle and having at least 15 years of exposure to the index case. The positive cases (either index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA ≥ 6 months, 2-Adults (above 18 years) of both sexes 3-Any stage of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC) based on the following criteria: positive Anti-HCV but negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnostic and PCR HCV to confirm HCV infection. Sequencing analysis of the NS5B region of HCV was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were +ve while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among house hold contacts was 17.29% & negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnostic and PCR HCV to confirm HCV infection. Sequencing analysis of the NS5B region of HCV was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were +ve while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among house hold contacts was 17.29% & negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnostic and PCR HCV to confirm HCV infection. Sequencing analysis of the NS5B region of HCV was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Conclusion: The prevalence of HCV was found to be 18.5% among household contacts of Egyptian families. The genotype 4 was predominant in upper Egypt (97.1%) more than lower Egypt (91.7%). On the other hand genotype 1a was higher in lower Egypt (8.3%) more than upper Egypt (2.9%).

CANCER INCIDENCE IN VARIOUS ORGANS OTHER THAN THE LIVER FOLLOWING DIRECT-ACTING ANTIVIRAL (DAA) THERAPY FOR HEPATITIS C

B. Endoh1, N. Esaka2, S. Katsusima3, K. Chikugo4, S. Nakano4, T. Shimogama4, T. Komeda1

Reference

39(3):862–3; author reply 863.
cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

**Aims & Methods:** We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as documented by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method with Log-Rank analysis. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

**Results:** There was a significant difference in the age and sex of the patients treated with DAAAs (n = 324, median age: 70, male: 41%) and those treated with IFNs (n = 445, median age: 58, male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 23 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancers occurred most frequently in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract/pancreas, lungs, and other organs. The median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0% and 5.0% for the DAA group, and 0.2 and 0.0% for the IFN group, respectively. The difference between the groups was significant (p = 0.02) based on Cox regression analysis using IPTW.

**Table:** Cox regression analysis for cancer incidence other than the liver in IPTW samples

**Conclusion:** Because cancer detection in organs other than the liver can be challenging in management of hepatomas, some cases with cancer found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the present study, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors, including age and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

**Introduction:** The shift from therapy with interferon to Direct antiviral agents (DAAs) has been a watershed for the management of HCV-related chronic liver diseases. In fact, treatment with second-generation DAAs cures the major proportion of those patients infected with HCV chronic infection, with the exception on genotype 3 cirrhotic patients.

**Aims & Methods:** The present report focuses on HCV genotype 3 cirrhotic patients treated with second-generation DAAs in order to identify which of the several treatment schedules recommended for genotype 3 would constitute the best option. Methods: 1. Twenty-four Italian centers (ITAL-C consortium) were involved in this real-life study where HCV genotype 3 patients treated with DAAs. Eligible patients were >18 years old with chronic HCV infection, neither naive or treatment-experienced. Any patients with any of the following features were excluded: infection with HCV genotypes other than 3, active HCC on imaging, HIV and/or HBV co-infection, liver-transplant recipients, patients with an estimated glomerular filtration rate <30 ml/min. 2. With the intent to delineate a treatment schedule with the new DAAs that would offer the higher chance of SVR to patients with HCV genotype 3, a systematic search of the literature data was implemented and the retrieved information was pooled and evaluated by a meta-analytical approach. Electronic, systemic review of the available evidence in the published literature was undertaken to identify all studies. The systematic literature review was performed via Medline from 2012 to 2016 by the following search keys: HCV Genotype 3 AND (DAA/OR (sofosbuvir) OR (daclatasvir) OR (ledipasvir) OR (velpatasvir)). Results: 1. A total of 233 HCV genotype 3 patients were enrolled. In the entire population, the SVR rate was achieved by 205 subjects (88.0%). A successful treatment outcome was documented in 79.0% of patients treated with sofosbuvir in combination with RBV, in 92.0% of those who received sofosbuvir/ledipasvir with or without RBV, and in all 7 patients treated with sofosbuvir/ledipasvir with or without RBV. At the univariate analysis, baseline predictors of the SVR12 were gender (female patients being more responsive than males), BMI <30 and the treatment schedule. Of relevance, age, stage of liver disease (in advanced fibrosis or cirrhosis), RBV use, and treatment length were irrelevant to SVR12. At the stepwise logistic regression analysis, the only two factors independently associated with SVR12 were regimen containing sofosbuvir in combination with daclatasvir or ledipasvir (OR = 4.25; 95% CI: 1.81–9.97; p = 0.001), and the BMI <30 (OR = 2.64; 95%CI: 1.04–6.72; p = 0.041). 2. The systematic review of the literature provided data of 331 patients from 17 full text article and two abstracts. The mean weighted SVR12 rate was 89.4% (95%CI: 80.4–87.8); the rates varied from 79.0% (CI: 70.9–85.3) with sofosbuvir/ledipasvir to 84.4% (CI: 80.4–87.8) with sofosbuvir/ribavirin, to 92.3% (CI: 86.2–93.1) with sofosbuvir/daclatasvir. Conclusion: HCV genotype 3-infected patients, and in particular those progressed to cirrhosis, should be no more considered difficult-to-treat individuals, provided that an optimal therapeutic schedule is applied. Patients without cirrhosis should be treated with sofosbuvir and daclatasvir for 12 weeks. Patients with cirrhosis should be treated with sofosbuvir and daclatasvir for 24 weeks with or without RBV.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References:**
Conclusion: In this cohort the “de novo” incidence of 3.8% of HCC after the transplantation was directly mainly in patients with decompensated cirrhosis, not eligible for treatment with interferon in the past, and in a short interval of time after treatment. These results alert for an eventual need to increase the frequency of screening in the post-treatment period and carefully evaluate the best timing for liver transplantation in these patients. We could not conclude about recurrence due to the small number of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

3. - Reig M, Suzuki F, Fujisawa Y, Sawaoka H, Hosaka T, Akuta N, Suzuki Y, Saitoh S, Arase Y, et al. Sustained virologic response affecting proteins involved in different biological processes including mitochondrial metabolism. In hepatococytes, miR-506: i) induced dedifferentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; ii) increased oxidative and endoplasmic reticulum (ER) stress; iii) caused DNA damage; iv) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and loss of mitochondrial membrane potential) and PDC-E2 overexpression. Co-culture of miR-506 over expressing hepatocytes with PBC immune cells induced activation and proliferation of PBC immunocytes.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
Area under the curve and receiver operator characteristic (AUROC) compari-
ses the diagnostic performance of the eight features in the interquartile range (IQR) and median of 10 SWE measurements using body mass index (BMI) and age were analysed using the Mann-Whitney U test.

Results: The study population consisted of 106 men and 94 women with a mean age of 48.2 years (range 18-78 years) and BMI of 25.6±4.6 kg/m². Fatty liver was present in 50% of these patients. BMI of 25.7 was considered to be the diagnostic threshold for hepatic steatosis. AUROCs of the factors are presented in the table. AUROC values ranged from 0.735 (A) to 0.903 (H), respectively. In the cohort of obese (BMI > 25), 52% of patients (n = 124) and older patients (age > 65), 22%, p < 0.012) indicated significantly higher IQR/median. There was no significant difference in the diagnostic accuracy between using the median or mean of five, and 10 measurements. The AUROCs to diagnose patients with severe fibrosis were: F0/F1/F2/F3/F4 in 70/34/20/23/25 patients, respectively. The median AUROC of one measurement was 0.876 (H). AUROC increased based on the number of measurements. A significant difference between 1 and 5 (p < 0.05), 10 and (p < 0.01), 2 and 10 (p < 0.05) measurements was observed in pairwise comparison. Likewise, A significant difference between patients with severe (F3) and moderate fibrosis (F2) was observed (A) to 0.923 (G). A significant difference (p < 0.05) was seen between one and 10 measurements. In the cohort of IQR/median < 0.3, the diagnostic accuracy of ≥F2 and ≥F3 ranged from 0.806 (A) to 0.877 (H), and from 0.832 (A) to 0.928 (H), respectively. In the cohort of obese (BMI > 25) and old patients (age > 65), the diagnostic accuracy of ≥F2 and ≥F3 ranged from 0.752 (A) to 0.862 (D), and from 0.735 (A) to 0.903 (H), respectively. Comparing the AUROC of one measurement, IQR/median < 0.3 showed greater AUROC than those of other cohorts, however, the AUROCs of ten measurements were similar in each cohort.

Conclusion: No difference was found between reporting mean or median SWE measurements. The diagnostic performance of SWE increased with the number of measurements. Our results suggest that 10 measurements are recommended to ensure the accuracy of SWE measurements in a practical setting.

Introduction: Percutaneous radiofrequency ablation (RFA) is a commonly used locoregional interventional procedure in treatment of hepatocellular carcinoma (HCC). There is growing evidence that apparent diffusion coefficient (ADC) value can be used in evaluating RFA therapeutic efficacy in treatment of HCC and thus represent a reliable predictor of local HCC recurrence after ablation.

Aims & Methods: We aimed to determine the therapeutic efficacy of RFA in patients with hepatocellular carcinomas using ADC value. A total of 52 patients with 58 HCCs were included, and were treated with RFA according to the guidelines. All lesions were evaluated by diffusion weighted imaging (DWI) and ADC value measurement before and after RFA treatment. DWI was obtained using axial a single-shot echoplanar imaging with two b-values (500, 1000 mm²/s) using 3 tesla MRI machine. Quantitative ADC maps were calculated using commercial software and an imaging post-processing. Diagnosis of HCC relied on triphasic CT and MRI, showing enhancement at the arterial phase of dynamic contrast enhanced CT or MRI with rapid washout at the portal venous & delayed phases. Follow-up post ablation by triphasic CT and/or MRI with ADC value measurement was done after one and three months to detect the response cases (no residual tumoral activity) and non-responsive cases with residual tumor activity.

Results: Forty-eight lesions responded to treatment and 10 lesions had shown no response. ADC values were significantly higher in lesions that responded to RFA than in non-responding lesions. The mean ADC value before treatment was 1.26±0.16 × 10⁻³ mm²/s (mean±SD), while after treatment it was 1.46±0.12 × 10⁻³ mm²/s with a statistically significant difference (P =0.003) using paired samples t-test. The b value 1000 before treatment was 1.32±0.28 × 10⁻³ mm²/s, and increased in after treatment in responding lesions to reach 1.52±0.1 × 10⁻³ mm²/s with a statistically significant difference (P=0.003). Using b value 500, the mean ADC value before treatment didn’t show a significant difference between responding (1.26±0.12 × 10⁻³ mm²/s) and non-responding lesions (1.26±0.12 × 10⁻³ mm²/s; P=0.97). While using b value 1000, there was a significant difference with higher mean ADC values before RFA in responding lesions than in non-responding (1.46±0.12 × 10⁻³ mm²/s and 1.26±0.12 × 10⁻³ mm²/s in non-responding, respectively; P=0.03) The change in ADC in responding lesions is significantly higher than in non-responding lesions, and it was 19.6% vs. 6.2%, respectively (P=0.01) using b value 500 and was 23.7% vs. 21.2%, respectively (P=0.001) using b value 1000.

Conclusion: ADC is a good quantitative measurement allows effective evaluation of the therapeutic efficacy of RFA for treatment of patients with HCC and can be used as good non-contrast alternative to conventional imaging methods in post ablation follow-up.

Introduction: To study the effect of NAFLD on the results of shear wave elastography (SWE) in patients with chronic diffuse liver disease.

Aims & Methods: We have performed outcome analysis in 100 patients with diffuse liver disease which were treated from 2015 to 2016. There were 41 male patients (41%), and 59 female patients (59%), age Me (LQ-UQ) 49 (39–56), minimal age was 18 years, maximal age was 77 years. All patients were found to have chronic diffuse hepatic diseases and were hospitalized for morphological and functional characterization. All patients had shear wave elastography (SWE) with quantitative measure tissue stiffness, Metavir score staging for received results.

Results: Based on the obtained morphological results, we have formed the following subgroups of patients: F0 - F1-31 people, F2-9; F3-15 and F4-45 patients. Given that patients with a degree of fibrosis on the scale METAVIR F0 and F1 do not require active conservative therapy, we combined the data of the group into one F0-F1. The obtained results of shear wave elastography are presented in the form of quantitative variables. Median stiffness with interquartile range (25%-75%) in groups: F0 - F1 - 5, (4, 8-7, 2) kPa, F2-8, (5, 3-8, 9) kPa, F3-13, (5, 10-14, 8) kPa and F4-22, (18, 2-28, 5) kPa. The parameters of liver stiffness in the various subgroups of patients with different stages of fibrosis were presented in the form of median and interquartile range.

Conclusion: No significant correlation was found between the shear wave elastic modulus and the stage of fibrosis in this population. However, there was a significant correlation (P=0.001) between the degree of liver stiffness and the stage of fibrosis. A strong correlation was revealed: the Spearman coefficient was r = 0.97. The coefficient of correlation between the stiffness index (BMI) and age were analysed using the Mann-Whitney test.

Contact E-mail Address: benedetta.conti1@gmail.com

Introduction: The estimation of liver stiffness (LS) has recently been evaluated by new elastographic techniques, such as Shear Wave Elastography (SWE), with a wider applicability than transient elastography (1). No studies evaluated LS in patients with alcoholic liver diseases (ALD) by using the elastographic methods. Moreover, exploring the possibility to assess the elasticity of other organs and tissues, few studies have evaluated the results of SWE in patients with diffuse liver disease, the possibility of fatty dystrophy should be taken into account, since an underestimated of this fact can lead to false-positive results in the staging of fibrosis by METAVIR. The SWE method can be recommended for evaluation of the degree of hepatic steatosis, in the absence of correlation with elastometry data.

Disclosure of Interest: All authors have declared no conflicts of interest.
0.21–0.57). At univariate analysis LS was associated with liver cirrhosis (p < 0.01), steatosis (p = 0.0003), liver surface nodularity (p = 0.0003), active alcoholic abuse (p = 0.015), alcohol consumption/day (p = 0.0134), diabetes (p = 0.0223). At multivariate analysis cirrhosis (p < 0.0001) and steatosis (p = 0.0073) were independently associated with LS. At both univariate and multivariate analysis, PS was significantly correlated only with liver cirrhosis (p = 0.0058).

Conclusion: The present is the first series assessing LS and PS in ALD patients by using SWE. The feasibility of the technique was excellent. The reproducibility was good for LS and fair for PS. SWE was a good predictor of liver fibrosis in the ALD cohort. Liver cirrhosis was the only independent variable correlating with PS, whose estimation could be useful to detect alcohol-related pancreatic damage in patients with severe ALD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0061 EXOSOMIC MIR-224 REGULATED TUMOR INVASION AND MIGRATION THROUGH IL-6/STAT3 PATHWAY IN HEPATOCELLULAR CARCINOMA

F. An, D. Chen, Q. Zhan, M. Xia, X. Wu
Gastroenterology, West China's Medical University, West China, Sichuan, China

Contact E-mail Address: wdd8025@163.com

Introduction: A previous study was found regulated progression of liver cancer in our previous studies, IL-6/STAT3 pathway play key role, but the precise underlying mechanism remains to be explored. It was found exosomes are the vesicles released by the tumor cells into tumor microenvironment, they are a powerful mechanism to transfer RNAs and proteins. The study of exosomes provide the new way to develop new therapy.

Aims & Methods: The expression of miR-224, IL-6, STAT3 and SMAD4 in tumor as well as adjacent tumor tissues of HCC were detected by RT-PCR. Aims & Methods: Seven main miRNAs (miR-125a, miR-139, miR-34a, miR-221, miR-16, miR-145 and miR-199a) were selected due to their expression patterns in HCC as well as their contribution to the development of hepatocarcinogenesis. A total of 165 patients were enrolled in this study, from which serum samples were collected and categorized into four main patient groups: 42 chronic hepatitis C (CHC); 45 CHC with cirrhosis (LC); 38 HCC with HCV infection; and 40 healthy controls. The expression profile of the seven miRNAs was analyzed using TaqMan real-time transcription-polymerase chain reaction. Additionally, the expression levels of liver-specific microRNAs (miR-221, miR-199a) and ALP were measured using commercial kits.

Results: Serum levels of miR-125a, miR-139, miR-145 and miR-199a were significantly decreased (p < 0.01) in HCC than in the CHC and LC groups (Table 1). On the other hand, miR-16 and miR-34a were significantly increased (p < 0.01) in HCC patients compared to the normal group. However, no significant difference was shown in the expression of miR-16, miR-34a, and miR-221 between the CHC, LC, and HCC groups. As a single biomarker, miR-34a showed the highest sensitivity and specificity among all miRNAs investigated, followed by miR-221, miR-125a, miR-139, miR-145, and miR-199a.

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-221 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145, and miR-199a in the HCC patient group indicates that these microRNAs can differentiate HCC from CHC and LC.

Introduction: Primary hepatocellular carcinoma (HCC) is one of the most common malignancies all over the world. HCC is associated with poor prognosis. However, the mechanism of HCC initiation and development remains unclear. In our previous work, high-throughput microarray assay in collected clinical HCC samples followed by bioinformatic analysis suggested that Metallothionein 1G (MT1G) might be one of the key factors in HCC. Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSP (Methylation specific PCR) and BGS (Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was investigated by overexpression or knockdown in HCC cell lines. The effects of MT1G re-expression were also determined by flow cytometry.

Results: MT1G was inactivated in all (6/6) HCC cell lines tested, but was readily expressed in immortalized liver cell line LO2. The expression of MT1G was
regulated in cancer tissues compared with the adjacent non-tumor tissues (B). The expression level of MT1G in the liver cancer tissue cell lines was closely correlated to the promoter hypermethylation status. The MT1G expression in silenced HCC cell lines could be restored by demethylation agent. We generated HCC cell lines overexpressed MT1G. Ectopic re-expression of MT1G by stable transfection in SMCC-7721 and Hep3B cells inhibited colony formation (P < 0.001), suppressed cell motility and invasiveness (P < 0.05), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP13 and Vimentin. The in vivo growth of HCC cell lines in normally was also markedly inhibited after stable expression of MT1G (P < 0.001). MT1G over-expression in HCC cells induced the cell apoptosis (P < 0.01).

Conclusion: Our results demonstrate that MT1G promoter methylation directly mediates the transcription down-regulation and commonly occurs in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, inva-

Introduction: Hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) may be confused on medical imaging. Both tumours are not connected to the biliary tree, however only FNH accumulates bile salts, suggesting that hepatocellular uptake and secretion of bile constituents differs in FNH and HCA. Therefore, one would anticipate changes in the Farnesoid X receptor (FXR) expression. However, the expression of FXR and its targets in HCA and FNH is relatively unknown. Targets of FXR regulate uptake and excretion of hepatobiliary contrast agents, possibly altering the presentation of FNH and HCA on medical imaging. We studied the expression of FXR and its targets in HCA and FNH and compared this with the appearance of lesions on MRI.

Aims & Methods: Tumour tissue and normal tissue from 7 patients with HCA and 7 patients with FNH was obtained. Diagnosis was confirmed by histopatho-

Introduction: CXU1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze the role exerted by CXU1 during deacetylase inhibitors mediated cell death in liver cancer cells. CXU1, endoplasmic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CXU1 and furthermore treated with deacetylase inhibitors panobinostat, SAHA and trichostatin A. Thapsigargin, an endoplasmic reticulum stress inducer, served as positive control.

Results: CXU1 knock down caused a suppression of ER stress and autophagy markers BIP, CHOP, ATF4, ATF6, Becn1, MAP1LC3B, UVRAG and TFEB at early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BIP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CXU1 over-expression after 6 hours of treatment, whereas they showed to lose this ability after 24 hours. CXU1 knock-down reduced not significantly its protein level after treatment with deacetylase inhibitors. CXU1 knock down counteracts the accumulation of BIP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BIP independently from CXU1.

Conclusion: ER stress and autophagy markers are under the control of CXU1. The cell death induced by deacetylase inhibitors is strictly connected with CXU1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CXU1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CXU1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CXU1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CXU1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL then-signalors). The cell death assays were analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed. Western blotting was performed for caspase 8 and Flp detection.

Results: Treatment with superkiller TRAIL, at 50 and 100ng/ml, caused cell death in HepG2 and Hep3B cells after 48h proven by an accumulation of 40% of sub-G1 events. CXU1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100ng/ml). CXU1 knock down did not change the expression of TP53, KRT18, CDKN1A and CDKN1B. Interestingly, silencing CXU1 caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events to 40% of sub-G1 events. prolonged transfection did not affect the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Conclusion: Limited by sample size, this study suggests that misdiagnosis based on imaging might actually correlate with aberrances on hepatocyte trans-

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alpha fetoprotein (AFP).

Methods: Serum samples were obtained from 300 consecutive patients with chronic hepatitis C, of whom 150 had cirrhosis and 150 were without cirrhosis. By using an enzyme-linked immunosorbent assay (ELISA) method, serum SCCA and AFP levels were measured. The correlation between these markers and tumor size, staging, and survival was calculated. SCCA and AFP levels were also compared between patients with and without cirrhosis, patients with and without HCC, patients with and without BCLC stage B, patients with and without BCLC stage C, and patients with and without BCLC stage D.

Results: The median SCCA level in patients without cirrhosis was 7.8 ng/ml (range: 0.2–56.7 ng/ml) and in patients with cirrhosis was 15.0 ng/ml (range: 0.6–154.0 ng/ml). The median AFP level in patients without cirrhosis was 0.6 ng/ml (range: 0.1–20.0 ng/ml) and in patients with cirrhosis was 3.3 ng/ml (range: 0.6–20.0 ng/ml). The correlation between SCCA and AFP levels was significantly positive in patients with and without cirrhosis and in patients with and without HCC.

Conclusion: SCCA and AFP levels were significantly higher in patients with cirrhosis and HCC than in patients without cirrhosis and HCC. The correlation between SCCA and AFP levels was significantly positive in patients with and without cirrhosis and in patients with and without HCC.

4Department of Surgery, Cairo/Egypt

Contact E-mail Address: daliaomran@kasralainy.edu.eg

Introduction: Hepatocellular carcinoma (HCC) is the first most common primary malignant tumor of the liver, the fifth most common cancer and the third most common cause of cancer-related death worldwide. (1) Early detection of HCC provides the best chance for a curative treatment which in turn improves patients survival. However, more than 60% of HCCs are diagnosed at a late stage (2). This could be explained by poor compliance of cirrhotic patients to the surveillance programs and lack of a sensitive and specific tumor marker. Serum AFP – commonly used for HCC diagnosis has a low sensitivity, and specificity for HCC detection (3).

Aims & Methods: The aim of this study was to develop Hepatocellular Multidisciplinary clinic – Cairo University (HMC-CU) score and test its accuracy in HCC detection in comparison to the widely used AFP. In the current study, we reviewed the data of 2363 Egyptian patients with HCV genotype-4 related liver cirrhosis and no HCC. Diagnosis of HCC related liver cirrhosis was based on clinical, laboratory and imaging evidence of chronic liver disease in addition to detection of HCV antibodies and HCV RNA by PCR technique. Each patient signed an Informed consent and the study was carried out according to the ethical guide-lines of 1975 Helsinki Declaration.

Results: On bivariate analysis, the HCC patients were significantly older, anemic and showed significant thrombocytopenia, hyper- bilirubinemia, elevated serum AST and AFP serum levels. Serum albumin was significantly lower in HCC patients consequently, we entered these significant variables in a multivariate regression model that demonstrated that only age, gender, hemoglobin, albumin, AFP and INR were independently associated with HCC development.

Table: Multivariate analysis for calculation of the HMC-CU score.

<table>
<thead>
<tr>
<th>Age Gender</th>
<th>Hb</th>
<th>INR</th>
<th>OR</th>
<th>Lower</th>
<th>Upper</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

The best overall formula that could best predict HCC was then constructed. HMC-CU score = 0.080 x Age + 1.164 x Hb + 0.886 x INR - 2.653 x Hb + 0.0498 x INR + 0.347 x Hb + 1.022 x INR + 0.080 x Hb

The overall accuracy (cutoff point) of 0.56 HMC-CU enabled the correct identification of HCC with 92% sensitivity and specificity. The area under the ROC curve (AUC) was 0.93 and 95% confidence interval was 0.91–0.94. On comparing the diagnostic performance of HMC-CU to the performance of serum AFP for early diagnosis of HCC, it was found that serum AFP was able to diagnose HCC at cutoff value of 11.9 ng/ml with sensitivity of 68% and specificity 66%. AUC was 0.76 and the 95% confidence interval was 0.74–0.78.

Conclusion: The HMC-CU score constructed from routine parameters is accurate in the early diagnosis of HCC as compared with HCV related CLD. The advantage of our score is based on its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes only routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non HCC patients all are Egyptians with a background of HCV type 4 related CLD. A prospective validation study is being planned and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

MULTIPLE BIOPOLAR RADIOFREQUENCY ABLATION IN TREATMENT OF MEDIUM TO LARGE HEPATOMAS – EXPERIENCE IN A REGIONAL HOSPITAL

P. Hsieh, C. Yen

Department of Gastroenterology And Hepatology, Chang-Gung Memorial Hospital Keelung branch, Keelung/Taiwan

Contact E-mail Address: 88802050@gmail.com

Introduction: Monopolar radiofrequency ablation (RFA) treatment for hepatomas has been unsatisfactory with local tumor recurrent rates of 8–40% in tumors ≥3 cm. Bipolar RFA devices have been developed to overcome the limitations of monopolar RFA devices.

Aims & Methods: This study aimed to evaluate the therapeutic effect and long term survival in medium and large hepatomas using multiple bipolar radiofrequency ablation system (Celon). The study subjects had a Child-Pugh classification of A or B. The patients who were ineligible for surgical intervention or other palliative treatment were included in the study and compared between medium and large hepatomas using Kaplan-Meier survival and the prognostic factors were using multivariate analysis.

Results: 30 patients were divided equally into two groups with 15 patients in each of medium and large hepatoma groups. 17 patients underwent artificial ascites (56.3%). The complete necrosis rate after ablation was 93.3% (14/15 patients) for either medium or large hepatomas. The local tumor progression rate and distant tumor recurrence rate of 40% and 60% (p = 0.098) vs 73.3% and 80% (p = 0.652) for medium and large hepatomas during 30 months follow up were not statistically significant. The overall survival rates of 80%, 66.7% vs 60%, 46.7% at 12 and 30 months, respectively, was not statistically significant (p = 0.390). By multivariate analysis, BCLC stage (HR = 3.904, p = 0.023) MELD score (HR = 1.220, p = 0.021) and pre-treatment AST level (HR = 1.028, p = 0.019) were independent prognostic factors for overall survival.

Conclusion: Multiple bipolar RFA system can achieve high complete tumor necrosis rates and low complication rates in treating medium to large hepatomas with shorter pre-treatment BCLC stage. MELD score and AST level were independent prognostic factors for overall survival. The therapeutic effect and long term survival for large hepatomas (≥5 cm) was not inferior to that of medium hepatomas by multiple bipolar RFA.

PO070 RECENT TRENDS IN HEPATOCELLULAR ADENOMAS: CLINICAL FEATURES, DIAGNOSIS AND OUTCOMES

M. Silva, A. Peixoto, R. Coelho, H. Cardoso, G. Macedo
Gastroenterology, Hospital São João, Oporto/Portugal

Contact E-mail Address: marcoscostas87@gmail.com

Introduction: Hepatocellular adenomas (HCA) are rare, benign tumors of pre- sumable epithelial origin, that occur predominantly, but not exclusively, in young women. Although, they are considered benign neoplasms. The Bordeaux adenoma tumour markers are a promising method of identifying the high-risk HCA of malignant transformation into hepatocellular carcinoma (HCC)

Aims & Methods: Aims: The authors propose to evaluate the demographics, etiology, clinical manifestations and prognosis of HCA. We undertook retrospective analysis of patients with HCA, histologically confirmed (by guided biopsy or surgical resection), between 2008 and 2016, in a tertiary referral centre. When feasible, the subtype classification of HCA proposed by Bordeaux group, was performed. Descriptive statistics, univariate and multivariate analysis were performed using IBM SPSS Statistics 22, with p < 0.05 deemed to be statistically significant.

Results: In this study 27 patients were included, 2 man and 25 women, with a median age of 38±11 years, followed for a mean time of 78±36 weeks (lost follow-up in 7 cases). Three cases of hepatic adenomatosis were included. Forty-one percent of the women used OC and 38% of the patients had dyslipidemia. The mean size of the HCA was 70±42 mm; 65% of the patients had abnormal liver tests at diagnosis, 46% were symptomatic and in 21% the diagnosis was performed due to ruptured HCA. Surgical resection was performed in 88% of the cases; complete resection was achieved in 75% of the cases. Of the 19 patients who performed abdominal-CT scan or abdominal-MRI before histological confirmation, only 20% had an imagiological diagnosis of HCA. In 12 (44%) cases, immunohistochemical analysis was performed. According to the Bordeaux classification of HCA, 8 (67%) cases were classified as inflammatory, 2 (17%) as HNF-1α-mutated, 1 (8%) as β-catenin mutated and 1 (8%) as unclassified. During the follow-up period, a hemorrhagic shock related with HCA rupture and in 2 (10%) was necessary surgical revision due to incomplete resection. There was no HCC diagnosed during the follow-up. The median size of the HCA that weren’t completely resected and also of those presenting with HCA rupture was significantly higher: (110±55 mm [p=0.035] and 105 vs 47 mm [p=0.037], respectively). The 2 male patients had inflammatory HCA (p=0.011).

Conclusion: In this cohort, HCA were prevalent in female taking OC and the inflammatory type HCA was the most common. In many cases, abdominal imaging is insufficient for a correct diagnosis, and biopsy specimen or surgical resection should be performed for a correct diagnosis. Lesion size was associated with the risk of rupture and incomplete surgical resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Currently, the standard treatment using transarterial chemo-embo- lisation (TACE) for patients showing solitary large (~40 mm) hepatocellular carcinoma (HCC) is unsatisfactory with high rate of recurrence. Data from literature suggest the alternative use of thermal ablation.

Aims & Methods: We aimed to evaluate the efficacy and safety of Laser Ablation (LA) in comparison to TACE in patients with large tumor size HCC. Between January 2009 and December 2012, 41 cirrhotic patients (29/12 M/F; median age 72 years, range 54-88, Child-Pugh 37/4) with a single node of HCC ≥ 40 mm (median size 46 mm, range 40-75) were enrolled in this study. The patients were treated with multifiber technique of LA. The control group consisting of 41 patients (29/12 M/F; mean age 72 years, range 49-86; Child-Pugh A/B: 34/7; LA: n=20 and 22G PCN: n=23). The baseline liver radiofrequency ablation of hepatocellular carcinoma with a multi-pin bipolar system. J Surg Oncol 2011;103:69-74.

Results: Twenty-six (63.4%) patients of LA group and 8 (19.5%) patients of TACE group showed a complete response after treatment (p < 0.001). The superior eficacy of LA was confirmed in all categories, also after the stratification of the tumor size according to the thresholds (40-50 mm, 51-60 mm and >60 mm). Disease recurrence, during a mean ± SD period of follow-up of 37.4±20.7 months, was observed in 13 (24%) LA-treated patients (24%) and in 24 (58.5%) TACE-treated patients (p=0.00315). Overall survival probability at 5 years was 90.2% and 55.4% in LA group and 85.4 and 40.8. in TACE group.

Conclusion: LA is a more efficacious therapeutic option than TACE in patients with solitary large HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO072 ENDOCISTIC ULTRASOUND GUIDED BIOPSY FOR LIVER MASS USING CORE BIOPSY NEEDLE

H.K. Chou1, T.H. Kim1, K.H. Choi2
1Internal Medicine, Wonkwang College of Medicine, Iksan/Korea, Republic of Korea
2Pathology, Wonkwang College of Medicine, Iksan/Korea, Republic of Korea

Contact E-mail Address: ktw@kwu.ac.kr

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS- FNA) is one of the alternative methods for tissue sampling of liver solid mass. However, the diagnostic efficacy using cytology alone was limited. Aim & Methods: In this study, we evaluated the feasibility and diagnostic accuracy of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G ProCore needle (PCN) was performed to evaluate the patient with solid liver mass. The primary outcome was the diagnostic accuracy of EUS-FNB for malignancy, and adequacy of the specimen for histology. The secondary outcomes were (1) the proportions of patients in whom immunohistochemical (HIC) stain was possible, and (2) compared diagnostic yield of FNB according to the needle size, and (3) safety of EUS-FNB.

Results: Forty-one patients (13 women; mean age, 67.9±10.3 years [range, 46- 86]) underwent evaluation with EUS and identified hepatic lesions ranging in size from 0.7 cm to 15 cm. EUS-FNB with 20G (n = 10), 22G (n = 24) or 25G PCN (n = 7) was performed (right lobe: n = 10, left lobe: n = 31). The median number of needle passes was 2.4±0.8 (range, 1–5). Technical success rates for tissue acquisition were 97.6%, but both specimen adequacy for histology and available HIC stain was 92.6%. Three (7.3%) were non-diagnostic (7.3%) and subsequently proved to be malignant; 2 by smear cytology and 1 after surgical resection. The diagnostic yield, sensitivity and specificity of EUS-FNB for the diagnosis of malignancy were 92.6%, 92.6% and 100%, respectively. The diagnostic yield in 25G PCN and 22G PCN was significantly superior to 20G PCN (p = 0.045). There was one bleeding complication, but controlled with endoscopic hemostasis with endoclips.

Conclusion: EUS-FNB with core biopsy needle may be a safe and useful modality in the management of patients with hepatic solid mass. Moreover, 20G and 22G FNB may be adequate for liver biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0073 COMPARISON OF METHODS TO ESTIMATE LIVER FUNCTION IN NEWLY-DIAGNOSED HEPATOCELLULAR CARCINOMA PATIENTS WITH ASCITES

Y. Ko
Internal Medicine, Samsung Medical Center, Seoul/Korea, Republic of Korea

Contact E-mail Address: bs2-32@hanmail.net

Introduction: Liver function is a key element in determining outcome of patients with hepatocellular carcinoma (HCC). For HCC with ascites, estimation of liver function is particularly important, as they already have decreased liver function. Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly-diagnosed HCC patients with ascites (mean age = 56.0 y, male = 74.8%, hepatitis B virus = 73.2%) were analyzed. We compared Child-Pugh score, Model for End-Stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival. Results: During a median 9.0 months of follow-up (range: 0.1~154.0), mortality was 371 (85.4%) patients. MELD-Na showed highest time-dependent area under receiver-operating characteristics curve (AUROC)s at 1 year (0.672) that was significantly higher than ALBI grade (0.605), MELD score (0.580), and Child-Pugh score (0.580). The median survival was significantly lower for those with MELD-Na < 12 than those with MELD-Na ≥ 12 (median: 13.6 vs. 37.3 months, p < 0.001). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by sorafenib (29.9%). Conclusion: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, in which mortality rate was not significantly different from that of those who did not receive treatment (median survival: 13.3 vs. 24 months, p < 0.001). When patients were further stratified by mUICC stage and MELD-Na score, treatment was not associated with better outcome for mUICC stage IV patients with MELD-Na ≥ 12 (median survival: 2.2 vs. 12 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups. Disclosure of Interest: All authors have declared no conflicts of interest.

P0074 DIAGNOSTIC AND PROGNOSTIC ROLE OF SQUAMOUS CELL CARCINOMA ANTIGEN IN HEPATOCELLULAR CARCINOMA: SEROLOGICAL AND TISSUE DETERMINATION

F. Pelizzaro1, L. Ferrara1, R. Cardin2, M. Piciocchi3, G. Peserico3, P. Todesca3, A. Imondi1, L. Ferrara1, R. Cardin1, M. Piciocchi2, G. Peserico1, P. Todesca1, A. Vitiello

3Gastroenterology, Ospedale dell’Angelo, Venezia-Mestre/Italy

Contact E-mail Address: filippo.pelizzaro@gmail.com

Introduction: The ideal serological marker in hepatocellular carcinoma (HCC) has not been identified yet since Alpha-fetoprotein (AFP) has unsatisfactory characteristics. Squamous Cell Carcinoma Antigen (SCCA) is expressed in tissues of determined immunocomplexed with IgM (SCCA-IgM) has satisfactory diagnostic and prognostic performance. Aims & Methods: Aim of our study was to evaluate, in HCC patients, the diagnostic and prognostic role of SCCA determination in tissue and in serum samples. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, response to treatment and survival were evaluated. Results: HCC patients had SCCA-IgM levels significantly higher than cirrhotics (P < 0.0001). Sensitivity, specificity, positive and negative predictive values were 76%, 52%, 60% and 76%, respectively. In comparison, sensitivity and specificity of SCCA-IgM levels were 76% and 76% in HCC etiology and size. A cut-off of 130 AU/mL (validated in literature) was used for the prognostic analysis: patients with SCCA-IgM levels <130 AU/mL showed a slightly better survival (p = 0.015) than those who presented SCCA-IgM levels ≥130 AU/mL. In conclusion, SCCA-IgM levels were significantly higher in patients with higher tumor stage and good correlation between SCCA-IgM levels and survival were found. SCCA-IgM levels and survival were also significantly higher in patients with high tumor grade and size. SCCA-IgM levels were significantly associated to the BCLC stage IV, Child-Pugh classes C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5months, while in patients managed differently was 31.9 months (p < 0.0001). Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required. Disclosure of Interest: All authors have declared no conflicts of interest.

P0075 ADHERENCE TO BARCELONA CLINIC LIVER CANCER GUIDELINES IN FIELD-PRACTICE: RESULTS OF PROGETTO EPATOCARCINOMA CAMPANIA

M. Morici1, M. Guarno1, A. Vitelli1, R. Tortorà2, G. De Stefano3, C. Coppola4, A. Salomone Menna1, F. Izzo5, G. Nardone1, L. E. Adinolfi1, G. D’Adamo1, G. B. Gaeta5, A. Vitiello6

2Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: anna-vitiello@hotmail.it

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients’ survival. Aims & Methods: We analyzed the region-wide Italian database of Progetto Epatocarcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 regional centers. Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapy recommended by BCLC algorithm, while 29.4% underwent different treatment. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP > 200 ng/ml, more early stage and monofocal HCC, lower frequency of nodules >5cm, portal vein thrombosis and metastases were observed. The multivariate analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes B-C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5months, while in patients managed differently was 31.9 months (p < 0.0001). Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required. Disclosure of Interest: All authors have declared no conflicts of interest.

P0076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Y. Zhang1, X. Li1, N. Cui2, Y. L. Liu2
1Dept. Of Gastroenterology, Peking University People’s Hospital, Beijing/China
2Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: medical yuan@qq.com

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common cause are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, et al. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression. Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People’s Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group were...
were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHOQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SDS). The questionnaire scores of the two groups were analyzed.

Results: A total of 95 valid questionnaires were collected and divided into cirrhosis group (n = 40) and control group (n = 45). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081, showing no difference from cirrhosis group. WHOQOL includes four domains: physiological domain, psychological domain, social relationship domain, environment domain. The scores of the liver cirrhosis group: physiological domain (22.23 ± 3.312), psychological domain (19.59 ± 3.925), social relationship domain (9.64 ± 2.497), environment domain (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological domain, 19.87 ± 3.152 in psychological domain, 10.58 ± 2.061 in social relationship domain and 28.36 ± 5.091 in environmental domain), they had no significant difference between the two groups (P > 0.05). The depression-self satisfaction group (P = 0.034) was significant higher than that of control group (42.61 ± 11.564). Meanwhile, there was no significant difference between the Self-rating Anxiety Scale scores of the cirrhosis group (38.46 ± 11.917) and control group (37.00 ± 12.521) (P > 0.05) (Table 1).

Conclusion: The quality of life and anxiety score in cirrhosis group had no significant difference from the control group, but the depression score was higher than that of the control group.

P0078 NON-GOVERNMENTAL HCV SCREENING IN A VILLAGE IN NILE DELTA IN DAAS ERA IN EGYPT

A. Sadek1, A. Salem2, W. Wafy3, A. Abdelatif4
1Gastroenterology- Hepatology, Theodor Bilharz Research Institute, Giza/Egypt
2Gastroenterology & Hepatology, Naser Institute, Cairo/Egypt
3Public Health, Theodor Bilharz Research Institute, Giza/Egypt
4Free Physician, Cairo/Egypt

Contact E-mail Address: ahmedsadek48@yahoo.com

Introduction: HCV is highly endemic in Egypt with a prevalence of 12%. The ministry of health through the national committee for hepatic viruses has done an extra-ordinary effort since the beginning of the DAA’s era which resulted in treatment of almost one million infected patients till now. Still this looks as the summit of the iceberg and there is still estimated more than 10 million Egyptians infected with the virus, the majority of them are still undetected.

Aims & Methods: The aim of this work is to give an example of non-governmental efforts which can be done to solve this tough national problem. A group of young medical and non-medical volunteers all from El Salam village in Mansoura, Dakahilia governorate, Egypt have worked together. They contacted mosques and pharmacies in the village and distributed brochures to announce for the free of charge screening for the virus in the village. They contacted businessmen in the village to sponsor the campaign. They contacted the laboratory of the village to do the HCV Ab test with nonprofit price.

Results: A total of 2220 citizens have visited the referral lab to do the antibody test. Only 419 persons proved positive. This gives an estimated prevalence in the village of 19.0%. 119 patients were insurance patients and they went to treatment and did not complete the study. The rest 300 Ab +ve patients completed the study. All patients were Hbs Ag –ve. 132 PCR +ve (44%) patients from the 310 HCV Ab +ve group. The rest 168 patients were +ve for HCV RNA (56%). 18 patients of the HCV PCR –ve had previous HCV treatment (6.5%). Only 2 patients of the 168 HCV RNA +ve (1.2%) were previously treated. The PCR +ve patients without previous treatment were 114 patients (38%). So only 62.0% of the HCV Ab +ve in the community are PCR +ve and require treat- ment. The total cost for the screening of the 2220 patients was 40.000 L.E. which means 18.0 L.E per person (almost one Dollar).

Conclusions: The screening of the HCV Ab positivity can be markedly reduced if it is done in each village depending on volunteers from the same village working in related fields like medical, pharmacists, laboratory and social jobs. Only 62.0% of the HCV Ab +ve in the community are PCR +ve and require treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Early Diagnostics of NAFLD: Analysis of Risk Factors Using Biliary Pressure with ERC.

**Aims & Methods:** In order to evaluate the practical use of the technique of using only BMI when evaluating the chances of development of hepatic steatosis among practically healthy young persons, a valid, repeatable non-invasive method for the assessment of NAFLD was developed. The purpose of the work was frequency estimation of the prevalence steatosis according to elastometry with controlled attenuation parameter (CAP®) among young people and associated with them specific body composition.

**Aims & Methods:** Fifty-nine volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in the research. There were 22 men (37.3%) and 33 women (62.7%) among them with verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the body mass index (BMI), body fat, and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal values in 23 (40.3%) women, and the mean body composition of S/N/3 in 19 (33.3%), and BMI was statistically insignificant.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Aims & Methods: The aim of current study is to develop the multi-layer drug eluting membrane using ultrasonic spray coating method, which have uniform capacity of drug in all tested area. The releasing drug capacity and duration was measured by using drug releasing test in vitro for 3 days.

Results: The mean thickness of membrane was 50um. The mean capacity of drug per unit area was 100 ug/cm², and the amount was constant in all tested area (Standard deviation, 5 ug/cm²). In drug release test, the capacity of releasing drug was different depended on the kinds of polyurethane. The total amount of released drug in 24 hrs was 919 ug, 836 ug, 681 ug and 580 ug in tecophilic coating, tecothean coating, tecoflex coating, and pellethane coating. The total of released drug amount depended on polyurethane was described in table 1.

Table 1: The total of releasing drug amount in 72 hours

<table>
<thead>
<tr>
<th>Drug release amount</th>
<th>Gemcitine (ug)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coating Polymer</td>
<td></td>
</tr>
<tr>
<td>Tecophilic</td>
<td>24 hrs 248 hrs 72 hrs</td>
</tr>
<tr>
<td>Tecotehean</td>
<td>919 927 933</td>
</tr>
<tr>
<td>Tecoflex</td>
<td>681 690 698</td>
</tr>
<tr>
<td>Pellethane</td>
<td>580 604 622</td>
</tr>
</tbody>
</table>

Conclusion: The ultrasonic spray coating technique could be applied to multi-layer drug eluting membrane with regular thickness. The membranes contained the uniform capacity of drug in all tested area. The releasing drug capacity is able to control by applying different kind of polyurethane.

Introduction: Local treatment of primary bile duct cancer is a challenge and endoscopic stent insertion is widely used to maintain the bile duct patency. Drug eluting stent is currently developed to add the ability of antitumor effect.

Aims & Methods: We aimed to evaluate the antitumor effect of the paclitaxel, gemcitabine, and mitomycin C eluting polyurethane membrane in a tumor model. Total of 24 mice were used in current study and divided into four groups, each group had six mice. Membranes containing different antitumor drugs (paclitaxel, gemcitabine, 250ug/ml; mitomycin C, 119.02 mm3, P value 0.0029; control 1362.62mm3). The antitumor effect of gemcitabine was superior compared to the other drugs. However, it was not statistically difference. No significant difference in body weight change was observed among groups.

Membrane only Paclitaxel Gemcitabine Mitomycin C

| Mouse weight (g) | 24.28 21.05 19.56 20.67 |
| Tumor volume (mm³) | 1362.62 291.77 63.38 119.02 |
| Tumor weight (mg) | 1025 524 496 443 |

Conclusion: The drug-eluting membrane showed significant antitumor activity. However, the effect was not different according to kinds of the antitumor drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0087 ADVANCES IN CYTOLOGY FOR THE EARLY DIAGNOSIS OF PANCREATICO-BILIARY MALIGNANCY

C. Meredith, P. Irandoust4, P. Baird2
1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/ Australia/NSW
2Cytology, Laverty Pathology, Ryde/Australia/NSW

Contact E-mail Address: dcrmeredith@gmail.com

Introduction: Liquid-based sample preparations for cytology have improved the cellular yield in pancreatico-biliary (PB) malignancy.1,2 The SurePath (SP) method-ology produces a pellet of concentrated cellular material which enables addi-ional slides for immunohistochemical (IHC) staining for tumour markers Ki67, p53 and CDX2. The presence of the mitosis-related marker, Ki67, in high con-centration is useful for the diagnosis of malignancy. The aim of this study was to assess the Ki67 staining in biliary epithelium obtained from patients with bile duct obstruction.

Aims & Methods: Brushings were obtained from the common bile duct during endoscopic retrograde cholangiopancreatography (ERCP) in patients presenting with biliary obstruction. After collecting the sample, the brush was placed immedi-ately into a SurePath vial and shaken vigorously to fix and suspend the cells. In the cytology laboratory, the vial (with brush included) was agitated on a platform vortex for 10 minutes to shake the cells off the brush into the solution. The high cellular content enabled the preparation of multiple slides for IHC and these slides were reviewed independently by two senior cytopathologists.

Results: Thirty-four (34) consecutive patients with bile duct obstruction were included in the study. The cohort had a mean age of 70.2; 41% were female. Adenocarcinoma was identified in 19 (56%) and atypical/reactive cells in 9 (26%). Ki67 positive nuclei were present in 90% of the cells in each of the different cell clusters, with sheets of normal cells had positive nuclei in less than 20% of cells. Atypical cells sheets had an intermediate percentage range.

Conclusion: SP is superior to conventional slide-based cytology preparations in the diagnosis of malignant bile duct structures. Advantages include ease of collect-ion, no requirement for a cytology technician, a sizable pellet of intact cells for the cytopathologist to examine and the ability to undertake IHC staining. Ki67 is a marker of cell division and cells stained with Ki67 are increased significantly in adenocarcinoma as confirmed by this study. The presence of a large number of cells stained with Ki67 as well as the pattern of intracellular staining adds a level of confidence for the cytopathologist to diagnose malignancy, particularly when there is no clinical or scan evidence of a tumour mass. Early diagnosis is the key for current surgery and specific cell tumour markers &/or their pattern may impact significantly on the outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0088 IMPACT OF PALLIATIVE BILIARY DRAINAGE BETWEEN METAL STENT AND PLASTIC STENT ON SURVIVAL RATE IN UNRESECTABLE DISTAL MALIGNANT BILIARY STRicture IN SOUTH OF THAILAND

T. Pattarapuntakul, B. Ovartlanporn, N. Netinatsunton
Faculty Of Medicine, Prince Of Songkla University, NKC Institute of Gastroenterology and Hepatology, Hatyai/Thailand

Contact E-mail Address: tanawat_kuey@hotmail.com

Introduction: Palliative biliary drainage was used to improving obstructive jaun-dice, nutritional status, quality of life along with survival rate in unresectable distal malignant biliary stricture patients. The ERCP with biliary drainage with or without systemic chemotherapy are mainstay of treatment in these patients. The benefits of biliary stent type, which are different in cost on survival rate, nutritional status and efficacy of biliary drainage in DMBS patients are still questionable in limit health budget country.

Aims & Methods: We aimed to assess the impact of endoscopic palliative biliary drainage stents on survival rate, nutritional status and efficacy of biliary drainage of patients in distal biliary malignant stricture patients. All of the computerized medical records of distal biliary malignant stricture patients, who were undergoing to endoscopic biliary drainage from January 01, 2012 to December 30, 2015 in Songklanagarind hospital were retrospectively review. ERCP with biliary drainage stents was undertaken at the discretion of attending physicians. The overall survival rate, nutritional status (body weight), efficacy of biliary drainage (level of total bilirubin) after biliary drainage between the metal stent group, plastic stent group and plastic stent followed with metal stent group were compared.

Results: Sixty eight patients (45 males, mean age 63.7+/-14.8 years) were enrolled, 35 patients were classified into the plastic stent group, 18 patients were classified into the metal stent group and 15 patients were classified into the plastic stent followed to metal stent group. Demographic data, primary malignancy, tumor staging and ECOG score, initial total bilirubin and stricture length were similar between 3 groups. The median survival time was 5.4 months 95%CI (3.2-8.5) and overall survival rate was lowest in the metal stent group (median 3.2 months 95%CI 1.8-6.9). Mean weight reduction and the decline of total biliary after biliary drainage were not significantly different between biliary...
stent types. The plastic stent group had lowest cost of total ERCP statistically significant. The complications rate was not different between biliary stent types. Conclusion: Palliative biliary drainage with plastic stent in unresectable distal malignant biliary stricture was slightly better on survival rate and was not different in nutritional status, efficacy to drainage and complication rate compared with metal stent or plastic followed with metal stent. But the plastic stent group had lowest cost of total procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The most widely used standard for determining the effectiveness of chemotherapy is a set of rules called Response Evaluation Criteria in Solid Tumors, or RECIST. However, it is often difficult to evaluate radiologic response to chemotherapy especially in patients with biliary tract cancer (BTC) mainly because of the pathognomonic tumor progression along bile duct and/or inflammatory reaction induced by indwelling biliary drainage. Therefore, quantitative evaluation using tumor markers is expected to play complementary roles to assess treatment efficacy, however, the prognostic value of carbohydrate antigen 19-9 (CA 19-9) kinetics in patients with advanced or recurrent BTC receiving chemotherapy remains to be elucidated.

Aims & Methods: Between January 2006 and March 2016, a total of 185 advanced or recurrent BTC patients receiving a first line systemic chemotherapy for at least two cycles were retrospectively studied. Serum CA 19-9 was measured at baseline (CA19-9_Pre) and after two cycles of chemotherapy, and patients were categorized into three groups based on CA19-9 response: CA19-9 decrease group (≥30% decrease), stable group (<30% decrease and ≥20% increase) and increase group (≥20% increase). The Cox proportional hazards model was used to analyze the prognostic factors for OS and PFS, using the landmark method.

Results: The primary tumors were located as follows: 68 (37%) in intrahepatic bile duct, 43 (23%) in extrahepatic bile duct, 64 (35%) in gallbladder and 10 (5%) in ampulla. As for chemotherapeutic regimen, single-agent or combination therapy was given in 49 (26%) or 136 (74%), respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median CA 19-9 levels at baseline and after two cycles were 264 IU/mL and 194 IU/mL, respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median PFS and OS were 5.62 months (95% confidence interval [CI], 2.59-13.28) and 13.71 months (95% CI, 11.38-22.06). There was a statistically significant trend for CA 19-9 and RECIST responses (p=0.001), compared with CA19-9 decrease group, hazard ratios for stable and increase groups were 1.22 (95% CI, 0.79-2.00) and 2.42 (95% CI, 1.57-3.72) for PFS, respectively (p for trend <0.001), and 1.04 (95% CI, 0.68-1.59) and 2.54 (95% CI, 1.68-3.85) for OS (p for trend 0.060). Multivariable analyses showed that CA19-9 response was prognostic both for OS and PFS in addition to CA19-9_Pre and performance status.

Conclusion: CA 19-9 response after two cycles as well as baseline served as a prognostic factor for OS and PFS in patients with advanced and recurrent BTC on systemic chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0090 BILIARY DRAINAGE IN PATIENTS WITH UNRESECTABLE PERIHILAR CHOLANGIOCARCINOMA: HAS A VERY HIGH COMPLICATION AND FAILURE RATE

1Surgery, Erasmus University Medical Centre, Rotterdam/Netherlands
2Surgery, Academisch Medisch Centrum Dept. of Surgery, Amsterdam/Netherlands
3Surgery, Albert Schweitzer ziekenhuis, Dordrecht/Netherlands
4Gastroenterology And Hepatology, Erasmus MC University Medical Center Rotterdam, Rotterdam/Netherlands

Introduction: Patients with unresectable perihilar cholangiocarcinoma (PHC) typically present with obstructive jaundice. They require percutaneous or endoscopic biliary drainage for symptom relieve and eligibility for palliative systemic chemotherapy. However, biliary drainage in unresectable PHC is complex with a high failure and complication rate even in tertiary referral centers.

Aims & Methods: The aim of this study was to investigate the failure and complication rate of the initial drainage procedure in patients with unresectable PHC. Consecutive patients with unresectable PHC on imaging in two tertiary referral centers between 2002 and 2014 were identified. Patients were included if a biliary drainage procedure was performed. Baseline patient and tumor characteristics
Cholangitis: Elevation in temperature more than 38, 5°C and Leukocytes ≥10 *10^9/L, thought to have a biliary cause, without concomitant evidence of acute cholecystitis, requiring invasive intervention.

Acute cholecystitis: Radiologic evidence of cholecystitis, elevation in temperature more than 38.5°C and Leukocytes ≥10^9/L, and requirement of percutaneous drainage or emergency cholecystectomy.

Failure of drainage or Reintervention: Rising or steady bilirubin level after therapeutic success had initially been obtained, without signs of cholangitis or cholecystitis, requiring new cannulation of the tumor. Bilirubin levels >50μmol/L within 14 days after the initial procedure

Unsuccessful cannulation during the initial drainage procedure.

Acute pancreatitis: Second drainage procedure ≤14 days after the initial procedure.

Biliary injury: Injury to the bile duct documented by any radiographic technique requiring intervention.

Duodenal perforation: Injury to the bili duct documented by any radiographic technique requiring intervention.

Cardiopulmonary complications: Any pulmonary or cardiac abnormality occurring during the drainage or in the post-intervention period that produces identifiable disease or dysfunction which is clinically significant and adversely affects the clinical course.

and data on the biliary drainage procedure were collected from medical records.

Definitions of failure of drainage or other severe drainage related complications are shown in Table 1. Results: In total, 187 patients were included. Initial drainage was performed in a non-referral center in 125 patients (66.8%). The initial drainage procedure was endoscopic in 158 patients (84.5%) and percutaneous in 29 patients (15.5%). A stent was placed in 91 patients (61.5%) at the initial drainage procedure. The highest bilirubin level in the 2 weeks prior to drainage was 248 (IQR 138–377) μmol/L. Only 14 (8.1%) patients had cholangitis prior to the initial drainage procedure. Failure of drainage or other severe complications related to the initial drainage procedure were noted in 117 (62.6%) patients. Failure of drainage or reintervention was most common and was noted in 95 patients (50.8%). Bile duct injury occurred in 3 (1.6%) patients, acute pancreatitis in 5 (2.7%) patients and cholangitis in 11 (5.9%) patients. Two (1.1%) patients had cardiopulmonary complications and 1 (0.5%) patient had a duodenal perforation. The median period between the initial and second drainage procedure was 13 (5–31) days and the bilirubin level dropped below 50 μmol/L in 27 patients (14.4%). After initial drainage, 20 patients (10.7%) died within 30 days and 66 patients (35.3%) within 90 days. The median OS after initial drainage was 6.6 (95% CI: 2.0–15.2) months.

Conclusion: Patients with unresectable PCHC on imaging have a very high failure rate and complication rate after initial biliary drainage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0091 BRUSH CYTOTOLOGY GUIDED BY ENDSOCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY OF BILIARY STRICTURES

Centro Hospitalar De São João, Porto/Portugal

Contact E-mail Address: armanda@ufpe@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP)-guided brush cytology has become the most widely used method, although with limitations, in the initial diagnostic evaluation of patients with biliary strictures. Aims & Methods: The objective of the study was to evaluate if the systematic use of 10 brush passages improves the diagnostic yield of brush cytology guided by ERCP of bile strictures. ERCPs between 2012 and 2015 involving brush cytology of bile strictures for suspected malignancy were included in the study. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: In total, 62 patients underwent cytology of biliary strictures, with a median age of 69 years (IQR: 55–81). The cytological analysis was compatible with identifiable disease or dysfunction which is clinically significant and adversely affects the clinical course.

Conclusion: The systematic use of 10 passages in the cytology of the biliary tract modestly increases the accuracy of the detection of malignant versus benign situations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0093 UNILATERAL VERSUS BILATERAL STENT-IN-STENT PLACEMENT OF METAL STENTS FOR MALIGNANT HILAR BILIARY OBSTRUCTION

H. Toyonaga, Y. Taniguchi, T. Inokuma
Gastroenterology, Kobe City Medical Center General Hospital, Kobe/Japan

Contact E-mail Address: toyonaga.pc@gmail.com

Introduction: Endoscopic biliary stenting is widely accepted as effective palliation therapy for unresectable malignant hilar biliary obstruction (MHBO). Although drainage more than 50% of liver volume is associated with better outcomes, this is technically difficult. Aims & Methods: The aim of this study was to evaluate differences in technical feasibility and clinical efficacy between unilateral and bilateral stent-in-stent (SIS) placement of metal stents for MHBO. We retrospectively reviewed 23 consecutive patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group).

Introduction: We placed crossed wired metal stents with the SIS technique. Technical success rates, complication rates and stent patency were compared between groups.

Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups (p = 0.669).

Conclusion: Endoscopic bilateral SIS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0094 CLINICAL ASSESSMENT OF THE SAFETY AND EFFICACY OF A NOVEL BIODEGRADABLE STENT IN PATIENTS WITH BILIARY OBSTRUCTION: A PILOT STUDY

H. Oldman1, N. Y. Yaacob2, E.J. Koslan3, R. Jarmin3, Z. Mohamed2
1Surgery, UKM Medical Centre, Kuala Lumpur/Malaysia
2Radiology, UKM Medical Centre, Kuala Lumpur/Malaysia

Contact E-mail Address: hairol@gmail.com

Introduction: The commonest indication for biliary stent is for the treatment of obstructive jaundice and for the management of bile leak. The currently available stents are made of either plastic or metal alloy. The stents can be inserted endoscopically to provide internal drainage of the bile into the duodenum. Among the disadvantages of plastic stents are recurrences of jaundice due to biofilms formation, which require a repeat ERCP procedure to remove the stent before 3 months. We have embarked to study the safety and feasibility of a biodegradable stent (BBS) which can treat biliary obstruction without the need to undergo a repeat endoscopic procedure to remove the stents.

Aims & Methods: This is a pilot study enrolling 30 subjects with symptomatic jaundice and pruritus caused by either benign or malignant biliary obstructions that were amenable to treatment by ERCP guided stenting. Primary objective was technical success and safety. Procedural and technical successes were assessed during the stenting procedure. Adverse events or complications were monitored throughout the studies. The secondary endpoints were clinical success, which was measured by a reduction of at least 20% of the initial serum bilirubin level at Day 7 post stenting. A simple self-assessment scale from 0 to 10 was used to assess quality of life before and after the stenting.

Results: 30 patients had the Biodegradable Biliary Stent (BBS) implanted. 18 patients (60%) were males, the mean age was 58.9 years. 26 patients (86.7%) had benign biliary duct disease and 4 (13.3%) patients had malignant condition.
9 patients had the fast and medium degradation stents respectively and 12 had the slow degradation stents implanted. All stents were 3.4 mm in diameter and the length ranges from 60 to 120 mm depending on the level of obstruction. It took an average of 29.6 minutes to complete each procedures, and the mean stent deployment duration was 6.0 minutes. It ranges from 13.5 minutes in the initial phase and improved to 1.5 minutes in the later phase. Biliary sphincterotomy was not used in single biodegradable stents, but however, all patients with biliary stone had sphincterotomy to facilitate retrieval of the stones. Serum bilirubin level (SBL) showed reduction of 52% from the mean SBL of 54.9 m before to 26.2 µmol/L at Day 7. Quality of life score improved from 2.0 up to 8.5 after stenting. The BBS ranks high in terms of loadability, trackability over guide-wire, and pushability with push catheter. There was minimal force required to implant it and it has good visibility by fluoroscopy. The BBS is as flexible as the conventional plastic stents and can be accurately deployed under fluoroscopy. Technical success or completion of the ERCP and stent deployment was achieved in all 30 patients.

**Conclusion:** This pilot study has shown encouraging results. It benefit the patient to avoid the burden of a second ERCP procedure for plastic stent removal. However, these results should be interpreted with caution since this is a pilot study to assess the safety and efficacy of the biodegradable stent on limited number of volunteers with symptomatic jaundice. We plan to conduct a phase 2 study involving a larger number of cohorts with a more specific indication of benign and malignant biliary stricture.

**Disclosure of Interest:** H. Othman: The Biodegradable Biliary Stents used for this study is sponsored by ang International Gmbh, Winsen, Germany. The authors have no financial relationship with the company which could inappropriately influence or bias the content of this presentation.

**Introduction:** Stellate cells contribute significantly to the development of several diseases. In particular, liver stellate cells are responsible for liver fibrogenesis and further for cirrhosis that culminates into cancer development eventually. In pancreas, it is known that stellate cells sustain the tumor cells via autophagy mechanisms.

**Aims & Methods:** This study aimed to clarify the involvement of Toll-like receptor 5 (TLR5) in the activation of human stellate cells. LX-2 liver stellate cells and HPSC (human pancreatic stellate cells) were treated for 48 hours with 2.5 mg/ml TGF-beta 1. The analysis of activation markers was performed by RT-qPCR, western blotting and immunofluorescence. Real-time cell monitoring with Incucyte was performed. TLR5 PCR Array was performed. TLR5 knock down was obtained with commercially validated siRNAs.

**Results:** Treatment with 2.5 ng/ml TGF-beta 1 caused the activation of both LX2 and HPSC cells. Over-expression of alpha smooth muscle actin (a-SMA) and collagen 1 (COL1A1) transcripts was observed. The protein level of a-SMA and COL1A1 significantly increased also. Interestingly, SNAIL 1, SLUG, TLR3 and TLR5 transcripts were induced by treatment with TGF-beta 1 in both cell lines. SNAIL 1 was over-expressed at protein level also. Knock down of TLR5 neutralized the activity of TGF-beta 1 by keeping the expression of the above markers at basal level or even not expressed.

**Conclusion:** TLR5 for the first time, has been identified as key player of the activation of stellate cells. Its contribution represents a new aspect in terms of interaction between immune system and stellate cells and could represent a potential new target for the diseases of the gastrointestinal tract involving the activity of stellate cells. TLR5 and its natural agonist flagellin could be a key link between impairment of microbiota and organo-fibrosis in the gastrointestinal tract.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The cystic fibrosis transmembrane conductance regulator (CFTR) has a major role in pancreatic ductal secretion and it’s genetic defects damage the pancreas. It is known that intracellular Ca2+ homeostasis is disturbed in bronchial epithelial cells in cystic fibrosis (CF), but the connection of CFTR and the intracellular Ca2+ signaling has never been suggested in pancreatic damage in CF patients.

**Aims & Methods:** Our aim was to characterize the Ca2+ homeostasis of CFTR-deficient PDC. Wild type (WT) and CFTR knockout (KO) mouse pancreatic ductal and acinar cells and iPSC (induced pluripotent stem cell) derived human organoids from 2 CF patients and controls, human CF pancreatic cell line (CFPAC-1; ΔF508 mutant) were used for intracellular Ca2+ measurements. Mitochondrial membrane potential (ΔΨm) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

**Results:** The plateau phase of the agonist-induced Ca2+ signal was elevated in CFTR-deficient PDC, which was caused by decreased function of the plasma membrane Ca2+ pump (PMCA). The functional inhibition of CFTR had no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24 h treatment of the CF organoids with VX-809 have restored the PMCA function to the control level. Similarly native CFPAC-1 cells and PDEC treated with siRNA to inhibit the expression of CFTR showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained [Ca2+]i levels decreased ΔΨm and induced cytochrome c release in CFTR KO PDEC without significant alterations in mitochondrial morphology.

**Conclusion:** Dysfunction of PMCA leads to disturbed Ca2+ homeostasis in CFTR-deficient PDC and the consequent cellular Ca2+ overload impairs mitochondrial function contributing to the pancreatic damage in CF patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Given their capability to differentiate to every cell type of the human body, human induced pluripotent stem cells (hiPSCs) provide a unique platform for developmental and regenerative medicine. The pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE) and pancreatic endoderm (PE). We have recently reported the generation of a novel three-dimensional pancreatic organoid culture system that generates functional acinar-/ductal-like structures from pluripotent stem cells (Hohwieler et al., *GUT*, 2016).

**Aims & Methods:** In the current study we implemented this culture system to understand the role of exocrine differentiation and proliferation factor (Expdf), a signalling molecule proposed to be involved pancreatic differentiation in zebrafish. CrisprCas9 technologies were used to ablate Expdf in human embryonic stem cells, while a piggy bac engineering approach allowed us timed expression to study the role of both loss and gain of Expdf function during pancreatic differentiation.

**Results:** First, a limited role of Expdf was observed until the PE stage, while PP differentiation were induced by treatment with Expdf knock out leading to mostly cystic structures. Phenotyping for ductal and acinar lineage allowed to investigate these
changes in more detail and genome wide expression profiling helped us to under-
stand the role of Expdf in more detail.

Conclusion: Thus, we report a novel signalling molecule playing a critical role 
during human pancreas development based on a pluripotent stem cell differen-
tiation platform.

P0098 MELATONIN METABOLITE, N1-ACETYL-N2-FORMYL-5-
METHoxykynuramine STIMULATES PANCREATIC ENZYME 
SECRETION VIA CCK RELEASE. STUDY ON THE RATS
J.M. Jaworek
Dept. Of Medical Physiology, Jagiellonian University CM, Krakow/Poland

Contact E-mail Address: jolanta.jaworek@uj.edu.pl

Introduction: N1-acetyl-N2-formyl-5-methoxykynuramine (AFMK), melatonin 
metabolite, has been demonstrated recently as effective pancreatic protector 
against acute inflammation. AFMK significantly attenuated acute pancreatitis; 
however, its effect on pancreatic exocrine function has not been investigated yet.

Aims & Methods: 1. To investigate the effects of intraduodenal (i.d.) application of 
AFMK on pancreatic enzyme secretion under basal conditions and following the 
stimulation of this secretion with diversion of pancreatic-biliary juice (DPBJ) 
and to examine the role of CCK in this process. 2. To assess the effect of AFMK on 
CCK receptor in pancreatic acinar cell line AR42J. Material and methods: 
For in vivo study Wistar rats weighing 300 g were employed. Under pentobarbi-
tane anesthesia the animals were surgically equipped with silicone catheters, 
inserted into pancreatic-biliary duct, and into duodenum. AFMK (5.10 mg/kg 
i.d.) was given to the rats under basal conditions or following stimulation of 
pancreatic secretion with DPBJ. Lorglumide, the CCK1 receptor antagonist (1 mg/kg i.d.) was administered 15 minutes prior to the application of AFMK. 
Samples of pancreatic-biliary juice were collected to measure the amylase outputs. 
The blood samples were taken for determination of CCK by ELISA kit. For in 
vitro study acinar cells AR42J were incubated in presence of AFMK alone or in 
combination with CCK. The protein signal of CCK receptor was determined by Western blot.

Results: AFMK given i.d. produced the dose-dependent increases of pancreatic 
amylase secretions both; unstimulated, as well as that induced by DPBJ. The rise of pancreatic amylase outputs were accompanied by significant increase of CCK plasma levels. Administration of lorglumide, a CCK1 receptor blocker, comple-
pletely abolished the stimulation of pancreatic exocrine function induced by 
AFMK. This melatonin metabolite failed to affect protein signal for CCK recep-
tor in AR42J cells.

Conclusion: The stimulatory effect of AFMK on pancreatic enzyme secretion in 
the rats is indirect and dependent on the release of CCK by this melatonin metabolite.

Introduction: Aberrant intracellular Ca2þ signaling is the hallmark of acute pancreatic 
secretion is crucially impor-
tant in the physiology and pathophysiology of the exocrine pancreas. However, 
the role of human pancreatic secretory processes is great challenge due to the 
limited access to human pancreatic ductal cells. The recently developed three-
dimensional pancreatic organoid cultures (OC) may help to overcome this limi-
tation. However, the ion secretory processes in pancreatic OC is not known.

Aims & Methods: Our aim was to characterize the ion transport processes in 
mouse pancreatic OCs. Mouse pancreatic ductal fragments were isolated by 
enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a 
week in a CO2 media. Changes of the intracellular pH was measured to characterize 
the ion transporter activities of the epithelial cells in OC.

Results: Basolateral administration of 20 mM NH4Cl in standard HEPES or 
CO2/HCO3- buffered solution resulted in rapid intracellular alkalinization, 
however, its effect on pancreatic exocrine function has not been investigated yet.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is the most common inflammatory disorder 
in the gastrointestinal tract with an overall mortality of 20–30% in severe cases. 
The treatment of AP is not resolved yet, urging the identification of novel drug 
targets. Toxic cellular Ca2+ overload was highlighted as a key event in pancreatic 
acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition 
of Orai1 in pancreatic acinar cells markedly decreased the Ca2+ toxicity and the 
severity of AP. However, we have no information regarding the role of Orai1 in 
pancreatic ductal physiology or pathophysiology.

Aims & Methods: Wild type FVB/N mice were used for the isolation of pancreatic 
ductal fragments. The intracellular pH and Ca2+ level of the pancreatic ductal 
cells (PDC) were measured by microfluorimetry. The effect of selective Orai 
inhibitors provided by CalCiMedica was evaluated.

Results: The tested compounds dose-dependently inhibited Ca2+ influx during 
the carbachol induced Ca2+ signal in PDC. Inhibition was complete at a con-
centration of 10μM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reti-
culum Ca2+ stores were depleted with cyclopiazonic acid and the inhibition of 
store-operated Ca2+ entry (SOCE) was investigated after the re-addition of 
extracellular Ca2+. Under these conditions CM-B and CM-C significantly, but not 
completely, decreased SOCE in PDC (55.96% and 55.03% respectively). The 
removal of extracellular Na+ to abolish activity of the Na+/Ca2+ exchanger 
had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed 
that the inhibition of Orai1 has no effect on the basal secretion of HCO3- by 
PDC, which is the main physiological function of these cells.

Conclusion: We showed that Orai1 has a significant role in the Ca2+ signaling of 
PDC. In the next step we will evaluate the pathophysiological relevance of the 
channel.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: rozh.noel@slu.se

Introduction: Cholecystectomy during the index admission may reduce risk of recurrent biliary events but concerns have been raised about complications if surgery is performed to early. The objectives of this study were to compare gallstone- and cholecystectomy-related complications and patient reported quality of life. The primary outcome was recurrent biliary events. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients reported quality-of-life and pain.

Results: Sixty-four patients between May 2009 and March 2017 were randomized into either index- or scheduled cholecystectomy (IC vs. SC). IC was performed when patients showed recovery and within 48 hours from randomization. SC was planned after 6 week from randomization. The primary outcome was recurrent biliary events. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients reported quality-of-life and pain.

Conclusion: Delaying cholecystectomy in mild gallstone pancreatitis is associated with increased risk for recurrent gallstone-related events. Cholecystectomy performed at the index admission is safe and feasible.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0103 THE FACTORS FOR PREDICTING HOSPITAL MORTALITY IN EARLY STAGE OF SEVERE ACUTE PANCREATITIS

Introduction: Severe acute pancreatitis has high mortality and needs intensive care. However it is difficult to stratify the severity of acute pancreatitis in early stage because revised Atlanta classification requires persistent organ failure lasting at least 48 hours.

Aims & Methods: We searched factors to predict hospital mortality in early stage of severe acute pancreatitis. This was a retrospective cohort study of all consecutive patients with severe acute pancreatitis who admitted at 44 institutions between June 1, 2009 and December 31, 2013. We evaluated ten factors that associated with mortality in previous study.

Results: The mortality was 12.7% (142/1114 patients). All ten factors were associated with mortality in univariable analysis. In multivariable analysis, four factors, namely "partial pressure of oxygen in blood ≤60 mmHg (room air) or mechanical ventilation", "age ≥70 years", " blood urea nitrogen ≥40 mg/dL (or creatinine ≥2.0 mg/dL) or oliguria (daily urine output <400 mL even after adequate intravenous fluid resuscitation)", and "lactate dehydrogenase ≥2 times upper limit of the normal range" were associated with mortality. The other factors, namely "base excess ≤−3.5 meq/L", "platelet count ≤100,000/mm³", "serum calcium ≤7.5 mg/dL", "c-reactive protein ≥15 mg/dL", "number of positive measures in systemic inflammatory response syndrome criteria ≥3" and "computed tomography grade" were not associated with mortality.

Conclusion: Advanced age, respiratory failure, renal failure and high lactate dehydrogenase could predict mortality in early stage of severe acute pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0101 COMPARISON OF PREDICTIVE SYSTEMS TO PREDICT MORTALITY IN SEVERE AND MODERATE PATIENTS ACCORDING TO THE REVISED ATLANTA CLASSIFICATION
Aparato Digestivo, Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain

Contact E-mail Address: ruben.pique@salud.madrid.org

Introduction: The course of acute pancreatitis (AP) ranges from life threatening to mild, so accurately predicting its outcome is important. The revised Atlanta classification breaks the previous mild/severe dichotomy, so the absence of predictors of severity does not preclude a mild course. Studies designed according to the new classification evaluating existing predictors are still scarce.

Aims & Methods: Our study aims at evaluating the diagnostic accuracy of easily available prognostic scores to predict mortality, persistent organ failure (severe AP) and mild AP. We analyzed a single-center retrospective cohort including all adult patients admitted between 2010 and 2015. Patients with a previous episode of AP in the six months before admission, with other primary diagnosis at discharge and those partially attended at other institutions were excluded. Severity and local complications were defined according to the 2012 Atlanta classification. Four different scores (BISAP, SIRS, APACHE II and HAPS) and the following predictors: C reactive protein (CRP) at 24 h, hematocrit and BUN at admission.
and their evolution after 24 h were evaluated. Accuracy was measured using discriminant function operating characteristic (ROC) analysis.

Results: Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.1–72.7), 57.4% males. Most frequent comorbidities were: diabetes (10.6%), hypertension (16.6%) and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 16.8%. There were 42 (6.6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1.5–3.9%), 35.7% (23–50.8%) among severe cases. BUN at admission AUC: 0.88 (0.85–0.90), BISAP score (AUC: 0.88 [0.85–0.90]) and APACHE II (AUC: 0.87 [0.84–0.89]) were the best predictors for mortality. The BISAP score presented the highest sensitivity, 100% (81.6–100%), while the BISAP score presented the highest specificity, 93.1% (90.6–94.9%). BUN at admission (AUC: 0.89 [0.86–0.91]) and the BISAP score (AUC: 0.87 [0.84–0.89]) also presented the best predictive power. The BISAP score identified the highest sensitivity (94.2% [92.2–95.8%]), although with a low PPV, 32.1% (21.4–45.2%). On the other hand, diagnostic accuracy for mild AP was poor, as all predictors presented an AUC < 0.7. The HAPS score reached the highest specificity, 87.8% (83.91%), but presented a very poor sensitivity (28.9% [24.3–33.9%]).

Conclusion: The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 0.9. New scores are needed to predict a mild course, as none of the available indexes presented an AUC > 0.7.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0106 PANCREATIC DUCT ASCARIASIS

P. Somani, M. Sharma
Department Of Gastroenterology, Jawant Rai Specialty Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Although uncommon in the West, Ascariis lumbricoides is a common cause of acute pancreatitis in developing countries. The mechanism of acute pancreatitis in ascariasis may be due to obstruction of papilla of Vater, infection of common bile duct (CBD) or pancreatic duct (PD). The inflammation of pancreatic duct occurs rarely owing to its smaller calibre. Ultrasonography (USG) is an effective tool for the diagnosis of biliary and pancreatic ascariasis; however, the diagnosis may be false negative in up to 30% of cases. Pancreatic ascariasis is an extremely rare clinical entity. Only case reports have been described in literature. We present our retrospective data of last 10 years of 15 cases of pancreatic ascariasis.

Aims & Methods: During a study period of 10 years, 15 cases of pancreatic ascariasis were diagnosed by USG or endoscopic ultrasonography(EUS). EUS was performed with a linear or radial echoendoscope. 13 patients presented with symptoms of acute pancreatitis. Out of 13 patients, 9 presented with first episode of idiopathic pancreatitis while 4 patients presented with recurrent episodes of idiopathic pancreatitis. The patients underwent side viewing endoscopy/ERCP using a standard enteroscope. EUS features were single or multiple echogenic nonshadowing linear, tubular structures and curved strips with anechoic tubular central lines. EUS features were single or multiple hyperechoic structures without acoustic shadowing in the PD or CBD (“single-tube sign” or “strip sign”) or with central hyperechoic tube representing alimentary canal of the worm (‘‘double tube sign’’ or “inner tube sign”) and movements of worms inside the duct. Live rondworms were removed from PD without undertaking sphincterotomy. In endemic areas, sphincterotomy facilitates the risk of migration of worms into the CBD or PD. An important cause of acute pancreatitis is usually cold and EUS is the investigation of choice. The recurrence is rare and treatment is side viewing endoscopy with removal of worms. EUS significantly improves the diagnostic yield for idiopathic acute pancreatitis (IAP). Our retrospective study shows that EUS is a highly accurate method to diagnose the etiology of IAP with reference to biliary or pancreatic ascariasis. Although USG is quite sensitive for diagnosing BPA, its sensitivity significantly falls when the worm is thin, in the PD, or the CBD is non-dilated. EUS is more sensitive for diagnosis of ascariasis in the pancreatic duct than other radiological investigations. The probable reasons are excellent imaging of pancreas by EUS and in and out movement of ascaris which might be missed by other investigations. Endoscopic retrograde cholangiopancreatography, considered the gold standard for diagnosis of biliary ascariasis, should be reserved for therapeutic rather than diagnostic purposes. EUS can lead to reentry of the worm into the common bile duct. EUS should be used early in the work-up of IAP after the first episode. We propose EUS to be investigation of choice for PD ascariasis. Most of the episodes are of mild pancreatitis with no mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The severity of acute pancreatitis varies widely, from a mild self-limited disease to one with a severe clinical course complicated by multiple organ failure. No pharmacological or surgical therapy has been shown to improve the prognosis of patients with severe acute pancreatitis, while the quality of supportive care including early fluid resuscitation is critically important. Fluid resuscitation maintains adequate intravascular volume by compensating for fluid shifts to the third spaces. However, there is a lack of consensus regarding the details of optimal fluid administration such as the type of fluid, infusion rate and volume of administration, and the physiologic goals of fluid resuscitation.

Aims & Methods: The aim of this study is to evaluate the association between the total fluid administered in the first 24 hours and 6000 ml with the outcome of severe acute pancreatitis. We conducted a secondary analysis of data from a multi-centre retrospective study of patients with severe acute pancreatitis in Japan, which was registered with the University Hospital Medical Information Network Clinical Trials Registry (Registry number 00012220) and approved by the Institutional Review Board or the Medical Ethics Committee at each institution. The diagnosis of severe acute pancreatitis was based on criteria of the Japanese Ministry of Health, Labour and Welfare (Japanese Severity Score). Patients ≥18 years old and admitted to ≥250-bed hospitals in Japan with severe acute pancreatitis diagnosed according to the revised Atlanta classification.

Results: We analysed 1097 patients, and the mean fluid volume administered was 5619 ± 3018 ml (mean ± standard deviation), with 708 and 389 patients stratified into the fluid < 6000 ml and fluid ≥6000 ml groups, respectively. Overall in-hospital mortality was 12.3%. The fluid ≥6000 ml group had significantly higher mortality than the fluid < 6000 ml group (15.9% vs. 10.3%, p < 0.05). However, in multivariable logistic regression analysis, conversely fluid ≥6000 ml within the first 24 hours was significantly associated with reduced mortality (OR 0.58, 95%CI 0.34–0.98). We performed subgroup analyses for patients diagnosed with severe acute pancreatitis based on the revised Atlanta classification. One thousand-seven-seven patients were classified in the fluid < 6000 ml group, and 201 patients classified in the fluid ≥6000 ml group. There were no significant differences between the two groups with regard to in-hospital mortality (fluid < 6000 ml: 35.3% vs. fluid ≥6000 ml: 28.4%, p = 0.18). In multivariable logistic regression analysis, patients ≥6000 ml with severity 3 were associated with significantly less mortality (OR 0.56, 95%CI 0.32–0.98).

Conclusion: In patients with severe acute pancreatitis, administration of fluid ≥6000 ml within the first 24 hours is associated with decreased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly used for therapeutic management of various biliary and pancreatic diseases. However, ERCP is not a procedure without complications. The most frequent complication after ERCP is post-ERCP pancreatitis (PEP); this is the most common and serious complication after ERCP.[3]

Aims & Methods: To detect risk factors for post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) and investigate the predictors of its severity. This is a prospective cohort study of all patients who underwent ERCP. Pre-ERCP data, intraoperative data, and post-ERCP data were collected.

Results: The study population consisted of 996 patients. Their mean age at presentation was 58.42 ±14.72 years, and there were 454 male and 442 female patients. Overall, PEP occurred in 102 (10.2%) patients of the study population; the highest AUC in terms of severe acute pancreatitis (SAP) predictions whereas Lactate had was the best in terms of mortality prediction.

Conclusion: Biomarkers are quick but incomplete tools for SAP prediction, which can be easily obtained at any moment throughout the disease. Our study shows good values of specificity and AUC for BUN, Cr and lactate but not for CRP concerning SAP and mortality prediction on admission, but since they are low prevalent outcomes in our sample, PPVs are low and not very reliable. Although many of these parameters have been analyzed in previous studies, we present lactate as a new biomarker with similar performance than that of Cr and BUN, suggesting a possible role for scores building or outcome monitoring.

P0112 COOTON VS. REVISED ATLANTA CRITERIA TO DEFINE SEVERITY OF POST-ERCP PanCREATITIS

X. Smeets1, A. C. Tan2, J. P. H. Drenth1, E. Van Geenen1
1Gastroenterology & Hepatology, Radboudumc, Nijmegen/Netherlands
2Canisius Wilhelminia Hospital Dept. of Hepatogastroenterology, Nijmegen/ Netherlands

Contact E-mail Address: xaviersmeets@gmail.com

Introduction: The Cotton criteria (1) and the revised Atlanta classification (2) are advocated to define post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) severity (3). Whereas Cotton puts the emphasis on length of hospitalisation, Atlanta focuses on the presence of local (necrosis) and systemic (organ failure) complications. The number of hospitalization days may not be a proper representation of PEP severity, because it is influenced by other diagnoses such as ERCP complications and comorbidity. The goal of this retrospective cohort study is to compare the Cotton and Atlanta criteria for the severity of PEP.

Aims & Methods: All ERCP procedures from a Dutch university medical center and a teaching hospital between 2012 and November 2016 were checked retrospectively for patients with PEP. Patients were eligible if they met the Cotton criteria or Atlanta criteria for acute pancreatitis. All records were checked up to 48 hours after ERCP to capture delayed PEP. Patients were excluded if they had acute pancreatitis prior to ERCP or had chronic pancreatitis. In the primary analysis, mild/moderate and severe PEP were compared between Cotton and Atlanta with Fischer’s exact test. Atlanta was regarded as the golden standard. Secondly, we compared the sensitivity and specificity of both definitions for mortality.

Results: Out of a total 2156 ERCPs, 66 patients (3%) had PEP. Two patients were excluded due to missing data for hospital stay. Of the 64 patients analysed, 39 (60.9%) were female, mean age was 60.6 years and the most common indication for ERCP was choleclocholethiasis (n=33, 51.6%). Four patients (6.3%) developed organ failure, 3 patients (4.7%) died. The table below depicts the PEP severity distribution according to Cotton and Atlanta. No significant differences were found (p=0.64). Of the 25 severe patients according to Cotton, 23 were categorized due to hospital stay exceeding 10 days, but were mild according to Atlanta. In 11 patients (44%), concomitant disease (syndrome of inappropriate antidiuretic hormone secretion, cholangitis, pneumonia, perforation or biliary leakage) was the cause for prolonged stay.

Severity of PEP according to Cotton and Atlanta

All 3 patients that died had severe PEP according to Atlanta due to persistent organ failure. Cotton classified them as mild, moderate and severe based on hospitalization. Two patients died within 10 days of early multiple organ failure. No other Cotton criterion for severity was met. Thus, the Cotton criteria did not capture early deaths due to multiple organ failure. The sensitivity and specificity of Atlanta and Cotton for mortality were 100%, 98.4%, 33.3% and 60.7% respectively.

Conclusion: The Cotton criteria for PEP overestimate disease severity, but underestimate mortality. Therefore, the Atlanta criteria should be used for defining severity of PEP.

P0113 RISKS FACTORS AND OUTCOMES OF INFECTED PanCREATIC NECROSIS: RESULTS FROM A COHORT OF 148 PanCREATITIS ADMITTED IN ICU FOR SEVERE ACUTE PanCREATITIS

C. Garret1, M. Péro2, A. Le Thuaut1, M. Le Rhun4, C. Guitton1, J. Gournay2, J. Reigner3, E. Corson3

Introduction: Acute pancreatitis (AP) is a common but potentially lethal pathology due to the multiplicity and severity of its complications1. Infected pancreatic necrosis (IPN) occurs in 30% of patients with necrotizing AP and is associated with an increase in mortality ranging from 15% to 39%2. While interventional drainage and/or removal of the infected tissue remain the mainstay of therapy of IPN, important progresses have been achieved over the last decade and minimally invasive interventional treatments have been developed. The aim of this study was to identify factors associated with IPN and to describe outcomes and mortality.

Aims & Methods: This was a retrospective study of collected data from all patients admitted in Intensive Care Unit (ICU) in a single centre from 2012 to 2015 for a severe AP. Baseline characteristics of the overall population were expressed as frequencies (percentages) for categorical variables, and as mean ± standard deviation (SD) for continuous data. For the analysis of mortality, multi-variante analysis with Cox proportional hazards regression modeling was used to identify independent predictors. Association between IPN and patients’ characteristics at baseline was evaluated using logistic regression.

Results: In total, 148 patients were included in this study. Overall mortality was 17%. Body mass Index, computed Tomography Severity Index (CTSI) ans persistent (>48H) organ failure (OF) were independently associated with overall mortality. 16 patients died during the early phase (<8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality of drainage (radiologic or transgastric) and did not required any necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organ occurred more frequently in the IPN group (14% vs 19.4%, p < 0.001 and 9% vs 8.5%, p = 0.02 respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 1.4%, p < 0.01). In multivariate analysis, factors associated with IPN were number of OF and postoperative venous venous thrombosis (table 1). 39 patients (68%) received anticoagulants with a median time of 6 [3–6] months and among them, 25 patients developed cavernoma, irrespective of whether or not they receive systemic anticoagulation (p=0.31).

Conclusion: In conclusion, this study performed in routine practice conditions showed that IPN occurs in almost half of patients hospitalized in ICU for severe AP, and is associated with increased mortality and complications rates. Overall mortality was 17.6%, and factors associated with mortality were a high BMI, CTSI and persistent OF. Those results are consistent with previous studies3, 4, but we reported a high rate of mesenteric ischemia (7/26 patients deceased) while this complication is occasionally described. IPN patients required an intervention for drainage of infected tissue removal, which was performed using minimally invasive techniques in the vast majority of cases, with no complication or severe side effect. 35% of patients were treated with drainage alone without any additioanl necrosectomy. Finally, PSVMT and early OF appeared to be associated with risk of developing an IPN but anticoagulation for PSVMT did not protect for cavernoma occurrence and can expose to intestinal bleeding. Our results also suggest that the optimal and early management of OF and detection of PVSMT might prevent IPN and/or its complications. Such hypothesis will need to be tested in large multicentre prospective studies.

P0114 EARLY PREDICTORS AND OUTCOMES OF FLUID SEQUESTRATION IN ACUTE PanCREATITIS

S. Goyal
Gastroenterology, Banaras Hindu University, VARANASI/India

Contact E-mail Address: drsundeepegoyal@gmail.com

Introduction: Although it is well known that some patients with AP have an increased need for fluid therapy, it is not clear who should get fluids aggressively. Changes in hematocrit, BUN and serum creatinine, has been documented to limit need for fluid therapy. The early prediction of fluid sequestration may help to select patients for more or less aggressive fluid resuscitation. In this prospective cohort study 300 consecutive patients of acute pancreatitis were included. Fluid sequestration was calculated by adding the total amount of fluid administered and subtracting the total amount of fluid lost in the first 48 hours of hospitalization. Local complications were defined...
according to the revised Atlanta classification. Univariate and multivariate analysis were performed.

**Results:** The median fluid sequestration in the first 48 h after hospitalization was 4.7 liter (2.8–6.8 L). It was 3.2 L (1.4–5.1) and 4 L (2.9–5.7) in those with necrosis and those with necrosis, and 7.5 L (4.4–12 L) in those with persistent organ failure. The univariate and multivariate analysis showed that alcohol etiology, an increasing number of SIRS criteria and Hematocrit were significantly associated with increased fluid sequestration (Table). Body mass index, APACHE II score, sodium, creatinine and blood urea nitrogen levels did not help predict fluid sequestration. Patients with and without acute fluid collections had a median sequestration of 7.2 and 4.2 L (p < 0.001), respectively. 22 patients died (73.3%); median fluid sequestration in the patients who died was 6.5 L compared to 4.2 L.

**Variable**

<table>
<thead>

</tr>
<tr>
<td>SIRS score</td>
<td>5.3 (2.7–4.1)</td>
<td>&lt;0.01 (p &lt; 0.05)</td>
</tr>
</tbody>
</table>

**Conclusion:** Alcohol etiology, increased number of SIRS criteria, hemococoncentration and younger age were independent predictors of increased fluid loss. Patients with increased sequestration of fluid are at a higher risk of local complications and prolonged stay.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0116 AUTOIMMUNE PANCREATITIS CLASSIFIED AS NOT-OTHERWISE-SPECIFIED (NOS) ACCORDING TO INTERNATIONAL CONSENSUS DIAGNOSTIC CRITERIA: CLINICAL FEATURES AND OUTCOMES IN 47 PATIENTS**

N. De Pretis, A. Brandolese, L. Brozzi, F. Vaccelli, A. Amodio, M. Ruffini, S. Crinò, A. Gabbrilli, L. Frulloni

**Gastroenterology, University of Verona, Verona/Italy**

Contact E-mail Address: martina.ruffini@libero.it

**Introduction:** Autoimmune pancreatitis (AIP) is a well-recognized fibro-inflammatory disease of the pancreas characterized by a dramatic response to steroid therapy. (1) Three different types have been identified according to the International Consensus Diagnostic Criteria: type 1, type 2 and type not otherwise specified (NOS). (2) Despite the significant number of studies published on AIP type 1 and 2, (3, 4) no studies have been focused on AIP type NOS and therefore very little is known about clinical features and long-term outcomes of these patients.

**Aims & Methods:** Aim was to investigate clinical features, risk of other organ involvement, risk of relapse and long-term outcomes of AIP type NOS patients. Patients classified by International Consensus Diagnostic Criteria (ICDC) as AIP type NOS at clinical onset included in our database prospectively maintained since 1995 have been evaluated. AIP type 1 (168 patients) and AIP type 2 (63 patients) were excluded. Epidemiological and clinical data have been collected and analyzed.

**Results:** 47 patients fulfilled inclusion criteria. Symptoms at clinical onset were mainly weight-loss (40, 5%), jaundice (34%) and pancreatitis (28.9%). Six patients (12, 8%) had other organs involvement (5 proximal biliary involvement and 1 salivary involvement) and only two (4, 3%) patients had serum IgG4 levels > 140 mg/dL at clinical onset. Six patients (12, 8%) developed ulcerative colitis (UC) during follow-up and were therefore reclassified as AIP type 2. The mean time between the clinical onset of AIP-NOS and development of UC was 14 months (range 4–48). Eight patients (17%) experienced a relapse after steroid treatment and two (4, 3%) patients needed immunosuppressive drugs (Azathioprine) because of recurrent relapses. None underwent resective surgery despite 30 patients (63, 8%) had a focal pancreatic involvement of the pancreas at imaging. **Conclusion:** Patients suffering from AIP type NOS have own clinical features. The risk of relapse is low (17%) but not irrelevant, as well as the risk of developing UC (12%) during follow-up switching the diagnosis to AIP type 2.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

CONCLUSION:
By EPDBD therapy, the relapse rate of pancreatic stone decreased, minor papilla with good prognoses. Case C; 72 y/o male. alcoholic chronic pancreatitis. After EPDBD, EPS was successful in 2 cases via major papilla, and 14 cases via divisum. The 16 cases of divisum consisted of 6 complete and 10 incomplete type. EPBDB respectively. Complications after these therapies are also evaluated.

Results:
The purpose of EPDBD therapy for pancreatic stone was to ease endoscopic procedures in the pancreatic duct and stone removal, and to reduce stone relapse rates. 568 cases of pancreatic stone were treated by EPDBD. They consisted of 90 cases treated by endoscopic method alone (via major papilla 62, and 48 cases treated by EUSWL+ endoscopic method (via major papilla 38, and 11 minor papilla 20). After EPDBD therapy, the stone free rate was 75.3%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A; 22 y/o male. idiopathic chronic pancreatitis, pancreas stone: After 4th EUSWL, small stones remained in the head duct which can’t be removed by basket catheter and severe pain continued, so EPDBD was done under good informed consent. After several dilation of the orifice and the head duct was done easily. This is one of the good result. In our hospital, EPS and ENPD (endoscopic nasal pancreatic drainage) are the preferred choice for pancreatic pseudocyst therapy after dilation of the stenotic duct. 114 cases were successfully treated without major complications, and their prognoses were good. Case B; 59 y/o male. alcoholic chronic pancreatitis, pancreatic stone: ERP via minor papilla revealed the duct rupture in the body portion and contrast medium flowed out into thoracic and abdominal cavity. After dilation of the stenotic duct in the body, EPS placement was done and she recovered quickly. The histopathology of divisum consisted of 6 complete and 10 incomplete type. After EPDBD, EPS was successful in 2 cases via major papilla, and 14 cases via minor papilla with good prognoses. Case C; 72 y/o male. alcoholic chronic pancreatitis, pancreatic stone: ERP revealed type 2 incomplete divisum. After ERP placement was done via minor papilla, then EPS was placed into minor papilla successfully.

Conclusion:
By EPDBD therapy, the relapse rate of pancreatic stone decreased, and the success rate of endoscopic drainage and stenting in pseudocyst and divisum cases are also evaluated. Their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.
This was done in consideration of the current knowledge about lesions mimicking cancer in the setting of a normal pancreatic parenchyma or existence of signs for pancreatic cancer.

Aims & Methods: Retrospective analysis of prospectively collected data in our tertiary University center. From March 2007 to October 2015, 218 (124 men, 94 women; age range: 60–14 years) patients underwent EUS for suspected solid pancreatic neoplasm because of cross sectional imaging results, idiopathic acute pancreatitis, weight loss, pancreatic hyperenzymemia, painless jaundice and elevated Ca 19-9 values. Cystic pancreatic lesions, pseudocysts and cystic pancreatic neoplasm were excluded from the analysis.

Results: Malignant lesions were diagnosed in 98 (45%) patients. 54 patients (24.8%) underwent surgery and 61 patients (28% of all patients) underwent clinical follow-up (16.5 ± 2.7 months, 18 needed surgery). 43 lesions not undergoing surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer (n = 6, 9.8%), neuroendocrine tumor (NE T) (n = 10, 16.4%), paradoxe

nal neoplasms (n = 5, 8.9%), chronic pancreatitis (n = 13, 21.3%), necrosis (n = 3, 4.9%), autoimmune pancreatitis (AIP) (n = 3, 4.9%), micro cystic serous neoplasms (n = 1). Ventral/dorsal split (n = 1), lipomatosis (n = 1). EUS showed sensitivity and specificity for malignancy of 91.4% and 97.7%, respectively, in the non-pancreas group (n = 121) and 44% and 87.1% in the pancreatitis group (n = 97). Ca 19-9 elevation, rapid onset jaundice, double duct sign are useful indicators of malignancy both in the setting of normal and inflamed pancreas. Patients without pancreatitis the presence of enlarged lymph nodes or a mass in EUS, weight loss and worsening diabetes are predictor of malignancy. In patients without pancreatitis and without jaundice Ca 19-9 sensitivity for malignancy was 95% and specificity was 39%. In the pancreatitis group, Ca 19-9 sensitivity for malignancy (in patients without jaundice) was 45% and specificity was 86%. IgG4 elevation presented a sensitivity of 83.3% and a specificity of 84.8% for AIP, where one false elevation was seen in a d i s s t e l o u n g e o l o g i c a l l y.

Conclusion: Diagnostic accuracy of EUS is lower in the presence of pancreatitis.

P0121 GALECTIN-1 EXPRESSED IN PANCREATIC STELLATE CELLS PROMOTES TUMOR PROGRESSION IN PANCREATIC CANCER VIA UPRREGULATION OF SDF-1 AND ACTIVATION OF NF-

Introduction: Pancreatic cancer is characterized by a high density of stroma. Interactions between tumor and stromal cells play a critical role in tumor progression since there is increasing evidence that pancreatic stellate cells (PSC), a main component of the stroma, may participate in the development of pancreatic cancer[1]. However, details of the mechanism underlying the interaction between PSCs and pancreatic cancer cells (PCC) are poorly understood.

Stromal cell-derived factor-1 (SDF-1) or CXC chemokine ligand 12 (CXCL12) belongs to the CXC chemokine family and is the ligand of CXCR4 [2]. I t has been implicated in promoting the metastatic potential of breast, gastric, ovarian, prostate, lung and pancreatic cancer cells. Although SDF-1 reports of SDF-1 in pancreatic cancer cell lines are rare, the role of SDF-1 in pancreatic cancer is controversial. The SDF-1 production is correlated with the presence of cancer cells [3], suggesting that SDF-1 induced active PSCs may be an integral factor in tumor-stroma interactions.

Gale cin-1 mediates communication between cells by binding to glycol-conjugated proteins on the cell surface. Studies have shown that it is involved in multiple cancer-related processes, including immunosuppression, angiogenesis and metastasis [4]. We previously reported that Gale cin-1 was highly expressed in pancreatic cancer tissues; furthermore, the primary source of Gale cin-1 was in activated PSCs within the stroma of cancer cells [5]. It has previously been hypothesized that Gale cin-1 may also induce activation of PSCs and stimulate secretion of chemokines [6]; however, the biological mechanism and its activities in PCCs are unclear.
mural nodules, it is useful to analyse genetic mutations of cystic fluids or walls. Currently, adequate samples from EUS-FNA were unavailing and in some cases, we could not make a pathological diagnosis. Even in such cases, genetic analysis and the subsequent diagnosis of malignant or benign tumours may be possible. We could identify several cancer-related genes, such as GNAS, KRAS, TP53, and BRAF.

Conclusion: In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

P0123 PTEN11 DRIVES TUMOR DEVELOPMENT AND DEFINES A NOVEL THERAPEUTIC TARGET IN KRAS-MUTANT CANCERS

D. A. Ruess
II. Med. Klinik, TU Munich, Klinikum rechts der Isar, Munich/Germany

Contact E-mail Address: dietrich.ruess@uniklinik-freiburg.de

Introduction: The ubiquitously expressed non-receptor protein tyrosine phosphatase SHP2, encoded by PTEN11, is involved in the regulation of multiple signaling cascades. SHP2 was the first reported oncogenic tyrosine phosphatase, required of Shp2 for pancreatic carcinogenesis. Spontaneous as well as cer-
cinated in mutant Kras-driven lung adenocarcinoma GEMMs, in which the lack of SHP2 significantly delayed carcinogenesis suggesting a central role for Shp2 in tumour development and defines a novel therapeutic target in KRAS-mutant cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Circular RNAs (circRNAs) are a novel class of noncoding RNAs (ncRNAs) that are widely distributed in mammalian cells and involved in the regulation of gene expression. Increasing reports have shown that circRNA is dysfunction in neuro system diseases, cardiovascular diseases, human cancers and many other diseases. CircRNA have been demonstrated involving in tumorigenesis, proliferation, apoptosis, angiogenesis, metastasis and invasion in human carcinoma. CircRNA can act as microRNA (miRNA) sponge and regulate the targets of miRNA. Circular RNA HIPK3 (circHIPK3) is originated from second exon of HIPK3 gene, which is consistently upregulated in various cancer, such as liver, esophageal. However, the mechanism remains unclear. Previous studies revealed that signal transducer and activator of transcrip-
tion 3 (STAT3) as an oncogene that was activated in pancreatic carcinoma. Phosphorylation of STAT3 (p-STAT3) is a downstream target of interleukin 6 receptor (IL6R). Activation of STAT3 leads to malignancy of tumorgenesis, cell proliferation and migration. Knockdown STAT3 induces cell apoptosis by Bcl-
X L, c-Myc, cyclinD1, etc. CircHIPK3 regulates BxPC3 cell proliferation through IL6R/STAT3 pathway. It may be a new target for the therapy of pancreatic carcinoma.

Aim & Methods: Our research is to study whether circHIPK3 can promote proliferation of pancreatic carcinoma cell line, BxPC3, and to explore the mechanism of circHIPK3 in cell proliferation. Cell viability was determined by cell counting kit-8 (CCK-8). Transient knockdown of circHIPK3 using specific RNA targeting the conjunction of circHIPK3. Overexpression of miR-124 was transfected with synthetic miRNA mimic. Real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed to detect circHIPK3, miR-124 and mRNAs. The expressions of p-STAT3, IL-6R, pSTAT3, IL-6R were measured by Western blot. Overexpression of STAT3 was transfect with STAT3 plasmid. Dual-Luciferase Reporter Assay was performed to detect the interaction of circHIPK3 and miR-124.

Results: CircHIPK3 was upregulated in BxPC3 compared to human pancreatic duct epithelial cells (HPDE6-C7). Knockdown of circHIPK3, which didn’t affect the linear transcript, significantly decreased cell viability of BxPC3. Bioinformatic analysis and luciferase assay demonstrated that circHIPK3 interacts with miR-124. qRT-PCR was performed in the cells, the expression of miR-124 decreased of miRNA levels of STAT3 and IL-6R and protein levels of STAT3, p-STAT3 and IL-6R. Previous studies confirmed that miR-124 significantly regulates STAT6, IL-6R via interacting with 3’-UTR (untranslated region). Real-time qRT-PCR expression of miR-124 decreased the expression of miR-124 by 1.5 fold. CircHIPK3 was significantly decreased by knockdown of miR-124 in BxPC3 cells. The expressions of p-STAT3 and IL-6R were upregulated in BxPC3 cells than HPDE6-C7 cells while miR-124 was downregulated. CircHIPK3 was negatively correlated with circHIPK3 and STAT3, p-STAT3 and IL-6R.

Conclusion: In this study, we identified circHIPK3 promotes BxPC3 pancreatic carcinoma cell proliferation by targeting miR-124 and its target gene STAT3 and IL-6R. We found that miR-124 was a negative regulator of proliferation in BxPC3 and overexpression of STAT3 could attenuate the anti-proliferation effect of circHIPK3 and miR-124. These results demonstrated that circHIPK3 regulates BxPC3 cell proliferation by acting as miR-124 sponge.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intraductal papillary mucinous neoplasms (IPMN) are precursors of pancreatic ductal adenocarcinoma (PDA) and are also associated with multicentric lesions (field defect), where concurrent de novo PDA, independent of index IPMN lesion, can also develop. However, there are cases where PDAs arise adjacent to the index IPMNs, and occasionally they are pathologically indistinguishable whether the carcinoma developed from IPMN or was coincidental to the IPMN. A genetic approach can be useful to clarify the origin of each tumor compartment to determine if they shared molecular signatures.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims & Methods: Twenty concomitant PDAs and IPMNs (39 samples, including concurrent lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMN was measured after precise pathological mapping. Target amplicon sequencing that covers 18 PDA-associate genes, including KRAS, LIN28A, TP53, SMAD4, CTNNB1 and RNF43, was performed using Ion PGM™ system (Thermo Fisher Scientific). Protein expression of TP53, SMAD4, p16, catenin, and RNF43 was also analyzed immunohistochemically.

Results: KRAS mutations were detected in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. “Adjacent” concomitant PDAs, defined as those that are 5 mm or less away from the IPMN (n = 11), tended to harbor identical KRAS mutations as the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%). Among cases with contiguous neoplastic lesions via the main pancreatic duct between PDAs and IPMNs had identical KRAS mutations. In contrast, 7 of 9 “distant” concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n = 9), possessed distinct KRAS mutations from the index IPMNs (78%). Mutations in KRAS were demonstrated in 14/20 (70%) of index IPMNs and in 29/39 (74%) of all IPMNs, but not in PDAs, supporting de novo carcinogenesis rather than progression from the IPMNs. PDAs harboring identical mutations in KRAS as IPMNs were significantly closer to the IPMNs (KRAS identical; n = 16, 0–35 mm, average 9 mm) versus PDAs with distinct KRAS mutations in the PDAs and IPMNs (n = 23, 0–75 mm, average 20 mm, p = 0.0397). The KRAS identical group had a better prognosis than the KRAS different group (disease-free survival p = 0.0249, overall survival p = 0.205). Curiously, the molecular signature of 18 PDA-associated genes was not significantly different between two groups.

Conclusion: Multiple clones with distinct KRAS mutations were identified in pancreas during initiation and progression of IPMNs, and a subset of PDAs arising within the field defect share the same KRAS mutation with index IPMN lesions. Interestingly, PDAs adjacent to IPMN tend to have identical KRAS mutations, suggesting PDAs and index IPMNs may arise from a common founding event. The KRAS identical group appears to have better prognosis relative to the KRAS different group, implying distinct molecular programs may govern their biological behavior.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0126 POLYMPHORIS System of TP53 Gene, Levels of INFLAMMATORY CYTOKINES IN PATIENTS WITH PANCREATIC CANCER
1Gastroenterology, Federal State Budgetary Scientific Institution «Institute of Internal and Digestive Medicines», Novosibirsk; 2Russian Federation

Contact E-mail Address: igrigoreva@ngu.ru

Introduction: The pancreatic cancer is a leading cause of death in cancer carriers worldwide.

Aims & Methods: To study the polymorphism of the TP53 gene on the suppressor of apoptosis gene and to evaluate proinflammatory cytokines in PCa; TNF-α insulin blood serum levels at patients with various pathologies of the pancreas (PCa), acute and chronic pancreatitis (OP and CP) with various genotypes of TP53. 150 patients were followed in a one-stage clinical trial (42 patients with PCa, 81 with CP, and 27 with PCa). The diagnosis has been verified by clinicogenic examination. The concentration of IL-1beta after admission to hospital, patients with CP were examined at the stage of exacerbation. The frequency of Arg/Pro genotypes was 35% in patients with PCa and 38% in patients with PCa, 49% in the control group. In patients with PCa there was significantly higher in patients with OP than in patients with CP and PCa. The Pro/Pro genotype of the TP53 gene was significantly more prevalent in patients with PCa than in patients with PCa. The level of IL-1β was significantly lower in patients with PCa than in patients with CP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0128 COMBINED HISTO-CYTOLOGICAL ANALYSIS OF EUS-FNA SAMPLES FROM SOLID LESIONS USING STANDARD FNA NEEDLES GIVES BETTER DIAGNOSTIC YIELD AND ACCURACY
A. K. Banerjee, A. Cairns2, L. Sanni2, B. Paranandi1, M. Huggett1

Contact E-mail Address: ashwinibanerjee@gmail.com

Introduction: Diagnostic yield from EUS-FNAC (fine needle aspiration cytology) has improved in the past few years with better tissue acquisition techniques. Core biopsy needles are now available but are more expensive than FNAC needles. We assessed the diagnostic yield and accuracy of FNAC samples processed for both cytology and histology.

Results: A total of 211 patients (118 male) were included. Samples were sent to cytology (n = 135; 107 pancreas, 10 biliary, 7 lymph nodes, 11 other), or cytology & histology (n = 76; 56 pancreas, 12 biliary, 5 lymph nodes, 3 other). Sample adequacy was 80.7% and 98.7% (p = 0.0004). Diagnostic yield (64.4%, 94.7%) and accuracy (81.3%, 96.1%) was significantly better in the combined (histology & cytology) group (p < 0.0001, p = 0.003). Within the combined group, diagnostic yield and accuracy improved by 20.5% (p = 0.007) and 26% (p = 0.0002) respectively when the sample was processed for both cytology and histology.

Disclosure of Interest: Our study confirms significant improvement in diagnostic yield and accuracy when samples were sent for both cytology and histology using standard FNAC needles.

Disclosure of Interest: All authors have declared no conflicts of interest.
BIOPSY FORCEPS IN DIAGNOSING PANCREATIC CYSTS – A USE OF A NOVEL THROUGH-THE-NEEDLE MICRO-

Tanaka M, Fernandez-del Castillo, C, Adsay, V et al. International consensus diagnosis in such cases is a problem for the future. 15% of carcinoma patients did not have nodules, and the handling of the diagnosis was acceptable. Mural nodules observed with EUS was considered as the cutoff value for the size of MN, the diagnosis of malignant carcinoma without MN was present in 8 patients (8/45 (17%) among 78 WF patients. Pathological findings of these patients were noninvasive carcinoma in 6, invasive carcinoma 2.

Conclusion: Algorithm for the management of BD-IPMN of International Consensus Guidelines 2012 was acceptable. Mural nodules observed with EUS had significant factors. In multivariate analyses, size of MN (p < 0.0001) and cyst size of BDPs (p = 0.0004) were independent predictors of malignancy, and in ROC analysis AUC for these factors was 0.74 and 0.72, respectively. Among 78 cases with WF (BPD cyst size ≥30 mm), 45 cases (58%) had malignant IPMN. The rate of malignancy was significantly higher than that of patients without WF(26%) (p < 0.0001). Among 78 WF patients, 54 cases had MN with EUS observation. The rate of malignancy in patient with MN was significantly higher than that of WF patients without MN (69% vs 33%). With 7 mm taken as the cutoff value for the size of MN, the diagnosis of malignant IPMN had sensitivity of 76%, specificity of 73% and accuracy of 74%. Carcinoma without MN was present in 8 patients (8/45 (17%) among 78 WF patients. Pathological findings of these patients were noninvasive carcinoma in 6, invasive carcinoma 2.

Conclusion: Algorithm for the management of BD-IPMN of International Consensus Guidelines 2012 was acceptable. Mural nodules observed with EUS had high predictive ability in BD-IPMN patients with WF. However, about 15% of carcinoma patients did not have nodules, and the handling of the diagnosis such as a problem for the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cystic lesions of the pancreas represent a diagnostic dilemma as some of the lesions are non-neoplastic or benign, whereas others are malignant or have potential for malignant transformation. As indicated in a recent meta-analysis, the diagnostic accuracy of endoscopic ultrasound (EUS)-fine needle aspiration (FNA) cytology, it is often impossible to obtain sufficient cellular material when diagnosing these lesions with current modalities [1]. Recently, a novel biopsy forceps (MorayTM, US Endoscopy, Mentor, USA) has become available. It can be introduced through a 19 G FNA-needle, enabling the endoscopists to obtain histological specimens from the pancreatic cyst wall for the first time [2].

Aims & Methods: The aim of this study was to evaluate the use of the novel micro-forceps in a multicenter clinical setting. The patients referred for EUS evaluation of pancreatic cysts were included retrospectively from five European tertiary centers. Inclusion criteria were age of 18 or above and a pancreatic cyst of a size that allowed for FNA puncture. Exclusion criteria were pregnant or lactating females. A standardized data collection sheet including the information about patient demographics, cyst size, EUS/FNA findings, technical and clinical success, and the results of the biopsies taken was sent to the collaborating centers. Technical success was defined as successful puncture of the pancreatic cyst, subsequent successful mounting of the micro-biopsy forceps, and extraction of at least one micro-biopsy. Clinical success was defined by obtaining useful histological results.

Results: Twenty patients were included. There was a slight overrepresentation of female patients (n = 12, 60%) and the median age was 65 (range: 41–80). The patients had a median cyst size of 30 mm (range: 15–130 mm) and a median procedural time was 30.5 min (range: 17–58 min). We report a technical success rate of 93% (n = 17) - technical failure was only seen in transduodenal puncture (n = 3, 15%). Biopsies were generally of good quality and contributed to the diagnosis in 14 patients (clinical success of 82%). Among these, there were ten cases of intraductal papillary mucinous neoplasia, two serous cyst adenomas, one mucinous cystic neoplasm, one chromidipapillary tumors, and one pseudocyst. Two mild adverse events were recorded (10%), a case of re-admission due to non-specific abdominal pain and a mild acute pancreatitis.

Conclusion: The use of micro-biopsy forceps was until now only reported in case reports of 85% [2]. This is a first larger-scale feasibility study. We conclude that the use of the micro-forceps seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

P0131 Pancreatic ductal cytology: an underused diagnostic tool

Contact E-mail Address: armandoafp5@gmail.com

Introduction: The diagnosis of pancreatic malignancy can be performed by brush cytology of the common bile duct or main pancreatic duct (MPD) during endo-}
endoscopic ultrasonography fine needle aspiration. One patient developed mild pancreatitis (16.7%).

Conclusion: In patients with suspected cephalopancreatic adenocarcinoma referred for ERCP, MDP brush cytology may be performed beyond biliary cytology, as it may improve cytologic diagnosis of malignancy without increasing complications rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

Aims & Methods: The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 hospitals in Japan (8 pancreatic cancer, 7 colorectal cancer, 3 lung cancer, 2 breast cancer, 2 sarcoma, 2 gastrointestinal polyposis, 2 malignant mesothelioma, 1 pituitary tumor, 1 sarcoma, 1 gastric cancer, 1 thyroid cancer, 1 liver cancer, 1 adenocystic carcinoma, 1 multiple myeloma, 1 other cancer, 1 unknown origin) between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytologically diagnosed with PM. Kaplan-Meier analysis and Cox’s proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

Results: We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n = 61), followed by lung cancer (24.5%, n = 39), colorectal cancer (11.3%, n = 18), sarcoma (6.3%, n = 10), breast cancer (6.3%, n = 10), and other cancer (n = 21). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgical resection, and no surgical resection was performed in 95 patients (60%). Additional therapies were chemotherapy (n = 69), chemoradiation (n = 4), radiation (n = 3), palliative care, and unclear (n = 2). Eight patients were lost during follow-up and 151 patients were included in the statistical analysis. All patients with PM had a median overall survival of 43.0 months, with 3- and 5-year survival rates of 52.5% and 42.6%, respectively. Among the five frequent primary sites of PM, prognoses of RCC, breast cancer, and colorectal were better than those of lung cancer and sarcoma. Univariate Cox proportional regression analysis identified four prognostic factors: pancreatic resection (hazard ratio [HR] 0.31, 95% confidence interval [CI] 0.18–0.57, p < 0.001), extra-pancreatic metastases (HR 3.07, 95%CI 1.71–5.51, p < 0.001), tumor-related symptoms at PM diagnosis (HR 3.88, 95%CI 1.29–8.65, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001). Multivariate Cox proportional regression analysis identified three independent prognostic factors: extra-pancreatic metastases (HR 2.13, 95%CI 1.11–4.07, p = 0.02), tumor-related symptoms at diagnosis (HR 3.02, 95%CI 1.71–5.51, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001).

Conclusion: Treatment strategies and prognoses for PM completely differ according to the primary tumor type. A definitive pathologic diagnosis of PM is essential for selecting the appropriate treatment.

Introduction: National Comprehensive Cancer Network (NCCN) guidelines recommend chest x-ray or chest computed tomography (CT) for the staging of potential resectable pancreatic adenocarcinoma (PDAC). However, there is limited data supporting these guidelines, and the prevalence of lung metastasis is not well defined on staging CT scans. We report our findings of patients with lung metastasis during initial staging and follow-up of patients with PDAC.

Aims & Methods: Data was prospectively collected from May 2013 to September 2016 for PDCA patients who were presented at a multidisciplinary pancreas conference (MDPC) at a large tertiary care center. All patients were staged with CT pancreatic protocol, CT chest and Endoscopic Ultrason sound. Patients with findings of lung lesions on initial staging chest CT were followed prospectively. Metastatic lung lesions were determined based on definite imaging characteristics with clinical consensus or lung biopsy results.

Results: A total 278 PDA patients referred to MDPC were staged with CT chest (Table 1). Out of these, 36 (12.6%) patients were found to have either malignant (N = 6) or indeterminate (N = 30) lung lesions on initial staging chest CT. Out of the six malignant lung lesions, 5 (83.3%) patients had metastatic PDA lesions, and 1 (16.7%) patient had incidental primary lung cancer. On a follow-up of 30 patients with indeterminate lung lesions, 8 patients (27.6%) were later determined to be lung metastasis. The overall prevalence of definite lung metastasis was at least 4.8% (13/278). The prevalence of lung metastasis in pancreatic head cancer was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR = 3.83, CI 1.2–11.8, p = 0.02) compared to head. Overall CT chest result changed in change in management plan in 9 (29.6%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unresectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic in 2 (0.7%) patients. Prevalence of isolated PDCA lung metastasis without any other metastasis was 2.8% (8/278).

Conclusion: Our study showed that the prevalence of pulmonary metastasis in PDCA was clinically relevant to mandate routine staging with CT chest. Prevalence was significantly higher for pancreatic body and tail cancers compared to the head. Staging CT chest resulted in a change in the stage of PDA and management decisions.

### P0134 VALUE OF EUS IN EARLY DETECTION OF TUMOR LESION IN THE REMNANT PANCREAS

H. Maruyama1, A. Shimizu2, T. Minami2, N. Hirano2, K. Hanada2

1Dept. Of Gastroenterology, Onomichi General Hospital, Onomichi/Japan
2Gastroenterology, Hiroshima onomichi city, onomichi/Japan

Contact E-mail Address: hiromaruyama99@gmail.com

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for renal pancreas. In this retrospective study, 44 patients who underwent EUS for remnant cancers and 26 cases were enrolled. The definition of observation under the EUS for remnant pancreas was as follows, total observation for remnant pancreas observed from linear white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent resection at the JA Omotchi General Hospital December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for remnant pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of remnant pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of 6 cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage Ib. The other cases as IPMN, were able to perform EUS-FNA for lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (class III), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by Positron emission tomography (PET) and EUS-FNA was performed in 4 out of 7 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (P < 0.001).

Conclusion: EUS was able to observe remnant pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be performed for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Disclosure of Interest: All authors have declared no conflicts of interest.
pared with 33.1 months (95% CI, 9.0–27.2) in the 2nd PDAC group (N: 259 vs. 250) (log-rank ¼ 0.001). The 5-year OS rate of patients who underwent EUS-FNAB, the median OS was 10.7 months (95% CI, 10.0–11.4) in 1st PDAC compared with 10.8 months (95% CI, 9.2–12.3) in 2nd PDAC (N: 1094 vs. 66, p = 0.952).

**Conclusion:** This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. The postoperative bleeding rate in the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; P = 0.001). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≤40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; P < 0.001) was a sole independent risk factor for postoperative bleeding (Table 1). In subgroup analysis among continuous LDA users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Chronic gastrointestinal ischemia (CGI) results in insufficient blood supply to the gastrointestinal tract. The majority of CGI patients has systemic disorders of the circulatory system including hypertension, diabetes and other cardiovascular risk factors. Studies in patients with acute gastrointestinal ischemia found a correlation between intestinal ischemia and sublingual microcirculatory alterations. However, little is known about microcirculatory alterations in patients with CGI. We hypothesized that patients with CGI may reveal sublingual microcirculatory alterations. We further hypothesized that such alterations will be amplified when challenging the patient to enteral caloric challenges. This would provide a patient-friendly means to identify CGI.

Aims & Methods: Consecutive patients with CGI and healthy controls were prospectively included from September 2014 and August 2015. All patients received the standard work-up for CGI consisting of assessment of medical history and symptoms, radiological imaging of the gastrointestinal tract, and endoscopic visible light spectroscopy (VLS) for assessment of gastroduodenal capillary oxygen saturation. The sublingual microcirculation was evaluated before (T0) and 20 minutes after enteral feeding (T1). Total vessel density (TVD (mm/mm²)), perfused vessel density (PVD (mm/mm²)), proportion of perfused vessels (PorPV (%)) and microvascular flow index (MFI (AU)) were assessed.

Results: We included 12 consecutive patients (63.2 (IQR 48.8–70.4) years, 67% male) with CGI and 12 controls (32.7 (IQR 27.7–38.1) years, 42% male). At baseline, patients with CGI had a decreased PorPV of the sublingual small vessels (median 84.77% vs 95.70%, p = 0.006), PORPV of all vessels (median 85.38% vs 95.27%, p = 0.007) and MFI of all vessels (median 3.00 vs 2.80, p = 0.039) compared to healthy controls. After caloric challenge, PVD increased significantly in both in small (PVDs) and all vessels (PVDs) in patients with CGI (PVDs (T0) median 16.3 (IQR 13.3–22.1) mm²/mm² vs (T1) 19.9 (IQR 14.2–26.2) mm²/mm², p = 0.008; PVDs (T0) median 19.1 (IQR 16.2–23.6) mm²/mm² vs (T1) 22.2 (16.5–28.9) mm²/mm², p = 0.02; PorPVs (T0) median 84.8% (IQR 75.3–90.4) vs (T1) 91.0% (80.1–93.8), p = 0.01). In contrast, no significant changes in microvascular parameters were observed after caloric challenge in the healthy controls.

Conclusion: Patients with CGI have impaired sublingual microcirculation compared to healthy controls. They also show significant alterations in the sublingual microcirculation after oral caloric challenge compared to healthy controls. Sublingual microcirculation visualization may offer a fast non-invasive diagnostic opportunity to diagnose patients with CGI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0141 Conventional narrow band imaging has good correlation with OLGA staging of gastritis

A. Gawish1, A. Elbahrawy2, S. Mabrouk3, M. Abdelkhaliq1, M. El Fayoumi4, A. Abolfoth5, M. Eldahshan1, F. Al Ghamry1

1Internal Medicine, Al Azhar University, Cairo/Egypt

Contact E-mail Address: dr.ahmedgawish1988@gmail.com

Introduction: The operative link of gastritis assessment (OLGA) staging system is relatively new and has been proposed to assess the risk of Helicobacter pylori infection on the basis of biopsy samples taken from the antrum and corpus. However, little is known about microcirculatory alterations in patients with CGI. We hypothesized that patients with CGI may reveal sublingual microcirculatory alterations. We further hypothesized that such alterations will be amplified when challenging the patient to enteral caloric challenges. This would provide a patient-friendly means to identify CGI.

Aims & Methods: In this study we attempted to evaluate whether gastritis staging using conventional narrow band imaging (NBI) endoscopy is equivalent to that determined by histopathology. Fifty (50) consecutive patients with Helicobacter Pylori (H. Pylori) related gastric atrophy selected according to NBI endoscopic findings. The diagnosis of H. Pylori based on direct detection of the organism by histopathology assessment. The NBI grade of lower gastric atrophy scored from 0 to 3. The histopathological assessment of lower gastric atrophy was based on OLGA scoring system. Furthermore, we assessed the presence or absence of intestinal metaplasia. The NBI and histology stages of gastric atrophy were compared using a combination of scores for the antrum and corpus. These stages further classified into low risk (stage 0, I and II) and high risk (stage III and IV). Finally the degree of correspondence between NBI and histopathology, in prediction of gastric cancer risk, was assessed.

Results: The mean age of included patients was 38.7 ±15.6 years, they were 21 (42%) males and 29 (58%) females. 38 (76%) and 13 (26%) patients had peptic ulcer disease and high gastric cancer risk respectively. The sensitivity of NBI in diagnosis of Helicobacter Pylori infection, gastric atrophy, intestinal metaplasia and gastric cancer was 96% (n = 48/50), 100% and 61.5% (n = 8/13) respectively. The degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% (n = 43/50) for the antral intestinal metaplasia. The degree of correspondence between the high risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% (n = 40/50).

Conclusion: NBI is able to approximate histopathological staging of gastritis to a certain extent. More studies and comparative testing will further improve the performance of our suggested new staging method.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early gastric cancer. Development of the ESD device has been conducted repeatedly. Splash-M knife® is a new multi-functional needle-knife (ESD-C, n = 50). As primary endpoint, the lesions of Helicobacter Pylori (H. Pylori) related gastric atrophy selected according to NBI endoscopic findings. The diagnosis of H. Pylori based on direct detection of the organism by histopathology assessment. The NBI grade of lower gastric atrophy scored from 0 to 3. The histopathological assessment of lower gastric atrophy was based on OLGA scoring system. Furthermore, we assessed the presence or absence of intestinal metaplasia. The NBI and histology stages of gastric atrophy were compared using a combination of scores for the antrum and corpus. These stages further classified into low risk (stage 0, I and II) and high risk (stage III and IV). Finally the degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% (n = 43/50) for the antral intestinal metaplasia. The degree of correspondence between the high risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% (n = 40/50).

Conclusion: NBI is able to approximate histopathological staging of gastritis to a certain extent. More studies and comparative testing will further improve the performance of our suggested new staging method.

Reference
among two groups. As sub-analyses, the cutting time, rate of en-block/completion rate and all rates of adverse events were evaluated among two groups. 

Results: Propensity score matching analysis created 46 matched pairs. Adjusted comparisons between two groups showed a significantly smaller usage rate of hemostatic forces in ESD-N than that in ESD-C (4.35% vs 84.8%, p < 0.001), and the bleeding rates of both groups were the same (en-block resection rate 100% in both groups; complete resection rate: 97.8% vs 100%, p = 1). Cutting time: 84.6 min vs 53.0 min, p = 0.08; perforation during ESD: 0% in both groups.

Conclusion: Splash M-Knife® achieved better hemostasis and safer ESD for early gastric cancer compared to edaravone for ESD by reducing usage of hemostatic forces during ESD procedure.

Introduction: Intubation failure (IF) when a trained endoscopist is unable to progress into the upper oesophagus via the oropharynx. The incidence is unknown, but estimated at 1.8%. There have been no studies exploring IF and follow-up findings. We aimed to assess the incidence, causes of IF, predictors of pathology in patients with IF, and follow-up findings.

Aims & Methods: We retrospectively identified all gastroscopies performed at a district general hospital between August 2010-August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopist status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups: failure to tolerate (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s chi2 and Wilcoxon signed rank test.

Results: The incidence of IF was 0.95% (248/26130). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, n = 142), CT (21%, n = 50), repeat gastroscopy (29.4%, n = 70) and no further investigations (19.7%, n = 47). Structural pharyngeal abnormalities were diagnosed in 35% comprising of pharyngeal hypertrophy (24%), Zenker’s diverticulum (ZD) (14.6%), pharyngeal web (12.2%), ZD with CPH (9.8%), cervical spondylosis (7.3%) and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5-0.9, p = 0.007). Within the IF cohort, predictors of structural changes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5-11.8, p < 0.001), failure to progress (OR 5.2, 95% CI: 2.3-12.0, p < 0.001) and age ≥ 65 (OR 4.0, 95% CI: 1.8-8.9, p < 0.001). Repeat gastroscopy was successful in 65/70 (2 using nasendoscope) after increasing midazolam dosage (mean increase = 1.5 mg, 95% CI: 1.0-2.0 mg, p < 0.001). Diagnostic yield for barium radiology, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of IF in terms of diagnostic yield, and may be more helpful in evaluating pharyngeal and functional pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was therefore to determine the usefulness of the Kyoto classification for diagnosis of HP infection status. A total of 498 subjects were recruited during the period from January to October 2015 for this study after providing informed consent in writing. HP infection status was determined by the presence of HP-IgG antibody (E-plate II H. pylori antibody, Eiken Chemical Co., Ltd., Tokyo, Japan) and history of eradication therapy. HP infection status was judged to be “eradicated” if there was a definite history of eradication therapy. Without a history of eradication therapy, HP infection statuses were judged to be “infected” for an HP antibody titer of less than 3 U/ml, “eradicated” for an HP antibody titer of 3-10 U/ml and “infected” for an HP antibody titer of more than 10 U/ml. Seven endoscopists (5 well-experienced endoscopists and 2 trainees) who were blinded to history of eradication therapy performed the endoscopies. The following endoscopic findings were assessed according to the Kyoto gastritis classification: diffuse redness, regular arrangement of collecting venules (RAC), fundic gland polypl (FGP), atrophy, xanthoma, hyperplastic polypl, map-like redness, intestinal metaplasia, nodularity, mucus and 8.6 for enlarged fold in subjects with infected status.

Conclusion: The Kyoto classification is useful for diagnosis of HP infection and may be helpful in evaluating pharyngeal and functional pathology. Particularly important findings are RAC, FGP and red streak for uninfected status, map-like redness for eradicated status, and diffuse redness, mucosal swelling, sticky mucus and enlarged fold for infected status.

Contact E-mail Address: c.keung1@gmail.com

Introduction: Balloon tamponade such as with Sengstaken-Blakemore tubes (SBT), remains the main immediate salvage therapy for acute variceal bleeding uncontrolled by variceal ligation or injection therapy. Previous cohort studies from the 1970–1980s report success rates of 40–94% for initial haemostasis but high re-bleeding rates of 40–70% on removal [1–3]. Despite guidelines recommending balloon tamponade as initial therapy in treating endoscopically uncontrollable variceal bleeding, specialists and trainees feel uncomfortable with SBT insertion [4] given the perceived difficulties and complications [5].

Aims & Methods: We aimed to describe the current practices surrounding the insertion of SBT for acute variceal bleeding, the outcomes and to identify areas requiring improvement. A retrospective audit of all patients from 2008–2016 who required SBT insertion for control of acute variceal bleeding was undertaken at Monash Health, a large tertiary Australian centre. These patients were identified from coding classifications. Details regarding their admission were obtained via electronic records.

Results: Approximately 14% of all patients with variceal bleeding required insertion of SBT. Of these 42 patients, the majority were males (51%), with a mean age of 55 years (range 34–78). Alcohol was the most common aetiology for cirrhosis (62%), with 65% actively drinking. Most patients had cirrhosis severity scores of Child-Pugh B (67%) or Child-Pugh C (29%) and a median MELD score of 15 (range 3–39). At the time of endoscopic therapy (85%) were haemodynamically unstable and 29% were encephalopathic. All received standard medical therapy with octreotide or terlipressin, antibiotics and blood products as required. The time to initial endoscopy from 1st onset bleeding was prompt (median 6.6 hours). Most bleeding varices were oesophageal (90%). Initial ligation/injection was performed in 64% with the remaining patients having such large volumes of blood in the UGI tract that satisfactory views were unable to be obtained. The current practice surrounding SBT insertion is shown in the table.
Rebleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a rebleeding procedure, of these still died. The mean duration of hospitalisation and intensive care and mechanical ventilation was 13 days (1–56), 6.2 days (0.3–36.2) and 120 hours (1–708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, rebleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and long-term survival overall has not significantly improved since studies in the 1970s-1980s despite advances in pharmacological therapy. Current practice of SBT insertion and care for these patients are variable and would benefit from future education. Rates of direct visualization of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

Introduction: Preoperative diagnosis of invasion depth of superficial esophageal squamous cell carcinoma (SESCC) is very important to select appropriate therapeutic procedure. The Japan Esophageal Society (JES) classification using narrow-band imaging with magnification (M-NBI) was effective for predicting invasion depth of SESCC.2) Blue laser imaging (BLI) is an image enhanced endoscopy consisted of two different lasers with wavelength 410 and 450 nm as a light source, which can enhance superficial vascular and surface structure. In previous study, BLI with magnification (M-BLI) was useful for evaluating gastrointestinal neoplasms such as predicting invasion depth or tumor detection.3) Aims & Methods: We aim to investigate the diagnostic value of M-BLI by comparison with M-NBI. Our study was a single institution retrospective study and approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. All patients provided informed consent for undergoing both M-BLI and M-NBI. Consecutive 166 patients underwent endoscopic subs mucosal dissection (ESD) for esophageal tumor at Kyoto Prefectural University of Medicine between April 2014 and March 2016. Endoscopic images of SESCCs were recorded by both M-BLI and M-NBI prior to ESD. SESCCs were pathologically diagnosed by ESD specimens. Three endoscopists with no information of the lesions evaluated invasion depth of SESCCs using M-BLI and M-NBI images according to JES classification. The diagnostic value of each procedure was evaluated.

Results: 124 SESCCs were analyzed in this study. The numbers of male/female were 104/20, respectively. Median age was 68.5 years old. Median size of tumor was 17.6 mm. The proportion of tumor location at U/M/L/I was 13.7/70.1/17%, respectively. The proportion of macroscopic type for 0-I/0-IIa/0-IIb was 10/66/23%, respectively. The proportion of invasion depth of the lesions subclassified as IP or LP, M1, SM1, and SM2 were 80, 13 and 7% respectively. The overall diagnostic accuracy of BLI and NBI were 88.7% and 83.9% (P = 0.35), respectively. The intraobserver variability of three endoscopists with BLI and NBI were 0.679/0.560/0.559 and 0.568/0.822/0.560, respectively. The interobserver variability with BLI and NBI was 0.839/0.718/0.531 and 0.517/0.514/ 0.441, respectively.

Conclusion: M-BLI was efficient for diagnosing invasion depth of SESCC according to JES classification, similar to M-NBI.

P0148 IMPACT OF NEEDLE-BASED CONFOCAL LASER ENDOMICROSCOPY (NCLE) IN IMPROVING DIAGNOSIS OF PANCREATIC CYSTIC NEOPLASMS: SINGLE CENTER EXPERIENCE
F. Sharatt1, E. Verter2, M. Lucas1, C. Molina1, J. Adams3, V. Joshi3

Introduction: Endoscopic ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Cystic neoplastic antigen (CEA) tumor marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (NCLE) has been increasingly used for the diagnosis of PCN. NCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care EUS with combined CEA and NCLE to determine which combination of modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Negative Predictive Value (NPV) of EUS alone, EUS with combined CEA and NCLE were evaluated and diagnostic accuracy was compared with pathology using McNemar’s test. Worrisome features (increased cyst size, wall thickness, main pancreatic duct size, and presence of non enhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidian distance and later were used in hierarchical clustering to create two clusters based on Euclidian distance.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.73 and a NPV of 0.80. EUS and CEA with combined NCLE had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and NCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, p = 0.00289.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and NCLE. We also found that clustering of worrisome factors predicts pathology, however, a larger cohort is required for future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavourable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD.

Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric neoplasms were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and others), macroscopic type (protruded, depressed and others), tumor size (diameter of 200mm2), difficult location: 2 points, the number of biopsies, /others), and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L: 8.5; group S: 6.8, P = 0.0231), (group L: 616.7mm2; group S: 999.0mm2, P = 0.0026), biopsy visualization of SCJ was 92.9% (0.0086). Based on these factors and odds ratio, we prioritized sensitivity to avoid missing cases with removal difficulties during ESD and suggested predictive factors for removal difficulties during ESD. The size of the resected specimen >800mm2: 3 points, difficult location: 2 points, the number of biopsies > 7 pieces: 1 point, Group 5 on biopsy diagnosis: 1 point. Cases of 6 points or more was regarded as difficult to remove that takes over 70 minutes. We examined 43 patients who underwent ESD for gastric neoplasms between August to November 2016 the sensitivity was 87.5% and the specificity was 80%.

Conclusion: Our results suggest that the number of biopsies, size of the resected specimen, biopsy diagnosis, preoperative scar and biopsy location are predictive factors for difficulties in ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
in the lesser curvature (43.9%, 284/647). Posterior EGC was more frequent in the mid-to-upper part than the anterior part (20.4%, 31/157 vs. 16.4% (n = 51), respectively). For EGCC characteristics compared between the lower and mid-to-upper parts, submucosal invasive EGC was found to be significantly different (odds ratio, 1.919; confidence interval, 1.014–3.623; p = 0.045).

**Conclusion:** Most of the EGCC resectable with ESD were found in the lower part of the stomach and lesser curvature of the stomach. The incidence of the posterior part in the mid-to-upper part of the stomach was higher than that of anterior part. The EGCC located in the mid-to-upper part of the stomach was found to have a higher incidence of invasive cancer.

**P0152 A STUDY OF THE RECOGNITION OF ENDOSCOPIC IMAGES BY MACHINE LEARNING WITH CONVOLUTIONAL NEURAL NETWORK AND DEEP LEARNING**

R. Yamakawa, M. Harada, K. Kawauchi, S. Suzuki, M. Iwata
Gastroenterology, Kaetsu Hospital, Niigata/Japan

**Contact E-mail Address:** yamakawa.r#a.niigata-mir.or.jp

**Introduction:** The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is undetermined.

**Aims & Methods:** The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL. We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), gastric body (GB), gastric antrum (GA), duodenal bulb (DB) and descending part of the duodenum (DD). Each category had approximately 100 images. These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 8313 by adding additionally rotated images of each five degrees. We made an ML model with three CNN layers, three Activation Function layers, two Max-Pooling layers and two Dens layers by TensorFlow and Keras. We trained the ML model with the learning group images (n = 8313) and then tested it with the testing group images (n = 327) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same test utilizing the same images.

**Results:** It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories (n = 327), 77.1% in LP (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.3% in GF (n = 38), 61.5% in GB (n = 39), 79.5% in GA (n = 36), 68.5% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% in gastroenterologists (n = 35), 85.2% in junior residents (n = 2), 81.2% in endoscopy nurses (n = 5), 54.4% in medical clerks (n = 5) and 51.8% in nurses (n = 4).

The percentage of correct answers of the ML model was lower than those of humans who have knowledge about endoscopic images. However, it was higher than those of other humans who do not.

**Conclusion:** The possibility of the recognition of endoscopic images by ML with CNN and DL is further necessary to confirm the ability of it because this study was conducted in a simple ML model with three CNN layers and a small number of images.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The vessel plus surface (VS) classification system proposed by Yao is widely used for endoscopic diagnosis of early gastric cancer1. However, this diagnosis is performed by visual observation and no quantitative index exists.

**Aims & Methods:** In this study, a method for automatically detecting early gastric cancer lesions by narrow-band imaging (NBI) using a magnifying endoscopic image in the stomach is proposed to support diagnosis. The proposed system quantitatively shows the demarcation line (DL) of lesions in narrow-band images. Machine learning is introduced into the VS classification and image processing is performed. In addition, the obtained DL was similar to that indicated by an experienced gastroenterologist.

**Results:** The average detection rate of the lesion area greatly improved to 63.0% with the proposed system compared with 28.8% with the conventional method. In addition, the obtained DL was similar to that indicated by an experienced medical physician. Based on these results, the proposed system enabled the automatic detection of early gastric cancer DL in narrow-band images, suggesting that the proposed system is useful for the determination of DL.

**Conclusion:** In this study, a method to assess features of gastric lesions combined with the use of superpixels was proposed. The average detection rate of the lesion range using the proposed method greatly improved compared with that using the existing method, enabling the detection of DL without depending on a physician’s experience.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study was to evaluate different endoscopic approaches.

Aims & Methods: This retrospective study included all patients treated for PSGF in a referral center. "Closure" management was defined as initial treatment using covered-metal-stent and endoclips. ID management was defined as: initial management of duodenal and/or double-pigtail-stent. The failure was defined as: need for surgery, or death.

Results: Between 2007 and 2015, 100 patients (women: N=78; mean age: 42 ±12years) were included. The mean delay between SG and the first endoscopy was 92 ±53 days. Overall success of endoscopic treatment was 86% within 6 ±27months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful). Success of initial management was significantly higher for ID (p < 0.05).

Factors associated with failure of closure management were in multivariate analysis: recurrence of fistula (p = 0.02), patients with collection greater than 5 cm, an internal drainage should be proposed first. A collection greater than 5 cm, an internal drainage should be proposed first. A second surgical procedure before endoscopy is associated with longer care. It is well known that hormone for external use is more easily absorbed in broken skin. Accordingly, we explored an innovative strategy with oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel for prevention of the stricture.

Aims & Methods: To evaluate the efficacy of this mixture in single center of Beijing, China.

Patients and Methods: In total, 13 patients who underwent more than 2.3 circular or complete circular ESD for esophageal superficial squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups: randomly. Four patients received systemic steroid treatment (ST), three patients received endoscopic intraluminal steroid (triamcinolone acetonide 80mg) injection accompanied with systemic steroid treatment (IT + ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHA group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions. ST group started with 30mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT + ST group started with 80mg intraluminal steroid at the end of ESD procedure, and 30mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate and aluminum phosphate gel for 2 weeks and continued with a gradually tapering OHA dose on the second day post-ESD.

Results: There were two complete and two 75% circular ESD cases in IT + ST group, and one complete and five 75% circular ESD cases in OHA group, and 12 cases were resected en bloc with tumor free lateral and basal margins. No complications were seen after this procedure. The stricture rates of ST, IT + ST, OHA group after ESD were 100% (4 of 4 patients), 33% (one of three patients), 0% (none of six patients), respectively. One patient with stricture after ESD had lateral recurrence at the margin of ulcer. One EBD was performed in three patients in ST group and one patient in IT + ST group with esophageal stricture. One patient in ST group underwent alimentary fistula reconstruction. The secondary EBD was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2 mm diameter endoscope).

Conclusion: Short period, oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early stage esophageal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

The next day we performed a follow-up upper endoscopy to inspect the intake and administration of broad spectrum antibiotics. We clipped the visible vessel and decided to close the opening with clips (Figure 1). The esophageal opening was 11 cm long, with a Mallory-Weiss tear at the distal end. We also found mediastinal free air. Due to the hemorrhage we performed an emergency endoscopy and closed the opening using clips and hemostatic clips. We observed an amazing healing (Figure 2). The chest symptoms resolved one week after the intervention. All patients were discharged on the eighth day. We performed an upper endoscopy after one month with no bleeding. The mean follow-up period after upper gastrointestinal endoscopy was 3 months after the intervention. The presence of residual tumors was evaluated by conducting endoscopic examinations and histopathological tests with tissue samples obtained from the cold polypectomy scars. Subsequently, patients underwent upper gastrointestinal endoscopy annually, and when residual tumors could not be denied, biopsies were taken from the scars.

Results: A total of 43 lesions in 33 patients were removed using cold polypectomy. Of these 20 patients with one or more SNADETs that have been subjected to long-term follow-up. The area under the curve (AUC) of receiver operating characteristics (ROC) was 0.95 for the lesser curvature, greater curvature, and anterum of the stomach by EG-L580NW (FUJIFILM Co., Japan). Finally, we used a total of 639 LCI pictures in the study. The specifications of the AI used in this study were as follows: Operating system: Linux (Ubuntu 14.04 LTS), Neural network: GoogleNet2, Framework: Caffe3, and Graphic processor unit: GeForce GTX TITAN X (NVIDIA Co., Santa Clara, CA, USA), and we used R (version 3.3.2.) for all statistical analyses.

Disclosure of Interest: All authors have declared no conflicts of interest.

Resolution White Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and EGGIM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathological evaluation and diagnosis. The diagnostic performance of EGGIM was then compared to OLGIM (gold standard) and sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated.

Results: IM was staged as OLGIM 0, 2, 3 and 4, respectively: 32 (41.0%), 23 (29.5%), 17 (21.6%), and 6 (7.7%) pts (no patients with OLGIM 1 were found).

Table 1 showed detailed the EGGIM scores compared to OLGA. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGIM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. In the 6 patients with positive results using the EGGIM classification were H. pylori positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGIM was: sensitivity 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGIM classification were H. pylori positive. A high agreement between EGGIM and OLGIM scores was observed (83.3%).

### P0163 COMPARISON OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY VS PARENTERAL NUTRITION IN TERMS OF INDICATIONS, EFFICACY, COMPLICATIONS; A RETROSPECTIVE ANALYSIS

Introduction: Gastrostomy is the current method of choice for medium and long-term enteral feeding. Available techniques include Percutaneous Endoscopic Gastrostomy (PEG) and Percutaneous Radiologic Gastrostomy (PRG). Both techniques are preferred over surgical gastrostomy. Previous studies that have compared outcomes between PEG and PRG are limited due to small sample sizes, high risk of confounding and selection bias. Our primary aim was to retrospectively analyse data from our centre with respect to complications and mortality between PEG and PRG procedures in relation to indications. These data may help to predict which technique is best for an individual patient.

Aims & Methods: A retrospective analysis including all adult patients receiving initial PEG (January 2010 until April 2016) and PEG (January 2008 until April 2016) placement in our institution was performed.

Results: Outcomes were complications (early (≤ 30 days) and late), success rates and mortality (procedure related, 30-day, and overall). Chi², Fisher’s exact and t-tests were used. Multivariate logistic regression and Cox proportional hazards regression analysis were performed for complications and mortality.

### Results

- Out of 760 initial procedures (469 PRG and 291 PEG) were included in the analysis (62.9% male, mean age 62.8+ years [SD 12.6]).
- Most common indications for gastrostomy were Head and Neck cancer (HN), PEG 69.9%, PRG 64.4%, p = 0.001.
- Cerebrovascular Accident (CVA, PEG 13.7%, PRG 2.1%, p < 0.001) and Motor Neuron Disease (MND, PEG 2.7%, PRG 9.8%, p < 0.001). Success rates for placement were 91.2% for PEG (failure mostly due to absence of transillumination, n = 14) and 97.1% for PRG (p = 0.001).
- Major complications (e.g. abscess, buried bumper, peritonitis) and infections did not differ amongst groups, neither did procedure-related mortality, which was 1.7% in PEG (n = 5) vs. 0.4% in PRG (n = 2, p = 0.113).

### Conclusion

- The 30-day mortality was related more to the patients' general condition, than to the procedure itself.
- Overall survival was 46.7% vs. 44.1% (PEG vs. PRG; p = 0.049, OR 1.224[1.000–1.498]).
- Positive predictive factors for overall survival were PEG, ALS and a higher BMI before placement (adjusted OR for all three factors together 1.292[1.027–1.626]).

**P0165** COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS

Z. Liu¹, X. Zhang¹, Q. Li¹, P. Zhou¹
1Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai, China

**Introduction:** Porcelain endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on its learning curve are limited. A comprehensive evaluation based on risk factors is needed.

**Aims & Methods:** This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM procedures were performed. Patients were analyzed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.

**Results:** Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, full-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representativeness of the operative experience, is also an independent risk factor for a longer procedure time and hospital stay.

**Conclusion:** For POEM operators, seventy cases might be considered a threshold for technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0166** CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS

L. Liu, W. Liu, Z. Fan
Digestive Endoscopy Center, The First Affiliated Hospital of Nanning Medical University, Nanning, China

**Contact E-mail Address:** kit9178@sina.com

**Introduction:** Gastrointestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40%~70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFR) and combined endoscopic and laparoscopic surgery.

**Aims & Methods:** Our study is aimed to assess the safety and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 162 patients with gastric stromal tumor who underwent endoscopic treatments from June 2011 to July 31st 2015 were analyzed retrospectively. The mean diameter of the tumors was 1.5 cm (0.3~5.0 cm). 104 patients received endoscopic submucosal dissection, 58 patients received endoscopic full-thickness resection. Among them, 4 operations were completed under the monitor of laparoscopic surgery.

**Results:** Complications were observed in 8 patients (4.9%): bleeding during operations: 3 patients, post-operation perforation: 3 patients, respiratory tract infection: 2 patients. The mean post-operation feeding time was 2.67 days (range 1~9 days) and post-operation hospital stays were 5.39 days (range 2~10 days). The mean time of follow-up was 26.4 months (range 5~51months). The follow-up showed that 6 patients kept on treating with oral administration of imatinib. No patient was found recurrence or death.

**Conclusion:** Endoscopic treatments were demonstrated as safe and effective ways to resect gastric stromal tumors in this study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0167** GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AUGIB ENDOSCOPY TRAINING?

S. Budhil¹, P. Wurm²
1Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom
2United European Gastroenterology Journal 5(5S)

**Contact E-mail Address:** shivbudhil@yahoo.co.uk

**Introduction:** Much concern surrounds Gastroenterology Specialist Registrar (SIR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AUGIB). Recent evidence suggests there has been a decline in exposure and experience in AUGIB endoscopy. In July 2013 our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5 pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AUGIB endoscopy training after its implementation.

**Aims & Methods:** Endoscopy reports of patients presenting with haematemesis, melena or both who had undergone surgery during the period of 1st of March 2012 to 31st August 2012 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where SIRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/08/2012)

**Results:** A total of 7 SIRs (5 Full Time and 2 Less than Full Time) performed gastroscopies on AUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastroscopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. In UGIB cases Haemospray was used. On average each SIR was able to perform one case of oesophageal variceal banding and one case where Haemospray was utilised. Data from the 2012 cohort in comparison showed a total of 66 gastroscopies over 6 months with 13 EI. On average 13 procedures and 2.6 EIs were performed by each SIR. Dual therapy was applied in only 28.5% of the cases.

**Conclusion:** The introduction of the Registrar of the Week Service provides a valuable opportunity for SIRs to be trained in endoscopic haemostasis and augmentation to AUGIB exposure. As per this study each SIR on an average performed endoscopy on 24 AUGIB patients. If this is extrapolated, each SIR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of EI, on average a SIR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in 5 year program. This is significantly better than in the previous cohort and other centres. Hospitals should consider developing similar services not only to meet demands for 24/7 Consultant led AUGIB endoscopy service but provide adequate endoscopic training provision for current specialist registrars in order to ensure future competent and confident consultants.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Reference**

respectively. All cases of EAC were detected (7/7). In 18/75 (24%) patients referred with dysplasia (LGD/HGD) without a visible lesion, the referral diagnosis was thus upstaged to EAC. Overall, 41/82 (50%) lesions were found additionally.

**Conclusion:** The presence of any grade of dysplasia in random biopsies in BE screening in community hospitals is a potential marker for more severe future pathology after endoscopic work-up in an expert centre. Training in Barrett imaging is mandatory for non-expert endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Results:** A total of 22 patients were included and analyzed. The etiologies of ERF were esophageal surgery in 12 patients (54.5%), esophageal dilatation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 93 procedures were performed with a mean of number of endoscopies of 4.2±4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSC) placement and seven had OTSC associated with esophageal stent. The clinical success rate was 45.5% (n = 10), and 55% of the patients had a functional success (n = 12). Serious adverse events occurred in 9 patients (40.9%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impac- tion (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctiform ERF (p = 0.193), 50% of medium ERF (p = 1) and 14% of large ERF (p = 0.17). The factor associated with the failure of endoscopic treatment was the persistence of the fistula after 6 months (OR = 44; IC95: 3.38–573; 4; p = 0.004 multivariate ana- lysis). The orifice’s size was associated with the mortality with 71% of death among large fistulas (p = 0.001 univariate analysis).

**Conclusion:** Conclusions: Endoscopic treatment of ERF can lead to 45.5% of clinical success and 55.5% of functional success. However, this outcome appears to depend on the size of the fistula and the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0109 CLINICAL UTILITY OF NARROW BAND IMAGING MAGNIFYING ENDOscopy FOR MM/SM1 ESOPHAGEAL SQUAMOUS CELL CARCINOMA

**M. Inoue**, T. Omori1, K. Nastu1, K. Aiura1

1Department Of Surgery, Kawasaki Municipal Kawasaki Hospital, Kawasaki, Japan

**Contact E-mail Address:** masaz.inoue@gmail.com

**Introduction:** Esophageal squamous cell carcinoma (ESCC) is common in Asia. Predicting invasion depth of superficial ESCC is crucial in determining the pre- operative treatment because the rate of lymph node metastasis increases in proportion to the invasion depth of the carcinoma. According to Japanese guidelines for diagnosis and treatment of esophageal cancer, superficial invasions are divided into 5 categories: carcinoma in situ (EP), tumors invades lamina propria mucosa (LPM), lamina muscularis mucosa (MM), the submucosa to a depth of 200 µm or less from the muscularis mucosa (SM1), and the submucosa to a depth more than 200 µm (SM2). The rate of lymph node metastasis is extremely low in EP/LPM tumors, and endoscopic resection (ER) is certified as precise treatment. On the other hand, the rate of lymph node metastasis in MM/SM1 tumors are reported to 10–20%, and both operation and ER are considered as their treatment. Accurate pretherapeutic diagnosis of MM/SM1 tumor is very important for selection of appropriate treatment and interests of patients. In this point, endo- scope diagnosis is very important diagnostic approach.

**Aims & Methods:** The purpose of this study is to investigate the utility of Narrow Band Imaging (NBI) magnifying endoscopy for the diagnosis of MM/SM1 ESCC. From January 2011 to April 2017, 23 patients were diagnosed as patholo- logically MM/SM1 ESCC in our hospital. We retrospectively analyzed their endoscopic findings and pathological findings. The depth of invasion was diagnosed by NBI magnifying endoscopy according to the Japan Esophagus Society (JES) magnifying endoscopic classification1. Diagnostic criteria are based on the degree of microvascular irregularity in the target lesion observed by NBI magnifying endoscopy. Microvessels are grouped into 2 types. Type A microvessels are normal intrapapillary capillary loops or abnormal microvessels without severe irregularity. Type B microvessels are abnormal vessels with severe irregularity or highly dilated abnormal vessels, and subclassified into B1, B2, and B3 based on the running pattern or degree of dilation of severely irregular microvessels. When target lesions have B1 vessels, the invasion depth is predicted as EP or LPM. When B2 or B3 vessels are seen, the invasion depth is predicted as MM or SM1 and SM2 or deeper, respectively.

**Results:** In 23 pathologically MM/SM1 cases, clinical type diagnosed by endo- scope was 0-Ic in 16 cases (70%), 0-IIa in 3 cases (13%), 0-IIb in 1 cases (4%), and 0-IIp in 1 case (4%). Predicted depth of invasion by NBI magnifying endo- scope based on the JES classification was EP in 2 cases (9%), LPM in 7 cases (30%), MM in 10 cases (43%), SM1 in 3 cases (13%) and SM2 in 1 case (4%). Total diagnostic accuracy of MM/SM1 was 57% (13/23). When the B2 vessels were observed, diagnostic accuracy of MM/SM1 was 90% (9/10). In the cases that MM or SM1 invasion remained pathologically quite localized, B2 vessels could not be observed by NBI magnifying endoscopy. And also, in the cases with inflammation or keratinizing epithelium, precise diagnosis of microvessels were difficult.

**Conclusion:** Our data indicate that diagnosis of MM/SM1 ESCC by NBI magnifying endoscopy based on the JES classification is useful when the abnormal microvessels are observable, and NBI magnifying endoscopy is essential method for pretherapeutic examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0174 COMPARISON OF THE LINKED COLOR IMAGING (LCI) TECHNOLOGY AND CHROMOENDOSCOPY WITH ACETIC ACID FOR DIAGNOSIS OF BARRETT’S ESOPHAGUS**

1 Universitätsmedizin Johannes Gutenberg University Mainz, Mainz/Germany
2 Gastroenterologische Schenkl-Spitzenklinik Saalfeld/Germany
3 Department Of General, Visceral And Transplant Surgery, University Medical Center Mainz, Mainz/Germany
4 Interdisciplinary Endoscopy, University Medical Center Mainz, Mainz/Germany

**Aims & Methods:**

The aim of this prospective study was to evaluate the recently introduced LCI technique compared to conventional dye spraying with acetic acid for diagnosis of Barrett’s esophagus. Therefore, consecutive patients with Barrett’s esophagus were entered into the Prague classification and prospectively included. All Barrett segments were carefully evaluated by using high-definition white-light imaging, followed by LCI and acetic acid spraying. At each examination targeted biopsies were taken from all visible lesions, followed by random four-quadrant biopsy protocols.

**Results:**

The diagnostic yield of conventional dye spraying was significantly higher for diagnosis of Barrett’s esophagus compared to high-definition white-light imaging. Of note, no significant difference for diagnosis of Barrett’s esophagus was noted between acetic acid chromoendoscopy and the LCI technique. LCI diagnosis was always consistent to traditional dye spraying.

**Conclusion:**

The newly introduced LCI technique is superior to high-definition white light endoscopy for diagnosis of Barrett’s esophagus and equally effective to acetic acid dye spraying. Therefore, the LCI technique has the potential to facilitate the diagnosis of Barrett’s esophagus and to overcome the limitations of a random 4-quadrant biopsy protocol.

**P0175 ALBERTA FAMILY PRACTICE ELECTRONIC ENDOSCOPY (AFPEE) STUDY (AFPEE)**

M. Kolber1, L. Green1, N. Olivier1, R. Torrie2, G. Babenko1

1 Family Medicine, University of Alberta, Edmonton/Canada/AB
2 Taber Medical Clinic, Taber/Canada/AB

**Contact E-mail Address:** mkolber@ualberta.ca

**Introduction:** In Canada, gastroenterologists and general surgeons perform 97% of the colonoscopies. There are a small number of rural Canadian Family Physicians (FP) performing colonoscopies. These endoscopists may improve access for rural patients who require endoscopy and help improve provincial endoscopy wait times. Although some studies demonstrate that adequately trained Family Physicians are able to perform quality endoscopy, other studies question the quality of colonoscopies performed by non-gastroenterologists.

**Aims & Methods:** The Alberta Family Physician Electronic Endoscopy (AFPEE) study aimed to examine the quality of colonoscopies performed by Family Physicians in Canada. Primary outcome measures included the proportion of successful colonic intubations; proportion of patients 50 years and older having a cecal intubation; proportion of patients 50 years old with an adenoma on a first-time colonoscopy was 67.4%.

**Results:**

In this six-month study, 9 Family Physicians performed 1769 colonoscopies in 11 rural Alberta sites. The proportion of successful colonic intubations was 97.9% (95% CI: 97.2, 98.5). All physicians had over 90% successfully completed colonoscopies (ranging from 95.2 to 100%). The proportion of males and females ≥50 years old with an adenoma on a first-time colonoscopy was 67.4% (95% CI: 62.4, 72.7) and 51.1% (95% CI: 45.5, 56.7) respectively. All physicians achieved benchmarks of 30% of males and 20% for females having at least one adenoma. From all colonoscopies in the study there were 2099 pathologically confirmed adenomas or SSA, 628 advanced adenomas and 17 cancers, corresponding to 120 adenomas, 36 advanced adenomas and 1 colon cancer per 100 colonoscopies. There were 2 post-polypectomy bleeds, no perforations and no deaths.

**Conclusion:** Alberta Family Physician colonoscopists are meeting benchmarks in colonoscopy quality. Ongoing electronic collection of endoscopy quality markers should be encouraged. Supporting and training rural Family Physicians who perform endoscopy may help alleviate current wait times and improve access for rural Canadian patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** keith@siau.org

**Introduction:** In a randomised controlled trial, flexible sigmoidoscopy (bowel scope) reduced colorectal cancer incidence and mortality in a population aged 55-64. Patients progressed to colonoscopy based on ‘high risk’ features (Table 1).[1] Based on these pivotal findings, the UK bowel scope (BS) surveillance programme was introduced in 2013 to individuals aged 55. The Wolverhampton Bowel Cancer Screening Centre was the first UK site to fully roll out the programme. The correlation between BS findings and subsequent colonoscopy has not previously been evaluated in this specific cohort.

**Aims & Methods:** We prospectively collated data from all BS patients at our centre and identified those undergoing colonoscopy between August 2013–2016. We assessed conversion rates, compliance with BS protocol and correlated endoscopic and histological findings to identify predictors of detection of pathology at colonoscopy. Univariate analysis was performed using Pearson’s chi².

**Results:** 11,711 bowel scopes were performed, with an adenoma detection rate (ADR) of 8.5%, and conversion to colonoscopy in 421 patients (3.6%). 386 were included for analysis after excluding incomplete colonoscopy/histology. All patients were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 5% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), polyp ≥10mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, p < 0.001). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, p = 0.002), and male gender (OR 2.35, p < 0.001). These factors also significantly predicted new ≥10 mm adenoma. 57 (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, p < 0.05). After controlling for all high risk indicators, changing the conversion criteria from any villous to villous only histology altered sensitivity from 27.2% to 83.3%, and specificity from 84.5% to 80.5%.

**Table 1:** Indications for progression from BS to colonoscopy (in bold), and likelihood of new adenoma detection. *Patients in multiple categories are included multiple times. **p < 0.05

Aims & Methods: Cold snare polypectomy is an established method for the resection of small colorectal polyps (SCPs); however, significant incomplete resection rates still leave room for improvement. We aimed to assess the efficacy of cold snare polypectomy with submucosal lift (SL-CSP) compared to endoscopic mucosal resection (EMR), for nonpedunculated polyps 6–10 mm (ClinicalTrials.gov NCT02678663).

Results: Eligible participants were randomized (1:1) to be treated either with SL-CSP or EMR. The primary noninferiority endpoint was histologic eradication, with a noninferiority margin of 1%. Evaluation of histologic complete resection relied on a postpolypectomy biopsy protocol (4 biopsies obtained in a 4-quadrant fashion from the polypomcy site margins; 1 biopsy from the base). Secondary outcomes included occurrence of intraprocedural bleeding (IPB; defined as any immediate episode requiring endoscopic haemostasis), clinically-significant postprocedural bleeding (CSPP; any episode requiring emergency department presentation, hospitalization, or reintervention within 30 days of the procedure) and perforation.

Conclusion: SL-CSP appears to be an effective modification of standard cold snare technique, obviating the need to use diathermy for 6–10 mm colorectal small polyps and polyps measuring 10 to 19 mm, respectively. The use of cold snare for removing small and diminutive polyps is most frequent among gastroenterologists with a greater dedication to endoscopy (colorectal polypectomy once per week and performing advanced endoscopy) and among endoscopists with less than 10 years in practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

colonoscopy. Some operators participated in a follow up session in order to assess the improvement of the robotic microvasculature visualization.

Results: On average, experts required the shortest time to reach the caecum, followed by video gamers, trainees then novices. Polyp detection rate (as a proportion of total number in the model simulator colon) was the highest in the novices (91.67%) followed by the experts (86.11%), then equally, trainees and video gamers (79.17%). Four out of nine participants attended the second session where they were asked to repeat the procedure from the first session. Each participant had a lower caecal intubation time during session 2 in comparison with session 1 (p = 0.001). A significant difference in the prevalence of irregular WOS between mucosal (M) or SM-s cancer was 67.8% (21/31) and 75% (9/12), respectively. There was no significant difference in the prevalence between irregular WOS in M or SM-s cancer (p = 0.001), but in SM-m cancer (9/12) the prevalence of irregular WOS was 75% (9/12) and 75% (7/12) respectively.

Discussion: The WOS was determined for cases in which WOS was present and in whom WOS could not be investigated because of rich mucus. The analysis was conducted using 125 lesions from 96 patients. Of these 125 lesions, 33 were determined to have irregular WOS and 92 to have regular WOS. Of the 33 lesions showed irregular WOS, 13 (14.1%) were early cancer and 79 (92.3%) were adenomas. Of the 92 lesions demonstrated regular WOS, 13 (14.1%) were early cancer and 79 (88.5%) were adenomas. The prevalence of irregular WOS in early cancer was significantly higher than that in adenomas (p = 0.001, chi-square test). The diagnostic accuracy for the differentiation between early cancer and adenoma using irregular WOS as an indicator of cancer was 87%. The sensitivity was 91% and specificity was 86%. The frequency of irregular WOS in M or SM-s cancer and SM-m cancer was 67.8% (21/31) and 75% (19/12), respectively. There was no significant difference in the prevalence between irregular WOS in M or SM-s cancer and SM-m cancer (p = 0.727, chi-square test).

Conclusion: These findings suggest that in colorectal epithelial neoplasms in which WOS is visualized because of WOS, the morphological accuracy of the WOS may be a useful marker in the differential diagnosis of adenoma and carcinoma using magnifying endoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: To reduce costs of colorectal cancer screening, a repeat and discard strategy has been proposed for small polyps. The American Society of Gastrointestinal Endoscopy (ASGE) recommends achieving a diagnostic accuracy >90%, before implementing it (1). Narrow band imaging (NBI) is increasingly available and the NICE classification is frequently used to reach real time histologic classification. Endoscopists usually rely on short sessions, online courses or self-education for training in NBI, so we evaluated the learning curve in subjects with no previous endoscopic experience and their subsequent performance in patients with polyps ≤7 mm.

Aims & Methods: Participants (4th or 5th year medical students) attended one training session regarding NICE classification. All participants were posteriorly evaluated employing LC-CUSUM curves, with each participant individually assessing 100 lesions. Polyps were ordered by a computer-generated random sequence and divided into 6 sets of images (presenting 2 sets every week) consisting of 16–17 polyps. After evaluating each polyp, they received a correct diagnosis and a short explanation. The main outcome was a correct NICE diagnosis. A 90% accuracy defined an adequate performance and 80% was considered inadequate. A virtual cohort of 15000 evaluators was used to define the performance improvement cut-off of 3, 45 and 90% for diagnostic performance, consecutive patients with lesions ≤7 mm were included. Patients with polyps lacking classification, polyps > 7 mm or incomplete polypectomies were excluded. All participants received the same white light and NBI training. Training was provided to 10 polyps every week, including all polyps excised. Colonoscopies were presented in the same order as they were included in the study. Histological results were available with a 2-week delay. Evaluators pre-trained their polyp’s histology level of confidence, and recommended a surveillance interval for each patient. Diagnostic accuracy was evaluated at polyp level and for follow-up intervals.

Results: Thirty-eight evaluators (median age: 22.1 years, 71.1% women) completed the study. Of the 100 lesions (8.5 mm, IQR: 5.17.5 mm) included in the learning evaluation curve evaluation 19 were NICE 1.71 were NICE 2 and 10 NICE 3. Median diagnostic accuracy was 88% (IQR: 84.91%, range: 76–96%), increasing from 81.8% (IQR: 78.8–87.9%) in the first 33 lesions to 87.9% (IQR: 84.8–93.9%) in the last 33 lesions according to the LC-CUSUM curve. 20 evaluators (52.6%) reached diagnostic competence. During the diagnostic performance assessment, a total of 180 patients were included, presenting 307 polyps (range: 1–8 polyps/patient), with a median size of 3 mm (IQR: 2–5); 71.3% were adenomas, 21.8% hyperplastic (2.6%) serrated adenomas and 4.2% presented other diagnoses. Overall diagnostic accuracy was 76.9% (76.2–77.7%), reaching 81.3% (80.5–82.1%) in high-confidence diagnoses. Sensitivity for adenomas was 83% (82.2–83.8%), while for hyperplastic polyps it was 62.6% (60.8–64.5%). Surveillance intervals were correct in 78% (77.7%) of patients, 81.3% (80.2–82.4%) in those presenting highly confident diagnoses. Only 2 (5.3%) evaluators reached the 90% recommended threshold. Larger polyp size was associated with higher accuracy (p < 0.001), but neither competence according to the LC-CUSUM test (p = 0.99) nor the performance improvement of the histological results (p = 0.74) improved the evaluators’ accuracy.

Conclusion: Self-formation after a single training session did not allow most evaluators to reach the ASGE suggested thresholds, mainly due to the low sensitivity for hyperplastic polyps. Further studies are required to address if specific training for small polyps or different formation methods might make NBI assisted optical diagnosis a plausible option for small polyps outside expert centers.

Introduction: Effective colonscopy requires effective bowel cleansing. Inadequate cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and delay appropriate treatment. Successful colon cleansing is harder to achieve in patients aged over 65 than in younger patients. NER1006 is the first 1L polyethylene glycol (PEG) based bowel preparation, a patented combination optimised for effective bowel cleansing. Here, the efficacy of NER1006 at cleansing the colon in preparation for colonoscopy is compared to three active comparators, with attention to their efficacies in patients aged ≤65 years and >65 years who had a readable colonoscopy.

Aims & Methods: Colon cleansing efficacy of NER1006 was compared to three currently used bowel preparations in patients aged ≤65 years and in patients aged >65 years. NER1006 was compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB1, NOCT2 and MORA3, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either both in 1 day morning-only (N1D) or, as with 2L PEG + Asc, split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D Grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Results: Pooling the data from the three trials to assess colon cleansing in the two age groups showed successful cleansing in 80.5% (1158/1438) of patients aged ≤65 years and 79.6% (277/348) of patients aged >65 years. NER1006 compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB1, NOCT2 and MORA3, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either both in 1 day morning-only (N1D) or, as with 2L PEG + Asc, split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D Grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Conclusion: NER1006 was efficacious in successful colon cleansing in patients aged >65 years, who had a readable colonoscopy. In the elderly, NER1006 demonstrated an exceptionally high adequate level bowel cleansing success (90% or greater in the overall colon cleansing). NER1006 demonstrated an exceptionally high adequate level bowel cleansing success. A significant improvement was shown for both the overall colon and right sided colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Introduction: Effective colonscopy requires effective bowel preparation. For detection of polyps larger than 5mm, an ‘adequate’ segmental cleansing level has recently been defined as ≥2 or more on the Boston Bowel Preparation Scale (BBPS).1 The Phase 3 trial MORA compared NER1006 as an evening/morning split-dosing or a morning-only dosing regimen, against 2L PEG with ascorbate as an evening/morning split-dosing regimen (2L PEG + Asc). Treatment-blinded central readers assessed the bowel cleansing efficacy using both the Harefield Cleansing Scale (HCS) and the BBPS. This post hoc analysis shows the BBPS scores for the two primary endpoints, in those patients who had a readable colonoscopy.

Aims & Methods: In the MORA trial, 2,849 patients aged 18–85 were randomised to bowel preparation with morning-only or evening/morning split-dosing using either NER1006 or 2L PEG + Asc. Adequate level cleansing success was assessed according to the BBPS for both overall colon (all segments ≥2) and right colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Results: A total of 792 patients were analysed. When using an evening/morning split-dosing, 249/262 (94%) patients on NER1006 achieved adequate level overall colon cleansing compared to 232/260 (89%) on 2L PEG + Asc (Table 1). Using morning-only dosing, 243/270 (90%) patients on NER1006 achieved the same. Using evening/morning split-dosing, 254/262 (97%) patients on NER1006 achieved adequate level right colon cleansing compared to 242/260 (93%) on 2L PEG + Asc. Using morning-only dosing, 253/270 (94%) patients on NER1006 achieved adequate level right colon cleansing. Adequate level cleansing success was achieved significantly more often with NER1006 evening/morning split-dosing than 2L PEG + Asc, both in the overall colon (P = 0.013) and in the right colon (P = 0.042). The slight improvement seen with NER1006 morning-only dosing in the cleansing rate of the overall colon and right sided colon was not statistically significant. Table 1: Adequate level cleansing of the overall colon and right colon (BBPS segment scores ≥2) as determined by treatment-blinded central readers

Introduction: Indicators for colonoscopy quality assessment were developed and promoted during this last decade. However technical and human resources constraints limit local implementation of continuous recording of endoscopic quality indicators (QI). Automatic system of data extraction and presentation could help endoscopy units in their quest for quality improvement. We hereby report our local experience in implementing colonoscopy QI record trough an automatic data extraction from two separate databases (DB), and assess the colonoscopy quality at unit and individual levels.

Aims & Methods: We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathological results from another DB were extracted and merged together in a separate DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polyp detection rate, caecal intubation rate, quality of bowel preparation (using the Boston bowel preparation scale) and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was turned to be mandatory. The completeness of QI recording was evaluated across both periods, and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and we refer to them as all endoscopists. Results: Performance measures of all endoscopists were compared to global results of our department and we refer to them as all endoscopists. Results: During the 6 months “mandatory-filling” period (July-December 2016), 1802 colonoscopies were performed with a QI tab fully filled in 100% of cases compared to 63.1% after the “free-filling period” (p = 0.0001). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.76 with 86.9% of cases with adequate preparation (Boston score ≥ 5; 89.9% among outpatients and 81.9% among inpatients). Colonoscopy were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0%-55.7%). The polyp detection rate was 44.4% with a mean of 1.19 polyp removed by colonoscopy. Conclusion: This study illustrates that quality indicators for colonoscopy assessment in a Belgian tertiary hospital endoscopy unit could be easily implemented with limited human resources by adapting a company reporting system and link it with patient management database. Nevertheless, mandatory filling of QI was necessary for system implementation success. Our results were consistent with goals required by international guidelines. This system allows giving feedback to individual endoscopists for self-performance assessment and might be easily adapted in the future following guidelines updates.

Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CFH-240i (Olympus Corp., Tokyo, Japan). In this study, two endoscopists (M.M., Y.M.) manually annotated 43 colonoscopy videos with 238 min of 17,903,967 frames. These videos included 75 polyps (48 neoplasms, 27 non-neoplasms), and annotations were made on the presence or absence of polyps in every frame. Forty-three videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion that was used to validate the CAD algorithm and 21 no-lesion) videos were used at validation. A novel CAD algorithm was trained to detect a polyp with 90.9% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions.

P0191 MOTORIZED SPIRAL COLONOSCOPY (MSC) – A FIRST FEASIBILITY TRIAL

T. Beyna, M. Schneider, D. Pullmann, H. Neuhaus
Department Of Internal Medicine, Evangelisches Krankenhaus Düsseldorf, Düsseldorf/Germany

Contact E-mail Address: beyna@evk-duesseldorf.de

Introduction: Colonoscopy is widely accepted for the diagnosis and treatment of colonic diseases. Accepted quality parameters for colonoscopy include a cecal intubation rate of ≥ 90%, 10% of all colonoscopies are difficult and intubation of the cecum can sometimes be impossible. The novel motorized endoscope was developed by the Cybernet System Corporation (Düsseldorf, Japan) and represents a disruptive new technology in endoscopy. It is currently being evaluated for anterograde enteroscopy. Spiral technique offers the potential to overcome some of the limitations of standard colonoscopy with push technique by actively pleating the bowel onto the endoscope with motorized rotation of the spiral overtube. This may have advantages in cases of difficult standard colonoscopy to facilitate cecal intubation on the one hand and in all colonoscopies in terms of patient comfort, sedation and ease of use also in therapeutic situations.

Aims & Methods: To evaluate feasibility and safety of MSC for diagnostic colonoscopy. Secondary endpoints were ileum intubation rate, procedure time, need for sedation and external compression, patients' pain and satisfaction, adenoma detection rate (ADR) and feasibility of therapeutic interventions. 30 consecutive patients with indication for colonoscopy meeting the inclusion criteria at a single tertiary referral center were enrolled in the trial between December 2016 and January 2017. The study was conceived as proof of concept trial with the primary aim to achieve a cecal intubation rate of at least 90% according to quality guideline recommendations.

Results: 13 male and 17 female patients were enrolled. Mean age was 68.9 years (30–90), health status was ASA-1: 16.7%, ASA-2: 36.7% and ASA-3: 46.6%. 41 polyps were detected in the patients examined. Indications for colonoscopy were clarification of indeterminate iron deficiency anemia (IDA, n = 5), lower gastrointestinal bleeding (GIB, n = 6), surveillance after previous polypectomy (n = 6), screening for polyps and colorectal cancer (n = 11) and others (n = 2). Sedation level (ROC, EFAC) in all 31 patients was 3 (deep sedation). The mean amount of propofol was 305 [130–880] mg. Mean procedure time was 20.8 [11.4–55.3] min. Cecal intubation rate (technical success) was 96.7% (29/30).

One incomplete colonoscopy occurred due to patient's postinflammatory stricture of the sigmoid. All colonoscopies reaching the cecum also successfully intubated the ileum (96.7%). Only in one case external compression was needed. Adenoma detection rate was 46.7%. EMR was performed in 9 cases, 5 patients had forceps polypectomy. One case of incidental finding of submucosal invasive adenocarcinoma in EMR specimen was histologically proven to have R0 en-bloc resection. All other therapeutic interventions could also successfully be conducted (e.g. n = 3, argon plasma coagulation n = 1, tissue sampling n = 2).

Conclusion: For the first time, the presented computer-aided spiral-enteroscopy was successfully tested in a feasibility study. Mild adverse events were recorded (mild superficial mucosal lesions without further complications).

Conclusion: This study represents the first clinical evaluation of the novel motorized spiral enteroscope for examination of the colon. Our data show that it is effective and safe for diagnostic and therapeutic colonoscopy. It may also have potential advantages over standard colonoscopy technique in terms of effectiveness and convenience of colonoscopy.

P0192 TREATMENT OUTCOMES OF COLD FORCEPS POLYPECTOMY FOR PATIENTS WITH DIMINUTIVE POLYPS: A TERTIARY REFERRAL CENTER EXPERIENCE

Dept. Of Gastroenterology, JCHO Shiga Hospital, Otsu/Japan

Contact E-mail Address: hirohase@belle.shiga-med.ac.jp

Introduction: The results of the National Polyp Study are premised on the removal of all adenomatous lesions. Cold forceps polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (<5 mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated by CFP from June 15, 2015 to March 2017. Magnifying colonoscopy was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: CFP was performed for total 515 polyps from 277 patients. The size of the polyps was <3 mm/4 mm/5 mm = 379/101/35. The rate of one-bite polypectomy for adenoma was <3 mm/4 mm/5 mm = 79%/54%/33%. There was no significant difference in the one-bit rate between endoscopists’ experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antiplatelet drugs was found in 14% (72/548), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There were no polyps on surveillance or recurrent lesion. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 13 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rates of newly discovered polyps in the same segment were 8% and 23% in groups A and B, respectively. The rates of newly discovered polyps in the different segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of <5 years/5–9 years >10 years, the rate of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42%/ (8/18) 37%/11% (30, respectively).

Conclusion: The rate of one-bite polypectomy was significantly higher for diminutive polyps less than 3 mm. Importantly there are no polyps on surveillance or recurrent lesion. CFP is a safe and effective option for diminutive polyps (5 mm). Although the rate of one-bit polypectomy was not related to the endoscopists’ experience, adenoma detection rate is seemed to be low in young endoscopists. Since achievement of “clean colon” is essential for complete surveillance, multiple colonoscopy examination are necessary to achieve “clean colon” especially if the patients have more than two polyps at the first examination.

P0193 EFFICACY OF CIMETROPIUM BROMIDE ON POLYP DETECTION DURING COLONOSCOPIC WITHDRAWAL: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED, CLINICAL TRIAL

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of

Contact E-mail Address: sulsuplu@naver.com

Introduction: Colonoscopy is the most effective method for preventing colorectal cancer, as it offers easy detection and resection of polyps. Cimetropium bromide
results in colonic spasmylosis and may improve polyp detection. We studied the effect of cimetropium bromide on polyp detection during colonoscopic withdrawal.

Aims & Methods: Patients undergoing colonoscopy for screening examinations were included and randomized at cecal intubation to receive either 5 mg cimetropium bromide or placebo. We evaluated the polyp detection rate (PDR), adenoma detection rate (ADR), and advanced ADR (AADR) in the right side colon as well as in the colonrectum.

Results: A total of 181 patients were analyzed in this study. Cimetropium group consisted of 90 patients, PDR, ADR, and AADR were not significantly different in cimetropium and control groups (62.6% vs. 66.6%, P = 0.571; 51.6% vs. 47.7%, P = 0.603; 3.2% vs. 7.7%, P = 0.187; respectively). Similarly, PDR and ADR in the right side colon were not statistically different between the groups (46.1% vs. 47.7%, P = 0.827; 32.9% vs. 35.5%, P = 0.714; respectively).

Conclusion: Cimetropium bromide does not improve the PDR or ADR in the right side colon or the colonrectum. Thus, administration of cimetropium bromide can be used selectively in screening colonoscopy.

nontattooing group, both side injection group was better result (96.2% vs. 91.9%, p=0.022). Most results did not have statistical association with higher lymph node yield in colorectal cancer. But in T1 cancer, the rate of adequate lymph node harvest was higher in the both side injection group, statistically (94.7% vs. 81.0%, OR 4.235, p-value 0.047).

Conclusion: ICG was associated with higher lymph node harvest in colorectal cancer, especially in T1 cancer. And both side injection of ICG increased the rate of adequate lymph node harvest. Further studies and methods are needed to harvest adequate lymph nodes in colorectal cancer.

P0197 THE EFFICACY OF COLD SNARE POLYPECTOMY IN ACHIEVING COMPLETE RESECTION OF SUBCENTIMETRE COLORECTAL POLyps: A MULTICENTRE RANDOMISED CONTROLLED TRIAL (CRESCENT STUDY)

Objective: The aim of this study was to investigate the success rate of CPR for complete resection of subcentimetre colorectal adenomatous polyps compared to that of HSP.

Aims & Methods: This was a prospective, multicentre, randomised controlled, non-inferiority study, conducted in 12 Japanese colorectal units. Patients aged ≥20 years, undergoing elective colonoscopy/polypectomy, and who provided written informed consent were included. Patients who were taking anti-thrombosis agents undergoing hemodialysis were excluded, as well as those with inflammatory bowel diseases, polyposis, and pregnancy. Endoscopically diagnosed sessile adenomatous polyps, 4–9 mm in size, were randomly assigned to the CPR or HSP group. After complete removal of the polyp using the allocated technique, biopsy specimens from the resection margin after polypectomy were obtained. The primary endpoint was the complete resection rate, defined as no evidence of adenomatous tissue in the biopsied specimens, among all pathologically confirmed adenomatous polyps (full analysis set: FAS). Pre-planned subgroup analyses for the size of polyp were also conducted. The sample size was calculated according to the incomplete resection rate seen in previous articles and the required sample size was estimated at 780 lesions, including drop out cases. The protocol was approved by the institutional review board in each institution.

Results: A total of 796 eligible polyps were detected in 538 of 912 patients (males and females, aged 52–80 years) assigned to receive CPR (6–18 mL): i) Endoscopic Shielding Technique (CSP, n=400) and ii) Endoscopic Shielding Technique (CSP, n=402). Subgroup analysis according to the size of polyp (4–5 mm and 6–9 mm) showed a comparable complete resection rate for CSP and HSP for both subgroups of polyps.

Conclusion: The complete resection rate of CSP is not inferior to that of HSP. CSP can be one of the standard techniques for subcentimetre colorectal polyps.

P0198 EFFICACY OF PLATELET-RICH PLASMA (PRP) ON ENDOSCOPIC RESECTION TECHNIQUES: CLINICAL STUDY IN 15 PATIENTS

V. Lorenzo-Zúñiga1, V. Moreno De Vega1, I. Mariní2, N. Caballeró2, R. Bartoll1, I. Bon3, J. Boix1

Aims & Methods: In the EndoPRP study 15 patients (males and females, aged 52–80) were assigned to receive PRP (6–18 mL): i) Endoscopic Shielding Technique (CSP, n=400) and ii) Endoscopic Shielding Technique (CSP, n=402). Subgroup analysis according to the size of polyp (4–5 mm and 6–9 mm) showed a comparable complete resection rate for CSP and HSP.

Conclusion: The complete resection rate of CSP is not inferior to that of HSP.

with a defined AE. Treatment options, including none required, were taken from a predefined list of potential responses examined per country. Over 62% of providers were gastroenterologists and anaesthesiologists. Local guidelines determined practice in most cases, and propofol and midazolam were the main sedation agents employed. The most common AEs reported were hypotension and bradycardia, with 9% and 4% of respondents, respectively, estimating each to occur during >10% of procedures. Mean provider time required to treat AEs ranged from 1.7 minutes for mild desaturation in Germany to 3.10 minutes for cardiac arrest in the USA. Accounting for interventions and provider time, the mean direct cost per procedure ranged from EUR 12 for bradycardia in Germany to USD 3,877 for cardiac arrest in the USA (Table). When costs were “fully loaded” these became EUR 39 and USD 19, 722, respectively. Although of low direct cost, bradycardia in Germany was reported to cause procedure termination or substantial delay in 3.8% of cases. In Euro countries, the median of mean direct costs for an AE was EUR 40 (IQR: 29–67). When costs of outcomes of AEs were included the median “fully loaded” cost reached EUR 301 (IQR: 115–738).

Table: Costs of select adverse events by country. FL: Fully-loaded (costs including hospital admission, time, inpatient stays, delays, and cancellations, but excluding legal costs)

Conclusion: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

Conclusion: ESD R0 resections were 9 times greater than that of KAR on an ESD “intention-to-treat” basis. R0 resections were associated with lower recurrence rates in comparison with R1/Rx resections. LM involvement increased the recurrence rate but without a statistical significance when it was the only pathological risk factor for recurrence and the specimen was resected en bloc.

P0200 COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD), KNIFE-ASSISTED SNARE RESECTION (KAR) AND SPARENESS RATE: A WESTERN EUROPEAN EXPERIENCE IN SPAIN

J. C. Marin-Gabriel1, J.B. Diaz Tasende1, P. Canelas-Nova2, S. Rodriguez-Muñoz2, A.J. Del Pozo-García3, M. Alonso-Rialto3, Y. Rodríguez-Gil3, C. Barroso-De Andrade2, G. Castellano-Tortajada5,4, J.R. Lightdale: Jenifer Lightdale did not receive any remuneration for work on this research project. R. Saunders has previously consulted for Medtronic and Covidien P. Kranke: Peter Kranke did not receive any remuneration for work on this research project. He has previously consulted for Medtronic and Covidien J.R. Lightdale: Jenifer Lightdale did not receive any remuneration for work on this research project. She has previously consulted for Medtronic Inc.

Introduction: Performing CR-ESD remains challenging in Western countries and surveillance studies in this setting are not fully described. KAR has been advised as a reasonable strategy for non-expert endoscopists and difficult lesions. However, some KAR eventually requires a piecemeal resection (p-KAR). A direct comparison between these two techniques is lacking. Additionally, when the specimen is resected en bloc regardless of what procedure is used, and the only pathological risk factor for recurrence is lateral margin (LM) involvement, its implications concerning the recurrence rate should be assessed.

Aims & Methods: 1.) To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD “intention-to-treat” basis, in a Western European setting where CR-ESD is performed by non-experts. 2.) To evaluate the impact of LM involvement on local recurrence when neoplasms without risk factors for lymph node metastasis are resected en bloc. We prospectively included 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient’s safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, en bloc resection and R0 resection.

Results: The ER was aborted in 5 cases (perforation n = 3; technical difficulties n = 2). Surgical intervention was needed after ER because of submucosal or linvofuscular invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range 10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sm1-Vienna 5. En bloc resections were obtained in 44 cases (57.7%); 33 ESD (44%) and 11 KAR (14.7%). The ER finished as a p-KAR in the 31 remaining lesions (41.3%). R0 resections (n = 23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR [OR=8.9 (CI 95%; 2.8–28.3); p < 0.0001]. The median follow-up period was 16 months (1–91). Local recurrence occurred in 11 cases: 9 of the latter throughout the first year (81.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p = 0.03). When results were stratified according to histology and en bloc resections, no significant differences were found in the recurrence rate. When en bloc resections in pT1a (n = 84); (pT2; n = 34) were analysed separately, ESD distribution showed LM0 (52.3%); 18 LM1 and 3 LMx (6.8). There was a non-significant trend concerning the recurrence rate when LM0 (n = 23) lesions were compared with LM1/LMx (n = 21): 0% vs. 14.8% at 3 years; p = 0.06.

as either “proximal” or “distal” colon. Thereafter the division into six anatomical segments was considered (cecum, ascending, transversal, descending, sigmoid and rectum).

Results: A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.69 cm. The most common proximal colon was the most common location (73.4%) of occurrence of the LSTs, with 34% being at the ascending colon. The most common histological type was the low grade dysplasia adenoma (Vienna 3), followed by the SSA without dysplasia with 21.6%. There was significant correlation between size and histology (p < 0.005), where the adenomas and lesions were found to be larger than the other categories. This association, however, is not observed on follow-up histology was even higher (88%). The following adverse events were found to be larger than the other classifications. This association, however, is not observed between SSAs lesions. There is association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0202 SAFE AND SUCCESSFUL RESECTION OF DIFFICULT GI LESIONS USING A NOVEL SINGLE-STEP FULL-THICKNESS RESECTION DEVICE (FTRD)

P.V. Valli, J. Mertens, P. Bauerfeind
Division Of Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the novel full-thickness resection device (FTRD) opens a new dimension of possibilities for endoscopic resection.

Aims & Methods: Sixty patients underwent therapeutic endoscopic full-thickness resection (eFTR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD, Ovesco® Endoscopy AG, Tubingen), is fitted onto a therapeutic endoscope. The endoscope with the FTRD is advanced to the previously marked lesion. Grasping forceps are used to take hold of the target lesion and carefully pull it into the plastic cap of the FTRD®. Immediately after deployment of the OTSC®, eFTR is performed using the hyperthermic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

Results: EFR was performed for the following indications: 1. Recurrent adenomas (n = 22.3%) with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary non-lifting sign on saline injection (n = 2.3%). 2. Non-lifting base after extensive piecemeal resection of a spreading adenoma (n = 2.3%). 3. Diverticular polyps (n = 2.3%). 4. Polyps the cecal appendix (4.6%). 5. Submucosal lesions (n = 58.3%). 6. Early carcinoma (n = 71.2%). 7. Follow-up resection of a malignant polyph (n = 0.1%) had. 8. EFR over endoloop resection (n = 2.3%). In 97% (58/60) of the interventions, the FTRD®-mounted endoscope reached the previously marked lesion and eFTR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up histology was even higher (88%). The following adverse events occurred: Appendicitis of the residual cecal appendix after eFTR of an appendicular adenoma (1/58.2%). Minor bleeding at the eFTR site (2/58.3%). EFR performed accidently without proper prior deployment of the OTSC® (1/58.2%). There was no secondary perforation or eFTR-associated mortality.

Conclusion: In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eFTR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0203 VASCULAR AND PIT-PATTERN ANALYSIS ACCORDING TO KUDO, SANO AND NICE CLASSIFICATIONS: A FEASIBLE AND PRACTICAL APPROACH

F. Desideri1, G. Esposito2, S. Angeletti3, F. Iacopini3, M. Haefner3, E. Di Giulio2
1Gastroenterology, S. Maurizio Hospital, Bolzano/Italy
2Endoscopy Unit, S. Andrea Hospital, Rome/Italy
3Endoscopy Unit, S. Giuseppe Hospital, Alban/Italy

Contact E-mail Address: federico.desideri@gmail.com

Introduction: Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

Aims & Methods: The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopic unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colo-rectal neoplasms, before and after an image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colo-rectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endoscopists. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colorectal neoplasms' surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colo-rectal neoplasms' evaluation before and after the training was also calculated using the McNemar test. A value of p < 0.05 was considered statistically significant.

Results: A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ± 0.03) and Sano (0.12 ± 0.04), and poor for the NICE classification (0.24 ± 0.05). Diagnostic accuracy was 0.33 ± 0.07, 0.54 ± 0.12 and 0.60 ± 0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification (p < 0.0001) and to good for Sano and NICE classifications (p < 0.0001). Diagnostic accuracy increased significantly, too, with values of 0.00 ± 0.05, 0.76 ± 0.05, 0.80 ± 0.05 for Kudo, Sano and NICE classifications, respectively (p < 0.0001).

Disclosure of Interest: All authors have declared no conflicts of interest.

Classification Type N
Kudo I 0
II 2
III 3
IV 1
V 4
Sano I 2
II 19
III a 5
III b 4
NICE I 2
II 19
III 9

Conclusion: To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colo-rectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: CSP was performed to remove 2466 polyps in 1003 patients; cancerous lesions accounted for 0.2% of them, but all had negative margins. There were 549 polyps in the HR group and 1977 in the IR group. There had been taking antithrombotic medication before CSP (antithrombotic group), and 1977 (77.7%) in 817 patients not taking antithrombotic medication (non-antithrombotic group). In the antithrombotic group, 106 patients with 283 polyps continued taking the antithrombotic medication; specifically, aspirin in 41 patients with 113 polyps, clopidogrel in 13 patients with 17 polyps, dual antiplatelet therapy (DAPT) in 13 patients with 18 polyps, antiplatelet agents other than clopidogrel in 17 patients with 68 polyps, anticoagulant agents in 20 patients with 56 polyps, and antiplatelet plus anticoagulant combination therapy in 2 patients with 11 polyps. Heparin bridging was used in 13 patients with 38 polyps. Post-CSP bleeding occurred in patients in the antithrombotic group, the specific antithrombotic medication being used was aspirin in 1 patient with 1 polyp (0.88%, 1/113), and aspirin and clopidogrel a patient with 2 polyps (11.1%, 2/18). No post-CSP bleeding occurred in patients on other antiplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p < 0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% vs. clipping vs. 0.34% without clipping; p = 0.55).

Conclusion: CSP is a safe procedure even in patients on antithrombotic medication, in particular aspirin. The postprocedural antithrombotic therapy should be continued after CSP. The risk of bleeding in patients on antithrombotic medication (post-procedural bleeding rate, 0.09–0.61%) is lower than in patients on non-antithrombotic medication (post-procedural bleeding rate, 2.54%). Therefore, CSP can be performed safely in patients on antithrombotic medication.

P0205 SAFETY OF COLD SNARE COLON POLYPECTOMY IN PATIENTS ON ANTIMONTHROMBOTIC MEDICATION
M. Matsumoto
Dept. Of Gastroenterology, Hokkaido Medical Center, Sapporo/Japan
Contact E-mail Address: miosakura@outlook.jp

Introduction: Cold snare polypectomy (CSP) has been increasingly used in recent years because post-polypectomy bleeding is less common with this technique than with conventional polypectomy. According to the 2012 update of the Japanese guideline for periprocedural management of antithrombotic medications, the post-polypectomy colonoscopic surveillance intervals for patients undergoing antithrombotic medication were predicted correctly in 90% of patients with OE. The post-polypectomy colonoscopic surveillance intervals were predicted correctly in 90% of patients with OE.

Conclusion: Optical enhancement allows to accurately predict the histology of diminutive colorectal polyps in vivo in real-time and meets the PIWI thresholds for reliable and discarding diminutive polyps without histological assessment and for leaving diminutive colorectal polyps in place. Hence, optical enhancement can potentially reduce time, risk and costs associated with removal and histopathological assessment of diminutive polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.
P2020 \AN INNOVATIVE 3D COLONOSCOPE SHAPE IMAGING SYSTEM BASED ON FIBER BRAG GRATING ARRAY
I.K. Yoo1, B. Keum1, W. Kim1, S.J. Choi1, G. Min1, S.H. Kim1, J.M. Lee1, H.S. Choi1, E.S. Kim1, Y.T. Jeem1, H.J. Chun1, H.S. Lee1, C.D. Kim2, J.M. Lee1, J. Kim1, M.S. Jang1, Yang2

1\Division of Gastroenterology and Hepatology. Department of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of
2\Department of Bionics, Korea Institute of Science and Technology, Seoul/Korea, Republic of

Introduction: Colonoscopy is difficult procedure, largely due to unpredictable looping during insertion. If the endoscopist is able to see the colonoscope on the image display, fewer attempts are needed to straighten the shaft of the scope. A prototype Fiber Brag Grating (FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination.

Methods: The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonscope using FBG. In the first part of the study, the FBG sensor was inserted into the working channel of a routine colonoscope in the first 70 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movement in three dimensions. We evaluated loop formation such as N loop, alpha loop, reverse alpha loop, with the 3D imaging monitor. In the second part of the study, 5 patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. Fluoroscopy was used in all investigations for comparison.

Results: In the first part of the study, the results showed that the shape sensor was well correlated with the comparative findings at the same time. The mean average error was 1.722±1.678 mm, which corresponds to 1.50±1.46% of the total length of the sensor. Scope movement and loops were detected correctly in all cases through the monitor. The prototype used in the second part of the study showed high correlation and little discrepancy with the comparative findings at fluoroscopy.

Conclusion: Scope-guided endoscopy using FBG sensor can be successfully used to display colonoscope configuration. This flexible, thin and almost weightless FBG sensor based advanced image display would be a new technique for identification of colonoscope shape.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0211 LARGE (>30MM) POLYP ENDOSCOPIC MUCOSAL RESECTION: OUTCOMES AND PREDICTORS OF SUCCESS

K. Sia1, E. Karunadasa2, A. Kaweza2, S. Ishag1
1Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom
2Department Of Surgery, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Contact E-mail Address: keith@sia.org

Introduction: Endoscopic mucosal resection (EMR) is an established therapeutic option for large (>30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

Aims & Methods: We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2008–2016 in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

Results: Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colon in 81%. Bleeding occurred in 16.5%, of all whom achieved haemostasis. The 30-day complication rate was 1.1% (delayed bleeding in 1 patient), 54 (59%) were fully resected in one session, with overall EMR success in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured malignant polyps with R0 endoscopic resection. The overall malignant histology rate in this cohort was 119/121 (91%). In this cohort, the R0 EMR success rates was 4/11 (36%), with no recurrence after 60 months of follow-up. The overall 12-month recurrence rates following complete EMR was 1.5%, with no significant factors affecting EMR durability identified.

Table 1: Predictors of complete resection on first EMR attempt. p-values derived from bivariate regression, with bold values significant if <0.05. Increase in OR for each increase in year. **p-value < 0.05 considered statistically significant.

Conclusion: Large polyp EMR is a safe and effective alternative to surgical resection of large polyps. Endoscopist experience, polyp morphology, and benign histology are complete predictors of success. Further data are required to evaluate the longer-term outcomes of malignant polyps.

P0212 PROSPECTIVE RANDOMIZED CONTROLLED TRIAL COMPARING EFFICACY OF 1-L PEG-ASC WITH PRUCALOPRIDE AND 2-L PEG-ASC FOR BOWEL PREPARATION

1Gastroenterology And Hepatology, Korea University Anam Hospital, Seoul/Korea, Republic of
2Division of Gastroenterology and Hepatology, Department of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: drcoo@andy@gmail.com

Introduction: Although numerous research has enabled decrease of the bowel preparation solution volume, it is still a major complaint of patients preparing colonoscopy. There have been studied that additional administration of laxatives could lessen the amount of enema formula with prokinetic effect. Prucalopride is a serotonin (5-HT4) receptor agonist which stimulate colonic mass movements and provide main propulsive force for defecation.

Aims & Methods: The aim of this study is to compare 2-L PEG-Asc or 1-L PEG-Asc plus prucalopride with prucalopride. Group A, patients referred for colonoscopy were divided into group A (the split-dose 2-L PEG-Asc) and group B (1-L PEG-Asc + prucalopride) randomly. During colonoscopy, each patient’s bowel preparation quality was evaluated with The Boston Bowel Preparation Scale (BBPS) and Arochick Preparation Scale (APS). The tolerability and satisfaction of patients was determined based on a questionnaire-based survey.

Results: One hundred patients received either 2-L PEG-Asc or 1-L PEG-Asc with prucalopride. Regarding colon cleansing outcome (BBPS and APS), the 1-L PEG-Asc with prucalopride group showed similar, but non-inferior results compared to the 2-L PEG-Asc group on both BBPS (7.65 ± 1.27 vs 7.52 ± 1.40, p = 0.586) and APS scales (93.3% vs 95%, p = 0.717). Tolerability was similar for both 1-L PEG-Asc with prucalopride and 2-L PEG-Asc.

Conclusion: 1-L PEG-Asc plus prucalopride preparation showed comparable result to traditional 2-L PEG-Asc preparation. 1-L PEG-Asc plus prucalopride preparation method could be an alternative method for bowel preparation which can relieve patient discomfort.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0213 IMPROVING SURVEILLANCE FOLLOW UP RATES AFTER COLONOSCOPY ENDOSCOPIC MUCOSAL RESECTION: A QUALITY IMPROVEMENT PROJECT

Introduction: Endoscopic mucosal resection (EMR) is an effective and safe treatment for large (>30mm) laterally spreading colorectal lesions. Although colon EMR has been established as a minimally invasive technique for treatment of large colorectal lesions, risk of adenoma recurrence is the main limitation. Current guidelines recommend first follow-up at 3–6 months; however, there are no well-designed prospective-studies published establishing an optimal time interval. Although SC1 (the first surveillance colonoscopy after initial EMR) is scheduled and executed in the appropriate time. Inadequate or absent scheduling of SC1 can have an impact on the detection of recurrent adenomas, increasing potential patient morbidity, adding unnecessary costs and potentially leading to repeated and avoidable procedures. The aim of this study was to conduct a quality improvement initiative aimed at increasing compliance in SC1 by understanding the current scheduling process and developing strategies to standardize our endoscopy center practices.

Aims & Methods: Single tertiary referral center quality improvement project started in January 2017 and currently still in progress. We present here the interim data. Consecutive patients who had undergone or would have EMR of lesion ≥20mm were eligible for inclusion. The process of following-up patients after EMR was divided at two levels: a dedicated team generated a monthly report identifying patients who underwent colon EMR using our endoscopy procedure documentation program. The appropriate timeline for SC1 for each patient who underwent colon EMR was identified and orders and scheduling for the colonoscopy follow-up were carried out. Evaluation of follow-up: A dedicated team member reviewed the status of patients who underwent colon EMR six months prior to the start of the QI study. If patient did not show up on their scheduled follow-up, phone calls were placed to contact the patient. Patients who had followed-up with their local gastroenterologists were recorded. All the data in intervention group was compared retrospectively with non-intervention group who were not tracked through quality improvement process. The mean follow-up time and follow-up rate (%) at 6 months at SC1 after index EMR was compared between the two groups.

Results: Per-protocol 25 patients included in intervention group were compared to 60 patients in the nonintervention group. Mean age was 62 years in intervention group and 66 years in non-intervention group (p = 0.04). There were no differences in distribution in size of lesion, gender, EMR site, and polyp histology between two groups (Table 1). The mean follow-up time in intervention group was 8.2 months (±2.6) and nonintervention group was 10.4 months (±9.1). There was increase in rate of 6–9 months follow-up in intervention group when compared to the nonintervention group (88%, 95% CI [0.80%–0.94%] vs 64%, 95% CI [0.54%–0.73%]) (Table 1).

P0214 META-ANALYSIS SUGGESTS: INSPECT TWICE TO INCREASE RIGHT COLON ADENOMA DETECTION RATE

K. Triantafyllou, P. Gkolfakis, G. Tzatzios, G. D. Dimitriadis

2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: Missed adenomas in the right colon are of major concern for inter- 
val colon cancer (CRC) development. There is evidence from cohort and rando- 
mized controlled studies (RCTs) that a second examination of the right colon – 
either in direct view or in retroflexion- increases the diagnostic yield of the 
procedure. However, data are not accepted unanimously.

Aims & Methods: The aim of this meta-analysis was to examine the effect of a 
second, back-to-back mucosa inspection on the diagnostic yield of colonoscopy 
in the cecum and the ascending colon. We performed literature searches in 
MEDLINE to identify studies evaluating the effect of a second pass endoscopic 
examination on adenoma detection rate (ADR) and advanced ADR (AADR) in 
the right colon. Study outcomes effect sizes were calculated using RevMan 5.3 
software fixed or random effect model, as appropriate, and they are presented as 
OR[95%CI]. Heterogeneity was measured using the I² statistics. Publication bias 
was assessed by Funnel plots inspection and the quality of the meta-analyzed 
studies was assessed using the Jadad criteria.

Results: We identified 8 studies (5 cohort and 3 RCT, with 9 sets of data and 5639 
subjects – mixed CRC screening/surveillance and symptomatic population) that 
reported on the aforementioned outcomes. Two sets of data examined the yield 
of the second direct view as compared to that of a single inspection, one set 
examined the cumulative yield of two passes compared to that of an extended 
(timely) inspection of the right colon and six sets of data evaluated the yield of 
the second examination of the right colon with scope retroflexion compared to 
that of the single direct view. We were moderate risk of bias studies; suspicion 
for publication bias was detected in the direct view arm of the analysis. As 
compared to a single pass, the second right colon inspection significantly 
increased ADR (1.31 [1.15–1.48], I² = 69%). The effect size of ADR was 
higher in the direct view second pass arm (1.56 [1.41–2.12], I² = 0%) as compared 
to the retroflexion arm (1.17 [1.06–1.29], I² = 0%). Sensitivity analysis with 
removal of one study each time did not identify a single study responsible for 
the detected heterogeneity. Our analysis did not show significant increase in right 
colon AADR (1.5 [0.76–1.56], I² = 0%) after the second exam.

Conclusion: In comparison to a single pass, the second inspection of the right 
colon either in direct view or with scope retroflexion increases ADR in this colon 
segment. However, results should be interpreted cautiously due to the small 
number of meta-analyzed studies with mixed indications populations, and the 
detected moderate levels of heterogeneity and risk for bias.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal Endoscopic Submucosal Dissection (CR-ESD) is technically difficult, time-consuming, and has a long learning curve for Western endoscopists. Several factors related with greater difficulty while performing this technique have been described. Generally, during the learning curve phase, we select simple lesions while imitating the technique. Aims & Methods: Our goal was to assess those factors associated with greater difficulty during untutored DSE-CR without prior selection of less difficult lesions. All patients who attended the complex colorectal polyps consultation were included consecutively. No polyps regardless of their size, morphology, location or any characteristic of greater technical difficulty were ruled out. All CR-ESDs were performed by an endoscopist with previous animal model experience. The demographic and clinical characteristics of the patient, the morphology of the lesion and factors related to the technique were collected. A complex technique
A CT scan was performed in the 2 patients requiring 100 mcg of fentanyl, showing serositis in 1 patient and no abnormalities in the other. Both patients were admitted and managed conservatively (discharge day 6 and 2 respectively). The other 5 patients were discharged home on the same day after extended recovery. Predictors of PP were lesion size ≥45 mm (P = 0.003), Paris classification (P = 0.022) and intra-procedural bleeding requiring endoscopic control (IPB, P = 0.042). Lesion size ≥45 mm and IPB were also independent variables on multivariate analysis with an odds ratio of 2.8 (95% confidence interval 1.3-6.3, p = 0.012) and 2.3 (95% confidence interval 1.0-5.2, p = 0.042 respectively (Table 1).

Conclusion: Pain after EMR occurs in 20% of patients and is associated with longer lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the step down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0217 PERSISTENT PAIN AFTER COLONIC ENDOSCOPIC MUCOSAL RESECTION: PREDICTORS, A MANAGEMENT ALGORITHM AND OUTCOMES

Aims & Methods: We aimed to characterise potential predictors for PP and develop a simple and effective management algorithm for patients with PP based on the need for analgesics in recovery. Data on consecutive patients with a LSL referred for EMR at a single, tertiary referral centre were included. Patient and lesion characteristics and peri-procedural data were prospectively collected. Standard post EMR care included 2 hours in first stage recovery where clear fluids were given and collected. Standard post EMR care included 2 hours in first stage recovery with a LSL referred for EMR at a single, tertiary referral centre were included.

Results: No prospective data exist on the optimal selection of analgesics, the necessary was recorded. In the Paris classification, 0-Is was more frequent in the left colon than in the right colon (p = 0.042). An intra-procedural serositis in 1 patient and no abnormalities in the other. Both patients were admitted and managed conservatively (discharge day 6 and 2 respectively). The other 5 patients were discharged home on the same day after extended recovery. Predictors of PP were lesion size ≥45 mm (P = 0.003), Paris classification (P = 0.022) and intra-procedural bleeding requiring endoscopic control (IPB, P = 0.042). Lesion size ≥45 mm and IPB were also independent variables on multivariate analysis with an odds ratio of 2.8 (95% confidence interval 1.3-6.3, p = 0.012) and 2.3 (95% confidence interval 1.0-5.2, p = 0.042 respectively (Table 1).

Conclusion: Pain after EMR occurs in 20% of patients and is associated with longer lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the step down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

P0218 QUALITY OF SINGLE-SESSION COLONOSCOPIC EXAMINATIONS INTENDING TO REMOVE ALL NEOPLASTIC POLyps USING COLD POLYPECTOMY IN OUTPATIENT SETTING: RESULTS FROM CLINICAL PRACTICE DATA OF SINGLE CANCER CENTER HOSPITAL IN JAPAN

Division Of Endoscopy, Shizuoka Cancer Center, Nagaizumi/Japan

Contact E-mail Address: k.hotta@scchr.jp

Introduction: Some high-quality, large-scale cohort studies proved removals of colorectal neoplasms achieved prevention of colorectal cancer incidence and deaths. We introduced a strategy of removing all neoplastic polyps in single session colonoscopic examinations using cold polypectomy was started.

Aims & Methods: The aim of this retrospective study was to investigate about achievement of colorectal polyp remove in our clinical practice setting. Scheduled colonoscopic examinations for 40-79 years outpatient who had at least one colorectal neoplasm between January 2015 and December 2016 were collected from our endoscopic data base. Exclusion criteria were as follows: patients who had colorectal neoplasm larger than 20 mm, pre-examination of colorectal surgery or endoscopic submucosal dissection, inflammatory bowel disease, familial adenomatous polyposis, uncontrollable malignancies, by trainee endoscopists (<500 colonoscopies), no agreements of polyp removal, and/or patients with continuation of anti-thrombotic agents. Outcome measurements were polyp removal rate (per-lesion analysis), complete polyp removal rate (per-patient analysis) and complications. Proportions of each endoscopic removal method according to size were also analyzed.

Results: A total of 2527 patients (mean age 66.8 ± 799 females) with 8203 colorectal neoplasms (CRNs) (7675 adenomas, 423 serrated polyps and 105 Tis and T1 cancers) who met inclusion and exclusion criteria were analyzed. Mean number of CRNs per patients was 3.2. Mean size was 4.7 (±2.9) mm. Polyp removal rate (per-lesion) and complete polyp removal rate (per-patient) were 97.0% (95% CI 803) and 94.7% (95% CI 2527), respectively. Post-polypectomy bleeding requiring endoscopic hemostasis occurred in 7 patients (0.27%) and all origins of bleeding were of mucosal mucosal resection (EMR) and hot snare polypectomy (HSP). Post electrocoagulation syndrome requiring admission was occurred in one patient (0.04%) after pre-cutting EMR. Mean procedure time was 27.4 (±13.3) min. Proportions of each endoscopic removal method according to size were presented in an attached table. In 1-4 mm CRNs, both cold snare polypeotomy (CSP) (51.8%) and cold forceps polypectomy (CFP) (45.8%) for 1-4 mm CRNs were mainly methods. In 5-9 mm CRNs, CSP was a leading method (73.8%) and EMR was the second one (24.1%). CRNs larger than 10 mm were almost removed by EMR (94.4%).
2. Prosst RL, Joos AK, Ehni W, Bussen D, Herold A. Prospective pilot study
Further improvements should focus on increasing healing potency of the fistula
postop changes, long-term success may be achieved in around half of all patients.

Results:
0–100%, depending on the size of perforation, type and nature of lesion and the
special characteristics of these leaks were reported to make more difficult the
closure of a recto-urogenital fistula using the OTSC, but there was considerable
heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal
n = 10, rectovesical n = 7, rectourethral = 2, other rectal fistula n = 3).

Results: In most situations a previous interdisciplinary discussion was reported
before an OTSC attempt, or patients refused to undergo re-operation. However,
special characteristics of these leaks were reported to make more difficult the
OTSC procedure compared with other GI locations, e.g. the site of the fistula is
nearby located to L. dentata and anal sphincter, it includes a localization with
little space for endoscopic manipulation, fibrous and scarry tissue is around the
fistula in rectum or anastomosis and there may be sometimes suture material in
situ. Thus, the tissue is often fixed and there is not so much tissue for grasping
tissue into the OTSC.

The diagnosis of recto-urogenital fistula was usually made by endoscopic visu-
ization and radiologically documented extravasation of contrast media into the
vagina, urethra, bladder or into other adjacent tissue. For fistula closure traum-
atric OTSC was mostly used, but sometimes other adjuvant therapeutic mod-
alities were also combined locally (e.g. histoacryl injection, fibrin glue, argon
plasma coagulation, brushing etc) or systemically (e.g. argon ascorbic 7.5 g i.v.)
to stimulate wound healing. The procedural success of occluding various types of
recto-urogenital fistulae by the OTSC system was found to be successful in 71% (59
cases) in short-term, while a durable clinical success was found in only
52% (0–100%) of all 25 patients. The success rate was lower in cases of highly
fibrotic chronic fistulae, after dislocation of clips and when using the atraumatic
clip. Thus, even in this distal problematic site usage of a traumatic OTSC should
be tried in experienced hands before surgical repair.

Conclusion: In conclusion, recto-urogenital fistula may be a potential indication
for OTSC application, after interdisciplinary consensus, when re-operation is
avoided, deemed to be too risky or cumbersome. Although this type of fistula
carries some difficulties because of little space, tissue tension and fibrous or
postop changes, long-term success may be achieved in around half of all patients.
Further improvements should focus on increasing healing potency of the fistula
or better after performing anastomosis creation (ascorbic acid?), to avoid post-
operative recto-urogenital leaks.

Disclosure of Interest: All authors have declared no conflicts of interest.

5242-x.
Results: According to endoscopic or pathologic judgment resection was complete in 40 or 30 patients, respectively. During hospital follow-up (12-14; median 4 days) abdominal pain, fever or local peritonitis were noted in 6 and bleeding in 3 patients (hypotension in 1) with antibiotics/transfusions/surgery needed in 4/0 patients. There was no hospital mortality. Among those with histologic incomplete resection (n = 21), surgery or FTR was performed in 5 patients, endoscopic follow-up is pending in 7 and revealed no residual neoplasia in 9. Among those with cancelled ESD or endoscopic incomplete resection (n = 11), surgery or FTR was performed in 5, endoscopic follow-up is pending in 2 and revealed no residual neoplasia in 4.

Conclusion: After appropriate training, even in low volume European case series ESD in the colorectum appears to be safe and partially effective.

Introduction: Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Coloscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration room due to not meeting real-time constraints (40 ms max per image). In this abstract, we present a methodology to adapt and evaluate a real-time still frame-based method [3] to video analysis.

Aims & Methods: The still frame detection system used as reference [3] was based on an active learning method. We base the adaptation to video analysis on two aspects: (i) influence of the type of information used for polyp candidate characterisation, and (ii) introduction of spatio-temporal coherence. The former studies whether the combination of different types of information may lead to improve system performance whereas the latter fosters stability in the position of the detector output over consecutive frames. The learning stage of the method used a public still-frame database (CVC-Clinic, 612 images) whereas the testing was done on a new set of 18 sequences with a polyp (10,294 images) collected with an Olympus colonoscope CIF-H190 at Hospital Clinic, Barcelona. Performance was evaluated using two groups of metrics: (i) standard image/video metrics: Precision, Recall and F1-Score (ii) ad-hoc clinical metrics (assessing the clinical usability). Among the latter group we define: a) Polyp detection rate (PDR), checking if a method is able to detect polyp at least in the first appearance of a polyp in the sequence and the first correct detection procedure (providing each other). b) First time recognition (RT), checking if a method is able to detect polyp at least in the first appearance of a polyp in the sequence and the first correct detection procedure (providing each other).

P0223 REJECT AND DISCARD/DIAGNOSE AND DISREGARD STRATEGY FOR COLONIC POLYPS: ARE WE READY TO START IT?

Gastroenterology, Amato Lusitano Hospital, Castelo Branco/Portugal

Contact E-mail Address: richardazevedo13@gmail.com

Introduction: The use of Narrow Band Imaging (NBI) technology for in vivo histological prediction of colorectal polyps presents high accuracy in Referral Centers, particularly for diminutive polyps, which could be managed by the “reject and discard” strategy and, for sigmoid and rectum polyps, the “diagnose and disregard” strategy. However, the applicability of this practice in Community Hospitals still needs to be determined.

Aims & Methods: We aimed to determine the accuracy of NBI in predicting histology, according to NICE and WASP classifications, in a Center without previous NBI experience. This was a prospective study including patients submitted to colonoscopy between June 2016 and July 2017. Polyps characteristics: location, size, morphology (Paris Classification), NICE/WASP classification (hyperplastic, sessile serrated, adenoma, invasive carcinoma) and degree of confidence (low: <90% vs. high ≥90%). Comparison between NBI classification and histology SPSS 23.

Results: 163 polyps included (71 patients); mean polyp dimension of 6.1 mm (61.3% ≤5 mm); 91.4% sessile polyps; 62.6% on the left colon. Polyps classification according to NICE/WASP vs. histology: hyperplastic 49.7% vs. 42.9%; sessile serrated polyps 4.9% vs. 9.8%; adenoma 44.2% vs. 43.6%; carcinoma 1.2% vs. 0%. Inflammatory reaction on histology – 3.7%. Adenoma diagnosis using NICE/WASP classification presents an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 78.1%, 84.2%, 85% and 77.1%, respectively. For left colon polyps ≤5 mm (n = 61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariate analysis showed that high confidence prediction and ≥3 polyps/exam had a significant association with correct NBI classification (p < 0.05).

Conclusion: NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (≥90%). These results justify implementing additional training and monitoring.

Introduction: Cold forceps polypectomy (CFP) is commonly used to remove diminutive colorectal polyps (<5 mm). In addition, jumbo biopsy forceps are superior to standard forceps for removing colorectal polyps. However, problems remain for CFP with regard to residual adenomatous tissue on histological evaluation after a complete endoscopic cold forceps polyp resection.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of jumbo forceps biopsy using narrow-band imaging endoscopy in patients with diminutive polyps. In addition, we evaluated the factors related to one-bite resection, and factors for carcinomatous lesions associated with a high frequency of delayed bleeding and the perioperative periods.

Results: A total of 503 patients were prospectively assessed, and 1015 polyps were resected. The median age of the patients was 65 years. The patients comprised 329 men (65%) and 174 women (35%). The polyp morphologies were 0-Ia lesions in 886 cases (87.0%), 0-IIa lesions in 65 (6.4%), 0-IIp lesions in 63 (6.2%) and 0-IIp lesions in 1 (0.1%). Polyps were most often resected in the ascending colon (289 lesions) or the transverse colon (262 lesions). Of all the polyps, 88% (896 lesions) were adenomas, 10% (100 lesions) were hyperplastic, and 0.3% were adenocarcinomas. The mean procedure and treatment times were 26.5 and 20.4 min, respectively. The complete resection rate was 99.3%. The rate of one-bite polypectomy was 71.8%, which included rates of 100%, 91.5%, 81.8%, 56.9%, and 40.5% for lesions 1, 2, 3, 4, and 5 mm in diameter, respectively. Delayed bleeding that required endoscopic hemostasis occurred in only one case, but no other adverse events occurred. The most important factor related to one-bite polypectomy was polyp size (≤5 mm; OR: 5.58), followed by macroscopic type of polyps (non-Ha; OR: 1.95).

Conclusion: In this large-scale multicenter prospective study, 99.3% of all diminutive polyps were completely resected by using jumbo forceps biopsy and magnified endoscopy with NBI. In addition, we were able to do one-bite resection for more smaller polyps (≤3 mm). Jumbo forceps biopsy appears to be adequate for resecting diminutive polyps if no residual tissue is visible by using magnified endoscopy with NBI.

Contact E-mail Address: onosho@med.hokudai.ac.jp

Introduction: Heparin bridging therapy (HBT) is recommended for patients administered anticoagulants who have a high thrombotic risk and who undergo a high-risk procedure such as endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR). However, HBT is actually related to a high frequency of delayed bleeding. Aims & Methods: Our aim is to analyze bleeding and coagulation markers in the perioperative periods of patients with oral anticoagulants during the period from January 2013 to March 2017. Generally, administration of warfarin was continued during the perioperative period. Patients who underwent ESD or EMR were administered a direct oral anticoagulant (DOAC) during the period from January 2013 to September 2016. Patients aged 20 to 75 years with diminutive polyps were enrolled in this study. When lesions were found, we used magnification endoscopy with narrow-band imaging (NBI) in all the cases.

Results: Among the patients who underwent ESD or EMR during the study period, 5 patients received warfarin and 49 received DOACs. Delayed bleeding occurred in 6 patients (11.8%) in the warfarin group and in 8 patients (16.3%) in the DOAC group, and there was no significant difference. Only one patient with continued administration of antithrombotic agents had delayed bleeding among the patients in whom administration of warfarin was continued with the therapeutic range (5.3%: 1:19). Six (15%) of the 40 patients in the DOAC group for whom the DOAC was not administered only on the day of the procedure had delayed bleeding, and 23.8% (5/21) of the patients who received HBT had delayed bleeding. No thrombotic events occurred from one month after the procedures. One patient in whom the DOAC was not administered on the day of the procedure became positive for TAT, F1 +2 and DD after EMR and had a hemorrhagic coagulopathy.

Conclusion: For peroperative management of anticoagulants in patients undergoing ESD or EMR, continuous use of warfarin within the therapeutic range is recommended. DOAC should be carefully managed with attention to hemorrhagic risk and coagulable condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The indication of colonoscopy has a very important influence on the different quality indicators such as detection rates of lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: SpyGlass cholangioscopy system can be safe and useful for definite diagnosis with high accuracy in patients with indeterminate bile duct lesions, and successfully guided stone therapy. Further prospective multicenter trials of the system are warranted in the future.

P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic disorders in pediatric patients.

Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, therapeutic interventions performed and complications were collected.

Results: A total of 288 children (mean age 9.7 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common bile duct obstructions (n = 153, 54.2%), recurrent or chronic pancreatitis (n = 64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings were choledocholithiasis (n = 146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n = 204), including sphincterotomy (n = 97), stone extraction (n = 55), and stent insertion (n = 52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS’ EXPERIENCE AT A LARGE CENTER IN CHINA

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy were operated on at our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 291 patients met inclusion criteria for the study. The rate of adenoma recurrence after EMR was 4% (25/525). Complications occurred for only 13 patients (4.3%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYDNEY RECURRENCE TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESSECTION: A PROPENSITY SCORE ANALYSIS

D. Guerrero1, R. Lennon2, P. Kandel1, L. K. Mejia3, R. Bingham4, T. Woodward5, V. Gomez6, M. Raimondo6, E. Bouras7, M. B. Wallace
1Gastroenterology and Hepatology, Mayo Clinic, Jacksonville, Florida/United States of America/FL
2Biostatistics, Mayo Clinic, Rochester/United States of America/MN

Contact E-mail Address: daniejaguerrero@hotmail.com

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size ≥20 mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPB), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to compare the efficacy of the newer 190 colonoscopes versus standard 180 colonoscopes for complete resection of lateral spreading lesions (LSL) ≥20 mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT) score in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscope series from 2010 to 2016. Lesions ≥20 mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p = 0.85). Adenoma size (p = 0.002) and concomitant need for supplemental APC (p < 0.001) were risk factors for recurrence. SERT > 0 lesions had a higher risk of recurrence during follow-up (OR 1.71; 95% CI 1.00–2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

P0234 WALLED-OFF NECROSIS (WON): OUTCOMES OF AN ALGORITHMIC APPROACH TO NECROSECTOMY
J.Y. Bang1, U. Navaneethan2, M. Hasan, R. Hawes, S. Varadarajulu3,4
1Center For Intervventional Endoscopy, Florida Hospital, Orlando/United States of America/FL
Contact E-mail Address: jybang213@gmail.com
Introduction: Endoscopic necrosectomy (EN) in walled-off necrosis (WON) is a labor intensive, high-risk, non-standardized technique that is associated with significant morbidity and mortality.
Aims & Methods: This study was intended to compare the clinical outcomes of patients with WON treated by conventional EN versus an algorithmic approach that is tailored to the extent and location of WON.
Results: This observational study included 45 consecutive patients with WON who had suboptimal treatment response to EUS-guided transluminal drainage and subsequently underwent necrosectomy. The conventional technique using a diagnostic or therapeutic gastroscope involved removal of necrotic debris using snares and/or forceps. In order to avoid frothing that obscures visibility, intra-procedural lavage of the necrotic cavity was performed using normal saline mixed with 120mg gentamicin and 2% hydrogen peroxide was reserved for sterilizing the cavity at the end of the procedure. The primary outcome measure was to compare the treatment success and number of reinterventions performed between the two groups. Treatment failure was defined as death from underlying disease or need for open surgical necrosectomy.
Results: Of the 45 WON patients, 23 were treated using conventional techniques and 22 using the algorithmic approach. Treatment success was significantly higher for patients treated using the algorithmic approach, 100% vs. 66.7%, p = 0.009. Of the 7 patients who had treatment failure in the conventional technique cohort, 6 required open necrosectomy and 1 died of multi-organ failure. The median number of reinterventions required to achieve treatment success was significantly lower for the algorithmic approach, 1 (IQR 1–2) vs. 2 (IQR 1–2), p = 0.003. Multivariable logistic regression analysis revealed that the algorithmic approach was the only variable associated with treatment success (OR = 0.64, p = 0.02) when adjusted for patient demographics, lab parameters and disease/WON characteristics.
Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

P0235 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE MANAGEMENT OF PANCREAS DIVISUM ASSOCIATED WITH RECURRENT ACUTE PANCREATITIS IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA
G. Cui, J. Yang, X. Tang, J. Yang, X. Zhang
Gastroenterology And Hepatology, Hangzhou First People’s Hospital, Hangzhou/China
Contact E-mail Address: zxl387@163.com
Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Most PD patients are asymptomatic, but a few may present with symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatic-type pain. It is imperative to treat PD associated with RAP as early as possible to prevent it from developing CP. Unfortunately, to date, most PD-related studies have been concentrated on adults. Researches of PD in children are rare.
Aims & Methods: To evaluate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERCP) for the treatment of pancreas divisum (PD) associated with recurrent acute pancreatitis (RAP) in children. We retrospectively analyzed patients of PD associated with RAP who were younger than 18 years old from January 2011 to December 2015 in our center. All the patients were diagnosed and treated with ERCP. Patients of complete PD associated with RAP underwent endoscopic sphincterotomy, papillary balloon dilatation and/or intraductal ultrasound sonography to remove all choledochal debris. Patients of incomplete PD underwent biliary stenting (ESCS). Patients of incomplete PD underwent biliary endoscopic sphincterotomy combined with dorsal duct stenting (Bi-ESCS). ERCP-related data, complications and other relevant data were collected. The time-long time follow up was conducted after removal of the dorsal duct stent, and then to observe children’s recovery, as well as their weight, growth and intelligence.
Results: A total of 227 pediatric ERCPs were performed for 117 pediatric patients during this period. Of which 24 were PD cases. The endoscopic detection rate of PD was 20.5%. Of the 24 patients, 12 were PD associated with RAP, among which 10 were complete PD and 2 were incomplete PD. A total of 21 therapeutic ERCPs were performed for these cases. All procedures were successful with 100% (21/21) of cannulation rate of the minor papilla. The mean interval of changing pancreatic dorsal duct stent is 3 months (from 2 to 6 months). ERCP-related complications were mild with a rate of 9.5% (2/21). One was acute mild pancreatitis and the other was hyperamylasemia, both of which were managed conservatively. During follow up from 15 to 74 months (mean 33.9 months), all patients had pain relief with a relief rate of 100%, of which 10 were asymptomatic with no longer onset of acute pancreatitis. During follow-up, there was no recurrence of PD-related symptoms in all children and all presented normal in weight, growth, intelligence.
Conclusion: The techniques of EESCS and Bi-ESCS under ERCP are safe and effective methods to manage PD associated with RAP in pediatric patients. It seems very vital for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP.

Introduction: Endoscopic biliary stenting is the treatment of choice in presence of malignant biliary obstruction (MBO), especially if palliative treatment. The role of endoscopic biliary sphincterotomy (EBS) before stent insertion is not clearly defined. The primary outcome of our meta-analysis was to assess the technical success of biliary (plastic or metal) stent insertion. Secondary outcomes included early complications within 30 days from ERCP and late complications which (from 30 days since ERCP).

Aims & Methods: We performed a literature search by using PubMed, SCOPUS, Google Scholar and the Cochrane Central Register of Clinical Trials (up to February 2017) using full-text studies assessing the efficacy and safety of biliary stent positioning, with and without EBS, in patients with MBO not suitable to surgery.

Results: 14 papers were assessed via full text for eligibility. 8 articles were included leaving 6 prospective studies (total of 711 patients). Technical success: The overall rate of biliary stent insertion was not significantly different: 384/392 patients (98%) in the no-EBS group versus 331/339 (97.6%) in the EBS arm (OR: 1.05, 95%CI: 0.42–2.63).

Early complications: The overall early AEs developed in 43.2% (11%) of patients without EBS versus 68.3% (20.1%) of patients who received EBS, with a significantly different OR (0.55; 95%CI: 0.33–0.92). Post-ERCP pancreatitis (PEP) was no significantly different in the two groups: 24/392 (6.2%) in the no-EBS group versus 17/339 (5%) in the EBS group (OR: 1.13; 95%CI: 0.63–2.09). The bleeding was significantly different in patients without EBS: 0/351 patients in no-EBS group versus 15/298 (5%) in the EBS group (OR: 0.09; 95%CI: 0.03–0.34). The rate of duodenal perforation was not significantly different between groups: 4/392 (1.0%) in the no-EBS group versus 4/420 (1.1%) in the EBS group (OR: 0.52; 95%CI: 0.29–0.97). Early cholangitis was significantly more frequent in patients who didn’t receive EBS: 13/392 (3.3%) patients in no-EBS group versus 5/298 (1.7%) subjects in the EBS group (OR: 0.38; 95%CI: 0.17–0.83). Early mortality rate was 0% in both groups. Late complications: No significantly difference occurred in the overall adverse events in the two groups: 50/251 patients (19.9%) in no-EBS group vs 38/201 subjects (18.9%) in the EBS group (OR: 0.93; 95%CI: 0.56–1.53). No significantly differences in stent occlusion (11.6% patients in no-EBS group vs 11.4% EBS group) were found. The efficiency of biliary stent migration (4% in no-EBS group vs 5.5% - OR: 0.81; 95%CI: 0.29–2.25). No significantly differences in late cholangitis (2.6% in no EBS vs 0% in EBS group - OR: 1.83; 95%CI: 0.17–19.85). Long-term mortality was not significantly different (2.55% in no-EBS group and 2.9% in the EBS arm - OR: 1.18; 95%CI: 0.42–3.29).

Conclusion: Our meta-analysis showed no significantly differences in technical success and in PEP. In consideration of the significantly increase of the overall AEs in the EBS group, and in particularity of the bleeding and cholangitis, the EBS seems not be recommended in patients not suitable to surgery undergone biliary stenting.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic ductal carcinoma (PD) is frequently asymptomatic, usually encountered in patients undergoing endoscopic retrograde cholangiopancreatography (ERC). Aims & Methods: The aim of this study was to investigate the association of PD with bile duct stones, biliary cannulation success and different types of PAD. A total of 1164 ERCP procedures were performed in 833 patients in a single center by single operator from January 2012 to October 2016 after excluding PD post liver transplant, emergency procedures. Out of 1164 ERCP procedure 49 patients were encountered with PD, they were compared with 635 controls without PD in terms of age, sex, CBD cannulation success and complications of ERCP.

Baseline characteristics and comparison of findings

Results: PAD identified in 49 (4.2%) cases, PAD type (1 inside the diverticulum) was found in 7 pts (14.3%), Type II at (edge/brim) in 34 pts (69.4%). Type II (adjacent to near diverticulum) was found in 8 pts (16.3%). Patients with PAD had mean age of 59.10 years (range 18 to 84 years) 17 were < 50 yrs while 32 > 50yrs, compared to controls mean age 52.74 yrs (range 12 to 95 yrs) 230 were < 50 yrs while remaining more than 50yrs. P-value < 0.05. PAD predominantly occurred in women, individuals aged >50 yrs. In 35 patients with PAD had increase prevalence of gallstone/biliary stone disease compared with controls, 71.4%vs 33.1% (p < 0.01) compared with controls. Easy cannulation of CBD without difficulty (PRECUT)/Pancreatic cannulation/stent- ing) was more frequent in patients controls (82.3%) compared to PAD group (75.5%) p < 0.05. However, CBD clearance was same in both groups>90% (p value not significant) Incidence of complications in PAD group bleeding (2%) Pancreatitis (2%) and one small retroduodenal perforation (2%) all managed conservatively. In without PAD group bleeding 0.6%, pancreatitis 0.7% and no perforation.

Conclusion: PAD is seen with advanced age, predominantly in female and frequently associated with bile duct stones. In this control study PAD did not appear to be a barrier for successful ERCP with acceptable complication rates.

P0239 COMPARISON OF DIGITAL VS FIBEROPTIC CHOLANGIOSCOPY IN PATIENTS REQUIRING EVALUATION OF BILE DUCT DISEASE OR TREATMENT OF BILIARY STONES

I. D. Dimas, E. Vardas, M. Fragkaki, A. Mpitouli, E. Voudoukis

Aims & Methods: The aim of the present study was to assess the frequency of digital cholangioscopy (DC) to alter the diagnosis and clinical management of bile duct disease compared with fiberoptic cholangioscopy (FC). A prospective review of 68 cases needing cholangioscopy, and which were performed in our department. Patients undergoing their first cholangioscopy or exhibiting stenosis of the biliary tract (67.6%), stones (20.6%), primary sclerosing cholangitis (PSC 4.4%) or other rare cause for cholangioscopy (e.g. stent migration, guidewire passage).

Results: 30 women and 38 men with a mean age of 61 years underwent cholangioscopy.

Introduction: Tokyo Guidelines 2013 (TG13) have been used worldwide to assess the diagnostic criteria and severity grading of acute cholangitis. Acute cholangitis is a life-threatening disease, and the emergency biliary drainage procedure is necessary for moderate or severe cases, according to TG13, with an aging society, necessity to perform endoscopic retrograde cholangiopancreatography (ERCP) in elderly patients is increasing. However, few studies have examined the efficacy and safety of emergency ERCP in super-elderly patients with severe cases.

Aims & Methods: In this study, we examined the efficacy and safety of emergency ERCP in super-elderly patients with moderate to severe acute cholangitis, according to TG13. We performed 178 emergency ERCP procedures in 132 patients during 3 years (June 2014–December 2016). We determined patients ≥90 years as “super-elderly” and those <90 years as “non-super-elderly.” Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERCP procedure (examination time, endoscopic biliary sphincterotomy (EST) pre-cut papillotomy, treatment success rate, presence or absence of peripapillary diverticula and papilla after EST, suture dosage), ERCP-related complications (bleeding, perforation, post-EST pancreatitis, ERCP pneumonia, death within 30 days after ERCP procedure), anesthesia-related complications (blood pressure decrease, pulse reduction, respiratory depression).

Results: We examined 69 males (52.3%) and 63 females (47.7%). Women accounted for a larger proportion in the super-elderly group (71% vs 40%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERCP procedures (moderate, 32; severe, 22) against 124 ERCP procedures (moderate, 104; severe, 20) in non-super-elderly group, and severe cases observed in the super-elderly group were statistically significant (p < 0.001). Regarding comorbidities, chronic heart and renal failure were statistically dominant in the super-elderly group. However, no difference was seen in the incidence of other diseases and receiving anticoagulant medication between the two groups. The causes of acute cholangitis were common in both groups with common bile duct stone (46% vs 46%), followed by malignant obstruction (9% vs 12%) and benign stenosis (0% vs 5%), but no difference was found.

Regarding the ERCP procedure, the examination time was longer in the super-elderly group (37.5 ± 28.1 min vs 29.2 ± 24.0 min, p = 0.044), but there was no difference in the procedure success rate (93% vs 97%, p = 0.249) and the presence of peripapillary diverticula. The patients were sedated using midazolam (MDZ) plus pentazocine (PTZ). The amount of anesthetic used was less in the super-elderly group (MDZ 2.2 ± 3.3 mg vs p < 0.001, PTZ: 3.1 ± 5.4 mg, p = 0.005). Regarding (i) ERCP-related and (ii) anesthesia-related complications, these were higher in the super-elderly group [(i) 15% vs 9%, p = 0.293; (ii) 17% vs 7%, p = 0.040]. Regarding (i) complications, the complication rate was highest in the super-elderly group (9% vs 0.1%), and cases observed in the super-elderly group were statistically significant (p < 0.001). Regarding comorbidities, chronic heart and renal failure were statistically dominant in the super-elderly group. However, no difference was seen in the incidence of other diseases and receiving anticoagulant medication between the two groups. The causes of acute cholangitis were common in both groups with common bile duct stone (46% vs 46%), followed by malignant obstruction (9% vs 12%) and benign stenosis (0% vs 5%), but no difference was found.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Dysplasia may persist at the termination of the common bile duct (CBD) after endoscopic ampullectomy. Radiofrequency ablation (RFA) could be an interesting alternative to surgery to reduce the risk of invasive cancer with less morbidity.

Aims & Methods: The aim of the study was to evaluate the efficacy and morbidity of endo-biliary RF for the treatment of residual endo-biliary dysplastic lesions after endoscopic ampullectomy. A prospective open-label multicenter study
included 20 patients with low-grade dysplasia (DBG) or high grade (DHG) lesion. The lesion was excised by a double-balloon enteroscopy. In relation to a residual adenomatous bud after endoscopic ampullectomy for ampullary adenoma, the lesions should extend to a maximum length of 20 mm in the CBD. Endoscopic retrograde cholangio-pancreatectomy (ERCP) was performed in the Harbour EndoHPB probe (EMcision, UK) (effect 8, power 10Watts, 30 s). Biopsy ± pancreatic stent were placed at the end of the procedure. The primary endpoint was the rate of residual neoplasia (eg, DBG, DHG or invasive carcinoma) at 1 year after treatment. Secondary endoscopic ampullectomy at 6 months after treatment; 2) rate of surgery at 12 months; 3) adverse events.

Results: The mean age (±SD) was 67 years (±11), with 12 men and 8 women. RFA was performed on average (±SD) 1.9 years (±3.5) after ampullectomy. The mean resected ampullary adenoma size (±SD) was 24.9 mm (±10.2), and 7 patients had adjacent ductal mucosectomy at the time of ampullectomy. The histology of the resected ampullary adenoma was DBG for 7 patients, DHG for 12 patients, and in situ carcinoma for 1 patient. Lateral margins were satisfactory in the invasive cases. DBG resections were diagnosed predominantly on ERCP and/or endoscopic ultrasonography surveillance procedures with an estimated mean infiltration height (±SD) of 11.2 mm (±4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radiopaque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had biliary stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DBG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients had angiostasis requiring biliary stent replacement. One patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At M12, one patient presented with a biliary stricture resolved by dilation and a calibration biliary stent.

Conclusion: Endoscopic RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

Introduction: Simulation-based training has become an important pillar in competence-based learning in medicine, especially in training novice endoscopists. Several simulators have been validated and implemented in training curricula pertaining gastrointestinal endoscopy. Surprisingly, limited data are available on simulators in ERCP training, despite the fact that ERCP seems to be an ideal task for simulation-based training due to its technical complexity. Available simulators are difficult to implement in training settings due to the lack of realism or use of live animals or ex-vivo components. Recently, the Boskoski-ideal platform for simulator-based training due to its technical complexity. Several simulators have been validated and implemented in training curricula for competence-based learning in medicine, especially in training novice endoscopists. ERCP was performed on 40 ERCP experts. All experts were men, originating from 16 different countries with a mean age of 49.6 years (range 37-65). The participating ERCP experts were gastroenterologists (92.5%), 3 participants were surgeons (7.5%). The mean number of years of endoscopic experience was 20.9 (range 10-40). Experts’ opinion on realism of performing a sphincterotomy was rated 6.98 on a ten-point Likert scale, resemblance of the performed maneuvers 7.60 and tactile feedback 6.78. When asked if the cutting was perceived as expected, experts rated 6.35 and the cutting result was rated 7.30 on a ten-point scale. The potential as a training tool of the cutting papilla in training novices was rated 3.93 on a four-point scale, and there was a high agreement among the experts to include the papilla in the training of novices (3.93 on a four-point scale).

Conclusion: This is the first mechanical papilla available for training sphincterotomy on the Boskoski-Costamagna ERCP Trainer and demonstrates good expert validation. ERCP experts highly agree and added value of this papilla in the training curriculum of novice endoscopists.

PO2423 MEDICO-LEGAL CLAIMS IN GASTROINTESTINAL ENDOSCOPY: DOES PROCEDURE RISK RELATE TO SUCCESSFUL OUTCOMES?

S. Budihal, J. F Mayberry

Dietetic Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Complications in endoscopy can lead to adverse clinical events. The likelihood of developing a complication depends on the degree of risk associated with a certain procedure. It is generally noted that riskier the procedure larger is the chance for a complication and higher the likelihood for medico legal issues. This is relevant as in the event of risk materialising, patients make seek legal redress. The aim of this study was to investigate the degree of success of medico legal claims based on the nature of the endoscopic procedure and the outcome of the claims.

Aims & Methods: The National Health Service Litigation Authority (NHSLA) database in U.K. was searched using a Freedom of Information request (F/2405) for all cases with ERCP and ERCP related medico legal claims notified to the NHSLA between 2010/11 and 2014/15. The terms "Gastroscopy", "Sigmoidoscopy", "Colonoscopy", "PEG" and "ERCP" were used to search the database. They were then analysed for procedure type, characteristics and outcomes. StatsDirect statistical software was used for statistical analysis.

OUTCOME OF ENDOSCOPY CLAIMS

<table>
<thead>
<tr>
<th>PROCEDURE</th>
<th>OPEN</th>
<th>SUCCESSFUL</th>
<th>UNSUCCESSFUL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gastroscopy</td>
<td>10</td>
<td>7</td>
<td></td>
</tr>
<tr>
<td>PEG</td>
<td>12</td>

<td>22</td>
<td>26</td>
<td>24</td>
</tr>
<tr>
<td>Colonoscopy</td>
<td>50</td>
<td>40</td>
<td>28</td>
</tr>
</tbody>
</table>

Results: A total of 291 claims were notified to the NHSLA during this period. 107 (36.7%) of claims still remain ‘open’. Analysing outcomes by procedures reveals a success rate of 44%, 44%, 37%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmoidoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used).

Conclusion: A significant number of claims remain open leading to concern and worry among endoscopists. The impact on practitioners after a successful claim is unknown and merits further investigation. Procedures considered as dangerous like ERCP and Colonoscopy have the least successful claims. It is imperative that clinicians remain vigilant. Performing Gastroscopy is dangerous and so is undertaking a Percutaneous Endoscopic Gastrostomy. Endoscopists should tighten their approach to all procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO244 VISUALIZATION OF INTRA-AMPULLARY CHOLEDOCHOCOELE WITH CONTRAST MEDIUM FOR EVALUATING TECHNICAL DIFFICULTY IN ERCP

N. Nishino

Gastroenterology Center, Southern Tohoku Hospital, Koriyama/Japan

Contact E-mail Address: nishinon@tim.hi-ho.ne.jp

Introduction: Cholecdochocele has been rarely recognized. We focus on intra-ampullary cholecdochocele (IAC). We had experienced some cases with IAC as refractory access to bile duct (BD). IAC has small cyst within ampulla regulated by Oddi’s sphincter, so the BD axis has changed via IAC. The cases with IAC would require a high technical skill for axis alignment or alternative strategy such as infundibulotomy or precut. We propose advantage of conventional ERCP (cERCP) with contrast medium, which provides images of IAC and leads to the current study.

Introduction: This study aims to recognize the morphology of intra-ampullary biferucation of bile duct (BD) and pancreatic duct (PD). Its variation allows the elucidation of the reason for difficulties in cannulation. The current study is a retrospective consecutive case study that is conducted in a single facility, with a study period of 8 years. Our strategy for ERCP was carried out with the contrast medium injected via a catheter, but without guide wire (GW) seeking. Intra-ampullary biferucation was particularly visualized with the contrast medium, and X-ray images were magnified sequentially 5-10 times each. The eligibility criteria were: it must be naive papilla and both of BD and PD must be visualized. The following factors were evaluated: ampulla shape, number of orifices, angle of IAC. The mean age of the claims was used for statistical analysis.
Results: There were cases of 1223 naïve papilla out of 2226 cases in total. The success rate to access BD with naïve papilla was 97.2% (1195/1223) and overall post-ERCP pancreatitis (PPE) was 1.3% (29/2226). The eligible patients were 908 (505 male and 403 female), among whom IAC was identified in 6.0% (54/908). The prevalence of IAC in the L/N, D and F types were 59.0% (48/82), 2.0% (0/0) and 7.0% (2/29), respectively. IAC was significantly higher in the L/N type (p < 0.01) and F type (p < 0.05) than in the D type. The choledochocoele shapes of Sp, Sh and Q were 59.3%, 13.0% and 27.8%, respectively. The average size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were 63.0% and 37.0%, respectively. Patients of IAC in Ah were found in L/N shape only. Patients of 53.7% (29/54) required GW placement on PD to access BD. IAC was alternat-ively seen on MRCP in 10% (3/30).

Conclusion: Choledochocoele is rarely seen even on cERCAP, in addition the visual-ization on cERCAP has been rarely reported. IAC could be actually visualized with prudent contrast medium injection. Our results showed miscellaneous variations in the intra-ampullary images. IAC would require refractory pursuit of the axis alignment due to its unexpected pathway within ampulla to access BD. Moreover 6.0% prevalence of IAC should not be ignored. IAC can be one of the factor of refractory cannulation. cERCAP with focus on ampulla could the difficulty in cannulation. On the other hand, WGC would not do. The previous randomized control trials showed no difference to access BD between WGC and cERCAP. However, both procedures still remained cases with refractory cannulation. It has been reported that refractory cannulation might cause PEP1). Therefore careful attention should be paid while passing through IAC to avoid PEP. According to ampulla shapes, especially of L/N and F, cERCP would be recommended to be performed. According to IAC in Ah, cERCP would not be recommended to access BD due to unexpected pathway within ampulla.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: The aim of this study was to evaluate the diagnostic efficacy of EUS-FNA for a pancreatic mass using the CB method without rapid on-site cytology retrospectively. A total of 206 patients with pancreatic masses (head: 87; body: 86; tail: 33) who underwent EUS-FNA using a GF-U1240P or GF-UL240P (Olympus Medical Systems LTD, Tokyo, Japan) between June 2005 and November 2016 were included in this study. The needles used were 22/25G needles. At least two passes were made during the procedure (mean 3.0 ±0.9 passes). Adequate specimens were regarded to be those in which whitish flag was macroscopically achieved. The samples were immediately fixed in 10% formalin and processed by the cell block method using sodium algin. Rapid on-site cytology was not performed. All samples were stained by hematoxylin and eosin, periodic acid Schiff and Azan-blue, and immunostaining for synaptophysin, chromogranin A, CD56. The final diagnosis was based on histological findings of surgically resected specimen, image diagnosis and clinical course for more than six months.

Results: The final diagnosis was malignancy in 184 patients (pancreatic ductal cancer (PDC), 171; neuroendocrine tumor (NET), 7; malignant lymphoma, 2; metastasis of malignant melanoma, 1; solid pseudopapillary neoplasm, 1), and benignity in 23 patients (autoimmune pancreatitis (AIP), 11; chronic pancreatitis, 7; organizing pancreatic pseudocyst, 4; IPMN, 1). Adequate tissue sampling was successfully achieved in 197/199 (99.5%). Of 199 patients with successful tissue sampling, sensitivity, specificity and accuracy for malignancy were 98% (175/179), 95% (19/20) and 97% (194/199). The diagnostic accuracy of PDC only by HE staining was 97% (129/137) (Class V 97; IV 4; III 6; II 2), and by adding immunohistochemical staining, the accuracy of PDC was 98% (167/170) (Class V 112; IV 6; III 5; II 2). In the cases of highly suspicious NET, all samples were stained by chromogranin A and synaptophysin and the diagnostic accuracy of NET was 100% (6/6). No procedure-related complications occurred.

Conclusion: EUS-FNA of a pancreatic mass with the CB method without rapid on-site cytology showed high accuracy for definitive diagnosis.

P0250 A COMPARATIVE STUDY BETWEEN EUS-GUIDED BILIARY DRAINAGE AND PERCUTANEOUS BILIARY DRAINAGE IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION AND FAILED ERCP

Department Of Gastroenterology, Hangzhou First People’s Hospital, Hangzhou, China

Contact E-mail Address: zacharylu@126.com

Introduction: Patients with malignant biliary obstruction conventionally undergo percutaneous transhepatic biliary drainage (PTBD) after failed endoscopic retrograde cholangiopancreatography (ERCP) (1). While PTBD is effective, it is associated with significant morbidity, such as bile leakage, bleeding, and pneumothorax, and involves uncomfortable external drainage (2). Endoscopic ultrasound-guided biliary drainage (EUS-BD) is a minimally invasive endoscopic procedure increasingly offered for malignant biliary obstruction after failed ERCP (3). Although a recent meta-analysis reported better clinical efficacy and superior safety of EUS-BD when compared to PTBD (4), no prospective randomized comparison has been performed. Aims & Methods: We aimed to compare efficacy and safety of EUS-BD to PTBD in patients with malignant biliary obstruction after failed ERCP at a single tertiary referral center from mainland China. From November 2011 through December 2015, consecutive patients undergoing EUS-BD or PTBD for malignant biliary obstruction after failed ERCP were included. Demographical, biochemical, and outcome data were registered for each group. The primary outcomes included technical success rate and incidence of complications, the secondary outcomes were clinical success rates and re-intervention rate.

Results: A total of 93 patients (mean age 68 ±13.5 years, 49 males) were included, 33 in the EUS-BD group and 60 in the PTBD group. Both groups were similar in terms of age, gender, baseline bilirubin and functional status. Technical success was achieved in 32 (97%) of 33 patients in the EUS-BD group and in 57 (95%) of 60 patients (p > 0.05) in the PTBD group. The clinical success (jaundice relief: reduction in serum bilirubin by 50% within the first month) was achieved in all patients with technical success (32/32, 100% EUS-BD vs. 57/57, 100% PTBD). Procedure-related complication rates were higher in the PTBD group (18/57, 31.6%; 5 bleeding, 5 catheter site infection, 4 bile leaks, 2 cholangitis, and 2 tube malposition) than in the EUS-BD group (3/32, 9.4%; 2 bleeding and 1 cholangitis) (p = 0.018). Rate of re-intervention appeared to be lower in the EUS-BD group (3/32, 9.4%; 2 bleeding and 1 cholangitis) compared to the PTBD group (17/57, 29.8%; 6 stent occlusion, 5 catheter site infection, 4 bile leaks, and 2 tube malposition) (p = 0.009).

Conclusion: Despite similar high technical and clinical success rates compared with PTBD, EUS-BD was associated with reduced rate of complications, reduced rate of re-interventions. EUS-BD seems to be a better alternative than PTBD for malignant biliary obstruction after failed ERCP. Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Although lumen-apposing metal stents (LAMS) are being increasingly used for drainage of walled-off necrosis (WON), their advantage over plastic stents is unclear.

Aims & Methods: We aimed to compare the efficacy of LAMS and plastic stents for drainage of WON.

Symptomatic patients with WON (>20% necrosis) were randomized to undergo transmural drainage using LAMS (Hot AXIOMS, 15 mm × 10 mm) or two double pigtail plastic stents (7 Fr × 4 cm). Reintervention in persistently symptomatic patients included additional stent placement, percutaneous drainage and/or endoscopic necroscopy. Treatment success was defined as symptom relief in conjunction with resolution of WON on CT at 6-week follow-up. Main outcome measure was to compare the number of reinterventions. Secondary outcome measures were to compare treatment success, procedural duration, resolution of systemic inflammatory response syndrome (SIRS), clinical and stent-related adverse events, readmissions and length of hospital stay. Sample size to detect a difference of 1 in the no. of reinterventions performed at 90% power was calculated at 56 patients.

Results: 60 patients were randomized to LAMS (n = 31) or plastic stent (n = 29) placement. While there was no significant difference in the no. of reinterventions (median 1 [IQR 1–2] for both stent types, p = 0.78), the procedural duration was significantly shorter (15 vs. 42.5 mins, p < 0.001) and stent-related adverse event rate was significantly higher with LAMS placement (32.3 vs. 6.9%, p = 0.02). At an interim audit, significant adverse events (delayed bleeding [n = 3], buried stent [n = 2], biliary stricture [n = 3]) were observed in the LAMS cohort after 3 weeks post-intervention. This necessitated an amendment to the study protocol whereby a CT scan was obtained at 3 weeks following LAMS removal if the WON had resolved. After protocol amendment, no difference in stent-related adverse events was observed between the cohorts (LAMS 6.5 vs. plastic 6.9%, p = 0.90). Also, there was no significant difference in treatment success, SIRS resolution, clinical adverse events, readmissions or length of hospital stay between the cohorts (Table).

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

P0251 A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOLOGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MassES
P.N. Desai, M. Kabrawala
Endoscopy, Surat Institute Of Digestive Sciences, Surat/India
Contact E-mail Address: dp.desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used uptill now and also intraductal biopsies were used. The yield are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used uptill now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these masses and comparing it to ERCP guided brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for diagnosing tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we followed first - EUS was done using a linear echoendoscope, mass identified and FNA performed with a 25 G needle making 2 to 5 passes and material sent for cytology. Same patients subjected to ERCP. A wide papilotomy was performed and over the wire cytology brush was used and brush cytology was obtained. Two passes were made and material taken on a slide and sent for cytology after wet fixation.

Results: Total number of cases 56 Age (range) 57.2 ± 13.6 Male to Female 40: 16 Total Serum Bilirubin 90 mg/dl) 5.9

Conclusion: EUS FNA is a very effective method for diagnosis of distal bile duct masses with a diagnosis in almost 81% and a suspicious diagnosis in around 11% cases. Its efficacy is better than ERCP guided brush cytology. Even small masses are amenable to FNA using EUS guidance. Male over 57 years with jaundice and distal bile duct obstruction has a very likelyhood of have a distal CBD cholangiocarcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0253 TRANS AORTIC ENDOSCOPIC ULTRASOUND GUIDED FNA IN THE DIAGNOSIS OF LUNG CANCERS AND MEDIASTINAL LYMPH NODES
P. Somani, M. Sharma
Department Of Gastroenterology, Jswani Rai Speciality Hospital, Meerut/India
Contact E-mail Address: dr pijushsomani@yahoo.co.in

Introduction: Obtaining a tissue diagnosis from a lung tumour or a mediastinal lymph node provides an excellent medium to transfer ultrasound waves. Aortic arch and lateral to the descending aorta are difficult to access. Lymph nodes on the ‘far-side’ of major blood vessels can be visualized by endoscopic ultrasound (EUS), and may provide excellent medium for delivery of tumour cytopathology. Obtaining a tissue diagnosis from lymph nodes which are difficult to access may lead to erroneous diagnosis and planning of treatment.

Aims & Methods: The feasibility and safety of the trans aortic endoscopic ultrasound guided fine needle aspiration (EUS-GUIDED FNA) of lymph nodes on the ‘far-side’ of major blood vessels using a newly designed trans-aortic endoscopic ultrasound probe with a needle sheath is assessed.

Methods: The study included patients who had biopsy proved lung cancers or underwent video-assisted thoracoscopic surgery. EUS-GUIDED FNA of lymph nodes on the ‘far-side’ of major blood vessels were performed after an interim audit. Significant adverse events (delayed bleeding [n = 3], buried stent [n = 2], biliary stricture [n = 3]) were observed in the LAMS cohort after 3 weeks post-intervention. This necessitated an amendment to the study protocol whereby a CT scan was obtained at 3 weeks following LAMS removal if the WON had resolved. After protocol amendment, no difference in stent-related adverse events was observed between the cohorts (LAMS 6.5 vs. plastic 6.9%, p = 0.90). Also, there was no significant difference in treatment success, SIRS resolution, clinical adverse events, readmissions or length of hospital stay between the cohorts (Table).

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

A248 United European Gastroenterology Journal 5(5S)
Aims & Methods: We aimed to evaluate the feasibility, yield, and safety of EUS-guided drainage of lung tumors and pancreatic fluid collections.

We undertook a retrospective case series of 12 consecutive patients with suspected lung cancer or tuberculosis who underwent transaortical FNA during a study period of 7 years. In all cases, the para-aortal lesion was the only site suspicious for malignancy (other lesion/lymph node if present were negative). Based on CT/PET imaging, a transesophageal FNA performed through the aorta was considered as the only option to diagnose or stage these patients by means of a minimally invasive procedure. Seven patients had left-sided lesions, four patients had right-sided lesions, and one presented with both left and right thoracic lesions. Four patients have enlarged para-aortic lymph nodes (mean size 18 mm, range 8–22 mm), suspicious for IASLC stations 5n (n=1) and 6n (n=3). One patient had anterior mediastinum mass. EUS was performed with a linear echoendoscope. All aspirations were obtained under real-time US guided FNA by using a 22/25-gauge needle. A single real-time FNA of the left lung or mass lymph node was performed. The para-aortal area was observed on EUS for 5 minutes to assess for immediate procedure-related complications.

Results: The final diagnosis was known in 11 patients (5 non-small-cell lung carcinoma [NSCLC], 2 small-cell lung carcinoma [SCLC], 3 tuberculosis and one thymolipoma). EUS-FNA established diagnosis in 9 of 12 patients (75%) (4 NSCLC, 1 SCLC, 3 tuberculosis and 1 thymolipoma). One aspirate revealed reactive nodal tissue, and one demonstrated nonrepresentative material. One procedure was abandoned due to complication. Three patients in whom diagno- sis was established by transaortical FNA underwent subsequent surgical staging (1 thoracotomy, 1 mediastinotomy, and 1 VATS), and malignancy was found in 2 of the 3 patients. Trans aort FNA was found to be safe. In one patient, EUS images after FNA were suspicious for a small para-aortica hema-toma. This patient recovered without any adverse event.

Conclusion: Demonstrates the feasibility and probable safety of single EUS guided transaortical aspiration in para-aortic lesions. The diagnostic yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure includes day care procedure, less invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transaort FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact Email Address: marcoocositasia87@gmail.com

Introduction: Ultrasound-guided transaortical drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPSS) requires placement of multiple stents and can be restricted by inadequate drainage and risk leakage. Recently, the use of fully covered self-expanding metal stents (FCSEMSs) has been reported as an effective alternative.

Aims & Methods: We aimed to evaluate the successful placement of stents, the diagnostic yield and the yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure includes day care procedure, less invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transaort FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Histological examinations and immunohistochemical stains (IHC) are necessary for the differential diagnosis of gastrointestinal subepithelial lesions (SELS). Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is the primary modality in the diagnostic of SELS, but still has limited accuracy. A new 20 gauge (G) biopsy needle with a core-trap technology (EchoTip ProCore®, Cook Medical) has been developed with a large core size and enhanced flexibility.

Aims & Methods: The aim of this multicenter study was to determine the feasibility, efficacy and safety of EUS-FNB with the new 20G needle in diagnosing SELs. Data retrieved from a prospectively collected database at five medical centers were analyzed and all consecutive patients with SELs undergoing EUS-FNB with the 20G needle were included in the present study. The reference standards for the final diagnosis were histology on surgical specimen or clinical follow-up.

Results: A total of 50 SELs in 50 patients (22 males, mean age 61.5 ± 14.8 years) were included. The mean lesion size was 43.1 ± 17.5 mm. The lesion locations were esophagus (n=1), stomach (n=37), distal duodenum (n=5), rectum (n=6), and colon (n=1). The procedure was technically feasible in all patients. Multimodality of passes ranged from 1 to 14. A definitive diagnosis with full histological assessment including IHC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36 (72%) malignant SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinosarcoma), 17 (34%) benign SELs (3 leiomyomas, 7 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95% CI 70.2–94.3), 100% (95% CI 58.7–100), 100% (95% CI 85.1–100), and 62.5% (95% CI 27.7–84), respectively. No major complications requiring additional care were observed.

Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G needle core is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-approach anatomical locations. Comparative studies with different needle sizes are awaited.

Endoscopic Ultrasound-Guided (EUS)-guided ethanol ablation for pancreatic cystic lesions

1Department Of Internal Medicine And Liver Research Institute, Seoul National University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: pseudo.jh@gmail.com

Introduction: EUS-guided ethanol injection (EUS)-guided ethanol ablation for pancreatic cystic lesions (PCLs) is a recently introduced treatment option for PCLs. The aim of this study was to compare the clinical outcomes of EUS-guided ethanol ablation with those of the natural course of PCLs.

Aims & Methods: We performed retrospective study of patients with PCLs divided in two groups: EUS-guided ethanol ablation group (n = 118, performed between June 2006 to August 2015) and natural course group (n = 458, diagnosed between January 1993 to August 2015). The propensity score-matching analysis
between the two groups was applied in order to minimize the effect of selection bias. The success rate of reaching the biliary anastomosis was the rate of significant reduction in size (≥20% of initial size). The secondary outcomes were the rate of significant growth in size (>10 mm), complete remission rate, and surgical resection rate.

Results: In a propensity matched analysis of 88 pairs, the mean initial cystic size of EUS-guided ethanol ablation group and non-cirrhosis group was 23.72 ± 10.99, 23.15 ± 13.15 mm and the mean follow-up duration was 75.45 ± 38.12, 82.12 ± 59.06 months respectively. Significant reduction in size was detected in 53 (60.2%) of the EUS-guided ethanol ablation group and 17 (18.5%) of the control group (p = 0.023). Significant growth in size was detected in 6 (8.9%) of ablation group and 11 (12.5%) of natural course group. (p = 0.202). Seven patients (7.95%) underwent surgical resection in the EUS-guided ethanol ablation group and 17 patients (19.3%) in the natural control group (p = 0.028) during follow-up. Overall 28.8% patients (34 of 118) who underwent EUS-guided ethanol ablation had achieved the complete remission.

Conclusion: PCLs that underwent EUS-guided ethanol ablation can be seen the likelihood of getting clinical benefits such as reduction of the cystic size, the clarity in decision making for ablative treatment compared to the natural course of them. It is also expected to achieve a certain level of complete remission for PCLs.

Introduction: Liver tumors such as hepatocellular carcinoma and liver metastases sometimes occur in positions in which treatment using percutaneous radiofrequency ablation (RFA) is difficult, such as the caudate lobe and surface of the left lobe. EUS-guided RFA (EUSRATM) can offer an alternative treatment by accessing these tumors through the stomach or duodenum. To the best of our knowledge, only one report has described EUS-RFA of the liver in an animal model, using a 19-gauge EUS-FNA needle with an umbrella-shaped array at the liver edge.

Aims & Methods: We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. EUS guided needle (19-gauge needle) and a VIVA combo™ generator (TaeWoong Medical, Gimpso, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-, and 20-mm exposed tips) were used. After the echoendoscope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at 45–50 W for 2–6 min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrant lobe of the gallbladder through the bulb of the duodenum.

Results: All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect were evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

Conclusion: In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

Introduction: Small bowel varices (SBV) occur as a consequence of portal hypertension and may result in life-threatening mid-gut bleeding. First line management usually involves radiological intervention (RI) (e.g. TIPSS, stenting of occluded mesenteric veins +/- embolisation of culprit varices). In cases where RI is impossible, management options become very limited.

Aims & Methods: This case series evaluated the usefulness of DBE facilitated cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV at our institution (December 2015 to August 2016). Demographic, clinical, endoscopic and radiological findings, interventions and follow-up data were analysed.

Results: Seven DBEs were performed in 5 patients (3 women, median age: 73-years). Four patients had previous surgery (hepaticojejunostomy or Roux-en-Y bypass), 3 patients had a history of infra-abdominal sepsis in childhood causing portal vein thrombosis. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase CT mesenteric angiography. At DBE, a total of 10 nests of SBV were identified.
and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications. A lesion developed an appearance of a congenital arterial cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route and 1 patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for treading of further patent proximal SBV. At 30-day follow-up post-thrapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options are not feasible.

2Gastroenterology And Hepatology, Tokyo Medical and Dental University, Tokyo/Japan

Contact E-mail Address: n.ogata@hotmail.co.jp

Introduction: The development of balloon endoscopy and capsule endoscopy has markedly improved the assessment of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with 80x magnification has been recently developed.

Aim & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal crohn’s disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to February 2015. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo). Magnifying NBI was performed, and the images were evaluated by assessing visibility, increased vascularization, and the increased caliber of capillaries into three grades as follows: Normal, Visible and Irregular. Normal was indicative of inactive disease, while Visible and Irregular were indicative of acute inflammation in our study. The outcome measures included the diagnostic ability of magnifying NBI findings to distinguish active CD from inactive CD on the basis of histological activity.

Results: Twenty-four patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman’s r = 0.54, p<0.05). Visibility, specificity, positive predictive value, negative predictive value, and accuracy of magnifying NBI findings for diagnosing acute inflammation were 88.2%, 71.4%, 88.2%, 71.4%, and 83.3%, respectively.

Conclusion: The NBI magnifying findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0262 SINGLE-INCISION LAPAROSCOPIC-ASSISTED DOUBLE BALLOON ENTEROSCOPY: A NOVEL TECHNIQUE TO MANAGE SMALL BOWEL PATHOLOGY

Introduction: Double balloon enteroscopy (DBE) has revolutionised the diagnosis and treatment of small intestinal conditions. However, in expert hands, deep small bowel (SB) insertion can be challenging, especially in patients with a history of abdominal/pelvic surgery. Moreover, if the findings at DBE are not amenable to endoscopic therapy, a further surgical procedure is usually required to provide definitive treatment. Laparoscopic-assisted DBE (LA-DBE) using a standard enteroscopist is an option that can be applied for the management of a range of small bowel pathology. A SILS approach allows all therapeutic modalities to be available as needed during the procedure, including conversion to IOE, laparoscopic small bowel resection and laparotomy.

P0263 GASTRIC EMPTYING IN CROHN’S DISEASE – EVALUATION BY SMALL BOWEL CAPSULE ENDOSCOPY

A.M. Singeap1, A. Trifan1, S. Chirila1, I. Girlea2, T. Cucureanu3, C. Stanciu2
1Gastroenterology, “Grigore T. Popa” University of Medicine and Pharmacy, Iasi/Romania
2Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: anamaria.singeap@yahoo.com

Introduction: The complex relationship between inflammatory bowel disease (IBD) and motility disorders of the digestive tract is a complex area of study, so far incompletely elucidated. The association between Crohn’s disease and gastric emptying time modification has been relatively less studied. However, there is no single standardized method to study gastric emptying, one particular investigation that could bring direct information in this field being the small bowel capsule endoscopy (SBCE).

Aims & Methods: We aimed to study gastric emptying by small bowel capsule endoscopy in patients with suspected and confirmed Crohn’s disease. We evaluated gastric passage time showed by SBCE in patients with small bowel Crohn’s disease, compared to patients without IBD, investigated by SBCE (PillCam), following recognized indications, in the Institute of Gastroenterology and Hepatology of Iasi, tertiary center in North-East of Romania.

Results: 144 SBCE studies were included, 24 were cases of suspected and confirmed Crohn’s disease. The mean time of gastric passage in patients with Crohn’s disease was 51±21.9 minutes, longer than in patients without inflammatory bowel disease, in which the mean gastric passage time was 24±16.6 minutes.

Conclusion: Gastric passage time, evaluated by SBCE, is prolonged in patients with Crohn’s disease compared to patients without IBD, suggesting a relationship between chronic inflammation and gastric motor disorders. Globally, the values correlated with those considered as physiological by other exploration methods. SBCE studies may provide additional data on gastric motility (and in general gut motor disorders), with special usefulness in some individual cases, as particular symptoms or variations in the bioavailability of small bowel released drugs.

Contact E-mail Address: ktiriant@med.uoa.gr

Introduction: The value of purgative preparation (PBP) before small bowel video capsule endoscopy (VCE) remains controversial and it has been recently challenged.

Aims & Methods: The aim of this meta-analysis was to examine the effect of PBP on small bowel VCE outcomes. We performed literature searches in MEDLINE and Cochrane Library to identify randomized-controlled trials (RCTs) evaluating the effect of small bowel preparation –purgative (PEG, sodium phosphate,
## P0265 INTER-OBSERVER AGREEMENT IN BROTZ CLEANING SCALES FOR CAPSULE ENDOSCOPY

**Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal**

**Contact E-mail Address:** malcuda.m_p_sousa@hotmail.com

### Introduction:

The diagnostic yield of capsule endoscopy (CE) depends on the adequate visualization of the mucosa. As with colonoscopy, cleaning scales should be described in the report in order to better interpret results. In 2009, Brote et al proposed and validated 3 different cleansing scales in 40 patients.

### Aims & Methods:

A hundred CE videos (Mirocam®) were reviewed by 2 authors at a fixed frame rate of 100 frames per second in quadruple view (Miroview Client). The CE were evaluated according to Brotz scales: (1) Overall adequacy assessment (adequate/inadequate) (2) Qualitative scale (excellent, good, fair, poor) and (3) Quantitative scale (0-10 score, graded from 0-2 visualization of the mucosa, fluids, bubbles, bire and luminosity). The aim of this study was to evaluate the inter-observer variability of this cleaning scales. The kappa coefficient was used to calculate the inter-observer agreement in overall adequacy assessment and the intra-class correlation coefficient was used to evaluate the concordance of the qualitative and quantitative scales.

### Results:

In overall adequacy assessment, the quality of bowel preparation was classified as adequate by observer 1 in 100% and by observer 2 in 73%, with an inter-observer kappa index of 0.76 (p < 0.001) suggesting strong agreement. In the qualitative scale, most of the bowel preparations were considered reasonable (40% observer 1 vs 36% observer 2), with an intra-class coefficient of 0.89 (p < 0.001). In the quantitative scale, the mean score of the two observers was 6.5 and 6.7, resulting in an intra-class agreement of 0.78 (p < 0.001).

### Conclusion:

The optimization of quality of bowel preparation and the diagnostic yield of the CE requires, first, a well-validated cleaning scale. Brotz’s rating scales have strong inter-observer agreement. The quantitative scale is easier to apply and has better inter-observer agreement, so the authors propose that it should be used routinely in the CE report.

### Reference

Brote C, Nandi N, Conn M et al. A validation study of 3 grading systems to evaluate small-bowel cleansing for wireless capsule endoscopy. This pilot study shows that image quality is a defining factor in accurate diagnosis in CE. Image quality is commonly affected by the opacity of luminal fluid/residue, and the quality of imaging delivered by the CE system. More subtle mucosal lesions such as aphthae are affected more by decreased contrast. Interestingly, a relatively high level of image opacity can be tolerated by CE readers whereas blurriness seems to have a greater effect on visualisation quality and reviewer confidence in the diagnosis. The effects of these aspects in combination merit further investigation.

### Introduction:

Capsule endoscopy (CE) is the prime mode of investigation for small bowel (SB) pathology. However, as an entirely visual medium it depends heavily on image quality. The definition of optimal image quality remains undetermined between studies and poses significant limitations to the quality of study reporting. As yet, there is no widely-accepted or integrated method for scoring SB cleanliness during CE reporting. This pilot study aims to quantify the image properties contributing to adequate visualisation quality in CE images.

### Aims & Methods:

Five clear images of SB pathology were obtained using MiroCam® (Intromedic, South Korea), image resolution 320×320 pixels (px): P1 and P2 angioectasias, ulcer, aphtha and polyp. Each image was processed using GIMP2 image editing software (www.gimp.org) for 3 parameters: (1) opacity (opacity filter matched in colour to commonly-seen SB contents, 10-90% in 10% increments), (2) blur (Gaussian blur, radius 1–10px), (3) contrast (-50% to 50% in 10% increments). Gaussian blur was used to simulate the effects of rapid capsule movement as well as to affect image definition. A set of 5 original and 190 edited images was obtained. A web-based survey was created using Google Forms and 9 expert CE readers were asked to indicate whether each image was adequate or not for diagnosis. The order of images was randomised for each reader. For each type of pathology, we determined the threshold of image quality and contrast that was deemed adequate for diagnosis.

### Results:

For image opacity, both aphthae and the polyloid lesion were adequately visualised below 40% opacity whereas the threshold was lower for both the ulcer and aphtha (10% opacity). Increasing blur radius significantly impacted the acceptability of images for reaching a diagnosis with confidence; for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at ±10% contrast. Results are detailed in the table below.

Introduction: Chronic bowel diseases (IBDs) are chronic inflammatory diseases that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic evaluation of these parts is essential to assess disease extent and severity. The small bowel capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

Aims & Methods: The aim was to evaluate SBC-CE system functionality in suspected or established IBD (Crohn’s disease [CD] and Ulcerative Colitis [UC]) patients. This was a prospective 5 center feasibility study assessing the performance of the capsule and software. Subjects enrolled in the study were instructed the new capsule after standard bowel preparation plus boosts. Contraindications for its use include obstruction, dysphagia or swallowing disorders, pacemakers etc. GI patency was assured using the patency capsule. The performance of 50 points were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events.

Results: Of 50 patients (54 were enrolled and 49 ingested the capsule (14 patency failure, 5 withdrew consent). Mean age was 40.1 years, 51% were males. 69% of patients had established CD, 10% UC and 21% suspected CD. The disease was active in 62% of known IBD patients. One patient who underwent extensive colon resection was excluded from all colon analyses. Overall cleansing was regarded good or excellent in 96% of patients. All 49 underwent extensive colon resection was excluded from all colon analyses. 68 patients were screened, of which 54 were enrolled and 49 ingested the capsule. The primary endpoint was successful procedure in terms of video creation and report generation in accordance to the video reading methodology. Secondary endpoints were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events.

Conclusion: The small bowel capsule endoscopy (SBC-CE) system was successful in 92% of patients. The system was easy to use, especially for patients with severe impairment of small bowel motility. The new SBC capsule is a friendly, minimally invasive capsule allowing complete evaluation of the entire gut of IBD patients. The system may be used to assess disease severity and extent and for follow up of IBD patients.

P0268 THE UTILITY OF A NOVEL TRANSPAPILLARY DILATION TECHNIQUE WITH A DIATHERMIC CATHETER FOR SEVERE MAIN PANCREATIC DUCT STRicture DUE TO CHRONIC PANCREATITIS

S. Kato, M. Kuwatsuni, R. Sugiyari, I. Sano, K. Kawakubo, N. Sakamoto

Gastroenterology And Hepatology, Hokkaido University Hospital, Sapporo/Japan

Contact E-mail Address: shinchan1231@gmail.com

Introduction: Transepipillary biliary drainage for severe main pancreatic duct (MPD) stricture is sometimes difficult and diathermic dilation is now getting attention as a salvage technique for severe stricture; however its efficacy and safety remains unclear.

Aims & Methods: To evaluate the efficacy and safety of a novel transpapillary dilation technique with a diathermic catheter for severe MPD stricture due to chronic pancreatitis. Between April 2011 and March 2017, 143 patients with chronic pancreatitis underwent endoscopic transpapillary stent placement for MPD. MPD dilatation was indicated in 18 patients, and diathermic dilation was required in nine patients. We evaluated (1) the patients’ characteristics, (2) procedure characteristics, (3) clinical outcomes, (4) adverse events.

Results: (1) Six patients were men and three were women (mean age, 50.1 years). Alcohol abuse, unknown 1. The strictures were in the head of pancreas: 8, body: 1, tail: 7. The mean length of stricture was: 20.2 mm (range, 10.8–30.8). The mean MPD diameter was the distal side of stricture was 6.2 mm (range, 5.5–6.6). Stenting for chronic pancreatitis was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). RBO occurred in 1 patient with severe stricture (55.6%) among them had no former procedure for MPD including stenting. (2) A wire-guided 6Fr diathermic catheter with 30 W power was used for all cases. All cases underwent diathermic dilation as salvage procedure subsequent to conventional dilation. One to 7 diathermy procedures (mean 2.9) were applied to pass through each stricture. (3) Passage of the diathermic catheter and stent placement was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). RBO occurred in 1 patient with severe stricture (55.6%) among them had no former procedure for MPD including stenting. (2) Two adverse events (22.2%) were observed and both of them were mild pancreatitis. Multiple diathermy procedures (6 times and 4 times, respectively) and relatively long duration of total dilation time (39 sec. and 25 sec. respectively) were observed in cases with pancreatitis.

Conclusion: Transpapillary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. Care should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO270 OUTCOME OF ENDOSCOPIC REINTERVENTION FOR MALIGNANT BILIARY OBSTRUCTION TREATED BY STENT-IN-STEM DEPLOYMENT

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of Korea

Contact E-mail Address: subsupul@naver.com

Introduction: Endoscopic biliary decompression is widely used for advanced hilar cholangiocarcinoma. Bilateral stenting has become more feasible with more experienced endoscopists and the development of new devices. However, stent dysfunction develops in 3% to 45% because of tumor ingrowth, overgrowth, or debris as disease progresses. Endoscopic reintervention is difficult and complex with worsening bile duct strictures. The present study aimed to evaluate a suitable reintervention procedure for stent malfunction after stent-in-stent (SIS) deployment for malignant hilar obstruction.

Aims & Methods: From September 2009 to June 2016, a total of 52 patients who underwent SIS stenting at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

Results: Technical and functional success rates of endoscopic reintervention were 83.3% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) andivor conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO271 LONG-TERM OUTCOMES OF ENDOSCOPIC ULTRASOUND-GUIDED RIGHT INTRAHEPATIC DUCT DRAINAGE WITH TRANSMURAL COVERED METAL STENT

Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of Korea

Contact E-mail Address: dhcho81@daum.net

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been regarded as an effective alternative in cases of endoscopic retrograde cholangiopancreatography (ERCP) failure or inaccessible papilla. However, EUS-BD for right intrahepatic duct obstruction (EUS-BDR) remains challenging, although recent studies showed promising result. The aim of current study was to evaluate the feasibility and long-term outcomes of EUS-BD with transmural coved metal stents for right intrahepatic duct obstruction.

Aims & Methods: Retrospective study, a total of 24 consecutive patients who underwent EUS-BDR after failed ERCP were enrolled. The patients were consisted of 12 cases of benign strictures and 12 cases of malignant strictures. The biliary stents used in this study was covered metal stent with anchoring flaps. The rate of adverse events tended to be higher in Group A than in Group B (26.1% vs 13.5%, p = 0.10). The re-intervention rate tended to be higher in Group A than in Group B (16.7% vs 8.1%, p = 0.25). Groups A and B did not differ significantly in terms of median overall patient survival (75 days vs. 70 days, p = 0.70), and median time to stent dysfunction or patient death (68 vs 63 days, p = 0.08) In patients who underwent chemotherapy, there were no difference in the overall patient survival time (121 vs 137 days, p = 0.08) between the two groups although the time to stent dysfunction or patient death was significantly shorter in Group A than in Group B (71 vs 95 days, p = 0.02).

Conclusion: Technical success rate of HGS with AGS was lower than HGS, although HGS with AGS is superior to HGS in terms of stent patency in patients undergoing chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO272 UTILITY OF EUS-GUIDED HEPATICOGASTROSTOMY WITH ANTEGRADE STENTING FOR MALIGNANT BILIARY OBSTRUCTION OF ERCP INABILITY

H. Imai, M. Takenaka, M. Kudo

Gastroenterology And Hepatology, Kindai University, Osaka/Kyayama/Japan

Contact E-mail Address: codenamenchan1023@gmail.com

Introduction: Recently, EUS-guided biliary drainage (EUS-BD) techniques such as endoscopic cholecystostomy (EUS-GBD) have become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-BD with conventional percutaneous cholecystostomy.

Aims & Methods: This is a single-center, retrospective study to investigate long-term outcomes of EUS-BD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-BD for acute cholecystitis is obtained from prospective collected EUS database in HGS institute. In percutaneous cholecystostomy, electronic medical record of patients who underwent percutaneous cholecystostomy was reviewed and analyzed. Demographics and procedure related outcomes including early, late adverse events and need for re-intervention in each group was compared. Results: A total of 181 patients (74 in EUS-GBD group and 107 in percutaneous cholecystostomy group) were enrolled in this study. The cause of cholecystitis and ASA class were similar in both groups. The technical/clinical success rate was 100%/98.6% in EUS-GBD group and 99.1%/97.2% in percutaneous cholecystostomy group (P = 0.591 for technical success and 0.70 for clinical success). Early adverse events were also similar between two groups (6.8% in EUS-GBD group vs. 15.0% in percutaneous cholecystostomy group, P = 0.103). However, late adverse events including migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis was more frequently observed in percutaneous cholecystostomy group (3/74 in EUS-GBD group and 21/107 in percutaneous cholecystostomy group, P = 0.017). Percutaneous cholecystostomy tube was indwelled for
median 20 days (14.0–45.2) after the procedure. A total of 7 patients in EUS-GBD and percutaneous cholecystostomy were both effective interventions to urgent drainage for acute cholecystitis. However, EUS-GBD might be beneficial than percutaneous cholecystostomy in long term management for the patients with acute cholecystitis who are not suitable for cholecystectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0274 ENDOSCOPIC TREATMENT OF ANASTOMOTIC BILIARY STRICTURES IN PATIENTS WITH LIVING DONOR LIVER TRANSPLANTATION: MULTIPLE PLASTIC STENTS VS FULLY COVERED SELF-EXPANDABLE METALLIC STENTS

A.T. Eminler, E. Parlak, A. S. Koksal, B. Toka, M. I. Uslan
Gastroenterology, Sakarya University, Sakarya/Turkey

Contact E-mail Address: drrakanparlak@gmail.com

Introduction: The “fully covered self-expandable metallic stents” (fcSEMSs) were found to be non-inferior to multiple plastic stents (MPSs) for the treatment of anastomotic biliary strictures after orthotopic liver transplantation (OLT). However, there is scarce data about their efficacy in the treatment of anastomotic biliary stenosis after living donor liver transplantation (LDLT). We aimed to compare the efficacy of fcSEMS and MPSs for the treatment of anastomotic biliary strictures after LDLT.

Aims & Methods: We retrospectively analyzed the data of LDLT patients with biliary complications from our center within the last 3 years. fcSEMSs were inserted in 23 patients (13 males and 10 females) (Group-1) and 13 patients (8 males and 5 females) (Group-2) with mean age 51 ± 9 years). The diameter of the fcSEMSs was 10 mm in 11 patients and 8 mm in 12 patients. The patients were followed up for at least 3 months after stenting were included to the study. Primary endpoints were the number of endoscopic procedures and the time required for stricture resolution. The secondary endpoint was the recurrence rate of the stricture.

Results: fcSEMSs were successfully deployed in all cases. The diameter of the fcSEMSs was 10 mm in 22 patients and 8 mm in 1 patient. The length of the fcSEMSs measured 8 cm in 13 patients, 10 cm in 8 and 12 cm in 2 patients. Secondary branch ducts were prophylactically drained with a single plastic stent in 12 patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The median number of endoscopic procedures was 2 (2–4) in Group-1 and 4 (2–9) in Group-2 (p = 0.001). The time required for stricture resolution was shorter in Group-1 (65.7 ± 18.2 days) than in Group-2 (240.1 ± 183.4 days) (p < 0.001). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%) (p = 0.87) after a follow-up period of 315 ± 290 and 378 ± 36 days, respectively. Conclusion: fcSEMSs are an effective method for the treatment of anastomotic biliary strictures after LDLT, with a lower number of endoscopic sessions and a shorter stenting duration required for the resolution compared to MPSs.

Introduction: Colorectal stenting is a minimally invasive, reliable and effective intervention in patients with malignant colorectal obstruction, associated with a low complication rate, mortality rate, compared to surgical intervention. One of the actual problems associated with colorectal stenting is the recurrence of symptoms of obstruction. The most common cause is migration of covered stents and ingrowth of uncovered stents1–5. The aim of our study was to compare the results of the use of stents of a new design, the development of which was aimed at preventing these complications.

Aims & Methods: We aimed to evaluate the results of the use of the new design (double uncovered and dual coated colorectal stents). Between December 2012 and April 2017, 77 patients with malignant colorectal obstruction were implanted 78 stents (39 bare, 39 covered EGIS Colorectal stent, S&G Biotech Inc., South Korea). A double uncovered stent has a two-layer structure created by crossing two stents, resulting in a smaller cell size. Such a design theoretically can slow the migration and reduce tumor ingrowth. The covered tumor stent is coated with a silicone membrane between two layers of a metal mesh with distal, uncovered ends of 5 mm each. The role of the membrane is to prevent the ingrowth of the tumor, localization and uncovered edges prevent the migration of the stent. All interventions are performed by one operator using endoscopic and radiological control. Groups of patients using coated and uncovered stents were comparable in terms of sex, age, duration of symptoms of obstruction, and stenosis localization. The reasons for the obstruction were primary tumors of the colon 97.4%. The localization of the tumor is most common in the sigmoid colon - 54%. The median follow-up was provided to 43 (58.8%) patients, “bridge to surgery” – 34 (44.7%) patients.

Results: Clinical success was achieved in 74 (96.1%) patients. In two cases, when using covered stents, the symptoms of obstruction could not be relieved, the patient was operated. In one case, 18 hours after stenting with an uncovered stent, was diagnosed perfusion due to obstructive colitis. The average stay in hospital after the intervention was 3 days; the difference between the groups was statistically insignificant. 30 day mortality was 5.2%, the difference was statistically significant. Complications were detected in 3 patients in the group of bare stents and in 1 patient in the group of covered stents, the difference was statistically significant. One patient with the carcinoma of a sigmoid colon with invasion in anterior abdominal wall noted the appearance of subcutaneous emphysema without pneumoperitoneum, in 3 (3.8%) patients the occlusion of the stents. The reasons for obstruction of the stents were occlusion by the obstruction from stool (fibers) on the 83rd day (the endoscopic recanalization was performed) and tumor overgrowth by 163 days (endoscopic “stent-in-stent” placement). In one patient, the cause of occlusion is unknown, operated in another hospital 34 days after stenting - a transversostomy was performed, died on the 4th day after the operation.

Conclusion: Double bare and double covered colorectal stents were feasibility and efficacy for relieving malignant colorectal obstruction. Reobstruction was rare complication and not different in both groups stent groups. Necessary to continue to research for the accumulation of material from other centers.

Introduction: Endoscopic therapy has been emerged as alternative treatment to bariatric surgery for reducing weight. We developed a new endoscopic gastro-intestinal (GI) bypass stent and designed a preclinical study to assess the safety in a porcine model.

Aims & Methods: The aim of this study is to investigate the feasibility of our GI bypass device in animal. Before animal study, we performed an experimental study for durability test under simulated intestinal fluid flow. And next, we performed an animal study with 10 Yorkshire pigs. The stents were placed on pylorus with fixation by clipings or on duodenal bulb without fixation. Follow up endoscopy was done per one week after implantation. After they were sacrificed, gastric, duodenal, and jejunal tissues were harvested and examined for histologic assessment of any device or procedure-related effects.

Results: Our new GI bypass device showed a good durability in simulated solution flow. No breakage or migration of stent occurred under continuous water flow in simulation system setting. In animal study, the mean starting weight was 30.1 ± 1.5 kg. Delivery of the implant took an average of 19.8 min (range, 11–32 min) for pylorus gus group and 11.2 min (range, 6–18 min) in duodenal bulb stent group. It required an average clipping time of 10.8 min (range, 8–14 min). Followed for stent migration after implantation, the mean patency duration was 1.5 ± 0.7 weeks. One pig was died due to small bowel perforation and peritonitis after stenting. In histologic finding, there were moderate degree of mucosal erosions, but no definite ulceration on pylorus and duodenum.

Conclusion: New GI bypass stent has a good physicochemical properties in simulated intestinal system. In animal, all stents were successfully deployed and tumor overgrowth by 165 days (endoscopic “stent-in-stent” placement). In one patient, the cause of occlusion is unknown, operated in another hospital 34 days after stenting - a transversostomy was performed, died on the 4th day after the operation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: dianaacpmartins@gmail.com

Introduction: Dysphagia may occur due to benign pharingo-esophageal strictures, or post-surgery esophagus stenosis. The aim of this study was to access long-term efficacy of pharingo-esophageal dilatations due to anastomotic or post-radiation strictures.

Aims & Methods: Two retrospective studies: patients suffering of dysphagia due to radiation (Group I) or anastomotic (Group II) caused pharingo-esophageal benign strictures submitted to endoscopic dilation between January 2013 and December 2015. The long-term efficacy (after a minimum follow-up of 12 months) was prospectively assessed by telephone interview by: a) dysphagia improvement or b) resolution (grade 0 or 1 of Mellow-Piknas scale), c) absence of further dilations and d) absence of PEG. Additional therapy (PEG or per-oral-phagae dilatation, electrocoagulation or surgery) was considered inefficacy criteria and these patients were excluded from the interview. Post-procedure complications were registered. Efficacy predictive factors were assessed.

Results: Forty-eight patients (296 dilations) were evaluated (median of 4 dilations/patient): 85% were male, mean age of 62 years-old, 60% belonging in Group I. There salve between the two groups was statistically significant. Of 5 weeks. Pre-endoscopic dysphagia Mellow-Piknas score and luminal calibre were 3 ± 1 and 7 ± 2, 8mm, respectively. Twenty-eight patients (out of 30 live patients non-submitted to additional therapies) answered to the interview: a) 96% had improved, b) 60% had full resolution. Efficacy predictive factors were assessed by uni- and multivariate analysis; recurrent/refractory stenosis didn’t significantly improve the results. Mean follow-up was 29, 2 months. Number of dilations (range 0 to 21) and luminal calibre were significant predictors of combined efficacy in the univariate analysis; radiic strictures predicted a greater final dysphagia in the uni- and multivariate analysis; recurrent/refractory stenosis didn’t significantly predict global efficacy.

Conclusion: Our dilation programme presents relevant benefit to these patients and a low rate of complications. Patients with post-radiation strictures presented a worse prognosis. Even though retrospective we present the longest follow-up and focusing not only in objective measures but also in patient perception of relief.

Introduction: Current guidelines favour the use of bleeding stents over balloon tamponade for refractory variceal bleeding (EBV). However, data on the efficacy of and outcomes after the placement of an SX-ELLA – “Danis-Stent” – are limited.

Aims & Methods: Retrospective multicenter study including cirrhotic patients receiving Danis-Stents for massive/refractory EBV at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenanstalt Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic band ligation (EBL) prior to Danis-Stent placement. Danis-Stent controlled EBV in 80% (28/35) of patients. In the remaining uncontrolled bleeders (n=7), 3 patients had subsequent EBL, while in 3 patients the stent had to be replaced and 1 patient received a Linton-tube. Among these patients with initial Danis-Stent control 4 died of uncontrolled EBV. 2 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control. In total, early-rebleeding within 6 weeks occurred in 14.3% (including n=1 while Danis-Stent was still in place and n=5 after Danis-Stent was removed): 3 under- went a further EBL and received a second Danis-Stent, and 1 patient was supported by a Sengstaken tube. Moreover, among n=14 patients without early rebleeding within 6 weeks, only n=3 (21.4%) showed rebleeding later during follow-up: n=2 patients were treated with a Sengstaken-Tube (both experienced bleeding-related death) and n=1 had another Danis-Stent placed (successful bleeding control). Only n=1 (31.4%) patients did not experience any rebleeding after Danis-Stent removal, while n=8 patients died with the Danis-Stent in situ. Notably, no “early-TIPS” was performed in this study, but 4 (11.4%) received TIPS during follow-up. n=6 patients (17%) died due to uncontrolled bleeding (<5days) and n=10 died within 6 weeks (bleeding-related mortality: 28.6%). Overall, n=22/35 (62.9%) patients died. The median survival was 10.5 (IQR82) days after Danis-Stent placement. Median Danis-Stents dwell time was 5 (range: 0–13) days. The most common adverse events were stent disloca- tions (n=13; 37.1%), while ulcers/nerosion of the esophageal mucosa was seen only in 4 (11.4%) patients.

Conclusion: Danis-Stent controlled refractory massive EBV in 80% of patients but bleeding-related mortality was as high as 45%. While stent dislocations are frequent, ulcers/nerosion of the esophagus were rare with a dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome in Danis-Stent placement.

P0279 A NOVEL METHOD WITH SELF-EXPANDABLE METALLIC STENT FASTENED WITH CLIP AND LOOP FOR THE TREATMENT OF ANASTOMOTIC STRICUTURE AFTER SUBTOTAL GASTRECTOMY

J.K. Kang, S.G. Lim, K.M. Lee, S.J. Shin, B.M. Yoo, J. Kim, C. Noh Gastroenterology, Ajou university school of medicine, Sunwon/Korea, Republic of

Contact E-mail Address: pterson1@naver.com

Introduction: Benign anastomotic strictures are common adverse events of gastrectominal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic stricutures are balloon dilatation and bougination. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continous expanding effect for a long period. But, It has problem of frequent stent migration, because of slow stent expanding, 2–3 days. Self-expandable metalic stent (SEMS) placement has continous expanding effect for a long period. But, It has problem of frequent stent migration, because of slow stent expanding, 2–3 days. Therefore the new method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stricture. From January 2013 until February 2015, patients with benign anastomotic stricture after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), double-layered, were inserted. We made two nylon thread loops at the proximal bared section of the stents. After stent placement, stent fastening with loop and clip method was performed. Patients’ symptoms and oral intake were assessed once or twice a week with a clinical check-up or telephone interview. After two weeks, the loop and stent removals were done.

Conclusion: New method with fastening the stent with loop and clip can reduce the risk of stent migration.
Our fastening method can be feasible and useful technique for postoperative anastomotic stricture, especially, with some series studies estimating the rate at around 20%10. We report a single-centre, retrospective cohort study on the use of SEMS, and aimed to establish risk factors for stent migration.

Aims & Methods: Case note review was undertaken retrospectively on all patients who had fully covered SEMS inserted at a high-volume tertiary oesophageal cancer centre between Jul 13 to Feb 17. All SEMS were placed under fluoroscopic guidance by experienced endoscopists. Stent migration was confirmed endoscopically or radiologically and was defined as displacement of the stent from the stomach or the baseline stent insertion due to loss of the recanalised lumen. Shapiro-Wilks testing showed non-normal distribution of data. Non-parametric testing by logistic regression was therefore performed.

Results: 188 stents were inserted to palliate malignant strictures, 75% in males. We observed a migration rate of 20% (39) in our cohort. We observed a significant association between predilation (within 7 days of the stent procedure) and subsequent stent migration (31% in dilated vs 13% in undilated stents). This also met Bonferroni-corrected significance. We demonstrate a trend towards shorter strictures being associated with an increased risk of migration [OR 1.14 CI1.12–1.164 (p=0.0523)]. There were no significant associations between migration and whether patients received previous chemo-radiotherapy, or whether the stent crossed the GOJ.

Conclusion: Endoscopic placement of SEMS is a safe and effective procedure in the management of malignant dysphagia with a low risk of complications. Predilation of lesions within 7 days of SEMS insertion carries a risk of subsequent stent slippage – suggesting that a cautious approach to dilation may be prudent. Further, larger studies may demonstrate an association with shorter stents being more likely to migrate.

Severity of intrahepatic and intraabdominal lymphadenopathy: mediastinal lymphadenopathy at ≥19 (12.2%) and ≥20 (33.9%) patients, combined of 38 (64.4%) and 35 (59.3%). At pre-operated staging most newly advanced form of cancer: T4N1 at 16 (27.1%), T4N2 at 23 (38.9%). Sensitivity in staging of tumor 89.8%. Long-term results: 1-year survival at 1 group 96.1%, 3-year is 42.3%, 5-year 16.6% II group 1-year survival 6.45%.

Conclusion: The use of 3D-modeling performing with MRI, spiral CT and EUS, allows to planning the optimal surgery and lymph node for locally common form of esophageal cancer, and improve the results of survival.

The scope of surgery is advisable to plan taking into account the constructed 3D-models, which helps to solve the problem of the possibility of surgical intervention in esophageal cancer.

P0284 INFLUENCE OF CONTINUOUS ADMINISTRATION OF LOW-DOSE ASPIRIN FOR INTRAOPERATIVE BLEEDING ON GASTRIC ENDOSCOPIC GASTRIC DISSECTION: A PROPENSITY SCORE MATCHING ANALYSIS

Y. Horikawa, N. Mimori, H. Mizutani, Y. Kato, S. Fushimi, S. Okubo, S. Sato Gastroenterology, Hiraka General Hospital Dept. of Gastroenterology, Yokote/ Japan

Contact E-mail Address: horikawa.01@me.com

Introduction: Endoscopic submucosal dissection (ESD) was a promising method for the removal of higher complication rate of gastric early cancer. The use of antiplatelet agents has increased for first or secondary prevention of cardiovascular or cerebral disease. Continuous administration of low-dose aspirin (LDA) during ESD was recommended in American, British and Japanese guidelines. However, the influence of LDA for the hemostasis condition during ESD procedure is still unclear. Therefore, we performed this study for addressing intraoperative bleeding risk without cessation of LDA.

Aims & Methods: In this retrospective study, we assessed the hemostasis condition during ESD that were treated for superficial gastric lesions between January 2014 and March 2017. Patients with antithrombotic therapy by LDA (n = 42) and those with no antithrombotic therapy (n = 187; Control) were compared using propensity score matching. Primary outcome was frequency of intraoperative bleeding major. Secondary outcomes included procedure time, HB reduction rate, EN blec section rate, and adverse event rate.

Results: The propensity score analysis yielded 39 matched pairs. Adjusted comparison between the two groups showed similar with regards to major bleeding, mean (range): 1.0 (0-4.0) vs. 1.0 (0-4.0), p = 0.621. Procedure time was prolonged in Aspirin group by 16.7% without significant differences. Other aspects were the same in both groups with low incidence of adverse events; perforation (0%), thromboembolism (0%).

Conclusion: This study indicated the feasibility of gastric ESD with continuous administration of LDA including little intraoperative bleeding and adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0285 IMPACT OF POSTOPERATIVE COMPLICATIONS AND PERIOPERATIVE ONCLOGICAL TREATMENTS FOR GASTRIC CANCER PATIENTS AFTER GASTRECTOMY

S. Kamiya1, F. Klevebro, J. Rouvelas1, M. Lindblad2, L. Lundell2, M. Nilsson2

1Surgical Gastroenterology, Karolinska University Hospital, Stockholm/Sweden
2Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: satoxi_k@hotmail.com

Introduction: Recently, multidisciplinary treatments such as perioperative chemo/radiotherapy or postoperative intervention have been introduced to improve the prognosis of gastric cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastric cancer patients.

Aims & Methods: Consequent gastric cancer patients who underwent curative gastrectomy in Karolinska University Hospital between 2006 and 2016 were enrolled. Patients' characteristics, surgical data, postoperative courses and prognostic examinations were evaluated according to Clavien-Dindo classification. The significance of postoperative severe complications and perioperative oncological treatment for overall survival (OS) was evaluated by the Cox proportional hazard model.

Results: A total of 633-nine-sixty-nine patients were examined in this study. 89 (52.7%) and 66 (39.1%) patients had neoadjuvant and adjuvant treatment, 85 (50.3%) and 84 (49.7%) underwent distal and total gastrectomy, respectively. 24 (14.2%), 16 (9.5%) and 25 (15.0%) were diagnosed as grade III, IV, V complications. The prognosis of the patients with grade III or higher complication was significantly worse (3-year OS: 66.6% vs 47.3%, P = 0.001). Subgroup analysis by pathologic stage showed that the prognosis of pStage III/IV patients with postoperative complications was significantly poorer than the patients without grade III or higher complications (3-year OS: 45.3% vs 7.5%, P < 0.001). For the patients who had either neoadjuvant or adjuvant treatment, however, no obvious prognostic worsening were seen by the existence of complications (3-year OS: 69.2% vs 52.9%, P = 0.13). Multivariate analysis identified that severe complication was independent risk factor for OS (hazard ratio 1.82; 95% confidence interval 1.08-3.05), especially in pStage III/IV gastric cancer (hazard ratio 3.00; 95% confidence interval 1.53-5.86).

Conclusion: Postoperative severe complications had considerable impact on the OS, especially for pStage III/IV gastric cancer patients. Perioperative oncological treatment may be able to prevent the prognosis from deteriorating due to postoperative complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0286 ENDOCOSPIC PAPILLOLECTOMY OF DUODENAL PAPILLARY TUMOR: A REPORT OF 75 CASES

Z. Wang1, E. Linghu2, F. Cai2, Y. Yang2, G. Sun1, M. Li1, S. Li1, X. Wang2, J. Meng1, H. Du1, J. Zhu1, W. Li1

Introduction: Duodenal papillary tumor as rare gastrointestinal neoplasm is essential for curative therapy due to its malignant potential. Endoscopic papillectomy of duodenal papillary tumor has developed and is accepted as an alternative approach to surgery in recent cases. Endoscopic papillectomy as a relatively difficult endoscopic technique mainly performed by experienced endoscopists. Standardized endoscopic procedures for endoscopic papillectomy have not been established.

Aims & Methods: We aimed to investigate the clinical value of endoscopic papillectomy for duodenal papillary tumor based on the endoscopic and clinical characteristics. Between 2006 and 2017, seventy-five patients with duodenal papillary tumor under endoscopic papillectomy in the gastrointestinal endoscopic center of Chinese PLA General Hospital were included. These patients were diagnosed of duodenal papillary tumor by the clinical manifestations, laboratory tests, CT, MRCPE, endoscopy, EUS, ERCP along with biopsies and histopathologic tests. During the detailed clinical assessment combined with patients’ wishes, endoscopic papillectomy and followed ERCP procedures were performed successfully, and the clinical data of these patients were retrospectively analyzed.

Results: 75 patients (50 males and 25 females) with a median age of 58.6 yrs (range 27 to 82 yrs) were evaluated. The main clinical symptoms were predominated by abdominal pain followed by cholestasis and cholangitis, but nine cases presented as abdominal symptoms. Endoscopic papillectomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists. The majority of excised tumors were exogenous (90.7%, 68/75), and the tumor size ranged between 8 and 55 mm. The final histopathological diagnosis included adenoma (37.3%, 28/75), gastric adenocarcinoma with high-grade intraepithelial neoplasia (18.7%, 14/75), adenoa with low-grade intraepithelial neoplasia (26.7%, 20/75), adenoma combined with local carcinoma (16%, 12/75), and neuroendocrine tumor (1.3%, 1/75). In bloc resection was achieved in 53 cases (70.7%) and the piecemeal resection was performed in 22 cases (29.3%). After endoscopic papillectomy, the ERCP procedures were performed in 70 cases (93.3%). The prophylactic pancreatic duct stent was placed in 30 cases (40%) for preventing pancreatitis, the biliary plastic stent or nasobiliary drainage tube in 16% (12/75), the combined of both in 17.3% (13/75), and no stent placement in 26.7% (20/75). Moreover, intraoperative hemostasis was performed in 47 cases (62.7%), including pure endoscopic clip placement, followed by injection therapy, thermal therapy or in combination. Regarding to the postoperative adverse events,
hemorrhage was identified in 11 patients (14.6%) but mainly cured by endoscopic haemostasis, followed by pancreatectomy (9.3%, 7.75) but cured with medical treatment.

Conclusion: Endoscopic papillotomy can be considered as a feasible and reasonable treatment option for suitable patients with tumours of duodenal papilla.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0205 PSEUDOPHYLLUM CAMELUNICUM WITH EXTENDED INDICATION OF RECTAL PRESERVATION IN RELATED ACUTE FAMILIAL ADENOMATOUS POLYPOSIS: SYSTEMATIC REVIEW AND META-ANALYSIS

A. Pasquer1, G. Poncelet1, M. Poche2, J. Rivory2, O. Viet2, N. Benech2, J.C. Saurin2

Introduction: Prophylactic surgery of familial adenomatous polyposis (FAP) ranges from total colectomy with ileorectal anastomosis (IRA) to proctocolectomy with ileoanal anastomosis and J pouch (IAA). Rectal resection is based on studies that did not include systematic endoscopic treatment that we perform. The objective was to compare IRA to IAA in terms of oncological safety and quality-of-life.

Aims & Methods: Between January 1965 and November 2015, all consecutive patients that underwent prophylactic surgery for FAP with aggressive endoscopic follow up in our unit: systematic endoscopic treatment of adenomas (argon, mucosectomie), were prospectively included. MYH-related polyposes and patients who underwent abdominopenirectal resection were excluded from analysis.

Results: 296 patients were included: 92 proctocolectomy with IAA (31.1%), 197 IRA (66.5%) and 7 abdominoperineal resections (2.4%). Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of preoperative rectal adenomas was 24.7 (33.9) in the IRA group, 129.8 (188.8) in the IAA group (p = 0.06); secondary cancer incidence was 3.1% (n = 9). Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of lower endoscopies was 3.4 (2.5) in the IRA group vs. 3.4 (2.5) in the IAA group (p = 0.91); mean (SD) number of treated adenomas was 17.8 (20.8) and 12.9 (18.8), respectively (p = 0.06); secondary cancer incidence was 6.1% vs. 1.1% (p = 0.06). The 15-year recurrence-free and overall survival (IR vs. IAA) were respectively 99.5% vs. 100% (p = 0.09) and 98.9% vs. 98.8% (p = 0.82).

Conclusion: Combination of aggressive endoscopic treatment and extended rectal preservation appears to be a safe alternative to ileoanal anastomosis and J pouch.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0208 ANAL PROBLEMS DURING PREGNANCY AND POSTPARTUM: A PROSPECTIVE COHORT STUDY

K. Ferdinande, Y. Dorreman, K. Roelens, W. Ceelen, D. De Looze

University of Ghent, Ghent/Belgium

Contact E-mail Address: kymentie.ferdinande@ugent.be

Introduction: Many pregnant women have anal symptoms during pregnancy and postpartum. The most common proctological problems reported are haemorrhoids, anal fissures and anal incontinence. Literature about this problem is scarce.

Aims & Methods: The aim of this study is to determine the prevalence of anal problems and constipation during the second and third trimester of pregnancy, in the immediate postpartum and up to three months after childbirth. We also want to identify the risk factors for the development of anal symptoms. This is a prospective cohort study. Women between their 19th and 25th week of pregnancy are included. High-risk pregnancy and non-Dutch speaking are exclusion criteria.

Nine hundred and ninety-three women completed the symptom questionnaire in the second and third trimester, in the immediate postpartum (within 3 days) and 3 months postpartum. Descriptive data were obtained from the patient files. A specific proctological diagnosis was presumed on the basis of combined symptoms (rectal bleeding, anal pain and swelling). Constipation was defined by the Rome III criteria. Statistical analysis was performed with SPSS and risk factors were identified using multivariate analysis with binary logistic regression.

Results: Sixty-eight percent of the women developed anal symptoms during the whole study period. Anal symptoms occurred in 50% of the women during pregnancy, in 56.2% in the immediate postpartum and in 62.9% during the three months postpartum. The most prevalent symptom was anal pain. Constipation was reported by 60.7% during the whole study period. Most prevalent hemorrhoidal condition was hemorrhoidal thrombus (immediate postpartum), hemorrhoidal prolapse (3rd trimester and immediate postpartum) and anal fissure (not episode-related). Anal incontinence was only reported in 2% during the postpartum. Multivariate analysis identified constipation and a history of anal problems as significant risk factors for the development of anal complaints postpartum and postpartum.

Conclusion: Two-thirds of pregnant women deal with anal symptoms during pregnancy or postpartum, especially hemorrhoidal complications and anal fissure. This high prevalence emphasises the clinical importance of this problem. The most important risk factor is constipation. Therefore, prevention of constipation in pregnant women is recommended.

Introduction: Diverticulitis is a common gastrointestinal disease in developed countries, especially among elders. It is classified into five stages according to the severity of the inflammation with stage 5 involving peritonitis as a consequence of perforation and/or abscess formation, with 30-50% of the patients having complications and/or mortality ranging from 30% to 32%. This indicates that acute diverticulitis is an emergency case requiring rapid management. However, the surgical interventions of diverticulitis vary according to its grade and severity, there is a controversy about the preferable surgical procedures of these different grades of diverticulitis.

Aims & Methods: We aimed to systematically review and meta-analyze randomized controlled trials (RCTs) comparing outcomes and complications between different surgical approaches for acute diverticulitis and its complications. Nine electronic databases, including PubMed, Scopus, Google Scholar, ISI Web of Science, WHO Global health library (GHL), POPLINE, Virtual health library (VHL), NYAM (New York Academy of Medicine), and SIGLE (System for Information on Grey Literature in Europe), were searched for RCTs comparing different surgical procedures for different grades of diverticulitis. Out of 1738 articles, we included 14 studies with 1076 patients. The primarily assessed outcomes were post-surgical mortality rate besides short- and long-term post-surgical complications. The risk of bias was assessed using the Cochrane Collaboration tool. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated in the meta-analysis using the RevMan platform. The protocol was registered in PROSPERO (CRD42015032290).

Results: Nine RCTs comparing laparoscopic sigmoid resection (LSR) (n = 247) versus open sigmoid resection (OSR) (n = 237) for treatment of acute complicated diverticulitis with minimal heterogeneity. For short-term outcomes, there was no significant difference in postoperative overall morbidity (RR 0.89, 95% CI [0.61–1.31]; P = 0.56), all major postoperative morbidity (RR 0.79, 95% CI [0.12–5.07]; P = 0.80), and all minor postoperative complications (RR 0.98, 95% CI [0.62–1.57]; P = 0.94). Similarly, there was no difference between the two procedures regarding the long-term postoperative morbidity (RR 0.85, 95% CI [0.57–1.21]; P = 0.32). In other four RCTs comparing laparoscopic lavage with resection (sigmoidectomy) for treatment of perforated diverticulitis with peritonitis, the postoperative mortality rate was non-significant in both short-term (RR = 1.55, 95% CI [0.79–3.04]; P = 0.21) and long-term (RR = 0.67, 95% CI [0.29–1.58]; P = 0.36) follow up. Interestingly, the short-term reoperation rate and long-term precence of intra-abdominal abscesses were significantly higher in OSR (RR = 1.74, 95% CI [1.01–3.02], P = 0.04) and (RR = 1.47, 95% CI [1.03–5.92]; P = 0.04) respectively. The remaining five RCTs compared between different procedures, like primary anastomosis versus non-rectostomal resection, RP-LASR versus RNR-LASR, and primary versus secondary resection, for different situations and reviewed qualitatively.

Conclusion: The superiority of LSR over OSR was non-significant in the treatment of acute symptomatic diverticulitis regarding postoperative complications, mortality, hospital stay, and operational duration. Hence, LSS is feasible and can act as definitive treatment. Further RCTs are still needed to make a decision regarding these and other procedures.

Introduction: There has been enormous progress in diagnosing and treatment of colorectal cancer (CRC), however a great number of patients is nevertheless diagnosed at an advanced disease stage, which is often related to development of invasiveness, expensive, prognostic, diagnostic, and treatment predicting biomarkers in early diagnostics of CRC considering its incidence worldwide. There are studies suggesting that the systemic inflammation play an important role in CRC tumor stage development, which can be reflected by the levels of neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR).

Aims & Methods: This study was designed to investigate the efficiency of preoperative NLR, PLR as a tool for the assessment of synchronous lymph nodes
and liver metastases in newly diagnosed patients with CRC. Three hundred patients with CRC undergoing curative resection were included in this cross sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and PLR was estimated by ROC curve.

Results: Our results suggest that there was high statistically significant difference between NLR (p < 0.003), PLR (p < 0.002) and tumor stages (I to IV). ROC curve revealed high diagnostic accuracy of NLR (AUC 0.774, 95%CI = 0.683–0.790) and PLR (AUC 0.698, 95%CI = 0.649–0.732) for synchronizable lymph node and liver metastases. Also combination of NLR and PLR improved diagnostic efficacy (AUC 0.841, 95%CI = 0.811–0.863) for synchronous liver and lymph node metastases.

Conclusion: Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential use in early recognition of different stages of CRC.

P0292 IS HAEMORRHOIDECTOMY SAFE IN PATIENTS WITH ULCERATIVE COLITIS?
S. Lee1, Y.S. Choi2, E. Lee1, J.B. Lee1, D.S. Lee1, E.G. Youk1, D.H. Lee1, D.S. Kim1
1Dept. Of Surgery, Dachang Hospital Dept. of Surgery, Seoul/Korea, Republic of Korea

Introduction: Haemorrhoidectomy in ulcerative colitis (UC) have been considered to be potentially dangerous, but the evidence is poor.

Aims & Methods: A study was conducted to ascertain the safety of haemorrhoidectomy in UC patients in the clinical practice.市中合併症を用いてUC症例の術後鎮痛,術後の対症療法,術後に発症した合併症を観察し,その薬理学的評価,対症療法の検討,さらに経過観察により,術後鎮痛の適応を検証した。

Results: The results were 29 males (65.9%), median age 44 (range, 19–72) years. Predominant symptoms were bleeding and prolapse (n = 24; 54.5%), prolapse only (n = 6; 13.6%), bleeding only (n = 14; 31.8%). 17 patients (BD, 38.6%) were diagnosed with UC prior to surgery. 4 patients (9.1%) had haazioplon therapy before surgery. There was no other perianal disease. Disease was limited to the rectum (n = 33; 75%), left-sided (n = 9; 20.5%), and extended to right-sided (n = 2; 4.9%). During follow-up, there were no complications such as sepsis, anal stenosis, abscess and fistula formation, and recurrence. There were no differences in complications and other clinical characteristics between BD and AD. There was no difference in complications according to disease extent (p = 0.158).

Conclusion: Our data suggest that haemorrhoidectomy may be performed safely in UC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0293 EARLY VERSUS DELAYED CLOSURE OF TEMPORARY LOOP ILEOSTOMY AFTER COLORECTAL SURGERIES: A PROSPECTIVE RANDOMIZED STUDY
S. Gavini, V. Vutukuru, D. Annareddy, C. Chandramaliteeswaran, V. Dasari, N. Poudalad
GI Surgery, SYMS, Tirupathi/India

Contact E-mail Address: srkgavini@gmail.com

Introduction: Temporary loop ileostomies are commonly performed to protect a temporary ostomy (85.25–93.26) during temporary loop ileostomy or ileal conduit diversion for colorectal cancer patients. The study was conducted from May 2014 to September 2015. Following creation of loop ileostomy after colorectal surgeries, distal loop contrast study was done on POD 7. Patients who had no leak were randomized to either early closure (8–13 days) or delayed closure (after 6 weeks) group. Patient demographics, operative parameters, morbidity, mortality and quality of life data were recorded in both groups.

Results: There were 24 patients in each group. Both groups were comparable in terms of demographic data except for age, which was significantly higher (p = 0.012) in the early closure group. Incidence of stoma related complications (p = 0.01) and Pittam ostomy complication severity index (p < 0.01) were significantly higher in the delayed group. Operative time (p = 0.033) and Surgeons assessment score (p = 0.0012) for the stoma closure surgery were significantly lower for the early closure group. There was no significant difference in the duration of hospital stay and the incidence of postoperative complications in the two groups. Quality of life as calculated by the Ostomy Adjustment Index score (OAI 23) was better in the early closure group (p = 0.014).

Conclusion: Early closure of a temporary loop ileostomy is feasible with the advantages of decreased stoma related morbidity, operative difficulties without increased morbidity and mortality when compared with conventional delayed ileostomy closure.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0294 FULL-SCALE INTRODUCTION OF RADICAL LAPAROSCOPIC SURGERY FOR INGUINAL HERNIA EMPLOYING THE TRANSABDOMINAL PREPERITONEAL (TAPP) REPAIR AND EARLY OUTCOMES

Gastroenterological Surgery, Aichi Medical University, nagakute/Japan

Contact E-mail Address: tsaito726@gmail.com

Introduction: Ger reported the first laparoscopic hernia repair in 1982 by approx- imation with stainless steel sutures. First laparoscopic inguinal transabdominal preperitoneal repair (TAPP) repair was a revolutionary concept in hernia surgery and was introduced by Arregui and Dion in the early 1990s. Institutions performing radical laparoscopic surgery for inguinal hernia have been rapidly increasing since the NIH point was amended in Japan. However, in the 12th JAPAN SOCIETY FOR ENDOSCOPIC SURGERY questionnaire survey, the recur- rence rate after surgery employing the TAPP method was reported to be 4%, posing a problem regarding the thoughtlessness introduction of the TAPP method. Our hospital is a university hospital employing the TAPP method only occasionally until April 2015, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia treatment at our hospital. Surgical indication of inguinal hernia in our department is as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand on the left and right sides of the patient, respectively, an anesthesiologist stands at the patient’s head, and a nurse stands caudal to the assistant.

Aims & Methods: In this study, we investigated the current state of inguinal hernia treatment at our hospital. The subjects were 120 patients who underwent radical surgery for inguinal hernia before and after the full-scale introduction of the TAPP method (early period: October 2014-April 2015 (7 months), late period: October 2015-2017 (5 months)). Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Results: The median age was 70 years (19-91 years old). There were 114 male and 6 female patients with a total of 132 hernia lesions (60 right, 60 left, 48) and bilateral in 12). The hernia classification (Japanese Hernia Society) was 1, 2, 3, 4, rec in 91, 37, 0, 3, and 1 lesions. Surgery was performed under local anesthesia in 43, lumbar anesthesia in 1, and general anesthesia in 76. A laparo- scope was used in 70 and not used in 50. TAPP, mesh plug, and UHS were used in the early and late periods, respectively. Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Discussion: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m2. No conver- sion to open surgery was registered. The mean operative time and estimated blood losses were 184.3 ± 32.7 minutes and 81.2 ± 22.7 ml respectively.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0295 EFFECTIVENESS OF PURE LAPAROSCOPIC LEFT COLECTOMY WITH PRIMARY ANASTOMOSIS AND LOOP ILEOSTOMY FOR THE TREATMENT OF COMPLICATED HINCHRY 3 AND 4

F. Roscia, A. De Luca, I. Scandroglio
Galmariuti Hospital, ASST Sette Laghi, Tradate/Italy

Contact E-mail Address: francesco_roscio@yahoo.it

Introduction: For the effectiveness of laparoscopic left colectomy with primary anastomosis and loop ileostomy in the treatment of complicated acute diverticulitis with diffuse purulent peritonitis (Hinchey 3), also considering the lack of evidence about this topic due to the difficulty of carrying out comparative trials with the laparoscopic washing/drainage technique.

Aims & Methods: A consecutive unselected series of 44 patients undergone emerg- ency surgery for acute complicated Hinchey 3 diverticulitis from January 2012 to December 2016 was retrospectively evaluate. All patients were treated by pure laparoscopic left colectomy with primary colorectal anastomosis and temporary loop ileostomy. All the procedures were performed by the same surgeons (IS, ADL, FR). Perioperative care plan, operative steps and surgical instrumentations were standardized. We collected patients-, surgery- and hospital-stay–related data, as well as short-term outcomes. Complications were classified using the Clavien-Dindo classification system (CDCS).

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m2. No conver- sion to open surgery was registered. The mean operative time and estimated blood losses were 184.3 ± 32.7 minutes and 81.2 ± 22.7 ml respectively. All the specimens showed diverticulitis with peridiverticulitis. Length of hospital stay was 7.8 ± 2.8 days and we have not recorded any readmissions in patients dis- charged within 60 days after surgery. The rates of postoperative complications were 6.8% for grade I, 8.6% for grade II, 3.6% for grade III, 2.3% for grade IV, and 5 according to the CDCS respectively.

Conclusion: Laparoscopic left colectomy with primary anastomosis and loop ileostomy seems to be a good technique that resulted in encouraging short- term outcomes. In expert hands it represents an effective technique for the treat- ment of acute diverticulitis complicated by diffuse purulent peritonitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0296 LAPAROSCOPIC COMPLETE LATERAL LYMPH NODE DISSECTION FOR LOW RECTAL CANCER

T. Kinoshita, K. Komori, T. Oshiro, A. Ouchi, Y. Shimizu
Gastroenterological Surgery, Aichi Cancer Center Hospital, NAGOYA/Japan

Contact E-mail Address: t-kino@ms.aichi-cc.jp

Introduction: Total mesorectal excision (TME) with lateral pelvic lymph node dissection (LLND) is a standard procedure for low rectal cancer in Japan. However, ME alone is the international standard surgical procedure for rectal cancer. Complete LLND is difficult due to the pelvic wall, bladder wall and sciatic nerve. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccycgeal artery (Akoo’s canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were sepa- rated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.

Aims & Methods: After laparoscopic ME, the external iliac artery was exposed and the external iliac nodes were completely removed from iliac ligament. Obturator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall, bladder wall and sciatic nerve. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccycgeal artery (Akoo’s canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were sepa- rated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.

Results: Between 2015 and 2016, we performed laparoscopic ME with LLND for 10 patients with cT2 or deeper low rectal cancer. The median operative time was 502 min (429–679 min), and the median blood loss was 90 ml (5–500 ml). 32.7 minutes and 81.2

Disclosure of Interest: Our laparoscopic LLND provides good visual field and reduces an amount of operative bleeding and results in favorable clinical outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0297 TRANSGASTRIC-NOTES SIGNET RERECTION IN AN ANIMAL SURVIVAL MODEL USING THE ANUBIS-SYSTEM

J. Bernhardt, H. Steffen, P. Koehler, S. Schneider-Koriath, K. Ludwig
1Dept. Of Endoscopy, Klinikum Sudwest Rostock, Rostock/Germany
2Dept. Of Surgery, Klinikum Sudwest Rostock, Rostock/Germany
3Dept. Of Cardiovascular Surgery, Klinikum Sudwest Rostock, Rostock/Germany

Contact E-mail Address: joern.bernhardt@klinik-sued-rostock.de

Introduction: Since natural orifice transluminal endoscopic surgery (NOTES) pro- posed advantages should be established by comparison with standard proce- dures. Using a single side transluminal access, the feasibility of performing advanced surgical procedures is still limited, especially for a single endoscope. We used the ANUBIS-system for sigmoid resection with a transgastric access to the abdominal cavity assisted by colonoscopy and one trocar.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. After operation in an acute model, we started the study with 5 pigs using a survival model. Using the ANUBIS scope, a transgastric access was realized by needle-knife incision and balloon dilatation. CO2 peritoneum was achieved by insufflation via a working channel. By steoring the colonoscope, the colon was maneuvered endoluminally and the colic mesentery was exposed. Boweel-close preparation was carried out with a coagulating needle-laparoscopy and simulta- neously assistance by a grasper via the ANUBIScope. Both instruments have the possibility of two-directional movements. The access angle for preparation and visualisation could be altered during the procedure by maneuvering the colono- scope and the movements of the flexible endoscopic instruments. To prepare anastomosis, circular stapler anvil was introduced transluminally and penetration of the colon wall was carried out. Subsequently, proximal ressection of the sigmoid colon was performed using a linear stapler inserted through a trocar at the left

Disclosure of Interest: All authors have declared no conflicts of interest.
lower abdomen. The bowel extraction was performed by invagination transrec- taly. After the extraperitoneal distal linear stapling of the sigmoid, the colorectal anastomosis was completed by applying a circular stapling device transrectally, assisted by a transcutaneous inserted grasper. Function testing was performed by the colonoscope. Gastric access closure was performed by OTSC clip.

**Results:** The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic healing with a stenosis and consecutive prestenotic dilatation in one case. These abnormalities were not seen in the perigastric abscess beside the anastomosis. Gastric closure was healed and the OTSC clip still in situ in all animals. In one case we used two OTSC clips for gastric closure, there were severe adhesions with two peri gastric abscesses.

**Conclusion:** The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Flexible colonoscopy provided a fixed reference frame for orientation and dissection. For resorption and anastomosis, an additional transcutaneous access was necessary.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0298 ASCITES, COMPLEX ADNEXAL MASSES AND RAISED CA-125 IN POST-MENOPAUSAL WOMEN: OVARIAN CANCER OR TUBERCULOSIS?**

S. Jardak¹, H. Khchir², N. Maamouri², H. Chaabouni³, N. Ben Mami³
1Tunis, rabta B, Tunis/Tunisia
2Tunis, rabta B, Tunis/Tunisia

**Contact E-mail Address:** sondajardak1@gmail.com

**Introduction:** Peritoneal tuberculosis (TB) and advanced ovarian cancer, two conditions with different management and prognosis, have many similarities: ascites, complex adnexal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also seen in both of these two entities.

**Aims & Methods:** The aim of this study was to analyze patients’ characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB in post-menopausal women who presented with features mimicking ovarian malignancy from 2004 to 2014 in a Tunisian center.

**Results:** The mean age was 59.8 (46–87 years). Three patients have personal or family history of TB. A laparoscopic evaluation with biopsies was performed in 16 patients. Fluid protein content and ascitic fluid showing lymphocytic predominance and no malignant cells and absence of malignant ascitic fluid cultures was negative in all. CA-125 was elevated in all and the ascites were aspirated and sent for pathological analysis which showed a lymphocytic predominant pattern, and absence of malignant cells. A laparoscopic evaluation with biopsies was performed in 16 patients and an exploratory laparotomy in 4 women for suspected ovarian cancer. Intraoperative findings of tubercles on the pelvic organs and peritoneal surfaces were noted in 10 patients. In two, TB was not suspected intraoperatively. The diagnosis of TB was confirmed by histopathology in 95.2%. Response to therapeutic trial of anti-tubercular drugs was the basis of diagnosis in one case because of the clinical risk.

**Conclusion:** It is a diagnostic challenge to differentiate pelvic-peritoneal TB from ovarian cancer which has entirely different management and prognosis. Ascitic fluid showing lymphocytic predominance and no malignant cells and positive(FTG) are pointers to obtain a histopathological diagnosis by laparoscopic biopsy or frozen section at laparotomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0300 REGULATORY B CELLS CONTRIBUTION TO THE ALLEVIATION OF COLITIS INDUCED BY DEXTRAN SULPHATE SODIUM AFTER H. PYLORI INFECTION**

X. Li¹, N. Wang², Q. Xue¹, J. Tari¹, J. Wang³
1Department Of Gastroenterology, Peking University, People’s Hospital, Beijing/China
2Department Of Gastroenterology, Harbin Medical University, School of Medicine, China
3Department Of Gastroenterology, Tianjin Medical University, Tianjin/China

**Contact E-mail Address:** lixialyj@163.com

**Introduction:** Epidemiological studies have shown that there was an inverse relationship between H. pylori infection and IBD. Our previous research indicated that the regulatory immune responses induced by H.pylori infection were not limited to gastric mucosa, IL-10-producing B cells and Foxp3+ Treg cells expanded in spleen and mesenteric lymph nodes (MLN), the balance of intestinal mucosal immunity was influenced to a skewed regulatory immune response.

**Aims & Methods:** A murine model with H. pylori infection and acute and chronic colitis induced by dextran sulphate sodium (DSS) was established to explore the function of FoxP3+ Treg cells in the Breg cells in the context of H. pylori treatment on acute and chronic colitis induced by DSS. A C57BL/6 mice model of acute and chronic colitis was induced by 3% DSS with or without H. pylori infection in advance, the colitis performances were assessed by disease active index (DAI), colon length and colonic histological inflammatory scores. The CD19+IL-10+Breg cells and CD4+CD25+Foxp3+Treg cells in blood, spleen, MLN, PP and gastrointestinal mucosa were measured by flow cytometry, immunohistochemistry and immunofluorescence. The anti- and pro-inflammatory cytokines were also detected at mRNA level by real-time PCR.

**Results:** Compared with the DSS treated acute colitis group, H. pylori/DSS co-treated acute colitis group: (1) DAI and colonic histological scores reduced (9.25±2.88 vs. 16.00±2.00, P<0.025) and colon length shortened (0.83±0.22 vs 7.30±0.40, P<0.001). The percentages of CD19+IL-10+Breg cells detected by flow cytometry expanded in different tissues: blood: 5.05±0.68 vs 2.89±0.55, P=0.001; spleen: 4.32±0.56 vs 3.17±0.20, P=0.03; MLN:5.89±0.54 vs 4.94±0.65, P=0.047; PP: 6.95±1.67 vs 5.39±0.88, P=0.05; respectively. (2) The percentages of CD4+CD25+Foxp3+Treg cells expanded in different tissues: spleen: 13.50±1.37 vs 10.73±1.13, P=0.008; MLN: 17.50±0.82 vs 14.87±1.53, P=0.001; PP: 12.70±3.24 vs 8.58±1.71, P=0.01. The numbers of Foxp3+Treg cells per mm in colon Group 1 vs Group 2 were 3.44±0.40 vs 25.8±3.34, P=0.004. (4) mRNA expression in colonic mucosa: IL-10 (P=0.001) mRNA relative expression upregulated and IFNγ (P<0.04) mRNA relative expression downregulated significantly. Compared with DSS treated acute colitis group, H. pylori/DSS co-treated chronic colitis group: (1) DAI and colonic histological scores reduced (9.00±1.73 vs 14.67±1.53, P<0.001), and colon length shortened less (6.82±0.41 vs 5.98±0.15, P<0.001). (2) The percentages of CD19+IL-10+Breg cells expanded which were detected by flow cytometry in different tissues: blood: 7.09±0.58 vs 5.37±0.72, P=0.024; MLN: 4.78±0.73 vs 3.02±0.83, P=0.047; PP: 7.14±1.04 vs 4.34±1.03, P=0.005; respectively. (3) The percentages of CD4+CD25+Foxp3+Treg cells decreased dramatically in different tissues: blood: 6.61±0.51 vs 7.37±0.87, P=0.001; spleen: 9.07±2.88 vs 13.10±1.99, P=0.018; PP: 7.33±1.07 vs 12.80±0.96, P<0.001; the numbers of Foxp3+ Treg cells per mm in PP in colonic mucosa: 3.66±0.99 vs 4.08±0.56, P=0.392. (4) mRNA expression in colonic mucosa: IL-10 (P=0.023), Foxp3 (P=0.000) mRNA relative expression upregulated significantly, and IFNγ (P<0.001) mRNA relative expression downregulated significantly.
Conclusion: 1) H. pylori infection can alleviate the acute and chronic colitis induced by DSS and CD4+CD45R- Foxp3 Treg cells expanded significantly in H. pylori/DSS co-treated acute colitis mice. (3) CD19+IL-10+ Breg cells expanded while CD4+CD25+ Foxp3+ Treg cells reduced significantly in IFNγ/DSS co-treated chronic colitis mice. The potential protective effect of H. pylori infection on acute and chronic colitis induced by DSS may take through the expansion and function of CD19+IL-10+ Breg cells.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0301 FUNGAL COMPOSITION AND FUNGI-BACTERIA CORRELATION IN IBD PATIENTS WITH DIFFERENT TREATMENT STRATEGIES

Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD has not been fully understood. We studied the fungal gut microbiota composition and its expression is elevated in the inflamed tissue of patients with ulcerative colitis (UC) [1–3]. Pre-clinical models of colitis demonstrate a therapeutic benefit of administering colon IBD-protective effect of andecaliximab (previously GS-5745) is a high-affinity IgG4 monoclonal antibody against human Matrix Metalloproteinase 9 (MMP9). In a 36-day Phase 1b study in UC, andecaliximab demonstrated clinical efficacy relative to placebo treatment [5]. Here we describe bacterial microbiota analysis of stool samples collected during the Phase 1b study of andecaliximab in UC.

Aims & Methods: The objective of this study is to examine changes to the bacterial microbiota in pre- and post-andecaliximab treatment and relative to therapeutic response. stool was collected before and after therapy (Baselinel and after the end of the study (Day 36). Clinical response was defined as a Mayo score reduction ≥3 point and ≥30% reduction from baseline score; accompanying decrease in rectal bleeding sub-score of ≥1 or an absolute rectal bleeding sub-score of 0 or less and Dxy was extracted from fecal samples using a modified CTAB method and 16S rRNA amplicon sequencing was performed on 59 samples (27 paired and 5 unpaired samples). Alpha diversity, beta diversity (calculated in QIIME), and taxonomic differences were examined between placebo and andecaliximab-treatment, and between responders and non-responders.

Results: Compared to placebo-treated patients, those who received andecaliximab trended towards decreased alpha diversity (p = 0.06) at 36 days post-treatment. These changes in alpha diversity were not dose related. At Day 36, a trend towards a significant difference in community beta-diversity was observed between the andecaliximab-treated group relative to placebo (p = 0.07). Andecaliximab treatment was also associated with differences in bacterial taxonomy relative to placebo (p < 0.007). Specifically, the genera Clostridia and Akkermansia represented the most of the top organisms enriched post andecaliximab treatment relative to placebo. Andecaliximab treatment exhibited a non-significant expansion of Akkermansia from Baseline to Day 36 (p = 0.15). Amongst the clinical biomarkers, sex was the only marker to achieve a trend of increased relative abundance of Akkermansia muciniphila (p = 0.08).

Conclusion: Akkermansia muciniphila is the most consistently enriched organism for subjects treated with andecaliximab who respond to treatment. The presence of Akkermansia muciniphila may be an early marker for clinical efficacy. These preliminary results are unlikely to be pursued in relation to andecaliximab treatment effects, but may be beneficial as a reference for future trials in inflammatory bowel disease.

Introduction: Crohn’s Disease (CD) and Ulcerative Colitis (UC) are inflammatory Bowel Disease (IBD) with a complex etiology, including an immune response against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments. Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments (1).

Aims & Methods: This work was designed to investigate the pattern of cytokines that regulate the mucosal immune response occurring in different intestinal compartments of IBPD patients, using LCM technology (1). Frozen sections of colonic biopsies were obtained from 5 patients with active CD, 5 patients with active UC and 5 controls. None of the patients with CD or UC had been ever undergone mucosal biopsy (EP) and live mucosa (LP) (P<0.05). All the cytokines investigated were not significantly up-regulated in the surface EP of both CD and UC patients, when compared to controls.

Conclusion: Our data show that the LP compartment play a key role in the mucosal immune response in IBPD patients. In particular, CD seems to be prominently an innate immune response-mediated disease, which is characterized by an increased production of IFN-γ and TNF-α. On the opposite, UC seems to be prominently a CD4 lymphocyte-mediated disease, which is characterized by a decreased production of IL-17A.

The gut microbiota play important roles in the development of the mucosal immune response in IBD patients. In particular, CD seems to be prominently a CD4 lymphocyte-mediated disease, which is characterized by an increased production of IFN-γ and TNF-α. On the opposite, UC seems to be prominently a CD4 lymphocyte-mediated disease, which is characterized by a decreased production of IL-17A.

before treatment in the active stage to possibly be associated with increased proportions of Bacteroides, Parabacteroides, Rickenella, Clostridium, Flavonifractor, Pelagibacter, Bordetella, Massilia and Piscirickettsia species. In responders after treatment, populations of Bifidobacterium and Lactobacillus species were significantly increased. In this study, there was an especially strong negative correlation between Bacteroides and Bifidobacterium both before and after treatment.

Conclusion: These results suggested metagenomic analysis results to be associated with a remarkable change in gut microbiota after antibiotic combination treatment. In non-responders, in association to positive changes in Bacteroides and Lactobacillus species and a decrease in Bacteroides.

Introduction: Classically, enteroendocrine cells (EEC) are renowned for regulating gastrointestinal motility, secretion, and insulin levels by release of peptide hormones. Neuropeptides and EEC are capable of sensing the lamina propria and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin hormone Pyy is released by EEC in UC to Paneth cells. Since Pyy is a functional co-factor of GLP-1 and the amount of GLP-1 expressing EEC is reduced in the inflamed conditions of inflammatory bowel disease (IBD), a role for EEC in disease pathogenesis is limited and general disease symptoms like insulin resistance and altered intestinal motility. However, the total number of studies investigating EEC number and function in IBD and mouse models of intestinal inflammation is limited and results are conflicting.

Aims & Methods: To characterize alterations in GLP-1-expressing EEC numbers under intestinal inflammatory conditions, immunostainings for GLP-1 and Chga as well as mRNA expression analysis was performed in intestinal tissue specimens. Mouse models of intestinal inflammation used include genetic models, Il-10−/−, T cell receptor- and Foxp3−/− mice, as well as receptor and adoptive transfer models, Rag2−/− mice reconstituted with CD4+ T cells (cohost, chemically (DSS)-induced colitis and an infection model (Citrobacter rodentium).

Results: Numbers of GLP-1+ and Chga+ cells were consistently reduced in all mouse models of intestinal inflammation. These changes were confined to the site of intestinal inflammation. Neither absence of mature B and T cells in Rag2−/− mice alone was associated with reduced numbers of EEC, nor adoptive transfer of CD4+ T cells per se, since transfer of non-colitogenic CD4− CD25+ T cells did not lead to changes in Chga+ cell numbers in the colon. The reduction of GLP-1+ and Chga+ cells observed by immunohistochemistry was reflected by diminished levels of Gcg and Chga mRNA expression, whereby mRNA levels of the L-cell-derived hormone Pyy remained unaltered.

Conclusion: To our knowledge, this work provides the first comprehensive study of GLP-1+ and Chga+ cell numbers in different mouse models of intestinal inflammation. A reduction of GLP-1-expressing EEC seems to be a general feature of small as well as large intestinal inflammation. Further research will clarify if these alterations represent a consequence or causatively contribute to intestinal inflammation and elucidate the functional consequences on immune responses.

P0309 IMPAIRED MITOCHONDRIAL PROTEOSTASIS IS ASSOCIATED WITH MITOCHONDRIAL DYSFUNCTION AND INDUCES PHENOTYPIC TRANSITION OF LGR5+ STEM CELLS INTO PANETH CELLS

S. Khiloan Sarnagh, E. Rath, N. Waldschmidt, I. Gosch, E. Berger, D. Haller Chair Of Nutrition And Immunology, Technische Universität München, Freising-Weihenstephan/Germany

Introduction: The intestinal stem cell niche is a multicellular interface that is completely renewed every 3–5 days. Pluripotent stem cells reside at the crypt bottom giving rise to transient amplifying cells and subsequently differentiated intestinal epithelial cells (IEC) of all subtypes. Phases of cellular and functional transitions are characterized by distinct metabolic identities, reflected by changes in mitochondrial activity. Alterations in mitochondrial function and mitochondrial unfolded protein response (MT-UPR) activation are associated with various chronic pathologies including inflammatory bowel diseases (IBD) and cancer. We have previously shown that MT-UPR and mitochondrial function itself is involved in the regulation of cell cycle progression and intestinal stemness. Here, we present evidence that impaired mitochondrial proteostasis is sufficient to drive differentiation of Lgr5+ stem cells (ISC) into Paneth cells.

Aims & Methods: To depict the impact of imbalances in mitochondrial proteostasis on ISC, we used mice with a tamoxifen-inducible ISC or IEC-specific conditional knockout allele for the mitochondrial chaperone Hsp60 and the mitochondrial protease ClpP. Molecular consequences of the gene deletions in the different models were further characterized ex vivo using intestinal organoid culture. In situ hybridization, IHC and combinations of both as well as IF were performed to illustrate alterations of ISC subtypes. Readouts were complemented by RNA expression and biochemical approaches.

Results: Cln5 knockout as well as chemical inhibition of the respiratory chain in intestinal organoids led to diminished Lgr5 expression confirming our results from ISC and IEC specific Hsp60-deletion. In vivo, the IEC-specific loss of Hsp60 resulted in a transient drop in Lgr5+ cells with Lgr5 expression being reduced from day 2 after end of tamoxifen treatment and signals reappearing from day 4. Cells positive for the stem cell markers Olfm4 and Hopx expanded at day 2, indicating reserve stem cell populations compensating for the Lgr5 deficiency. Loss of minimal numbers of Lgr5+ stem cells at day 2 were further paralleled by increased numbers of Lgr5−, Lyz− Paneth cells and no signs of enhanced cell death, indicating differentiation of ISC into Paneth cells. Lgr5−, Lyz− Paneth cells displayed a premature phenotype with diffuse Lyz staining in the cytoplasm.
Concomitantly, these cells were positive for the WNT ligand WNT11A and autophagy/mitophagy-associated LC3, suggesting autoregulatory mechanisms for the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

**Conclusion:** Our results indicate that mitochondrial function not only reflects IEC phenotypic changes but seems to be the driving force in differentiation processes. Mitochondrial function might therefore represent a key player at the edge of intestinal tissue homeostasis and repair/healing processes in the context of disease.

**Introduction:** Previous studies have shown differences in disease phenotype of ulcerative colitis (UC) in South Asian (SA) migrants compared to Caucasians with pan-colonic phenotype predominant.1 The gut microbiota differs in Caucasian and SA patients with UC2 however, there is limited evidence on how this translates to the metabolome.

**Aims & Methods:** We aimed to examine the metabolomic profile in a newly diagnosed cohort of UC patients recruited from St. Marks Hospital, London, UK. Patients were stratified by ethnicity (SA, Caucasian, Other), treatment (None, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Metabolomics analysis was performed using a multivariate Gaussian mixture model for both clinical and metabolomic outcomes, ranging from an 85%3 to statistically insignificant level.4

**Results:** Fifty patients with UC of SA and Caucasian backgrounds were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Metabolomics analysis was performed using a multivariate Gaussian mixture model for both clinical and metabolomic outcomes, ranging from an 85%3 to statistically insignificant level.4

**Introduction:** Patients with active inflammatory bowel disease have elevated myeloid lineage leucocytes1 including the CD14+CD16+ DR+ e phenotype known as proinflammatory monocytes, and a major source of tumour necrosis factor-a.2 Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) is expected to promote remission or enhance drug efficacy. However, studies in ulcerative colitis (UC) patients have reported contrasting efficacy outcomes, ranging from an 85%3 to statistically insignificant level.4 Patients’ baseline demographic features may guide to selecting responder patients.

Aims & Methods: In a retrospective and single-centre setting we aimed to under- stand if patients’ baseline clinical and endoscopic features were relevant guide for identifying likely responders and non-responders to adsorptive GMA. The sub- jects were 145 consecutive UC patients who had undergone GMA with the Adacolumn as reinnovation induction therapy between 2012 and 2016. Seventy- five percent patients were steroid naive, 70 were steroid dependent, and 2 patients were steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity indexes defined as remission. Biopsies from endoscopically detectable inflamed large intestinal mucosa were processed to see the impact of GMA on leucocytes within the mucosal tissue.

Results: At entry, the average CAI was 12.8, range 10–17. Ninety-three patients (64.1%) had achieved remission (CAI ≤ 5) after GMA. 52 of 71 steroid dependent (71.7%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent subgroup. Observations on mucosal tissue biopsies showed that the expression of monocytes and macrophages were mostly normalised and monocytes and macrophages were mostly normalised. There was a marked reduction of infiltrating leucocytes in responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responders (96%), followed by steroid naïve patients. Additionally, a short duration of active UC prior to GMA marked a patient as a likely responder. Further, all patients who achieved remission were steroid free at week 12.

Conclusion: First-episode and steroid-naïve cases who responded well to GMA attained a favourable long-term clinical course. Additionally, GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is favoured by patients for its safety profile and for being a non-remission induction therapy. Patients with extensive deep ulcer, with long duration of UC refractory to multiple pharmacologicals are unlikely to benefit from GMA. In therapeutic settings, knowing baseline clinical and endoscopic features, which may identify GMA responder patients should guide to stop futile use of medical resources.

Introduction: Alterations in short chain fatty acid (SCFA) metabolism have been reported in inflammatory bowel disease (IBD). Among SCFAs, butyrate has been described as a potent communicator to the immune system eliciting an anti-inflammatory response and other positive effects to human health1. A reduction of faecal butyrate levels has been reported in IBD but results have been conflicting or discrepant because of small study numbers and failure to distinguish disease type, activity or other variables such as diet. Microbiota is receiving increasing attention as a key environmental factor influencing IBD2, and butyryl-CoA:acetate CoA-transferase (BCoAT) is considered the main enzyme involved in butyrate synthesis by gut microbiota3.

Aims & Methods: We performed a comparative assessment of the capacity of the microbiota for butyrate synthesis by quantifying BCoAT gene content in stool from patients with Crohn’s disease (CD; n = 71), ulcerative colitis (UC; n = 58) and controls (n = 75), and determined whether it was related to disease activity, inflammation, microbial diversity and composition and/or dietary habits. BCoAT gene content was quantified by qPCR. Disease activity was assessed clinically and faecal calprotectin concentration measured as biomarker of inflammation in the gut. Microbial composition was determined by sequencing 16S rRNA gene. Dietary data were collected using an established food frequency questionnaire.

Results: Reduced butyrate-synthetic capacity was found in patients with active and inactive UC (p < 0.001 and p < 0.01, respectively), but only in active UC (p < 0.05). In patients with CD, low BCoAT gene content (below 9.5 log10 copies BCoAT/g) was associated with active disease, increased inflammation, lower microbial diversity, greater microbiota compositional change and decreased butyryltaconic acid, while no major changes were observed between patients with UC grouped according to BCoAT gene levels. Reduced BCoAT gene content in patients with CD was, in part, linked with lower intake of certain foods containing fibre (vegetables, fruits, high-fibre cereals, brown/wholemeal bread and nuts).

Conclusion: Reduced butyrate-synthetic capacity by the microbiota is more evi- dent in CD than UC and may relate to reduced fibre intake. The results suggest that simple replacement of butyrate per se may be therapeutically inadequate, perhaps by other components in diet. Dietary means may be more appropriate and profitable for patients with CD.

**Introduction:** Antibiotics sometimes have an influence on colitis negatively. Although it is well known that dysbiosis is one of the major disturbances to the gut environment, the molecular mechanisms underlying the pathogenesis remains unclear.

**Aims & Methods:** We aimed to clarify how antibiotics affect the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin (VCM), both antibiotics, metronidazole, neomycin, or a combination of ABPC and VCM (AV) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Metabolites and short chain fatty acid (SCFA) in the feces were measured by a chromatography- tandem mass spectrometry. Faecal microbiota was determined by 16S rRNA sequencing.

**Results:** Gut microbiota was analyzed in the A-V mice. Moreover, Gln metabolites and SCFA including butyric acid were decreased and family S24-7 and order Clostridiales were less abundant in the A-V mice. Interestingly, Gln treatment improved the anti-inflammatory and anti-mutagenic effects of butyric acid in RAW264.7 and macrophage cell culture. Pre-treatment with 7-OH-DPAT decreased the mucosal layer thickness 1.1-fold (p<0.05) during IA-colitis. Furthermore, 7-OH-DPAT significantly increased the expression of microglial and macrophages in 0.5 h (1.6-fold, p<0.05) and in 2 h (1.3-fold, p<0.05) after IA enema. Pre-treatment with 7-OH-DPAT decreased the mucosal layer thickness 1.1-fold (p<0.05), crypt depth 1.1-fold (p<0.05) and Goblet cell staining or by the reaction with Folin reagent. The content of hexose, fucose and hexosamine were determined by standard biochemical assays. Morphometric analysis was performed to evaluate the histological changes of colonic epithelial and goblet cells. Oxidative metabolism and arginase activity (analyzed by colorimetric method) in peritubular microvessels were investigated.

**Results:** Pre-treatment with 7-OH-DPAT did not affect the glycoprotein levels in normal mucosa, but significantly increased total levels of glycoprotein (1, 1.6-fold, p<0.05) and hexose (1, 1.1-fold, p<0.05) during IA-colitis. Furthermore, 7-OH-DPAT significantly increased the expression of microglial and macrophages in 0.5 h (1.6-fold, p<0.05) and in 2 h (1.3-fold, p<0.05) after IA enema. Pre-treatment with 7-OH-DPAT decreased the mucosal layer thickness 1.1-fold (p<0.05), crypt depth 1.1-fold (p<0.05) and Goblet cell intersection area 1.1-fold (p<0.05) after IA enema.

**Conclusion:** Pre-treatment with D3R-agonist increased levels of mucus secretion and activated natural immune response by macrophage activation during experimental colitis, which could indicate about the protective role of D3R.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0316 THE MECHANISM OF PROTECTIVE ROLE OF D3 DOPAMINE RECEPTORS IN PATHOGENESIS OF ULCERATIVE COLITIS**

A. Priyazhniuk, T. Dovbynychuk, Y. Holota, I. Varenich, L. Garmanchuk, G. Tolstanova

Taras Shevchenko National University of Kyiv, ESC ‘Institute of Biological and Medicine’, Kyiv/Ukraine

**Introduction:** Our previous study showed that activation of D3 dopamine receptors (D3R) had the beneficial effect in experimental colitis treatment while the mechanism of this effect is unclear [1]. The disruption of surface colon mucosa layer with subsequent activation of local immune response by the bacterial infiltration into the inner layer of the mucosa are the key pathogenic mechanisms of ulcerative colitis progression and perpetuation. We found the localization of D3R on the goblet cells in colonic mucosa [2].

**Aims & Methods:** We aimed to clarify how activation of D3R improves colonic mucus secretion during experimental colitis. Study was done on male Wistar rats (180–230 g). Experimental colitis was induced by 6% dextran sodium salt (IA) (0, 1 ml, enema). Selective D3R agonist 7-OH-DPAT (0.02 mg/kg, s.c.) was injected m. b. prior to IA enema. Rats were euthanized 0, 5 and 2 h after IA enema. In the autopsy 7 cm colon from the anus has been removed. Surface mucous layer was separated from epithelial cells with N-acetyl-L-cysteine and glycopolymers were measured by periodic acid/Schiff (PAS) staining or by reaction with Folin reagent. The content of hexose, fucose and hexosamine was determined by standard biochemical assays. Morphometric analysis was performed to evaluate the histological changes of colonic epithelial and goblet cells. Oxidative metabolism and arginase activity (analyzed by colorimetric method) in peritubular microvessels were investigated.

**Results:** Pre-treatment with 7-OH-DPAT did not affect the glycoprotein levels in normal mucosa, but significantly increased total levels of glycoprotein (1, 1.6-fold, p<0.05) and hexose (1, 1.1-fold, p<0.05) during IA-colitis. Furthermore, 7-OH-DPAT significantly increased the expression of microglial and macrophages in 0.5 h (1.6-fold, p<0.05) and in 2 h (1.3-fold, p<0.05) after IA enema. Pre-treatment with 7-OH-DPAT decreased the mucosal layer thickness 1.1-fold (p<0.05), crypt depth 1.1-fold (p<0.05) and Goblet cell intersection area 1.1-fold (p<0.05) after IA enema.

**Conclusion:** Pre-treatment with D3R agonist increased levels of mucus secretion and activated natural immune response by macrophage activation during experimental colitis, which could indicate about the protective role of D3R.

Results: Of 104 ileoecal resections, 30 (29%) and 15 (14%) had inflammation at the resection margin, respectively. After a median follow-up of 8.6 years, clinical recurrence was seen in 57%, and surgical recurrence in 26%. A significantly increased recurrence rate was seen in patients with active inflammation at the distal resection margin whereas recurrence rates were comparable for inflammation at the proximal site and radical resections (87%, 61%, and 50% resp., p < 0.001). Active inflammation at the distal resection margin (HR: 3.189 (1.635–6.220); p = 0.001) and smoking (HR: 2.502 (1.331–4.703; p = 0.004) were the only independent predictors for clinical recurrence. The incidence of surgical small bowel recurrence was significantly lower in randomised controlled trials compared with non-RCTs (25% vs. 38%, p = 0.004).

Conclusion: At the distal (colon) resection margin, and not the proximal ileum, after ileocecal resection was associated with significantly increased risk of clinical recurrence. This unexpected finding suggests that radiosensitivity in correctly diagnosed terminal ileitis (I1 disease), while it is of crucial importance to exclude colonic L3 disease. As this different phenotype is unlikely to benefit from more extensive surgery, pathological finding of positive distal resection margin should be regarded as a risk factor, warranting prophylactic drugs or close monitoring.

P0319 LIPOSOMAL FORMULATION AS A NEW DRUG DELIVERY SYSTEM FOR CROHN’S DISEASE - VALIDATION IN THE MOUSE MODEL OF TNBS-INDUCED COLITIS
J. B. Krajewska, P. Pietruszka, D. Tomczyk, J. Fichna
Department Of Biochemistry, Medical University of Lodz, Lodz; Poland

Introduction: Crohn’s disease (CD), a chronic inflammatory disease of the gastrointestinal tract, constitutes a significant healthcare burden, especially in the developed societies. Current methods of treatment are only partially effective and/or associated with major adverse effects. New therapeutic solutions are therefore urgently needed to ameliorate the often complex medical therapy, reducing complications and improving patients’ quality of life.

Aims & Methods: The objective of the study was to assess the effectiveness of delivery of anti-inflammatory drugs encapsulated in the liposomal formulation. Liposomes were prepared using thin-lipid hydration method. 0.9% sodium chloride was used as a solvent. The hydration solutions contained a nonionic surfactant (sodium cholate) and a cholesterol analogue (cholesteryl dimyristoyl phosphatidylethanolamine), and were prepared by thin-lipid hydration method. In order to evaluate the capacity for drug delivery of the liposomal formulation, the best anti-inflammatory effect was obtained when liposomal suspension with berberine was used, while the treatment with 5-ASA was less effective. Additionally, we assessed the efficacy of a liposomal suspension containing 5-ASA and berberine for the treatment of Crohn’s disease.

Results: The macroscopic scoring index included the evaluation of the colon length and bowel thickness as well as the presence of ulcers, haemorrhage, faecal blood and diarrhea. Additionally, tissue myeloperoxidase (MPO) activity was determined and body weight was measured. The obtained results indicate that the best anti-inflammatory effect was obtained when liposomal suspension with berberine was used, while the treatment with 5-ASA was less effective. Surprisingly, CGA administration caused a detrimental effect as demonstrated by higher macroscopic score and increased MPO activity.

Conclusion: Drug-loaded liposomes may enhance the penetration of active compounds through the gut wall and therefore allow for increased bioavailability and effectiveness of the treatment at lower doses. We also showed that plant-derived compounds, such as berberine and CGA, provide a new direction in the search of anti-inflammatory substances. However, increased bioavailability of anti-inflammatory compounds may result in adverse effects.

Introduction: Diarrhoea is a common indication for colonoscopy. International guidelines recommend colon biopsies should be routinely taken at lower GI endoscopy in patients with diarrhoea [1, 2] to look for microscopic colitis. The epidemiology of contemporary microscopic colitis is largely unknown with published data based on an earlier time period pre-2001 and in small retrospective series. We have systematically collected a large and contemporary cohort of patients with incident microscopic colitis to help further our understanding of this disease.

Aims & Methods: Colonic biopsies demonstrating microscopic colitis between 2001 and 2007 were identified from the pathology reports of the Endoscopy Department. GI endoscopy procedures taking place during this time period were identified from an electronic database. Incidence rates were calculated using the total population for Nottinghamshire derived from UK mid-year population estimates [3]. Poisson regression models were used to determine rate ratios.

Results: 843 people were diagnosed with microscopic colitis of which 60.7% were female (n = 512). The mean age at diagnosis was 65.0 (95%CI 64.0, 65.9) years. 57.5% (n = 485) had collagenous colitis and 42.5% had lymphocytic colitis. The
incidence rate of microscopic colitis appeared to increase with time (Table). The incidence of microscopic colitis in 2016 was twice that observed in 2009 (incidence rate ratio 1.86; 95%CI 1.41, 2.46). There was a strong, independent graded association between the incidence of microscopic colitis and the number of lower GI endoscopy procedures undertaken (p = 0.03).

Conclusion: Microscopic colitis diagnosis is becoming more common. It is unclear whether microscopic colitis itself is increasing or greater numbers of lower GI endoscopy are being undertaken causing an ascertainment bias. Further work is required to explore environmental exposures such as drugs associated with microscopic colitis and to observe its natural history.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Data on extra-intestinal manifestations (EIM) and their impact on disease course of ulcerative colitis (UC) in population-based cohorts are scarce, particularly in paediatric- and elderly-onset UC patients.

Aims & Methods: The aims of this population-based study were to assess 1) the occurrence of EIM in paediatric- and elderly-onset UC; and 2) their impact on long-term disease outcome. Paediatric-onset (<17 years at diagnosis) and elderly-onset UC patients (>60 years) from a French prospective population-based Registry (EPIMAD) were included. Data on EIM and other clinical factors at diagnosis and at maximal follow-up were collected.

Results: 158 paediatric- and 470 elderly-onset UC patients were included (median age at diagnosis 14.5 and 68.8 years; median follow-up 11.2 and 6.2 years, respectively). EIM occurred in 8.9% of childhood- and 3% of elderly-onset patients at diagnosis and in 16.7% and 2.2% of individuals during follow-up (p < 0.01). The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset). Presence of EIM at diagnosis was associated with more severe disease course (need for immunosuppressive or biologic therapy or colectomy) in both paediatric- and elderly-onset UC (HR = 2.0, 95%CI: 1.0–4.2 and HR = 2.8, 9–7.9). Extensive colitis was another independent risk factor in both age groups.

Conclusion: Elderly-onset UC patients had lower risk of EIM either at diagnosis or during follow-up than paediatric-onset UC. Presence of EIM at diagnosis predicted more severe disease outcome including need for immunosuppressive or biologic therapy or surgery in both paediatric- and elderly-onset UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Data on long-term natural history of microscopic colitis (MC), including collagenous (CC) and lymphocytic colitis (LC) are lacking.

Aims & Methods: All new cases of MC diagnosed in the Somme area, France between January 1st, 2005 and December 31th, 2007 were prospectively included. Colonic biopsies from all patients were reviewed by a group of 4 expert gastro-intestinal pathologists to assess the diagnosis of CC or LC. Demographic and clinical data were retrospectively collected from diagnosis to February 31th, 2017.

Results: One hundred and thirty cases of MC, 87 CC and 43 LC were included (median age at diagnosis 70 and 48 years, respectively). The median follow-up was 9.6 years (Q1 = 7.6; Q3 = 10.61). By the end of follow-up, 37 patients (28%) relapsed after a median time of 3.9 years (1.2; 5) since diagnosis, without significant difference between CC and LC (30% vs 25%, p = 0.47). Twenty patients (15%) were hospitalized for a disease flare and 32 (25%) presented with another autoimmune disease. Budesonide was the most widely used treatment (n = 74; 59%), followed by 5-aminosalicylic acid (n = 31; 25%). Median duration of budesonide treatment was 92 days (70–168) and no adverse event to budesonide were reported. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticosteroid-resistant. Only one patient was treated by immunosuppressants (azathioprine). No colorectal cancer was reported during follow-up. Any of the death (n = 25) observed during follow-up were linked to MC. In multivariate analysis, age at diagnosis (HR 1.03; 95%CI, 1.00–1.06; p = 0.02) and budesonide exposure (HR 0.46; 95%CI, 0.18–0.90; p = 0.03) were significantly associated with relapse.

Conclusion: This population-based study showed that after diagnosis, two third of patients with MC observed long term clinical remission. Age at diagnosis and budesonide exposure were associated with a risk of relapse.

Introduction: It has been demonstrated in many chronic conditions, including inflammatory bowel disease (IBD), that better patients’ knowledge about pathology and treatment improves the course and management of disease. The aim of this study was to develop an updated self-questionnaire to assess patients’ level of knowledge of IBD.

Aims & Methods: The IBD-INFO included 3 parts: an original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohn’s and Colitis Knowledge score (CCKNOW) (Q2) and Crohn’s and Colitis Pregnancy Knowledge score (CCCPNOW) (Q3). The reliability and discriminatory ability of the questionnaire were validated with 3 groups of non-IBD volunteers with various theoretical knowledge levels. The final questionnaire (64 validated questions) was then tested on 364 in- and out- IBD patients from 4 French university hospitals. The score for each part of the questionnaire was calculated and factors associated with low scores were identified by uni- and multivariate logistic regression analyses.

Results: The scores obtained by the 3 non-IBD volunteer groups differed significantly (p < 0.0001) and the IBD-INFO questionnaire showed excellent internal reliability and consistency (α = 0.98). The median total score obtained by the IBD patients was 27/64 [0–59], and scores for Q1, Q2 and Q3 were, respectively, 10/23
Within the first 10 years after UC onset. Furthermore, biological therapy investigation of the average disease activity in 5-year-intervals in UC patients lighted that allow better targeting of patients and areas requiring an improve-
ment in IBD treatment.

**Conclusion:** Using the IBD-INFO, an updated self-administered questionnaire built to assess IBD patients' knowledge, several risk factors have been high-
lighted that allow better targeting of patients and areas requiring an improve-
ment in IBD treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2Institute Of Biostatistics And Clinical Research, University of Münster, Münster/Germany

**Contact E-mail Address:** annafriederike.cordes@ukmuenster.de

**Introduction:** Primary sclerosing cholangitis (PSC) is a disease comprising Crohn’s disease (CD) and ulcerative colitis (UC), which are characterized by chronic remittent intestinal inflammation and carry the risk for extraintestinal manifestations including primary sclerosing cholangitis (PSC). Available data on the impact of PSC on the disease course in IBD patients is scarce. Therefore, we assessed the impact of coincidental PSC on the disease course in a large IBD patient cohort.

**Aims & Methods:** In total 1814 patients with histologically confirmed IBD were evaluated. Medical records from 795 UC and 1022 CD patients as well as from 77 UC-PSC and 10 CD-PSC patients were assessed. Data were evaluated using standard statistical methods. In matched-pair analyses, IBD patients with and without PSC were matched at the ratio of 3:1 by sex, disease entity, age at diagnosis, time from diagnosis to first presentation, and duration of follow-up. Time to event analysis was performed using survival analytic methods including Kaplan-Meier method and log-rank test.

**Results:** PSC was diagnosed in 77 and 10 patients out of 781 UC (9.8%) and 1022 CD (0.1%), respectively. Age at UC onset was significantly lower in UC-PSC patients than in patients without PSC (25.3 vs. 29.3 years; p < 0.001). Extensive disease manifestation was observed in 46% of UC patients, whereas pancolitis was more frequently diagnosed in UC-PSC patients (75% vs. p < 0.001). Concerning CD, all patients with coincident PSC showed colonic involvement, while only 69% of the CD patients without PSC had colonic manifestation (p = 0.044). Interestingly, IBD patients without PSC presented more frequently with active disease, as compared to IBD-PSC patients (p = 0.011; age: year; p = 0.055). Conveneniently, average disease activity assessed by complete Mayo score, was significantly higher in UC patients with acute flare as compared to UC-PSC patients (7.3 vs. 6.2; p < 0.001). Investigation of the average disease activity in 5-year-intervals in UC patients revealed a stronger disease activity in UC patients without PSC, especially within the first 10 years after UC onset. Furthermore, biological therapy including vedolizumab and anti-TNF-α antibodies was initiated more frequently (21.7% vs. 16.4%; p = 0.043) and earlier (20.4 vs. 28.6 years after onset, p = 0.087) in UC without PSC than in those with coincident PSC. Colorectal high grade intraepithelial neoplasia (HGIN) and CRC were detected in 25 IBD-PSC patients and in 7 IBD-PSC (4 UC and 3 CD) patients (1.45% vs. 8.05%). Of note, in IBD-PSC patients, HGIN/CRC occurred significantly earlier than in IBD patients without PSC (20-year-risk: 9.6% vs. 5.6%; p = 0.003).

**Conclusion:** In our large cohort study, IBD patients with coincident PSC showed a distinct disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Crohn’s disease is a chronic, immune mediated inflammatory condition which affects the gastrointestinal tract. NOD2/Card15 mutations have been linked to an increased risk of Crohn’s disease and to some of its phenotypes. This study aimed to determine the presence of the above mutations in Arab patients suffering from Crohn’s disease in Kuwait.

**Aims & Methods:** Blood samples were obtained from 103 Arab patients with Crohn’s disease and 100 normal Arab controls. The genomic DNA was isolated from the samples using QIAamp DNA Blood mini kit. The isolated DNA were used in a Polymerase Chain Reaction (PCR) using four sets of primers specific for each mutation in the NOD2/Card15 (rs2066842, SNP5, Exon 8; 902C>T; rs2066845, SNP12, Exon 2104C>T; and rs2066847, SNP13, Exon 3020insC). The PCR-amplified DNA were sequenced using ABI 3130xl Genetic analyzer, and specific mutations were detected by using the sequence analysis software.

**Results:** Table 1 shows the results of all homozygous and heterozygous mutations for each control subject. There was no association in rs2066842 (SNP5, Exon 802C>T) in the NOD2/Card15 sequence of 17 (16.5%) Arab patients with Crohn’s disease compared to 32 (32.0%) normal controls (p < 0.05). This difference was statistically significant if the mutation was heterozygous (p < 0.005). These results support previous studies that mutation in rs2066842 (SNP5, Exon 8 2722C>G) was found in 24 (23.3%) patients and 10 (10.0%) controls (p < 0.05). This difference was statistically significant if the mutation was homozygous (p < 0.05) but not in heterozygous. The mutation in rs2066845 (SNP12, Exon 2104C>T) was found only in one patient and no controls and rs2066847 (SNP13, Exon 3020insC) was not detected in any of the patients or controls. Table 1. Mutations in SNP5, SNP8, SNP12 and SNP13 of the NOD2/Card15 gene in Arab patients with Crohn’s disease and control subjects.

**Conclusion:** The above study suggests that mutation in rs2066842 (SNP5, Exon 8 2722C>G) occurs more frequently in Arab patients with Crohn’s disease compared to controls, but the disease is associated only with the homozygous mutation. Mutation in rs2066842 (SNP5, Exon 802C>T) occurs more frequently in controls compared to patients and the heterozygous mutation appears to have a protective effect against Crohn’s disease in the Arab population.
**P0330** VDR GENE BSM I POLYMORPHISM AND ULCERATIVE COLITIS

D. A. Razumova1, A. Razumov2, M. Merzlyakov2, G. Yavan1

1Department Of Pathophysiology, Medical And Clinical Biochemistry, Kemerovo State Medical University, Kemerovo/Russian Federation
2Department Of Endoscopy, Kemerovo Regional Clinical Hospital, Kemerovo/ Russian Federation
3Kemerovo Regional Clinical Hospital, Kemerovo/Russian Federation

Contact E-mail Address: lariwar@mail.ru

Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin D receptor gene (VDR) associated with disorders of innate and adaptive immunity, as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the VDR gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism of the VDR gene with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of the Bsm I polymorphism of the VDR gene (rs1544410) in UC among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method (“SNP-express” reagents, Lytech Co. Ltd., Russia) with electrophoresis. The association between the polymorphism and UC was determined using the software GenStat 16 (var) for variants of rs2241880, STAT3 (SNP rs744166), ECM1 (SNP rs3773240), NKKX2-3 (SNP rs10883365), was performed. Serological titers of anti-Saccharomyces cerevisiae (ASCA IgG and ASCA IgA), perinuclear anti-neutrophil cytoplasmic antibodies (pANCA), C-reactive protein (CRP), and antibacterial flagellin antibody (anti-CbIr1), were determined by specific enzyme-linked immunosorbent assay (ELISA).

Results: Fifty-nine out of 80 cases (74%) and 50/77 controls (65%) were positive for at least one of the serum antibodies (p = 0.09). A combination of any 4 of them was found in 3 cases (4%) and no controls (p = 0.28). No significant difference was found for any of the studied autoantibodies between cases and controls. Homozygosity for any susceptibility variant was found in 60 out of 80 cases (75%) and in 52/77 controls (67.5%) (p = 0.37), with no significant association between family history and genotype status. No combination of gene variants significantly differed between cases and controls.

Conclusion: Our preliminary results argue against a role of commonly recognized genetic polymorphisms and microbial antibodies as markers of disease susceptibility in siblings of children with UC. However, data from larger and prospective studies, possibly including microbial characterization, are warranted before drawing definitive conclusions.

Introduction: Although the pathogenesis of IBD is multifactorial, the role of genetic factors has been widely recognized. Among the numerous genetic factors associated with IBD, the proband is the most reliable proxy for the entire family. Hence, the current study aimed to investigate the genetic factors and serological markers associated with IBD in siblings of affected children, as well as to determine the likelihood of diagnosis in unaffected siblings.

Aims & Methods: The aims of this study were to identify genetic and serological markers associated with IBD in unaffected siblings. The study included 80 siblings of children with IBD and 77 healthy controls with no family history for IBD. Genotyping (TaqmanMGB) for variants of ATG16L1 (rs2241880), STAT3 (SNP rs744166), ECM1 (SNP rs3773240), NKKX2-3 (SNP rs10883365), was performed. Serological titers of anti-Saccharomyces cerevisiae (ASCA IgG and ASCA IgA), perinuclear anti-neutrophil cytoplasmic antibodies (pANCA), C-reactive protein (CRP), and antibacterial flagellin antibody (anti-CbIr1), were determined by specific enzyme-linked immunosorbent assay (ELISA).

Results: Fifty-nine out of 80 cases (74%) and 50/77 controls (65%) were positive for at least one of the serum antibodies (p = 0.09). A combination of any 4 of them was found in 3 cases (4%) and no controls (p = 0.28). No significant difference was found for any of the studied autoantibodies between cases and controls. Homozygosity for any susceptibility variant was found in 60 out of 80 cases (75%) and in 52/77 controls (67.5%) (p = 0.37), with no significant association between family history and genotype status. No combination of gene variants significantly differed between cases and controls.

Conclusion: Our preliminary results argue against a role of commonly recognized genetic polymorphisms and microbial antibodies as markers of disease susceptibility in siblings of children with IBD. However, data from larger and prospective studies, possibly including microbial characterization, are warranted before drawing definitive conclusions.

and decreased UPRE promoter activity. IRE1 signaling exerted by ORMDL proteins as shown by reduced XBP1 splicing in both in vivo and an acute and chronic DSS-coltis model using Ormdl3-deficient mice.

Results: Our in vitro studies demonstrated that ORMDL3 facilitates ER stress-induced ATF6 activation. Overexpression of ORMDL3 resulted in increased cleavage of ATF6 and augmented ERSE promoter activity. Mechanistically, we show that ORMDL3 colocalizes and directly interacts with ATF6. Furthermore, ORMDL3 overexpression induced the PERK pathway by elevating IRE1 and activating transcription factor 6 (ATF6) and ATFR6 promoters. In contrast, we observed an increased ratio of IRE1 signaling exerted by ORMDL3 proteins as shown by reduced XBP1 splicing and decreased UPRE promoter activity. Ormdl3-deficient mice showed an increased susceptibility to acute DSS-induced colitis compared to their wild-type littermates, Ormdl3−/− mice showed less body weight loss and an improved survival rate.

Conclusion: This study demonstrates for the first time the modulatory functions of ORMDL proteins as regulators of all three UPR signaling pathways. Altogether, our findings suggest that ORMDL proteins constitute a precise fine-tuning mechanism of the UPR determining cell fate decisions in response to ER stress.

Contact E-mail Address: hassiumahmoud7@hotmail.com

Introduction: Few studies have assessed Crohn’s disease (CD) according to disease activity using clinical, laboratory & radiological activity indexes; but few have analyzed the damage the disease bring about on the GI tract. Lémann score was designed to develop a comprehensive assessment of the structural bowel damage, including strictureing lesions, penetrating lesions (fistulas and abscesses), and surgical resection.

Aims & Methods: To calculate Lémann score in a cohort of Egyptian patients to determine its ability to assess the structural damage caused by CD in Egyptian patients. The Lémann score was calculated using specific computer software based on the original paper by Pariente B et al.1 in a cohort of Egyptian patients with CD followed from April 2013 - August 2015. The temporal relation between Lémann score and disease duration was also assessed.

Results: A total of 93 patients with CD were enrolled, 69% males and 31% females. Median age was 32 years, 36% were smokers. The clinical presentation varied between abdominal pain occurring in 90% followed by 69% with chronic diarrhea, 52% with weight loss. Few patients (26%) present with extraintestinal manifestations. According to ECCO classification of disease severity, 73% of our patients had mild disease, 17% had moderate disease, 10% had severe disease. According to Montreal classification, 25% of patients were type 1, 25% type 2, 19% type 3, 10% type 4 & 10% type 5. Radiological assessment of the digestive tract showed 3% with rectal inflammation, 3% with ileal inflammation and 12% with cecal inflammation. In contrast, we observed an increased ratio of IRE1 signaling exerted by ORMDL3 proteins as shown by reduced XBP1 splicing and decreased UPRE promoter activity. Ormdl3-deficient mice showed an increased susceptibility to acute DSS-induced colitis compared to their wild-type littermates, Ormdl3−/− mice showed less body weight loss and an improved survival rate.

3sz. Gyermekklinika, Semmelweis Egyetem, Budapest/Hungary

Introduction: The most relevant scope of serologic antibodies in Crohn’s disease [CD] is to stratify the risk of complicated disease course. Significance of distinct antibody classes and their characterisation was rarely considered. We aimed to address these concerns. Aims & Methods: Sera of 266 well-characterized CD patients (m/f=112/154, median age: 25 years, B1:80.1%, P1:18.0%) and 155 controls were assayed for traditional anti-microbial antibodies (ASCA IgA/IgG, anti-OMP IgA), Endotoxin core IgA (EndoCaB) and a panel of non-specific immunoglobulin A (IgA) antibodies (IgA1, IgA2 and secretory IgA) were also assessed by ELISA. An observational follow-up study [median, 143 months] was conducted to assess possible associations between serologic antibodies and the development of various complications and subsequent surgical interventions. A novel flow cytometry test system was established for characterisation of IgA type ASCA to reveal possible origin of the antibody.

Results: A total of 65.7% and 46.2% of the CD patients were positive for ASCA IgA/IgG and anti-OMP antibodies. Both ASCA types occurred equally. EndoCaB IgA positivity was more frequent (15.4% vs. 5.4%, p < 0.001) and IgA subtype (29%) and presence of the secretory component (89% of total ASCA IgA) concurrently. ASCA IgA subtyping assays revealed marked increase in the proportion of IgA2 subtype (29%) and presence of the secretory component (60% of total ASCA IgA) concurrently.

Conclusion: Consideration of antibody classes is an important novel parameter in serologic prediction in CD. Involvement of gut mucosal immune system is in center of IgA type antibody formation reflecting sustained exposure and dysregulated immune response to bacterial constituents.

Introduction: Double Balloon Enteroscopy (DBE) is a new endoscopic technique used to examine deep small bowel either oral or anal it could be of great utility in the management of Crohn’s disease patients.

Aims & Methods: We aimed to evaluate the diagnostic yield and therapeutic impact of DBE on small bowel CD. The medical records of 180 CD patients, from 2011 to April 2014 were retrospectively reviewed. Exclusion criteria were included if they had known CD based on clinical, colonoscopic and histological findings and had been subjected to DBE. If one patient underwent more than one DBE examination only the first examination was considered. The primary end point of our study was to evaluate small bowel involvement that is beyond the reach of conventional colonoscopy. The secondary endpoints were to determine the impact of DBE findings on management strategy of CD. The diagnostic yield of DBE in small bowel CD was determined. In addition, the changes in medical treatment, endoscopic intervention and surgical procedures, within three months after DBE, were analysed.

Results: Among 180 patients with CD, 90 patients underwent 168 DBE examinations and were included. The mean age of included patients was 40 ± 13.6 years. They were 63 males and 27 females. Eighty-two (91%) patients with established CD underwent DBE for evaluation of small bowel involvement and 8 (9%) patients underwent DBE because of suspicion of CD and had been newly diagnosed. The overall diagnostic yield of DBE was 69%, DBE revealed small bowel involvement proximal to the terminal ileum in 40 (64.5%) patients; of them 17 (42.5%) patients had isolated small bowel CD. Within 3 months after DBE examination the management strategy of CD changed in 47 (52.2%) patients, based on DBE findings. The medical treatment escalated in 20 (23.2%) patients, and decreased in 7 (11%). Forty-one (24%) patients underwent DBE-assisted balloon dilatation, and 6 (9.6%) patients underwent CD-related surgery.

Conclusion: DBE is able to detect small bowel involvement in a significant proportion of CD patients. The DBE findings modified the management strategy in at least one half of CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0340 IS THE CDMRIS USEFUL TO MONITOR PATIENTS WITH CROHN’S DISEASE BY MAGNETIC RESONANCE IMAGING?

C. Le Berre1, M. Tahora2, C. Trang1, M. Flamant3, P. Hallouin3, S. Bruley Des Varnanes1, A. Bourrière1, E. Frampas1

3Clinique Jules Verne, Nantes, France

Introduction: Magnetic resonance enterography is now recognized by the European Crohn’s and Colitis Organization (ECCO) as a reference procedure to assess the intestinal involvement of Crohn’s disease (CD), including extra-luminal complications, as well as to monitor patients under treatment. A new MRI index of severity was developed in 2015 by the GETAID consortium, specifically to evaluate lesions located in the small intestine. This score, labeled CDMRIS, is a Crohn’s disease’s magnetic resonance index of severity (CDRMIS), considers, for each 20-cm small bowel segment, the intensity of relative contrast enhancement (mild–moderate or severe), deep ulceration without fistula, “comb sign”, any fistula, and abscess. Although well standardized, this index has not yet been validated, either for the initial assessment of CD at diagnosis, or for monitoring patients under treatment. Its feasibility in routine practice has never been tested.

Aim and Methods: The aims of this study were to evaluate the feasibility of applying the CDMRIS score in clinical practice, to evaluate its variability after the initiation or optimization of an anti-TNF treatment, and to measure its correlation with an evaluation of clinical activity. Patients with known small bowel disease who underwent two MR exams at a maximal interval of 30 months were included between 2010 and 2015. Each exam was interpreted twice and the CDMRIS score was calculated on both exams in addition to classical criteria. All patients had a clinical evaluation over time, separating them in two groups: “active” and “inactive” disease.

Results: Seventy-two patients were included, with a mean CDMRIS of 3.4 at baseline, decreasing to 2.6 (p = 0.052) independently of clinical disease activity. The mean interval between the two MRIs was 15.4 months, and there was a significant larger decrease in the CDMRIS score when the interval was above 12 months. Two other radiological parameters decreased significantly: the rate of patients with a mural T2-hyperintensity (36.1% to 20.8% p = 0.042), with a good chimecorrelational correlation, and mean wall thickness (5.5 to 4.4 mm, p = 0.034).

Conclusion: This study demonstrated the feasibility of applying the CDMRIS in clinical practice, but sensitivity was too low to detect early changes. Accuracy for a long-term monitoring needs to be evaluated. Wall thickness and mural T2-hyperintensity emerged as useful radiological factors, significantly associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0341 CONCORDANCE OF STOOL FREQUENCY AND ABDOMINAL PAIN MEASURES WITH SIMPLE ENDOSCOPIC SCORES FOR CROHN’S DISEASE

1Center For Clinical Epidemiology And Biostatistics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia/United States of America/PA
2University of Leuven, Leuven/Belgium
3Academic Medical Center, Amsterdam/Netherlands
4Icahn School of Medicine at Mount Sinai, New York/United States of America
5University of California San Diego, La Jolla/United States of America/CA
Introduction: Crohn’s Disease Activity Index (CDAI) has been shown to correlate poorly with endoscopic measures of mucosal inflammation/ulceration.1, 2 There is a movement towards using components of the CDAI, namely stool frequency (SF) and abdominal pain (AP), to better define disease activity. Patients randomized in the EXTEND study3 with both major components of CDAI, and mean changes from baseline in both SES-CD and CDAI were assessed at weeks 12 and 52 using Pearson correlation coefficients. Endoscopies were scored by a central reader. Data are reported as observed.

Results: A total of 121 patients at week 12 and 80 patients at week 52 had both CDAI and SES-CD values. Mean (SD) CDAI and SES-CD values at week 12 were 193.8 (116.4) and 8.0 (7.4), respectively, and 132.5 (97.6) and 5.9 (6.6), respectively, at week 52. A significant, but weak correlation was observed between CDAI and SES-CD at week 12 (r = 0.31 [P < 0.001]) and at week 52 (r = 0.31 [P < 0.005]). Similar results were observed for correlations between mean changes from baseline in CDAI and SES-CD at weeks 12 (r = 0.35 [P < 0.001]) and 52 (r = 0.31 [P = 0.005]). Correlations between individual components of CDAI and SES-CD at weeks 12 and 52 are shown in the table. SF, AP, extra-intestinal manifestations, and SF + AP were significantly correlated with SES-CD at week 12; the strongest correlation was for SF (r = 0.46) and the addition of AP to SF did not increase the correlation (Table). At week 52, SF, hematocrit, and SF + AP were significantly correlated with SES-CD. At week 12, the correlation of SF + AP with SES-CD was significant regardless of whether the patient had disease of the ileum (r = 0.44 [P < 0.001] with ileal disease; r = 0.48 [P < 0.001] without ileal disease), while SES-CD correlated more strongly with AP in those with ileal disease (r = 0.27 [P = 0.036]) than those without ileal disease (r = 0.16 [P = 0.233]).

Introduction: Crohn’s disease (CD) with complications such as penetrating, structural, and perianal disease is called complicated CD. However, no validated, inexpensive, or sensitive models for prediction of risk are available in complicated CD. We have found that a novel immunological balance, the CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ ratio, consisting of CD8⁺/CD8⁺, and CD8⁺/CD8⁺ T cells, can predict the prognosis for patients with inflammatory bowel disease (IBD). Thus, we hypothesize that the CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ ratio can predict the poor outcome for patients with complicated CD.

Aims & Methods: To test the efficiency of CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ balance to predict the subsequent active stage, and to explore the correlation between the balance and the risk factors, for the newly diagnosed complicated CD. Seventeen patients with complicated CD were enrolled as the observation group, while the other 48 CD patients with no complications were enrolled as the control group. Peripheral blood samples were drawn from all the 65 newly diagnosed CD patients for CD8 T cells testing through flow cytometry (FCM) when enrolling. The potential risk factors, including demographic, pathophysiological, and therapeutic factors were compared between the two groups. A 30-week follow-up group was performed, and the CD8 T cells testing were repeated. The sensitivity and specificity of the CD8 T cells’ level and balance in predicting were analyzed through receiver operator characteristic (ROC) curves. The cumulative remission lasting rates (CRLRs) under the different risk factors were analyzed using the Kaplan–Meier method.

Results: I. Risk factors: compared with the control CD group, patients with complicated CD had a larger proportion in male (P = 0.001), younger in age (P = 0.019), lower body mass index (BMI) (P < 0.0001), higher prescriptions in immunosuppressants (P = 0.029) and steroids (P = 0.015), as well as as a significant higher surgical rate (P = 0.001). Pearson and Spearman correlation analysis showed that CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ ratio was associated with BMI, CDAI, steroids, and surgery (P all < 0.05). II. Follow-up and dynamic change of the ratios of CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ reached the bottom at the 30th week and were significantly lower at the 6th, 22nd, and 30th week during follow-up, in the complicated CD patients when compared to the control ones (all P < 0.05). A shorter lasting time of remission (LTR) was found in complicated CD patients (P = 0.044). ROC curve showed that CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ ratio could accurately predict the active stage for the complicated CD patients with area under curve (AUC) of 0.890, and 95% CI of 0.822 to 0.958], and the best sensitivity of 89.2% and specificity of 85.3% were found when the ratio was 1.03. III. Kaplan–Meier analysis: Undergoing of steroids and surgery was closely related to worse outcome for the complicated CD patients, and patients who underwent steroids and surgery had the significantly lower CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ ratio and lower CRLRs (all P < 0.05).

Conclusion: Depending on steroids and surgery stands for a more severe disease activity and thus disequilibrate the immunological balance, which could be the main reason for lower CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ activity and thus disequilibrate the immunological balance, which could be the main reason for lower CD8⁺/CD8⁺/CD8⁺/CD8⁺/CD8⁺ activity.

Introduction: The success of colonoscopy is dependent on efficient bowel cleansing. Inadequate bowel cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and potentially delay appropriate treatment. The increasing frequency of the incidence of colorectal cancer arising in the ascending colon necessitates effective cleansing of this area; additionally these cancers are often associated with poorer prognoses. Data suggest that detection in the ascending colon is more dependent on higher grades of cleansing, perhaps due to the nature of polyps present, which may be more likely to be sessile or serrated. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The NOCT study (a multicentre randomised Phase 3 clinical trial investigating bowel cleansing efficacy of NER1006 vs trisulfate solution) reported bowel preparation quality assessed by central readers. This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision making; hence this study may be more relevant for clinical practice than previous studies.

Aims & Methods: In the NOCT study 621 patients (males and females, aged 18–85) were randomly assigned in a 1:1 ratio to receive either NER1006 or trisulfate solution, each administered as an overnight split-dose. Data from the 523 patients who underwent a colonoscopy and had a site colonoscopist assessment were used in this analysis. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the Harefield Cleansing Scale;2 following segmental scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Cleansing of the ascending colon was graded from 0 to 4; grades 3 and 4 were judged as high-quality cleansing. N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or score of 3 or 4 (ascending colon, high quality)

Results: As Table 1 shows, bowel preparation quality of NER1006 when assessed by site colonoscopists did not show a statistically significant difference to trisulfate for the overall colon (93% vs 94%, P = 0.681; 95% CI: 5.1–3.3%) or ascending colon (80 vs 74%, P = 0.079; 95% CI: -0.7–13.6%). There was, however, a numerical advantage in favour of NER1006 on the proportion of patients achieving high-quality cleansing success in the right colon.

Table 1: Successful colon cleansing rates when treated with NER1006 or trisulfate solution.

Conclusion: For both preparations, site colonoscopist findings demonstrated similar very high rates of cleansing success for the overall colon (>93%) and high rates of high-quality cleansing of the ascending colon (>73%); however, statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists are notably higher than those previously reported by central readers.

Introduction: The efficacy of colonoscopy is dependent on the quality of bowel cleansing. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel cleansing solution and is a patented combination optimised for effective bowel cleansing. The DAYB study was a European multicentre, randomised trial that tested the hypothesis that NER1006 would be non-inferior to sodium picosulfate and magnesium citrate (NaPic + MgCit) in terms of overall bowel cleansing and high-quality cleansing of the ascending colon plus caecum [1]. Bowel cleansing was assessed using the Harefield Cleansing Scale (HCS) [2]. The primary endpoints of the study were assessed by video review by a central reader. Bowel cleansing on the HCS was also assessed by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopists.

Aims & Methods: In the DAYB study, 515 patients (aged 18–85, median age: 55.0 years) underwent screening, surveillance, or diagnostic colonoscopy and were randomly assigned in a 1:1 ratio to receive either NER1006 or NaPic + MgCit, each on the day before colonoscopy. In this analysis, data from 479 patients who underwent a colonoscopy and had a completed assessment by the site colonoscopist were included. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the HCS; cleansing of each segment of the colon was scored from 0 to 4. Scores 3 and 4 of the ascending colon were judged as high-quality cleansing. Cleansing of the overall colon was graded from A to D; grades A (all segments scored 3 or 4) and B (≥2 segments scored 2, no sections scored 1 or 0) were judged as successful cleansing.

Results: As indicated in Table 1, in the overall colon, successful cleansing was achieved in 122% more patients who received NER1006 than who received NaPic + MgCit (73% vs 61%, P = 0.003, 95% CI: 4.9–20.7). In the ascending colon, high-quality cleansing was achieved in 20% more patients who received NER1006.
Ner1006 than who received NaPic + MgCit (34% vs 14%, P < 0.001, 95% CI: 12.7–27.8).

Table 1: A comparison of bowel cleansing efficacy as assessed by site colonoscopists based on Ner1006 and NaPic + MgCit

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or score of 3 or 4 (ascending colon, high quality)

Conclusion: Ner1006 was shown to provide significantly better cleansing of the overall colon and high-quality cleansing of the ascending colon compared to NaPic + MgCit, when both treatments were administered the day before colonoscopy. The cleansing efficacy rate of the comparator was within its previously reported cleansing rates for day before administration, suggesting the improvement seen with Ner1006 is of clinical relevance.

P0346 LOW VITAMIN D LEVELS ARE RELATED TO CLINICAL ACTIVITY, MUCOSAL INFLAMMATION, AND INTESTINAL FIBROSTENOSIS IN CROHN’S DISEASE

Introduction: Several studies in recent decades have revealed new roles for vitamin D. For example, vitamin D plays a role in regulating skeletal muscle, as well as in cardiovascular and renal physiology, producing antinflammatory effects, suppressing fibrosis, and as a regulator of the immune system. In light of these new roles—especially as a regulator of the immune system and suppressor of fibrosis—vitamin D deficiency is considered to be related to disease activity and intestinal fibrosis, including that seen in Crohn’s disease (CD). Several reports have demonstrated a relationship between vitamin D deficiency and CD activity according to clinical parameters such as Crohn’s disease activity index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship by using endoscopic parameters such as endoscopic activity, mucosal inflammation, and intestinal fibrostenosis.

Aims & Methods: The aim of this study was to clarify the relationship between vitamin D deficiency and CD by using endoscopic parameters, as well as clinical parameters. Of the CD patients visiting Nagoya University Hospital from May 2011 to February 2016, 82 patients were enrolled in this study. Serum 25-hydroxyvitamin D (25(OH)D) levels, disease activity, and clinical factors of the subjects were investigated prospectively. Endoscopic findings of 52 of the 82 total patients enrolled were investigated retrospectively from endoscopic records. This study design was approved by the ethics committee of Nagoya University Hospital. Clinical remission was defined as CDAI ≤150. Mucosal healing was defined as a simple endoscopic score for Crohn’s disease (SES-CD) ≤1. Moreover, to evaluate endoscopic activity from two aspects (mucosal inflammation and fibrotic stenosis), we divided SES-CD score into endoscopic mucosal inflammation score and fibrotic stenosis score. Mucosal healing was defined as mucosal inflammation score ≤1, fibrostenosis was defined as narrowing score 0.

Results: Mean age of the subjects was 41.11, and the male/female proportion was 64/18. The mean serum 25(OH)D level of subjects was 17.1 ng/mL, and 61 cases (74.4%) were classified as severe deficiency or deficiency. Mean serum 25(OH)D levels of the clinical remission and clinically active groups were 18.7 ± 8.1 ng/mL and 12.4 ± 3.6 ng/mL, respectively (P < 0.001). In a multivariate analysis, low levels of serum 25(OH)D and serum albumin and positive C-reactive protein (CRP) results were correlated with clinical activity. Mean serum 25(OH)D levels of the mucosal healing and non-healing groups were 24.0 ± 9.8 ng/mL and 15.1 ± 6.6 ng/mL, respectively (P < 0.001). Mean serum 25(OH)D levels for the no mucosal inflammation and mucosal inflammation groups were 21.6 ± 9.6 ng/mL and 14.3 ± 5.5 ng/mL, respectively (P < 0.001); and those of the no fibrostenosis and fibrostenosis groups were 20.2 ± 8.3 ng/mL and 14.2 ± 6.7 ng/mL, respectively (P < 0.001; Mann-Whitney U test). In a multivariate analysis, low serum 25(OH)D levels were related with mucosal inflammation and intestinal fibrotic stenosis of CD (P < 0.05; logistic regression analysis).

Conclusion: This study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing of inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

Introduction: Inflammatory bowel diseases (IBD), such as ulcerative colitis (UC) and Crohn’s disease (CD), are chronic gastrointestinal diseases that are associated with protein-energy malnutrition (PEM). Although the frequency of altered body composition, such as reduced fat-free mass or skeletal muscle volume, has been shown to be high in patients with IBD, the relationships between skeletal muscle volume and the prognosis are yet to be elucidated.

Aims & Methods: We have conducted a retrospective study on 61 IBD patients who have admitted due to exacerbation of the disease. We have enrolled IBD patients who had had abdominal computed tomography and assessed the nutritional indices, such as the Onodera’s prognostic nutritional index (O-PNI) and controlling nutritional status (CONUT). O-PNI was calculated based on the serum albumin and total lymphocyte count, using the following equation: O-PNI = 10 × [serum albumin (g/dl) + 0.005 × total lymphocyte count (×109/l)]. The L3 skeletal muscle index (SMI) which is the cross-sectional area of the skeletal muscle at the level of the third lumbar (L3) vertebra normalized by the height squared is used to identify sarcopenia.

Results: Sarcopenia defined as low SMI were observed in 44% of all IBD patients (P = 0.047). The cumulative operation-free survival rate was significantly lower among sarcopenic patients in all IBD patients (P = 0.039) and stratified analysis in CD patients (P = 0.032) using Kaplan-Meier method and log-rank test. Conclusion: The L3 skeletal muscle area can be a prognostic factor of intestinal resection in IBD, especially in CD. The results may originate from the fact that CD presents the gastrointestinal diseases which accumulate intestinal deformity.

5Klinik für Innere Medizin I, Medizinische Fakultät, Heinrich-Heine-Universität, Düsseldorf, Germany
6IBG, Division of Endoscopy, Shiga Univ. of Medical Sciences, Otsu/Japan

Introduction: Crohn’s disease (CD) spans a wide range of severity, from mild to severe and is avoided under-as well as overtreatment is challenging. While factors determining bad prognosis are studied in detail, factors predicting a mild course with the chance of simple treatments are less known. Here we show first results of a prospective evaluation of a retrospectively created score (JCC 2013;7:263) for prediction of mild CD which consists of age at diagnosis, CRP, an endoscopy score, presence of perianal lesions and complications.

Aims & Methods: This is a prospective, ongoing study performed in 12 IBID-specialized private gastroenterology practices (outpatients only) in Germany. All consecutive new CD patients (diagnosis ±56 weeks) are included. At screening ileocolonoscopy with histology, investigation of the perianal area, laboratory tests including CRP are performed and CD complications (stenosis, fistula, extraintestinal manifestations or fever > 38°C) evaluated to complete of the above quoted score. Patients are treated at the discretion of the physician. In case of a score indicating a good prognosis (≤2) or of mild clinical appearance mesalamine is started. In all other cases patients are treated according to guidelines. 5 year follow up is planned for all patients. If initial therapy fails, treatment is escalated. Source data verification is performed by external monitors. Primary aim of the study is to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalamine therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This interim analysis presents preliminary data.

Results: Currently, 78 patients (33 male, 45 female; age 16–72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up ≥2 weeks (mean 8.5 months), mean age 35 years, 25 female, mean CRP 12.2 mg/l were included into the interim analysis. In 28 patients a score from 0-2 step-up treatment occurred in 77%, whereas in 28 patients with a score >2, step-up treatment rate was 43% (p = 0.043). Differences between patients with a score 0–2 > > 2 were 41 (vs. 28 years, p = 0,011), CRP < 2 mg/l (17/28 patients vs. 0,28, p < 0,0001), endoscopy score 1.4 vs. 2.7, p < 0,01), survival of 728 vs. 4, 28, stenosis 1/28 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and lever.

Conclusion: In this early analysis of a prospective study planned with a 5-year follow up, a significant proportion of patients with mild CD and simple mesalamine therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

Introduction: The Spanish Working Group on Crohn’s Disease and Ulcerative Colitis (GETECCU) and other international guidelines recommend testing of latent tuberculosis infection (LTI) before anti TNF therapy by screening with tuberculin skin test (TST) and, in a potential state of energy, double screening by TST and interferon-gamma release assays (IGRAs) or two-time tuberculin test (TST/booster). Routine repetition is not recommended.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and IGRA as using QUANTIFERON-TB (QFT) and the usefulness of repeating periodic (annual or biannual) screening in a population of IBD patients of Zamora (Spain). In a single cohort of IBD patients attended in the department of gastro-enterology of Zamora Hospital, we implemented a questionnaire and collected TST,booster performed previously to February 2015. Afterwards, prospectively, between February 2015 to February 2017, TST and QFT were performed at the same day, and the TST-booster 7 days after. Finally we compared the results of the TLI screening performed prospectively with the screening of the retrospective cohort.

Results: A total of 404 patients were included with a mean age of 51.5 (SD 16.6), 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%), 60/355 (16.9%) were smokers. The prevalence of LTI and the correlation between TST-booster and QFT is shown in table 1.

Table 1: Prevalence of LTI and correlation between TST-booster and QFT.

Prevalence of LTI in patients on immunomodulator therapy

Prevalence of LTI in patients on anti-TNF therapy

TST/booster or QFT (≥) 130/399 (32.6%) 47/239 (28.5%) 9.49 (18.4%) 10%, 28% TST/booster positives 116/371 (31.3%) 45/100 (45.4%) 10%, 28% TST/booster (−) 3272 (10.3%) 12/135 (9.8%) 3.42 (7.0%) QFT positives QFT (−) 28/12 (15.5%) 6/105 (5.7%) 0.12 QFT/booster positives 12/95 (4.5%) 3/89 (3.4%) 0.11 QFT/booster (−) QFT/booster (≥) 24/37 (6.4%) 4/162 (2.4%) 3.49 (6.1%)
Prevalence of LTI in retrospective testing was of 54/246 (22.0%). Prognostic factors such as >5 cm jejunal lesion were strong correlations (r = 0.61 – 0.74, p < 0.001) for both. CEAGA and QFT levels were moderately correlated with 3rd tertile LS (r = 0.68 p = 0.001) for both. The odds ratio of testing positive by TST and IGRA decreased to 0.57 if immunosuppressed (95% confidence interval [CI] 0.31–1.03, p = 0.06). The odds of testing positive by TST if immunosuppressed was 1.14 (95% confidence interval [CI] 0.31–1.03, p = 0.001 for both). There was a moderate correlation between both scores and CFC levels that was somewhat stronger for CEAGA (r = 0.39, p = 0.002 vs r = 0.53, p = 0.001 for both). There was a weak correlation between LS and CFC levels (r = 0.27, p = 0.04) and none for CEAGA and CFC (r = 0.21, p = 0.07). Conclusion: In our prospective study, CEAGA and LS strongly correlated and performed similarly for quantitative assessment of mucosal inflammation in established CD.

Disclosure of Interest: U. koplyov: The study was supported by a generous grant by the Helmsley Charitable fund

All other authors have declared no conflicts of interest.
A. Orlando, M. Principi, M.L. Scribano et al., Medication adherence in patients with TGN, but MARS (Pearson 0.09; p = 0.39) did not. The 7 patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. Correlation analysis was performed using Pearson tests.

Results: Of 100 approached patients none refused participation and TGN levels were available for 69. These included 38 women. Diagnoses were Crohn’s disease in 27, ulcerative colitis in 41 and IBD-U 3 cases. Concomitant therapy included 5/ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant report tool 71% (TGN), 87% (VAS), 87% (Morisky) and 77% (MARS). VAS (Pearson 0.315; p = 0.005) and Morisky (Pearson –0.363; p = 0.001) correlated moderately with TGN, but MARS (Pearson 0.09; p = 0.39) did not. The patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had a TP of 0.15-0.25 TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

Conclusion: Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for assessing adherence, but the correlation with TGN levels was only moderate. All authors have declared no conflicts of interest.

P0357 DIAGNOSTIC DELAY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE - A STUDY OF THE AUSTRIAN IBD STUDY GROUP (ATISG)

Aims & Methods: In a multicentre cohort study adult patients with IBD (CD, UC, IBD), especially in Crohn's disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

Introduction: Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn’s disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

Overall, 102 patients were enrolled in the study (Table 1). Study outcome was the diagnostic delay defined as the time required in complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics. Study outcome was the diagnostic delay defined as the time required in complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics.

Introducognition: Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn’s disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

Contact Email Address: emile.vazeille@udmail.fr

Introduction: Enterobacteria, especially adherent and invasive E. coli (AIEC), are suspected to play a key role in Crohn’s disease (CD). These bacteria are able to highly adhere to the ileal mucosa of CD patients through the CEACAM6 receptor (Carcinoembryonic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice oversexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.

Aims & Methods: We aimed to assess the correlation between the level of CEACAM6 in the saliva and the level of CEACAM6 in the ileum in CD patients and to define the best threshold of CEACAM6 in the saliva to detect overexpression of ileal CEACAM6. In addition, we attempted to identify non-invasive biomarkers of AIEC infection. In this prospective multicentre study (8 centers), all the patients requiring ileocoloscopy, regardless the indication, were consecutively included between September 2015 and September 2016. Clinical and endoscopic data were collected on the day of colonoscopy. Blood samples, stool samples (before bowel cleansing), saliva and ileal biopsies from healthy and IBD patients were also collected. CEACAM6 from ileal biopsies and saliva were measured (duplicates) using ELISA assays. AIEC were identified using phenotypic assays.

Results: Overall, 102 patients were enrolled in the study (Table 1). The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Baseline characteristics of the 102 CD patients included in the study.

| B2 | 26 (27.7%) |

References

ileal CEACAM6 level did not depend on disease severity or the site of biopsies, as the median level of ileal CEACAM6 was 854 pg/mg [570.3; 1646] and there was no difference in healthy or ulcerated ileum (756 pg/mg [487; 1617] vs. 947 pg/mg [604; 1828], p = 0.86). The median level of CEACAM6 from saliva was 3837 pg/mg [1889; 7338]. There was a positive correlation between the levels of CEACAM6 in saliva and CEACAM6 in the ileum (r = 0.47; p < 0.0001) in both macroscopically healthy areas (r = 0.53, p < 0.0001) and ulcerated areas (r = 0.39, p = 0.0082). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal CEACAM6. Using a ROC curve (area under the curve (AUROC) = 0.73), the cut-off value of 3800 pg/mg demonstrated the best performance to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9; 90.6]) and positive predictive value (67.5% [74.9; 95.3]). The number of enterobacteria was increased in CD patients with prior intestinal resection (562 [201; 1674] vs. 116 [70; 752] pg/mg, p = 0.003). Interestingly, the number of enterobacteria was also increased in AIEC-positive patients (640 [241; 2596] vs. 30 [0; 1029] pg/mg, p = 0.004). Using a ROC curve, we determined the best threshold of enterobacteria in the ileum to detect the presence of ileal AIEC bacteria. We found an area under the curve (AUROC) of 0.70 [0.61; 0.77]. The cut-off value of 60 cfu/biopsy demonstrated the best performance to detect the presence of ileal AIEC bacteria. The number of enterobacteria associated to the ileum is a convenient and reliable test to assess the overexpres-
sion inducing FGF19 release [3]. Disturbances in BA enterohepatic circulation (91.7% [73.0–99.0]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-consuming and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identify that the number of enterobacteria associated to the ileum is a convenient and reliable test to screen CD patients for AIEC bacteria.

Introduction: Crohn’s disease (CD) has a progressive course and often causes mucosal injury throughout the gastrointestinal tract. Mucosal healing (MH) has been proposed as a treatment goal for patients with CD. Endoscopy, computed tomography, magnetic resonance imaging, and other examinations are used to evaluate MH. However, repeated examinations require considerable effort and are highly invasive. Recent, fecal calprotectin (FC) has attracted attention as a new biomarker. The correlation between FC levels and CD activity is well established in ileocolonic or colonic CD, but few reports have described this correlation in ileal CD alone.

Aims & Methods: This study evaluated the correlation between FC levels and endoscopic activity in ileal CD. Fifteen patients with ileal CD who underwent double-balloon endoscopy (DBE) between May 2016 and February 2017 at our hospital were included in this study. The entire small intestine was examined with DBE and radiological enteroclysis. We evaluated the correlations of FC levels, C-reactive protein (CRP) levels, erythrocyte sedimentation rates (ESR), and CD activity index (CDAI) scores with the endoscopic activity. To evaluate the endo-
scopic activity of the small intestine, we used Double-Balloon Endoscopic Score for CD (DES-CD), which is a modified version of the Simple Endoscopic Score for CD (SES-CD). To determine the DES-CD, the small intestine was divided into four segments (upper jejunum, lower jejunum, upper ileum, and lower ileum), and four variables were evaluated in each segment (ulcer size, extent of ulcerated surface, extent of affected surface, and stenosis) in accordance with the SES-CD. For the evaluation of mucosal injury, the partial DES-CD (pDES-CD) was calculated by excluding “stenosis” from the DES-CD. The DES-CD and pDES-CD ranges were 0–46 and 0–24, respectively.

Results: Fifteen patients (11 males and four females) with a median age of 42 (range, 27–71) were assessed. No colitic lesions were observed in any of the patients. The DES-CD correlated with FC (r = 0.688, P = 0.005) and CRP (r = 0.765, P = 0.001) levels. In addition, the pDES-CD correlated with FC levels (r = 0.803, P = 0.001), CRP levels (r = 0.673, P = 0.006), and ESRs (r = 0.704, P = 0.003). The CDAI scores did not correlate with either of the endoscopic scores.

Conclusion: In this study, the endoscopic activity in ileal CD correlated with FC and pDES-CD levels. PDES-CD scores exhibited a stronger correlation with FC levels than did DES-CD scores. This might be because FC levels reflect mucosal injury and not stenosis. Our findings suggest that FC can be used for monitoring mucosal injuries in the small intestine and as a biomarker for evaluating MH.

**P0632 HOME MONITORING OF DISEASE ACTIVITY AND FECAL CALPROTECTIN IN ADULT PATIENTS WITH INFLAMMATORY BOWEL DISEASE: INTERIM ANALYSIS OF 68 PATIENTS**

D. V. Ankersen, D. Marker, P. Weimers, J. Burisch, P. Munkholm

**INTRODUCTION:** Due to the chronic and progressive nature of inflammatory bowel disease (IBD) it is of significant importance to detect and treat a relapse as soon as possible in order to decrease the total inflammation burden and avoid progression of intestinal damage, and possibly improve the disease course. A validated fecal Calprotectin (FC) home testing kit and smart phone application CalproSmart™ has been added to an existing eHealth web-application, enabling patients to monitor their disease activity using clinical scores and FC from home with results shown on their smart phone. eHealth allows for tight monitoring of disease activity, however, the frequency of an optimal screening procedure for adult IBD patients has not yet been determined.

**AIMS & METHODS:** The aim of this one-year randomized controlled trial of 120 adult IBD patients, was to determine if an eHealth screening procedure for disease activity should be implemented in clinical practice ‘every 3 months, 3M’ or according to patients own gut feeling, ‘on demand, OD’. Both groups used the health-program to tightly monitor their disease activity either OD or every 3M. Patients randomized to screen every 3M were also allowed to monitor themselves OD if they were feeling a flare was coming. The web-algorithm consists of a short disease questionnaire either Harvey-Bradshaw Index (HBI) for Crohn’s Disease or Simple Clinical Activity Indicators (SCI) for Ulcerative Colitis plus home monitoring of FC, which together gives a total inflammation burden scoring (TIBS). Based on longitudinal FC and disease activity scores area under the curve (AUC) were calculated by an algorithm taking into account the inclusion date and the first observation 357 days after inclusion into the calculation.

**RESULTS:** To date, 83 patients have been included, 15 patients have dropped out (7 in OD-group and 8 in 3M-group) and 68 (3M-group: n = 32, 47% 0.03). 52 (93%) patients have completed the first year of follow-up and were included in the analysis. There were no statistical difference between the two groups OD vs. 3M on the following indices: Active disease (FC > 600 mg/kg) at inclusion n = 17, 25% (3M-group: n = 6, 19%; OD-group: n = 10, 29%, p = 0.26), active disease at least once throughout the whole year: 41 patients (61%) (3M-group: n = 21, 66%; OD-group: n = 20, 57%, OD, p = 0.32). Patients screened themselves with regards to FC 233 times in the OD-group and 232 times in the 3M-group. The mean no of FC home measurements pr. patient was similar in the two groups 6.7 (3M-group: 5.9–9.8, p = 0.52). Median (range) AUC for FC and disease active scores were not significantly different in the groups (OD, 3M): 62016 (3782–541338) vs 89730 (10286–335881) p = 0.71, 549 (0-3726) vs 610 (0.2-884) p = 0.61. No significant difference were found in regards to disease course and resource utilization. A slightly but non-significant reduction in no of FC measurements pr. patient used in OD-group relative to 3M-group could argue for an economical benefit of the OD screening procedure. Long-term results are awaited.

**Introduction:** Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may relate to severity of the disease.1

**Aims & Methods:** The aim of the study was to determine the frequency of VitD (vitamin D) status in an Italian IBD cohort in relation to disease activity. Serum 25-hydroxyvitamin D was measured in 260 IBD outpatients, not supplemented with VitD (110 Crohn’s Disease (CD)) and 150 Ulcerative Colitis (UC); 145 males and 115 females; median age 50.7 ± 15 years), and compared to those of 205 healthy blood donors, matched by sex, age (+/−2 years) and month in which the blood sample was collected. VitD levels were correlated to C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Harvey Bradshaw Index (HBI) and Crohn’s Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.

**Results:** IBD patients were at higher risk of VitD deficiency (defined as <20 ng/ml) than controls (OR 4.5, 95%CI 2.9–6.9, p < 0.001). Of 260 IBD patients, 156 (60.7%) had VitD deficiency, more often in CD than in UC (72.7% vs 48% respectively, p = 0.001). Age ≤ 40 and ≥ 60 years, winter/spring season, CRP >0.5 mg/dl, ESR >20 mm/h, previous intestinal surgery and HBI ≥ 5 were significant risk factors for VitD deficiency. No differences were observed in relation to sex, smoking status, BMI, age at diagnosis, localization and behavior of disease, and need of steroids. There was a weak negative correlation between CRP values, HBI scores and VitD levels (R = −0.13, p = 0.037 and R = −0.26, p = 0.006 respectively).

**Conclusion:** VitD deficiency is significantly more common in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VitD severe deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Magnetic resonance (MR) imaging is one of the most accurate imaging methods for evaluating Crohn’s disease (CD) extent and intestinal involvement. The need for upper endoscopy in patients with Crohn’s disease (CD) with early symptoms is controversial. The aim of this study was to establish the prevalence of gastroduodenal involvement, regardless of symptoms, and its prognostic implications.

**Aims & Methods:** Patients from a single centre with established CD (n = 347) were retrospectively evaluated – inclusion criteria: upper endoscopy without treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, crypt irregularity, erosion ulceration and granuloma in the absence of Helicobacter pylori (HP) infection).

**Results:** We included 140 patients - phenotype: 50% inflammatory, 31% strictureing and 19% penetrating; Location: 42% ileal, 45% ileocolic and 13% colic. Upper endoscopy was performed in 19% for symptoms and in 81% for staging. Gastric macroscopic findings were detected in 49% (69/140); the most common were erosions (21%) and erythematous mucosa (18%). Biopsies were performed in 56% of patients: chronic gastritis 66%, normal 23%, granuloma 5%, focal gastritis 2% and cryptic microabcess in 2%. HP was positive in 25% of patients. In CD patients, endoscopic and histological features of the gastroduodenal lesions were observed in 35% of patients: 24% occurred in only 1/10 with a visible stenosis. Average MaRIAs: 2/7 (7 mild); 3/26 (23%) and 11/26 (42%). RCE was more frequent in only 110 with a visible stenosis. Average MaRIAs: 2/7 (7 mild); 3/26 (23%) and 11/26 (42%). RCE did not differ significantly between normal and subjects with disease; albumin 42 g/L vs 38.9 g/L in normal v stricture disease (p < 0.0181 95% CI −0.23 – 0.02). CRP 8.8 mg/L vs 18.3 mg/L (p < 0.003 95% CI −0.46 – 0.10) and v 29 mg/L (p < 0.002 95% CI −0.43 – 0.11) amongst normal v inflammation and stricture v respectively. Neither parameter could differentiate between inflammatory and stricture disease. 26 MREs performed with ileal CD have been further assessed; median age = 41yrs, male = 0.1038%. RCE > 24 and high T2 signal intensity (SI): 6/26 (23%) and 11/26 (42%). RCE was more frequent in only 110 with a visible stenosis. Average MaRIAs: 2/7 (7 mild); 3/26 (23%) and 11/26 (42%). RCE did not differ significantly between normal and subjects with disease; albumin 42 g/L vs 38.9 g/L in normal v stricture disease (p < 0.0181 95% CI −0.23 – 0.02). CRP 8.8 mg/L vs 18.3 mg/L (p < 0.003 95% CI −0.46 – 0.10) and v 29 mg/L (p < 0.002 95% CI −0.43 – 0.11) amongst normal v inflammation and stricture v respectively. Neither parameter could differentiate between inflammatory and stricture disease. 26 MREs performed with ileal CD have been further assessed; median age = 41yrs, male = 0.1038%.

**Conclusion:** The prevalence of gastroduodenal involvement by CD in this sample was 18%, and a larger percentage have macro/microscopic findings that are not disease specific. The presence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** CT enterography is one of the most accurate imaging methods for evaluating Crohn’s disease (CD) extent and intestinal involvement. The need for upper endoscopy in patients with Crohn’s disease (CD) with early symptoms is controversial. The aim of this study was to establish the frequency and clinical impact of the incidental findings in CD patients who underwent CT enterography.

This was a retrospective study that evaluated patients with CD who underwent CT enterography between January 2012 and December 2016. Incidental findings were defined as previously unknown extraintestinal lesions. The orientation of the patients after their detection was evaluated.
Results: A total of 520 patients who underwent CT enterography were identified, with 184 women (35.4%) and 336 men (64.6%) being reported. The median age was 43 (32-53) years and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 39), hepatic cysts (n = 55) and sarcoidosis (n = 46). The findings implicated orientations to another medical specialty in 80 patients (29%), the main ones being Urology (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); one suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

Conclusion: Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

P0368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE CARRIAGE IN PATIENTS ON IMMUNOMODULATOR FOR INFLAMMATORY BOWEL DISEASE
S.T. Law, W.M. Yip, K.K. Li
Department Of Medicine And Geriatrics, Tuen Man Hospital, Hong Kong/Hong Kong Pre

Contact E-mail Address: stl168@hotmail.com

Introduction: Clinical significance of asymptomatic Clostridium difficile (C. difficile) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

Aims & Methods: The aim of this study was to investigate the clinical implication of asymptomatic carriage of C. diff in IBD patients. Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013. Those cases were excluded if they had past history of total colectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate. Stool specimen for C. difficile cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrollment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for C. difficile cytotoxin RT-PCR assay was obtained. The primary outcomes were the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) (graded as follows: <150: remission; 150–220: mild-moderate; 220–450: moderate-severe; >450: severe); Ulcerative colitis Disease Activity Index (UC-DAI) in ulcerative colitis (UC) (graded as follows: the total index score ranges from 0–12; 0–2: remission; 3–6: mild; 7–10: moderate; >10: severe UC). The secondary outcome was C. difficile cytotoxin status which was defined in the patients with active lower gastrointestinal symptoms accompanying with positive RT-PCR assay of C. difficile at that instant.

Statistical inference of the variables was examined by Mann–Whitney U and j2 test for numerical and categorical parameters respectively.

Results: Of 197 IBD patients (CD: 98 (49.75%); male: 132(67.01%); age (yrs): median 43, minimum 17, maximum 79), 9(4.57%); CD: 6 patients) patients were found to be asymptomatic carriage of C. difficile during the study period. The demographic features, including age, gender ratio, smoking history and the duration of IBD, of the patient group with and without asymptomatic carriage of C. difficile were comparable each other. Four UC patients in the non-carriage group had received three doses of anti-TNF as rescue therapy for severe disease flare-up. Incidence rates of the disease flare-up were comparable (11.17 vs. 22.22%, p = 0.313) between the non-carriage and carriage groups in which all these flares were under-controlled by course of high-dose prednisolone.

The asymptomatic carriage group had a significant higher rate (33.33 vs. 7.45%, p = 0.007) and earlier onset (18.78 vs. 34.42 months, log rank p = 0.009). Mann–Whitney U test for numerical and categorical parameters respectively showed no significant differences (Table 1).

Clinical characteristics of the IBD patients with and without asymptomatic carriage of C. difficile

Introduction: Due to the relapsing and highly variable nature of ulcerative colitis (UC), it would be desirable to have reliable tools for measuring parameters of disease activity in order to monitor response to therapy and to detect relapse. In recent years, ultrasound has already shown that ultrasound (US) is a useful tool to monitor the disease activity.1 The hypothesis of the TRUST&UC (TRANsabdominal UltraSonography of the bowel To monitor disease activity in subjects with Ulcerative Colitis) study is that transabdominal US is an easy to use, easily repeatable, and accurate diagnostic tool in the assessment of UC activity, in monitoring the disease course, and response to therapy.

Aims & Methods: TRUST&UC is a German ongoing prospective, observational multi-center study in patients with active UC. The primary objective of this study is the prospective evaluation of bowel wall US in response to therapy in order to assess its value in monitoring UC patients in routine medical practice. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity.

Results: 176 patients with active UC have been enrolled in 37 German IBDD study group (GSG) centres until February 2017. 47.2% of the patients were female, median age was 38.9 years (range 19–77) with median disease duration of 152.2 days (range 8–1017). All of the patients with a clinical flare defined by SCCAI 90.3% showed a bowel wall thickening (BWT), and only 9.7% showed no US signals. At US examination, a BWT in the colon sigmoideum was present in 87.5% of the patients, in the colon descendens in 83.7%, in the colon transversum in 42.3% and in the colon ascendens in 18.3%. Loss of bowel wall

Disclosure of Interest: All authors have declared no conflicts of interest.
stratification was the case in 20.6% of the patients, mesenteric fibro-fatty pro-
life in more than 50%, had increased signal in the color Doppler US. At baseline systemic steroids were used in 62.1%, azathioprine in 36.2%, and TNF α antagonists in 40.0% of patients (N = 174).

All follow-up patients (N = 104) displayed acute inflammatory symptoms at baseline with all moderate disease activity which required an introduction or escalation of treatment. After 12 weeks, the US examination showed signifi-
cant improvements of the following parameters: BWT in colon segmentum (87.5% vs 33.7%, p = 0.034) and colon transversum (42.3% vs 15.4%, p = 0.012), loss of haustation (54.8% vs 33.7%, p < 0.001), ascites (9.7% vs 2.9%, p < 0.001), mesenteric lymphadenopathy (31.6% vs 14.3%, p = 0.005), mesenteric fibro-fatty proliferation (40.0% vs 10.0%, p = 0.041) and increased signal in color Doppler US (56.7% vs 23.1%, p = 0.039). A decrease of BWT was significantly accompanied by a decrease in SCCA1 (8.0 to 1.5 points, p < 0.001).

Conclusion: In this real-life cohort almost 90% of the patients showed a BWT, a pivotal IBD symptom and within 12 weeks selected bowel US parameters improved significantly from treatment intensification. Therefore, US examination is a useful tool to monitor disease activity and response to therapy in UC patients.

Introduction: Blocking TNFa is an important treatment option for inflammatory bowel disease (IBD). The etiology of the disorder comprises a permanent activation of immune cascades and imbalanced cytokine networks. Evidence has been put forward that alteration of the human gut microbiota may play a critical role in the pathogenesis of IBD. However, the impact of targeted cytokine blockade on dysbiosis of intestinal microbial communities is poorly understood. Here, we investigate the effect of anti-TNFa treatment on gut microbial community structures in a prospective, longitudinal study for 30 weeks. The study compares IBD as a disorder, which primarily affects the gut, with seropositive and –negative rheumatoid arthritis and ankylosing spondylitis as a rheumatic disorder (RD) as an inflammatory disease complex, which usually does not affect the intestine.

Aims & Methods: Anti-TNFa naïve patients suffering from IBD (n = 12) or RD (n = 17), subject to first-time anti-TNFa therapy were recruited for longitudinal stool sampling at baseline and 2, 6 and 30 weeks after therapy induction. Intestinal microbiota communities were studied by 16S rRNA gene (V4) sequencing. Changes in microbiota before and after therapeutic interventions were assessed in terms of alpha and beta diversity, indicator species and prediction of metabolic cooperative interactions. Samples from healthy controls (n = 19) were included as a benchmark of healthy microbial profiles.

Results: Intestinal microbial diversity and cooperativity are decreased in both disease entities, IBD and RA. In IBD, anti-TNFa therapy is able to restore microbial diversity and cooperativity. More over cooperative metabolic interaction is significantly increased only in anti-TNFa responders. In RA, anti-TNFa therapy did not significantly restore microbial community structures.

Conclusion: We show that anti-TNFα treatment increases the gut microbial diversity and coupling of cross feeding metabolic interactions towards the state of healthy individuals. Assessment of metabolic interactions of intestinal microbiota may serve as a marker for clinical response in IBD patients.

P0371 self-monitoring of the colonic inflammatory bowel disease by a rapid home based fecal calprotectin test and a symptom questionnaire
A. Puolanne 1, M.A. A. Färkkila 1, K. Kolho 2

1 Clinic Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland
2 Pediatric Gastroenterology, University of Helsinki Childrens Hospital, Helsinki/Finland

Contact E-mail Address: anna-maija.puolanne@hus.fi

Introduction: Fecal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease but commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-monitoring and eHealth technologies have been evaluated in managing patients with this life-long disease.

Aims & Methods: The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic accordingly. All patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

Results: By the end of February 2017, 134 of the 180 included patients had completed the 12 months’ follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 14/91 (15%) patients for 12 months. In the control group, 14/89 (16%) patients had filled in the symptom score at baseline and 7/86 at 24 months. There was an significant difference of the adherence between patients stratified for IBD-diagnosis, age, or sex. The satisfaction of the patients with the program as well as the reasons for the discontinuation of the study and influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic was the same in both groups.

Conclusion: The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was relatively low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
this study, the clinical and endoscopic features of CAC and ST, treatment method, and comparison.

Aims & Methods: Among 261 UC patients who underwent colonoscopy (CS) and had neoplastic lesions, the clinical features, treatment and diagnosis were compared between 71 patients (88 lesions) with CAC (including HGD; CAC group) and 47 patients (63 lesions) who underwent local excision (surgical or endoscopic resection) within the presence of the past/present inflammation of UC (ST group). Definition of CAC and ST was performed by conventional pathological and immunohistochemical findings.

Results: The age of UC onset (29.8 vs. 39.0) and tumor detection (45.5 vs. 57.3) in the CAC group were significantly higher than those in ST group (p < 0.01). The CAC group (47.1%) has a higher percentage of chronic persistent type than the ST group (2.3%), and the Mayo endoscopic score is also significantly higher (p = 0.031) in the CAC group (1.43) than the ST group (0.38). The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAC group than in ST group.

In patients with intraepithelial neoplasia (IEN) or submucosal lesions, flat lesion was found in 15 lesions of CAC group and whereas no flat lesion was observed in ST group, one lesion in ST group could not distinguish the lesions from the surrounding mucosa without magnifying colonoscopy. In ST group who received resections, 4 patients after resections observed ectopic CAC or low-grade dysplasia during follow-up. In CAC group, 50, 5, 4 patients received total colectomy, local colectomy, EMR and polypectomy, respectively. Although mortality from cancer was 11.4% (8/70 cases) in CAC group, no death due to cancer observed in patients whose lesions were found as IEN. On the other hand mortality from cancer was 2.1% (1/47 cases) in ST group.

Conclusion: Most sporadic lesions were endoscopically distinct and local resection was performed for patients diagnosed. After the sporadic lesions were resected in remitting UC patients, regular surveillance colonoscopy is necessary because 8.5% (4/47) of patients was found CAC/dysplasia. Even in CAC group, prognosis is still good in patients with IEN.

P0373 CAN WE PREDICT THE LACK OF RESPONSE TO CYCLOSPORINE AS SECOND LINE THERAPY IN PATIENTS WITH ACUTE SEVERE COLITIS REFRACTORY TO CORTICOSTEROIDS?

Gastroenterology, University Hospital Sahloal, Toulouse

Contact E-mail Address: aya_med@hotmail.fr

Introduction: Acute severe colitis (ASC) is a dangerous clinical condition that requires intensive intravenous (iv) corticosteroids treatment. Nevertheless, about 30-40% of patients fail to respond. Intravenous cyclosporine is an effective rescue therapy in steroid-refractory patients.

Aims & Methods: The aim of our study was to identify the clinical and biological predictive factors of lack of response to cyclosporine as second-line therapy in patients with ASC refractory to iv corticosteroids.

Results: Our study included 52 females and 30 males, with a mean age of 35 years ([14–70 years]. There were 34 patients with Crohn’s disease and 56 diagnosed with ulcerative colitis. Among the 90 enrolled patients, 68 patients (75.5%) had a good response to cyclosporine. Eleven patients were non responders and underwent corticosteroids withdrawal. In a Kaplan-Meier analysis, more than 6 bloody stools per day before initiation of cyclosporine therapy, a C-Reactive Protein (CRP) greater than 45 mg/l prior to treatment, and at day 3 and 7 of treatment by ciclosporine (p = 0.007; 0.002 and 0.001 respectively), ESR greater than 30-mm at day 3 of treatment (p = 0.05), thrombocytosis at day 3 of treatment (p = 0.05), a Litchiger colitis activity index scoring greater than 10 at day 3 of treatment (p = 0.001) and the need for blood transfusion (p = 0.0001) were significantly correlated with the lack of response to cyclosporine therapy. In a multiple linear regression analysis, only a CRP greater than 45 mg/l on day 7 of treatment, and the necessity of transfusion were predictive factors of no-response to cyclosporine (p = 0.008).

Conclusion: Cyclosporine therapy is rapidly effective in preventing surgery in patients with ASC with a response rate of 75.5%. A high CRP on day 7 of treatment with cyclosporine and the need for transfusion, predispose to poor response to intravenous cyclosporine.

Contact E-mail Address: zsuzsa.kurti@gmail.com

Introduction: Accelerated treatment strategy, including tight disease control and early immunomodulators (IM) and biological agents have become increasingly common in IBD.

Aims & Methods: The aim of the present study was to estimate the early treat-ment strategy and outcomes in newly diagnosed patients with Crohn’s disease (CD) diagnosed between 2004-2015 in Hungary based on the administrative database of the National Health Insurance Fund (OEFP). We used the administrative database of the National Health Insurance Fund (OEFP), the only nationwide state-owned health insurance provider in Hungary. Newly diagnosed CD patients were identified through previously reported algorithms using the ICD-10-CM codes for Crohn’s disease in the out-, inpatient, (medical, surgical) non-primary care records and drug prescription databases between 2004-2015. Patients were stratified according to the year of diagnosis and maximum treatment step during the first 3-years after the diagnosis.

Results: A total of 6173 (male/female: 46.12%/53.87%) newly diagnosed CD patients were identified during the observational period. Maximum treatment steps did not differ in patients diagnosed before and after 2009 (5-ASA: 11.7% vs. 11.4%; p = 0.816; anti-TNF: 26.7% vs. 26.3% p = 0.565; steroid 8.1% vs. 7.9% (p = 0.896), 5-ASA 10% vs. 11% (p = 0.816). Accelerated treatment strategy, including tight disease control and was commenced earlier. Of note, steroid and 5-ASA remained high after 2009. Maximal treatment steps were associated to hospitalization and surgery rates, suggesting that maximal treatment steps can be used as proxy marker of severity in CD. Hospitalization rates during the first 3-years after the diagnosis increased in all treatment groups, suggesting a change in the patient management.

Introduction: Numerous studies have shown that mesenchymal stromal cells (MSCs) have a high potential for differentiation and immunosuppressive properties and are currently under phase I-II trials evaluating the efficacy and safety of MSCs in the treatment of patients with inflammatory bowel disease - ulcerative colitis and Crohn’s disease.

Aims & Methods: We aimed to compare the frequency of relapses and duration of remission for 5 years of follow up in patients with luminal Crohn’s disease (CD) and the total defeat of ulcerative colitis (UC) receiving therapy with mesenchymal stromal cells (MSCs), bone marrow. We compared the frequency of relapses of IBD with luminal form and after 2009, although immunosuppressive agents were used as proxy marker of severity in CD. Hospitalization rates during the first 3-years after the diagnosis decreased in all treatment groups, suggesting a change in the patient management.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Mesenchymal stromal cells (MSCs) are used for the treatment of chronic inflammatory and autoimmune diseases in recent years, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). In most cases, treatment of the most important immunosuppressive effect. However, studies conducted by Huang HR et al. demonstrate that IFP rendered minimal impact on the MSC proliferation, apoptosis and cell cycle, while azathioprine inhibited cell proliferation and induced apoptosis of MSCs in vitro [2].

Aims & Methods: To evaluate the effectiveness of therapy mesenchymal stromal cells (MSCs) from the bone marrow of patients with Crohn’s disease (CD) receiving azathioprine. 34 patients with inflammatory (luminal) form CD were divided into two groups. The first group of patients aged 19 to 58 years (Mean: 36±10 years) was treated with anti-inflammatory therapy with MSCs in combination with AZA. The second group of patients with CD (n=19) aged 23 to 60 years (Mean: 35±10 years) received MSCs in a combination with AZA.

Results: After 2 months of therapy MSCs level of IFN-γ in 1st group was significantly decreased compared with baseline and amounted to 79.4±8.5 pg/ml in the 2nd - 80.8±7.3 pg/ml (between groups p=0.7). TNF-α in 1st group decreased to 44.9±6.3 pg/ml in the 2nd - 49.7±10.4 pg/ml (between groups p=0.7). IL-1β in 1st group - 53.6±10.7 pg/ml (between groups p=0.7). IL-10 in 1st group was decreased to 8.4±2.3 pg/ml in the 2nd - 6.5±10.7 pg/ml (between groups p=0.7). After 6 months of therapy MSCs level of IFN-γ in 1st group decreased and amounted to 79.4±8.5 pg/ml, in the 2nd - 80.8±7.3 pg/ml (between groups p=0.7). TNF-α in 1st group - 49.7±10.4 pg/ml (between groups p=0.7). IL-1β in 1st group - 53.6±10.7 pg/ml (between groups p=0.7).

Conclusion: Our study demonstrated that combined treatment with AZA and MSCs significantly reduces the level of pro-inflammatory cytokines, which could have a more pronounced anti-inflammatory therapeutic effect.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: serum sample (LLoQ 62.5 ng/ml). Quantities were added to ileal fluid concentrations. V565 was not detected in any subject 31003; and 125MTs (1260 mg) 2 h post dose from subject 31004. Overall, recovered 3 h post dose from subject 31002; 78MTs (458 mg) 3 h post dose from stored in a way to enable reliable analysis. 64MTs (containing 135 mg V565) were recovered from the ileostomy bags of all subjects. Each 1665 mg dose contained a In addition to the V565 concentrations in ileal fluid, partially dissolved MTs were streaked with blood. The examination revealed the exacerbation of UC, left-sided and the likely maximum daily dose for initial clinical efficacy assessment. High concentrations of active V565 were demonstrated in the ileal fluid of all four subjects as shown in Table 1 below.

Introduction: The oral delivery of therapeutic concentrations of anti-TNF to affected mucosa of patients with inflammatory bowel disease (IBD) has remained challenging despite advances in protein engineering, the attractions of oral dosing for chronic therapies, and the acknowledged benefit of anti-TNF monoclonal antibodies in the management of IBD. As the ileum is commonly involved in Crohn’s disease (CD), it is important to deliver drug there if treatment is to be effective. This is the first report of a domain antibody to TNF, V565, engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in the ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorobodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5. Aims & Methods: Following prior placebo-controlled demonstration of the safety and tolerability of high single and multiple doses of V565, this open label assessment was performed to confirm the delivery of active domain antibody to the terminal ileum of human subjects. Four subjects with a terminal ileostomy were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 2 hours post dose with further collections 6, 24 and 24h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition serial blood samples were taken for determination of V565 serum concentrations over 24h. Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of colonic obstruction) were given a single 1665 mg dose of V565. The dose was selected based on the prior demonstration of safety and tolerability of this dose and the likely maximum daily dose for initial clinical efficacy assessment. High concentrations of active V565 were demonstrated in the ileal fluid of all four subjects as shown in Table 1 below.

Introduction: Anti-TNF, such as adalimumab (ADA) and infliximab (IFX), have improved the therapeutic care of Crohn’s disease (CD). However their use may be associated with loss of efficacy, adverse events and sometimes primary failure. After failure of the first anti-TNF, it is possible to switch to another anti-TNF. In France, three anti-TNF are available in ulcerative colitis (IFX, ADA and golimumab), but only the first two are approved in CD, because golimumab has not been studied in this indication. The aim of this study was to report golimumab efficacy and safety in CD.

Aims & Methods: This national multicenter retrospective study included patients with CD from 12 French tertiary centers who received golimumab and analyzed: clinical response, duration of treatment, tolerance, reasons for discontinuation of treatment, adverse events and treatment associated with golimumab. The main endpoint was the efficacy of golimumab defined by the duration of treatment before failure (need for therapeutic optimization or cessation). Predictive factors of therapeutic response were determined (log rank and Cox model), and the tolerance was evaluated.

Results: One hundred and fifteen patients with a median duration of the disease of 13.5 years received on average golimumab in 3.6 line of biotherapy. The overall clinical response assessed by the physician was 55.8% at the time of the re-evaluation (on average, at 3.8 months [0.6–24] after initiation of therapy). The median duration of treatment (0.55–48.7 months) and 67% of patients received treatment for more than 6 months and 48.7% of patients were still treated with golimumab at the end of the follow-up. At 12 months, 34.9% of patients still received golimumab without optimization. At 24 months, this figure was 19.3%. In univariate analysis, the factors associated with a longer golimumab treatment duration without stopping or optimizing were the active smoking status (p = 0.043), the absence of anoperineal lesions (p = 0.012), the presence of extra-intestinal symptoms (p = 0.035), the presence of a co-immunosuppression (p < 0.001) and discontinuation of the first anti-TNFa for intolerance (p = 0.022). In multivariate analysis, discontinuation of the first anti-TNFa for intolerance and the presence of co-immunosuppression with thio- purine derivatives or metothrexate over 6 months were independently associated with golimumab efficacy (OR 2.16, 95% CI [1.25–3.36], p = 0.005) and OR 3.9895% CI [2.3–7.1], p < 0.001, respectively). Side effects led to discontinuation of treatment in 6% of patients. These were paradoxical psoriasis in three patients, paresthesia (n = 1), low extremity edema (n = 1), injection site reaction (n = 1) and not reported reason for discontinuation (n = 1). No significant differences were observed in control group (p = 0.339). We found a trend for better response in the EAP than in the sham group although the difference in FACIT-F score was not significant (p = 0.09). EAC also improved quality of life (+5.17 points, 95% CI [–5.2 to –2.06], Basal Vs 9th session p = 0.003); depression (8.9 points, 95% CI [4.3 to 13.8], Basal Vs 9th session p = 0.002); anxiety (10.6 points, 95% CI [3.6 to 17.6], Basal Vs 9th session p = 0.006) and sleepiness scores (1.46 points, 95% CI [0.096 to 2.83, Basal Vs 9th session p = 0.038). However, the differences in between EAC and sham and control groups were not significant (p > 0.05).

Conclusion: Both targeted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD. NCT02733276.

P0383 BIOLOGICS AND BIOSIMILARS: WHAT MATTERS TO PHYSICIANS?

A. Molinari1, A. Louiza-Bonilla2, D. Charles3

1Global Alliance for Patient Access, Washington, DC/United States of America 2Cancer Treatment Centers of America, Philadelphia, PA/United States of America 3AL

Contact E-mail Address: pavidcharles@gmail.com

Aims & Methods: The purpose of this survey was to determine physicians’ familiarity and comfort level with prescribing biosimilars to patients. The survey was sent to physicians residing in the European Union and specializing in the following clinical fields: dermatology, endocrinology, gastroenterology, oncology, and rheumatology.

Introduction: Biologic medicines and their biosimilar counterparts are effective therapies for many conditions, including inflammatory bowel disease, Crohn’s disease, and ulcerative colitis. The European Medicines Agency (EMA) has approved twenty-two biosimilar medicines, which are derivatives of eight original biologics, and four more biosimilar are scheduled to be reviewed this year. As the number of approved biosimilars rises, regulatory agencies must closely monitor their safety and efficacy.

Results: The majority of survey respondents specialized in endocrinology (19%) and gastroenterology (19%). Respondents were recruited almost equally from the five countries, with France being the most represented country (22%) and the UK being the least represented (18%). The majority (55%) indicated that safety and efficacy is the most important factor in determining whether a patient should be switched from a prescribed biologic therapy to its approved biosimilar. Thirty percent of respondents indicated that clinical trials related to the original biologic condition being treated are required before switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with innovation or productivity.

Conclusion: This survey suggests that the safety and efficacy of biosimilar medicines is of paramount importance to physicians and that physicians highly value clinical trial data for biosimilars. Given that biosimilars are structurally distinct from their original innovator biologic counterparts, the EMA should consider requiring more stringent clinical trials data for biosimilars seeking approval. Specific trials related to the original biologic condition being treated are required before switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with innovation or productivity.

P0384 ARE STEROIDS STILL USEFUL IN THOSE INFLAMMATORY BOWEL DISEASE PATIENTS UNDER IMMUNOSUPPRESSION? A RETROSPECTIVE POPULATION-BASED STUDY

L. Arias García1, G. Hontoria Bautista1, E. Badia Aranda1, F. Saez-Royuela2, D. Charles3,4

1Servicio De Aparato Digestivo, H. Universitario Burgos, Burgos/Spain 2Global Alliance for Patient Access, Washington, DC/United States of America 3Cancer Treatment Centers of America, Philadelphia, PA/United States of America 4AL

Contact E-mail Address: bsaezr@gmail.com

Introduction: Oral steroids are effective in inducing remission of moderate flares of patients with either ulcerative colitis (UC) or Crohn’s disease (CD). However, we know little about their efficacy in immunosuppressed patients or their possible role in reducing biologics and/or surgical needs in these patients.

References
A. Molinari1, A. Louiza-Bonilla2, D. Charles3
1Global Alliance for Patient Access, Washington, DC/United States of America 2Cancer Treatment Centers of America, Philadelphia, PA/United States of America 3AL
Aims & Methods: We aimed to determine the efficacy of systemic or local bioavailability in immunosuppressive treatment for moderate flares of patients with at least 6 months of immunosuppressive treatment, and describe long-term follow-up Inflammatory bowel disease (IBD) immunosuppressed patients (thiopurines or methotrexate) from our population-data registry were analyzed. For statistical analysis, Chi-square test, U Mann-Whitney test and Kaplan Meier survival analysis were used.

Results: 392 IBD patients with a median of 82 (6-271) months of immunosuppressive (IMM) treatment were identified (table 1). 89 patients (23%) (33% UC and 67% CD) needed at least one steroid treatment during follow-up (63% systemic steroid and 37% low bioavailability oral steroid) with a median time of steroid treatment of 4 (1–168) months. Average time from IMM to steroid treatment was 26 (6-207) months. In IMM patients there were no differences regarding sex, age, disease, location, perianal disease, extra intestinal manifestations, appendectomy, smoke habit, need for steroids at diagnosis and previous abdominal surgery between patients with no need of steroids and patients with steroid treatment during follow-up. In CD patients, biological treatment for perianal disease before IMM (OR = 0.12) or fistulizing (B3) behavior (p = 0.005; OR 2.284) were risk factors for using steroids after IMM treatment. In UC patients, no statistically significant variables were identified. 49 of these 89 steroid treatment patients (55%) needed biological treatment or surgery after a median of 13 months (0–178); 19 (21%) needed more than one steroid treatment (2–5) and just 31 patients (35%) did not need any other treatment. CD patients had higher risk (p = 0.007; OR: 3.529) to receive biological treatment or surgery versus UC patients. Otherwise, the more months using steroids in UC patients, the greater risk for biological or surgery treatment (p = 0.009). During follow-up, though it's not statistically significant (p = 0.078), we observe that 75% probability of rescue treatment for UC patients is 60 months versus 36 months for CD patients.

Conclusion: 23% of IMM immunosuppressive patients needed at least one steroid treatment after 6 months of IMM. Previous biological treatment and B2-B3 behavior predicted steroid treatment in CD patients, who had 3.5 times more risk to receive biological treatment or surgery after steroid treatment using it earlier than UC patients. Just 1/3 of patients who needed steroid treatment after IMM did not need any other rescue treatment.

Contact E-mail Address: loftus.edward@mayo.edu

Introduction: PYRAMID was an international multi-center non-interventional postmarketing registry assessing long-term safety and effectiveness of adalimumab (Humira® [ADA]) as used in routine clinical practice. Patients with and without prior ADA experience were allowed to enroll. The final long-term effectiveness of ADA is reported in adult ADA-naïve patients (those who had not received ADA before registry enrollment) with moderate to severe Crohn’s disease (CD) who were treated according to the local product label.

Aims & Methods: All patients entering the registry were followed for up to 6 years. Effectiveness of ADA was measured using Physician’s Global Assessment (PGA; [a composite of Harvey Bradshaw Index and rectal bleeding score]), Short Inflammatory Bowel Disease Questionnaire (SIBDQ), and 4 components of the Work Productivity and Activity Impairment (WPAI) questionnaire, including absenteeism, presenteeism, overall work impairment, and activity impairment. Effectiveness measures, captured in all patients who received at least 1 dose of ADA in the registry and had at least 1 post-enrollment measurement, were summarized descriptively by the number of observations that were not missing at each registry visit; data were reported as observed. Values at enrollment are considered as baseline values.

Results: Among 5025 patients evaluated in the registry, 2057 (40.9%) were ADA-naïve. Of these, 1199 patients (58.3%) were female; mean age 37.1 years at enrollment. Mean ± SD ADA exposure for the ADA-naïve subgroup during the registry was 1118.5 ± 842.3 days. A total of 1082 patients (52.6%) had prior exposure to at least 1 anti-TNF/biologic; 853 (41.5%) and 831 patients (40.4%) used immunomodulators and corticosteroids, respectively, at enrollment. Mean change from baseline in effectiveness measures for patients with CD is shown in the table. Mean PGA score and SIBDQ as well as WPAI domains improved in ADA-naïve patients from enrollment to 1 year and were sustained for up to 6 years (table). No new safety signals were identified in the registry.

Conclusion: At 1 year after entering the international postmarketing registry of ADA use in routine clinical practice, clinically meaningful improvements in disease activity, work productivity, and activity impairment were achieved in ADA-naïve patients with moderately to severely active CD. These improvements were maintained for up to 6 years of the registry among the patients who remained in the study.

Introduction: Adalimumab (ADA) has been shown to improve clinical outcomes among patients with ulcerative colitis (UC) with moderate to severe disease. The aim was to examine clinical and health-related quality of life (HRQoL) effects of ADA in patients with UC based on disease severity and prior use of tumour necrosis factor inhibitors (TNFI). InspirADA details have been presented.1 Pts received ADA 40 mg weekly starting from baseline in HRQoL outcomes was calculated, including Remission rate, odds ratio (95% CI)*

*Comparison between naïve and experienced groups was adjusted for baseline SCCAI. Because baseline SCCAI is highly correlated with PGA, adjustment for baseline SCCAI was performed.

Conclusion: ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs.

Introduction: Treatment with intravenous (IV) CT-P13, a biosimilar infliximab (INX) licensed for use in 80 countries, is highly effective and well tolerated. To increase treatment modalities with CT-P13 for patients, a new subcutaneous (SC) formulation was developed.

Aims & Methods: This phase I and open label study, conducted at a single site in Korea, was designed to evaluate safety and pharmacokinetics (PK) of SC administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the study cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by making the AUC0-last, Cmax, Tmax and T1/2.

Results: A total of 38 male subjects with median age of 23 years (range 19, 30 years) were treated with treatment-emergent serious adverse events or systemic hypersensitivity reaction. In SC cohort, two subjects experienced mild injection site reactions directly after the injection procedure.

Conclusion: SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.

Introduction: Biological therapy has been highly effective for inflammatory bowel disease (IBD). In addition to anti-tumour necrosis factor (anti-TNF) drugs, a gut-selective anti-integrin biologic, vedolizumab (VDZ), has been approved since 2014. However, the real-world comparative effectiveness of VDZ and anti-TNF has not been fully investigated.

Aims & Methods: This study aimed to evaluate all-cause and IBD-related healthcare utilisation in IBD patients (pts) newly treated with VDZ and anti-TNFs.

Cohn’s disease (CD) and ulcerative colitis (UC) pts ≥18 years old with ≥2 claims for VDZ or ≥2 claims for anti-TNF from 20/5/2014 to 31/12/2016 were identified from a large, de-identified administrative claims database in the US (Truven MarketScan® Commercial and Medicare Supplemental Databases). The date of the first VDZ/anti-TNF claim was defined as index date. New VDZ/anti-TNF treatment was defined as no claims for these agents in the 1 year before index date. All pts had ≥12 months enrolment prior to and ≥6 months follow-up index date. All-cause and IBD-related healthcare utilisation including hospitalisation, emergency department (ED) visits and outpatient visits during 6 months post-index were examined for the IBD cohort overall, as well as in CD and UC cohorts. Multivariable logistic regression was employed to estimate the odds ratio (OR) for hospitalisation and ED visits, while Poisson regression was used to examine the rate ratio (RR) for outpatient visits with VDZ compared to anti-TNF use, controlling for demographic characteristics, index year, baseline Charlson comorbidity index (CCI) and baseline hospitalisation and ED visits 1 year prior to index date. In sensitivity analyses, outpatient visits related to infusion administration for VDZ or anti-TNF were excluded to examine the RR associated with outpatient visits that were not related to the visits for infusion procedure.

Results: A total of 652 and 6974 IBD pts newly treated with VDZ and anti-TNF were identified, respectively (mean age [year]: 45 VDZ vs 42 anti-TNF: male: 47% vs 48%). VDZ pts had a higher CCI than anti-TNF pts (0.7 vs 0.5). During the 6 month follow-up, compared to anti-TNF, use of VDZ had significantly higher rates of all-cause hospitalisation (16.3% vs 13.1%, OR 1.30, 95% confidence interval [CI] 1.03–1.64), all-cause outpatient visits (mean visits 45.1 vs 31.0, RR 1.39, 95% CI 1.32–1.37) and IBD-related outpatient visits (mean visits 28.1 vs 17.5, RR 1.60, 95% CI 1.51–1.69). A sensitivity analysis excluding outpatient visits related to infusion administration showed similar results for IBD-related outpatient visits (RR 1.53, 95% CI 1.44–1.62). In pts with CD, the magnitude of risk of IBD-related hospitalisation was even higher (OR 1.67, 95% CI 1.17–2.38), but no significant difference in IBD-related hospitalisation (OR 0.57, 95% CI 0.30–1.06) was observed in pts with UC. The difference in IBD-related ED visits between VDZ and anti-TNF pts was not significant in CD (OR 1.32, 95% CI 0.96–1.82) or UC (OR 0.72, 95% CI 0.40–1.29). However, the rates of outpatient visits were consistently higher in VDZ vs anti-TNF across CD (RR 1.82, 95% CI 1.69–1.96) and UC cohorts (RR 1.29, 95% CI 1.18–1.42). The results were similar in the sensitivity analyses when infusion-related visits were excluded.

Conclusion: In this real-world setting, VDZ treatment was shown to be associated with higher all-cause hospitalisations and outpatient services compared to anti-TNF for pts with IB. A higher risk of IBD-related hospitalisation associated with VDZ use was observed in CD but not UC pts. Outpatient visit rates were consistently higher for VDZ users, regardless of taking into account the infusion-related visits for biologics. These results should be interpreted with caution as disease activity was not fully accounted for in this claims data analysis.

Aims & Methods: Over the past twenty years, the introduction of biological agents into clinical practice has radically improved outcomes in patients with infiltratory bowel disease (IBD), Crohn’s disease (CD) and ulcerative colitis (UC). Tumor necrosis factor (TNF) antagonists, such as infliximab, act by preventing TNF-α, a pro-inflammatory cytokine, neutralizing its activity and alleviating mucosal inflammation. However, biological agents are much more expensive than traditional treatments, and the high cost of these drugs in the treatment of IBD imposes a considerable burden on the national healthcare system. As a result, many patients have grown older during anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant immunomodulator (IM) (70%) were more than 65 years-old, patients on concomitant IM (28%) were in remission at 12 months.

Results: A total of 98 patients with inflammatory bowel disease (67 CD/31 UC) were included. 83.6% (56/67) of patients with CD were in remission at the time of the switch and 62.7% were in remission at 12 months. The HB score showed a significant change at 12 months (P = 0.007) but no significant change was observed in the Mayo score (P = 0.056). There were 46 severe AE overall, including 18 cancers and 16 opportunistic infections (5 tuberculosis). Malignancy (20.0% vs. 6.7%, P = 0.039) and cardiovascular events (16.0 vs. 4.1%, P = 0.036) occurred more frequently in the elderly, whereas dermatologic AE were more common in the younger group (43.3% vs. 24.0%, P = 0.044). The number of severe events (P = 0.794) including death (4.0 vs. 2.6%, P = 0.521) was not significantly different between groups.

Conclusion: Despite being at higher risk of malignancy and cardiovascular events, the total number of severe adverse events was not significantly increased in elderly patients. Particular attention to malignancy surveillance and treatment of cardiovascular comorbidities is advised in this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0391 CLINICAL RESPONSE TO VELODIZUMAB IN IBD PATIENTS IS ASSOCIATED WITH THE CONCOMITANT USE OF IMMUNOMODULATORS

I. Parisi, R. Vega, L. Whitley, S. Bloom, S. Mccurrently

Gi Medicine, University College London Hospitals, London/United Kingdom

Contact E-mail Address: ioannaparis@hotmail.com

Aims & Methods: The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn’s disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naive patients. Multivariate analysis searched for factors associated with response to treatment.

Results: 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn’s disease and the majority (n = 43, 73%) had mainly colonic inflammation (12 colonic Crohn’s, 29 UC, 2 IBDU). Median time from diagnosis to Vedolizumab initiation was 8 years. 17 (28%) were anti-TNF naïve (all UC) and 28 (67%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either methotrexate (MTX) or azathioprine (AZA). 12 (20%) patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline ≥3 points for Crohn’s patients or a reduction of partial Mayo score ≥2 points for UC patients. The rates of response were similar in Crohn’s and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95%CI 0.07-0.91, p = 0.036). 11(18.6%) patients experienced adverse events while treated with Vedolizumab, five of which were related to active IBD. There were two minor allergic reactions and two mild infections.

Conclusion: Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn’s disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNFα therapies have helped improved response rates, reduced complication rates, and quality of life for patients with inflammatory bowel disease (IBD). However primary loss of response (LOR) is still a big concern.

Aim & Methods: The aim of this study was to explore the relationship between infliximab (IFX) and adalimumab (ADA) trough and antibody levels with clinical response rates, at the end of anti-TNFα induction therapy. This was a prospective, single-centre study. Patients were recruited from the gastroenterology department at our centre, from July 2015 to August 2016. Inclusion criteria were all patients older than 17 years old with IBD who started treatment with anti-TNFα drugs, either infliximab or adalimumab, during the study period. Patient demographics, medication and clinical history were collected from the electronic hospital information system. Baseline clinical disease activity indexes were performed with the Harvey-Bradshaw Index for Crohn’s disease (CD), and partial Mayo scores for Ulcerative colitis (UC). Clinical response was defined as reduction in HBI ≤3 or reduction in partial Mayo score ≤4 and <30% from baseline. Anti-TNFα trough and antibody levels were measured using standard ELISA technique.

Results: 35 patients were recruited; 23 CD, 12 UC. 18 patients were treated with other week.

Overall response rate was 51.4% (n = 18/35) were on thiopurines and 9 (25.7%) had prior anti-TNFα exposure.

Discussion of Interest: All authors have declared no conflicts of interest.

©Case 1: the subject decided to terminate pregnancy based on potential risks of tofacitinib; Case 2: reason unknown;

### BID, twice daily

**Conclusion:** Based on the limited data and follow-up available, pregnancy and newborn outcomes among pts with UC with prenatals (maternal/paternal) exposure to tofacitinib appear to be similar to those reported for the UC population, as well as those previously reported in pts with RA and P0. Larger, long-term follow-up studies are needed to examine safety of tofacitinib during pregnancy.

**Introduction:** Granulocyte and monocyte adsorptive apheresis (GMA) has been shown to be effective and safe in patients with inflammatory bowel disease (IBD). We report an interim analysis of a post-marketing surveillance study of granulocyte and monocyte adsorptive apheresis using Adacolumn® for patients with inflammatory bowel disease who have special situations (PARTICULAR).

**Aims & Methods:** The aim of the PARTICULAR study was to assess the safety and efficacy of GMA treatment in patients with IBF who have special situations. This study was an interim analysis of the multi-centre observational study conducted at 80 institutions in Japan. Data were collected from patients with ulcerative colitis (UC) or Crohn’s disease (CD) who received GMA between November 2013 and September 2016. Patients who had at least one special situation were included in the study. GMA was performed using Adacolumn® (JIMRO, Takasaki, Japan). Each patient received up to a maximum of 11 GMA sessions. Safety assessments were performed on all patients in this study. All adverse events (AEs) during the study period were recorded. AEs for which the causality of GMA could not be ruled out were defined as side effects (SEs). Feasibility problems (FPs) included blood withdrawal difficulty, venous pressure elevation, coagulation in the apheresis system and venous access difficulty. The safety of GMA was investigated in the following six special situation subgroups: the elderly (>65 years), concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia (haemoglobin <10 g/dL), paediatric (<18 years) and other groups. We also compared AEs, SEs and FPs between the subgroups with/without each special situation by univariate analysis. The efficacy of GMA was also assessed in patients with UC. Patients with a partial UC disease activity index score (pUC-DAI) of <3, those with missing pUC-DAI scores and those receiving concomitant treatment with infliximab, adalimumab, tacrolimus or cyclosporine were excluded from efficacy analysis. pUC-DAI scores were calculated at baseline and then at the final GMA session or when GMA therapy had to be discontinued because of AEs or FPs. Remission was defined as a pUC-DAI score of ≤2 with no individual sub-score exceeding 1 point. Patients who received additional treatment by the final GMA session, including infliximab, adalimumab, tacrolimus and cyclosporine, were considered non-responders to GMA.

**Results:** This study included 363 patients (304 UC, 59 CD). Among these patients, 81.9% and 62.5% of the patients, respectively. There were 105, 112, 103, 89, 43 and 39 patients in the elderly, concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia, paediatric and other groups, respectively. The incidence of AEs was significantly higher in patients on multiple concomitant immunosuppressants compared with those not receiving them. Likewise, the incidence of AEs was significantly higher in patients of the anaemia group compared with patients with haemoglobin ≥10 g/dL. The incidence of FPs was significantly lower in patients of the retreatment with GMA group than in those who received GMA for the first time (Table 1). The efficacy of GMA was assessed in 209 UC patients. The number of patients administered prednisolone, infliximab, adalimumab, tacrolimus and cyclosporine were 24, 6, 3, 6 and 1, respectively, among patients who received concomitant treatment with multiple immunosuppressants. The incidence of pUC-DAI scores significantly decreased from 6.2 at baseline to 3.4 after the final GMA session (P < 0.001) and the remission rate at the final GMA session was 43.5%.

**Conclusion:** This multi-centre observational study showed that GMA has an acceptable safety profile in IBF patients and sufficient effectiveness in UC patients who have special situations. However, care should be taken when GMA is used in patients with anaemia or those who have received concomitant treatment with multiple immunosuppressants.

P0396 INTEGRATING PSYCHOLOGICAL SUPPORT INTO ROUTINE CARE FOR PEOPLE WITH INFLAMMATORY BOWEL DISEASE

1Department Of Gastroenterology & Hepatology, Royal Adelaide Hospital - SA Health, Adelaide/Australia
2Department Of General Medicine, Royal Adelaide Hospital - SA Health, Adelaide/Australia
3School Of Psychology, Deakin University, Melbourne/Australia
4School Of Psychology, University of Adelaide, Adelaide/Australia
5Clinical Psychology, Royal Adelaide Hospital - SA Health, Adelaide/Australia

Contact E-mail Address: charlotte.goess@sa.gov.au

**Introduction:** People with Inflammatory Bowel Disease (IBD) commonly experience health issues (MHIs) such as anxiety and depression. MHIs reduce quality of life and are associated with poor medication adherence and worse disease course. However, psychological support is not routinely provided to people with IBD. There are scant prospective, systematically gathered data on MHIs in IBD, despite solid evidence of the value of psychological input for people with other chronic diseases.

**Aims & Methods:** The current study is investigating: the prevalence of MHIs in MHS in an IBD cohort; the acceptability and uptake of psychological support and treatment; whether MHIs correlate with higher healthcare utilisation; and potential benefits of integrated psychological care to patients’ mental health, physical health, and/or healthcare utilisation. Potential participants were prospectively recruited from the IBD service of a large tertiary hospital in South Australia via post and in-person at scheduled/routine outpatient appointments. Data were collected at two time-points – at baseline screening and at 12 month follow-up. Health mental, medication adherence, and quality of life were measured by questionnaires: the Hospital Anxiety and Depression Scale (HADS), the Kessler 6 Scale of General Psychological Distress (K6), the Morisky Medication Adherence Scale (MMAS-8), and the Assessment of Quality of Life measure (AQoL-5D). Demographic and healthcare utilisation data were collected by electronic,
state-wide hospital records. Psychological support was offered where scores on HADS and/or K6 indicated likely need. Results: 500 patients were approached during the 12-month screening phase; 50.6% were male, 70.9% of whom was on a biological medication. Mean disease duration of 11 years, 43.3% in clinical remission, and 9.8% current smokers (Australia’s average 13.3%). Of these 500, 67% participated in psychological screening, 38% scored within the clinical range, and 17% accepted psychological support. Gender was a significant predictor of participation in psychological screening: women were 62% more likely to participate than men. Analogies and/or mental health medication increased the likelihood of scoring within the clinical range nearly fivefold (analogic use OR = 5.33, p = .030; psycho OR = 6.94, p = .001). Significant predictors of accepting psychological treatment included older age (OR = 1.03, p = .041), anxiety (OR = 1.09, p = .045), general distress (OR = 1.11, p = .003) and lower quality of life (OR = 0.93, p = .042). At baseline, anxiety and depression were both negatively correlated with medication adherence (anxiety r = −.33, p = .000, depression r = −.20, p = .000) and overall quality of life (anxiety r = −.708, p = .000; depression r = −.787, p = .000). Depression and general distress were related to overall healthcare utilisation (depression r = .131, p = .018, general distress r = −.124, p = .026). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of emergency department presentations (r = −.124, p = .024), outpatient appointments (r = −.119, p = .030), and appointment cancellations (r = .155, p = .055). Currently, approximately half of the twelve month follow-up data has been collected. Preliminary analysis shows improvements for patients’ mental health, quality of life and medication adherence (see table below).

*p < .05, **p < .01, ***p < .001

Conclusion: Psychological issues are prevalent in patients with IBD and associated with lower quality of life and medication adherence. Women are more likely to participate in psychological screening, and in general the screening approach was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrate a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

Introduction: Demonstration of biosimilarity is based on the evaluation of pharmacological, biological, preclinical, and clinical data. Based on this totality of evidence, a biosimilar may be approved for use in the same indications for which the reference medicine is approved without conducting a clinical trial in each indication. A prerequisite for this extrapolation is clinical confirmation of biosimilarity in a patient population sensitive enough to detect potential differences in efficacy, safety, or immunogenicity between the proposed biosimilar and the reference medicine. GP2017, a proposed biosimilar to adalimumab, was provisionally approved without the need for a direct comparison study

Aims & Methods: To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients with moderate-to-severe chronic plaque psoriasis were randomized to receive an initial dose of 80 mg subcutaneous GP 2017 or reference adalimumab, followed by 40 mg every other week, starting one week after the initial dose, up to 17 Week. At Week 17, patients with ≥50% improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial treatment or undergo a sequence of three treatment switches between GP 2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

Results: From randomization to Week 51, 168 and 171 patients continued treatment with GP 2017 or reference adalimumab, respectively. In the per-protocol analysis set, PASI75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 52 were 75.2% and 67.8%, respectively. In the intention-to-treat analysis, 79.8% of patients treated with continual GP2017/reference adalimumab groups, improving over time and remaining stable from Week 17 (60.0%/53.9%) to Week 51 (59.8%/55.1%). There were no clinically relevant differences between the continual GP2017/reference adalimumab groups in the frequency of adverse events (AEs) (61.3%/64.9%), treatment-related AEs (17.9%/17.8%), serious AEs (3.0%/8.8%), or AEs leading to discontinuation of study drug (4.8%/7.0%).

Infections/infections were the most commonly reported AEs, with nasopharyngitis most frequently reported by 8.9%/10.5% of patients treated with continual GP2017/reference adalimumab. Between Weeks 1 and 51, binding antidrug antibodies were detected in 38.8%/45.3% of patients treated with continual GP2017/reference adalimumab. 88.7%/84.7% of which were neutralizing.

Conclusion: Efficacy was similar and sustained in patients with psoriasis continuously treated with GP 2017 or reference adalimumab for up to 51 weeks. Safety profiles and immunogenicity were generally similar in both groups. Clinical data add to the totality of evidence suggesting GP 2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved, including inflammatory bowel disease.

Introduction: Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processes 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.
Aims & Methods: We performed a retrospective study of all patients treated with GMA (Adacolumn) in 3 IBD Units in Spain. The clinical and analytical data were assessed before and 1 month after the end of the GMA. The Ethics Committee of Euskadi approved the study protocol. The aim of our study was to evaluate the presence of clinical, analytical of technique–related factors associated to a better response to GMA.

Results: A total of 105 patients were included [51 female (49%), age 35.7 (SD 16.5)]. Ninety-three had UC (50% extensive, 45% left-sided), 10 Crohn’s disease (90% ileocecal) and 2 IBD-U. Mayo score at baseline was 5.3 (SD 4.6) and Harvey – Bradshaw was 10.1 (SD 3.8). The Mayo endoscopic subscore was 1 (16%), 2 (56%) and 3 (27%). Almost all patients (97%) have been previously treated with steroids and 42% were exposed to biologics. At baseline, 85% were on steroids, 38% thiopurines and 18% biologics. None of the previous or concomitant treatments were associated with a better response to GMA. Fifty-five subjects received weekly sessions for 5 weeks processing 1800 ml/session in 60 minutes. Forty patients received an intensive GMA regime: biweekly sessions with a mean of 8 sessions (SD 2.6), processing 3886 ml/session (SD 1729) and lasting 18 minutes (SD 24). The intensive group showed a slightly higher response rate to GMA as compared with those in the standard regime [response rate 67% vs 55%, p = 0.28]. Those subjects treated with > 5 sessions showed higher remission (24% vs 13%) and response rates (47% vs 24%) as compared to < 5 sessions (p = 0.004). A mean duration of > 60 min/session also showed better results in terms of remission (22% vs 16%) and response (45% vs 27%) when compared to ≤ 60 min/session (p = 0.04). There was also a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond. Contact E-mail Address:

References
The frequency of adverse events (AEs) was similar between the treatment groups: placebo (67.9%), 150 mg Q2W (60.4%), 150 mg QW (62.3%), 300 mg QW (69.8%). Common AEs included abdominal pain, nausea, fatigue, anemia, and pyrexia. One AE led to study discontinuation in the placebo group (1.6%) compared to 2 in the 150 mg QW group (3.8%) and 4 in the 300 mg QW group (7.5%). Three serious AEs occurred in the placebo group (10.7%) compared to 1 in the 150 mg QW group (1.9%), 6 in the 150 mg QW group (11.3%) and 8 in the 300 mg QW group (15.1%). Frequency of arthralgia and muscular-skeletal pain was similar or lower in anacalculism groups compared to placebo.

percentage of subjects achieving clinical response/remission and endoscopic response was similar between treatment groups (Table 1).

Conclusion: SC anacalculism was well tolerated; however, none of the treatment regimens demonstrated a treatment effect in subjects with CD.

P0401 TUBERCULIN SKIN TEST CONVERSION RATE IN INFLAMMATORY BOWEL DISEASE PATIENTS RECEIVING ANTI-TNF ALPHA AGENTS

M. Fragakaki, A. Mpitoulis, I. Dimas, G. Paspatis, K. Karmiris
Gastroenterology, Venizelion General Hospital, Heraklion/Greece

Contact E-mail Address: gpassapatis@gmail.com

Aims & Methods: Few data exist regarding the kinetics of this test during therapy. This study investigated the conversion rate of PPD-TST in IBD patients under anti-TNFAlphafaltra treatment. Anti-TNFAlphafaltra-treated IBD patients followed up in our centre with a baseline PPD-TST underwent a second one during therapy. Those with a positive PPD-TST either at baseline or during therapy (>10 mm in naı̈ve and >5 mm in those exposed to immunomodulators [IMS]) received 300 mg isoniazid orally for 9 months.

Introduction: Anti-TNFAlphafaltra therapy increases the risk of tuberculosis (TB) (re-)activation in inflammatory bowel disease (IBD) patients. Purified protein derivative tuberculin skin test (PPD-TST) is considered a pre-requisite at baseline.

Results: Sixty-eight IBD patients have currently been enrolled (males: 51.47%, Crohn’s disease: 82.35%). Median age at IBD diagnosis was 33.1 years [IQR: 20.3, range: 16.7–66.7]. Median duration of IBD was 7.7 months [IQR: 9.8, range: 1.4–32.7]. Nine patients (13.23%) had a positive PPD-TST at baseline. 48 patients have undergone a 2nd PPD-TST (median time between the 1st and 2nd PPD-TST: 44.26 months [IQR: 42.8, range: 6.3–190.1]). Twenty patients were under combination therapy with an IMS at the 2nd PPD-TST. Six patients with a negative baseline PPD-TST remained positive (in 5 patients the diameter was decreased & in one increased 7 mm). Out of the remaining 42 patients with a negative baseline PPD-TST, eight (19%) exhibited a positive 2nd PPD-TST; three of them were receiving infliximab for less than 3 years and five of them adalimumab (for less and 3 for more than 3 years). Only 2/8 were under combination therapy. There was no case of active tuberculosis during the study. All patients with a PPD-TST conversion received anti-tuberculous treatment.

Conclusion: A positive PPD-TST followed by anti-TB treatment before the initiation of anti-TNFAlphafaltra in IBD patients was not associated with an increased rate of TB infection during therapy. One-fifth of the patients with a negative baseline PPD-TST demonstrated a conversion but without any undeniable consequence if so treated. Therefore, the kinetic of PPD-TST in IBD patients under anti-TNFAlphafaltra treatment should be monitored.

P0402 THE TEMPORAL EVOLUTION OF IMMUNOGENICITY IN INFLAMMATORY BOWEL DISEASE PATIENTS TREATED WITH ADALIMUMAB

Contact E-mail Address: bellageyshi@gmail.com

Introduction: Adalimumab and anti-adalimumab-antibodies (AAA) levels have been associated with clinical outcome of Crohn’s disease (CD). Nevertheless, because adalimumab is usually self-injected at home, prospective serial-sampling studies are scarce. Thus, data on the temporal evolution of adalimumab immunogenecity is still limited, and the validity of comparisons of adalimumab versus infliximab immunogeneity remains questionable.

Aims & Methods: Our aim was to assess trends in adalimumab and AAA levels over time and their clinical implications. CD patients starting adalimumab therapy were followed prospectively in three participating medical centers in Israel, by establishing a program for home-visits by physicians at induction and every 3 months, or in case of relapse. At each home visit, patients’ clinical activity score were determined and blood tests obtained for CRP, drug and AAA trough levels. AAA levels were determined by a drug-tolerant assay. A comparison with temporal evolution of infliximab immunogeneity in a previously reported cohort using the same assay and methodology was additionally performed.

Results: 102 CD patients starting adalimumab were prospectively followed. Fourteen (14%) experienced primary non-response and 20 (20%) lost response to adalimumab therapy during maintenance. Thirty-three (32%) developed AAA, which were more common among those previously exposed to adalimumab (p = 0.002) but were not affected by co-treatment with immunomodulators or not (p = 0.28). AAA developed as early as week 2 in 18/33 (55%) of AAA positive patients (7/18 with history of interrupted therapy), and in 26/33 (79%) within week 14. Patients with week 2 AAA had 34% of primary non-response compared to 9% in patients without early AAA (OR = 4.8, p = 0.009). In 92.6% of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation rate over time was significantly lower (p = 0.01, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, p < 0.0001), and 85% of AAA events were associated with loss of response compared with 58% rate for ATI (p = 0.01).

Conclusion: AAA formation often occurs earlier than anticipated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenecity is lower for adalimumab compared to infliximab. However, once they occur, AAA are more specific than ATI.

Introduction: Golimumab (GBL) has been the last anti-TNF agent authorized for the treatment of Ulcerative Colitis (UC). Results from registratory trial (PURSUIT) documented a clinical response in 51% of patients after 6 weeks
of GLB with 47-49% of patients maintaining the effect after one year. Due to its relatively low cost, there are still few studies on clinical outcomes of patients receiving golimumab in the routine activities. In our region GLB became available starting July 2015.

Aims & Methods: Aim of this study has been to prospectively evaluate the efficacy and safety of GLB for the treatment of moderate to severe UC in the real-life setting of our referral centre. 13 patients (7 male, 4 female) with moderate-to-severe UC were enrolled in the study from June 2015 to December 2016. Patients received an induction dose of GLB 200 mg s.c. at baseline, 100 mg at week 2 and then a monthly dose of 50 mg or 100 mg for a body weight < or > or = to 80 kg, respectively, with no optimization allowed. Partial Mayo score was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score >30% and >3 points vs baseline) and the maintenance period, the secondary end point being the steroid-free clinical remission (Partial Mayo score =< 2 with all subscores =<1) at the end of the induction phase and thereafter the maintenance phase. Complete follow-up is available for all patients at week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sided colitis (22%) in 70%, pancolitis (13%) in 23% and proctitis (24%) in 7% of patients. Ten patients (77%) were anti-TNF-naive, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/13 (62%) patients. Three patients resulted in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission. Each patient is in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and non-naïve patients. No significant adverse events were reported in the study period.

Conclusion: Our findings seem to suggest that Golimumab, as compared to traditional therapies, is able to induce a better clinical initial response but shows a higher secondary loss of response in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimization, depending on the clinician and patient, remains to be evaluated.

during induction treatment. After the induction phase, 12 out of 19 patients reached to severe ulcerative colitis (UC). We investigated the association between systemic exposure (area under the curve (AUC)) of GLM during induction therapy and endoscopic response in moderate-severe UC.

Aims & Methods: In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopy score ≥2) received induction treatment with GLM 200 mg SQ (at week 0) and 100 mg (at week 2) followed by 50 or 100 mg at week 6, in patients with a bodyweight of less or more than 80 kg, respectively. Serum GLM trough concentrations at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 was associated with endoscopic response after the induction phase.

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 was associated with improved endoscopic outcomes.

Complete in small intestine 67% 100% HF 25%; LF 19% HF 0%; LF 13% 95% CrI 1.84, 154.78). AE rates were similar between tofacitinib 10 mg BID and 122.73) in TNFi-exposed patients. A higher rate of clinical remission was seen 3.71 [95% CrI 1.37, 10.64] and etrolizumab 300 mg (OR 12.09 [95% CrI 1.68, 1.82 [95% credible interval (CrI) 1.06, 3.14]) in TNFi-exposed patients. A higher rate of clinical remission was seen (OR 11.93 [95% CrI 1.84, 154.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall and TNFi-naive populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CrI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

Introduction: Patients with inflammatory bowel disease (IBD) experience higher events were similar between tofacitinib and other treatments.

Results: Twelve induction trials were identified from the SLR (ACT 1 & 2, EUCALYPTUS, GEMINI-I, PURSUIT SC, TOFACITINIB PHASE 2, Feagan 2005, 1 Probert 2003, UC-SUCCESS, ULTRA 1, ULTRA 2, Suzuki 2014) and included in the NMA. Unpublished data from tofacitinib Phase 3 induction trials (OCTAVE 1 & 2) were also used in the analysis. Fixed-effects NMA showed that tofacitinib 10 mg twice daily (BID) is associated with a higher rate of mucosal healing [80%:90%] in the overall population (odds ratio [OR] 1.25 [95% credible interval (CrI) 1.06, 1.47]) and vs vedolizumab 300 mg (OR 3.71 [95% CrI 1.37, 10.64]) and etrolizumab 300 mg (OR 12.09 [95% CrI 1.68, 122.73]) in TNFi-exposed patients. A higher rate of clinical remission was seen with tofacitinib 10 mg BID vs adalimumab in TNFi-exposed patients (OR 11.93 [95% CrI 1.84, 154.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall and TNFi-naive populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CrI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

Conclusion: This NMA suggests that tofacitinib may be more effective as induction therapy in moderately to severely active UC than adalimumab and vedolizumab in TNFi-exposed patients, and is associated with a higher rate of mucosal healing than adalimumab in the overall population. Rates of specific safety events were similar between tofacitinib and other treatments.

Introduction: Patients with inflammatory bowel disease (IBD) experience higher rates of C. difficile infection (CDI) than the overall population, often lack typical risk factors, and frequently experience severe and recurrent episodes. MODIFY I/II were global trials of the efficacy and safety of bezlo totoxumab (bezlo: a human monoclonal antibody against C. difficile toxin B), in which bezlo was superior to placebo at preventing CDI recurrence (rCDI) in participants with primary or recurrent CDI given antibacterial drug treatment for CDI. Participants with IBD could be enrolled if, in the opinion of the investigator, symptoms were more likely due to CDI than IBD.

Aims & Methods: The objective of this post-hoc subgroup analysis was to summarize CDI-related outcomes, including initial clinical cure and rCDI, through 12 weeks in participants with IBD enrolled in the MODIFY trials. CDI-related outcomes through 12 weeks in the subset of IBD participants enrolled in the MODIFY trials included: initial clinical cure (no diarrhea during the 2 consecu- tive days following completion of ≤14 days of an antibacterial drug treatment for CDI) and rCDI (new episode of diarrhea associated with a positive stool test for toxigenic C. difficile in participants who had achieved initial clinical cure). For this post-hoc analysis, participants randomized to bezlo or actoxumab+bezlo were pooled and are referred to as the “bezlo” group and participants rando- mized to placebo or actoxumab were pooled and are referred to as the “no bezlo” group.

Results: Overall, 2559 participants were included in the mITT population; 1554 participants were randomized to a bezlo group and 1005 were randomized to a no bezlo group. There were 44 participants with IBD: 23 (52.3%) had ulcerative colitis; 18 (40.9%) had Crohn’s disease; and 3 (6.8%) had non-characterized IBD. Compared with participants without IBD, participants with IBD tended to be younger, were more often treated as outpatients, were more often immu- nocompromised, and a smaller percentage had severe CDI. Among IBD parti- cipants, a higher proportion had initial clinical cure in the no bezlo group compared with the bezlo group and there was a higher proportion of participants with rCDI in the no bezlo group compared with the bezlo group. In IBD partic- ipants who did not receive bezlo, most of the recurrences (5 of 7) occurred within 4 weeks after study infusion, while most of the recurrences among partici- pants who received bezlo occurred after week 4 (3 of 4).

Conclusion: Participants with IBD and CDI enrolled in the MODIFY trials were younger, more likely to be diagnosed with CDI as an outpatient, to be immuno- compromised, and to develop rCDI compared with non-IBD participants. Bezlo yielded a 27.2% absolute reduction (50% relative reduction) in the incidence of rCDI in participants with IBD. The efficacy of bezlo in preventing rCDI may extend to patients with IBD, but additional data are needed due to the limited cohort size.

fetal microbiota was as effective as the endoscopic jejunal application in its combination to restructure the fetal microbiota. An increase in diversity and an overall restructuring of the microbiota into a composition resembling the donor not necessarily correlated with clinical outcome and clinical worsening was observed during three FMTs where the established microbiome structure reemerged that of the donor in diversity and composition. Interestingly, a high abundance of Ruminococcaceae was associated with remission in a recent study on ulcerative colitis (2). However, two patients showed worsening here despite a high increase in the relative abundance of Ruminococcaceae after FMT.

Conclusion: Fecal microbiome transfer in patients with chronic pouchitis is a promising therapeutic option and donor microbiomes could successfully be transferred via capsules or via jejunoscopy delivering fresh stool filtrate. However, a simple increase in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Introduction: We analyzed the success of fecal microbiota transfer (FMT) via encapsulated or endoscopic jejunal application to 14 patients with chronic, antibiotic refractory pouchitis. Activated FMT was performed either via encapsulated cryopreserved microbiota or via endoscopic jejunal application to 14 patients. Stool samples for FMT preparation derived from three unrelated healthy donors. Patients were treated by FMT every 4 weeks according to the individual therapeutic outcome. Stool samples before FMT and during follow-up were subjected to microbial community structure analysis through high throughput sequencing of the V1-2 regions of the 16S rRNA (1), clinical response and mucosal inflammation was assessed by fecal calprotectin (FCP) levels.

Results: Clinical response occurred in 7 of 14 patients after two to four FMTs. 4 patients showed clinical worsening and 3 patients showed no improvement. FCP dropped in responders from 536 mg/kg stool (med.; min-max: 116–3000) to 150 mg/kg (191–1409), whereas in patients with flare FCP values increased from 536 mg/kg (157) to 1450 mg/kg (1221–1778). Microbiota analysis of 10 patients and two donors revealed a significantly lower diversity in pouchitis patients compared to healthy donors as assessed by the total phylotype number, the Shannon diversity and Pielou evenness. In patients showing response, typical gut microbiota with high diversity was observed. This increase in diversity was due to the successful establishment of the donor microbiota as assessed by the analysis of sample-similarity matrices constructed using the Bray-Curtis algorithm and a detailed analysis of the taxonomic composition. The encapsulated fecal microbiota was as effective as the endoscopic jejunal application in its combination to restructure the fetal microbiota. An increase in diversity and an overall restructuring of the microbiota into a composition resembling the donor not necessarily correlated with clinical outcome and clinical worsening was observed during three FMTs where the established microbiome structure reemerged that of the donor in diversity and composition. Interestingly, a high abundance of Ruminococcaceae was associated with remission in a recent study on ulcerative colitis (2). However, two patients showed worsening here despite a high increase in the relative abundance of Ruminococcaceae after FMT.

Conclusion: Fecal microbiome transfer in patients with chronic pouchitis is a promising therapeutic option and donor microbiomes could successfully be transferred via capsules or via jejunoscopy delivering fresh stool filtrate. However, a simple increase in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Introduction: Mucosal healing (MH) has been established as co-primary treatment target in Crohn’s disease, predominantly defined by the absence of ulceration. However, even in patients with MH, inflammation may persist on histologic examination1. Filgotinib (FIL), a selective inhibitor of JAK1 that blocks cytokine signaling through inhibition of STAT phosphorylation, has recently shown efficacy in a double-blind, placebo (PBO)-controlled Phase 2 study in CD (Fitzroy2). Effects of filgotinib versus placebo have been demonstrated on centrally read endoscopy and histopathology assessments after a 10-week induction treatment.

Aims & Methods: In this post hoc analysis, we explored the correlation between histologic and endoscopic disease activity at baseline (BL) and following FIL induction therapy by comparison of total ileal Global Histology Activity Score (IGHAS)/colonic GHAS (CGHAS) score or IGHAS/CGHAS activity subscores (a; activity items: presence of epithelial damage, polymorphonuclear leukocytes in lamina propria, neutrophils in epithelium, erosion or ulceration, granuloma)3,4 versus total ileal Simplified Endoscopic Score for CD (ISES-CD)/colonic SES-CD (CSES-CD) score or ISES-CD/CSES-CD ulcer subscores (u; sum of size and percentage affected surface). CD patients were randomized 3:1 to receive 200 mg FIL or PBO (QD) for 10 weeks5. Histopathologic scores were collected at BL and Week 10 (W10) from the most affected areas of each predefined bowel segment (ileum, colon) and W10 respectively(aIGHAS v uISES-CD: Corr = 0.53, p = 0.001; BL aIGHAS v uISES-CD: Corr = 0.62, p = 0.001; BL and W10 respectively)aIGHAS v uCGHAS = 0.53, p = 0.001;
**Aims & Methods:** Patients achieving clinical response 8 wks after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w dosing. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249) and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The remission rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7 vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

**Results:** Of the 219 patients not in clinical response in UNITI 1&2, 37.6% and 60.5% respectively were in clinical response 8 weeks after the first maintenance UST dose (90 mg SC). Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection (16 weeks after the IV induction dose) for UNITI1&2 are 47.4% and 73.7% respectively (see table for response and remission rate). Similar assessments were calculated in the sub-population who were anti-TNF naïve upon enrolment into UNITI-2.

**Conclusion:** These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.

Response rates and Remission rates for all patients 16 weeks after induction of 6 mg/kg IV UST

1. Neurath MF. *Mucosal immunology* 2014; 7: 6–19
Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naïve. All patients with IBD (ulcerative colitis or Crohn’s disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥3 infusions within 98 days of index date); (2) were ≥18 years of age at index; (3) had ≥365 days of medical history prior to index (“baseline”); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic ≤90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids), respectively. Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ≥60% of patients in each cohort. In the baseline period, ~70% of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 3.1 years for IFX initiators. Median time to treatment discontinuation was 244 (IQR: 194–307) days for VDZ initiators vs. 240 (IQR: 194–307) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Conclusion: Among biologic-naïve IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

Introduction: Cancer development has been linked to oxidative stress by increasing DNA mutations or inducing DNA damage, genome instability and cell proliferation. Interestingly, reactive oxygen species (ROS) seem to modulate antigen presentation, a crucial event in the immune surveillance mechanisms. We recently showed that expression of the co-stimulatory molecule CD80 on epithelial cells has a critical role during the immune surveillance process occurring in colon carcinogenesis. Remarkably, ROS have been involved in the transcriptional regulation of CD80 gene expression, in addition, oxidative DNA damage was directly correlated to CD80 expression in colon mucosa dysplasia.

Aims & Methods: Therefore, the aim of this work was to examine the role of ROS on CD80 expression in colon epithelial cells using an in vitro and an in vivo model of colon carcinogenesis. A mouse colorectal cancer cell line, CT26, was used to quantify the expression of CD80 in response to pro-oxidant (such as Melphalan) and antigen presentation, a crucial event in the immune surveillance mechanisms. We aimed to determine if colonic antimicrobial gene expression profiles differ between IBS and healthy subjects and if potential alterations are linked to immune activity or gut microbiota composition. The expression of 84 key antimicrobial genes in sigmoid colon biopsies from patients with IBS, defined as being either immuno-active or immuno-norm based on systemic and mucosal cytokine profiles (Benett et. al Am J Gastro), 2016, and healthy subjects was assessed by Human Antibacterial Response RT2 Profiler PCR Array. Targeted 16S rRNA pyrosequencing was performed for faecal microbiota. To identify discrimination profiles based on multiple variables between IBS patients and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >0.7 was performed.

Results:

Table 1: Differences in mucosal antimicrobial mRNA expression between IBS (Immuno-active and Immuno-norm) and healthy subjects.

Data presented as p-values (Mann-Whitney t-test) *’* = non significant. We included 31 IBS patients (16 females, median age 32 (25–44) years) and 16 healthy subjects (8 females, median age 27 (24–30) years). An OPLS-DA model demonstrated that the antimicrobial profiles differed between IBS and healthy subjects (R² = 0.54, Q² = 0.16). The mucosal mRNA expression of 14 antimicrobial genes was downregulated, while one gene was upregulated in IBS patients compared to healthy subjects (Table 1). Antimicrobial profiles did not differ between IBS patients subtyped according to their predominant bowel habit (R² = 0.02). An OPLS-DA model showed discrimination between immuno-active (n = 16) and immuno-norm (n = 15) IBS patients based on their mucosal antimicrobial profiles (R² = 0.91, Q² = 0.61). This finding was corroborated by four antimicrobial genes being altered between the two IBS groups (Table 1). Adding healthy subjects to the model revealed three differing antimicrobial profiles for each respective group (R² = 0.44, Q² = 0.30). Compared to healthy subjects, 19 genes in the immuno-active and immuno-norm IBS groups were differently expressed (p < 0.05, Table 1). Only one of the antimicrobial genes differently expressed between IBS patients and healthy subjects was associated with faecal microbiota in immuno-norm IBS patients (Conserved Helix-Loop-Helix Ubiquitous Kinase (CHUK) with Anaerovorax r = -0.76, p < 0.01). In the immuno-active IBS group 11 associations were identified, including TNF...
Studies (I2 = 0.80, P < 0.01) comparing the relationship between antibiotic and CRC were included in the meta-analysis. Compared with no/low use of antibiotics, high use of antibiotics might play a role in the complex pathophysiology of CRC.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the effect of internal and external drainage on obstructive jaundice-induced intestinal barrier function rats on intestinal mucosal barrier function with special reference of intestinal immune-related index expression. Sixty male Sprague-Dawley rats were randomly assigned to four groups: OJ, sham operation (SH), internal biliary drainage (ID) and external biliary drainage (ED). All animals underwent surgical ligature of the bile duct, except SH was produced by separating common bile duct locally but not dividing on day 1. Then ED and ID were reoperated on day 8 for biliary drainage procedure. Blood from inferior vena cava were collected for the test of DAO and slgA activities by the method of ELASA. The terminal ileum specimens of each groups were collected for observation of the morphological changes with haematoxylin-eosin (HE) staining. The expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5mRNA were measured by RT-PCR. The expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01). While in ID group, the expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01), while the internal impaired mucosa have different degrees of recovery and ID group was more similar to SH group in intestinal mucosal morphology. The levels of the DAO in ID group were increased more dramatically that in SH, ID and ED groups while slgA were decreased (P < 0.01), and the activities of the DAO, slgA in ID group were similar to the level of SH group (P > 0.05), different to the level of ED group (P < 0.01). The changes of the plasma DAO and slgA activities were significantly correlated with the conditions of intestinal mucosa (P < 0.01). The expression of RD-5 mRNA in OJ group were decreased significantly than that in SH, ID and ED groups while GP-BAR1 mRNA, IgA mRNA, plgR mRNA were increased (P < 0.01). Interestingly enough, after external bile drainage, there is no improve- ment in IgA mRNA and plgR mRNA (P > 0.05). But in ID, the relative expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01), while the mRNA expression of GP-BAR1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GP-BAR1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of in SH group (P < 0.01). After internal and external biliary drainage to alleviate OJ respectively, the GP-BAR1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, P < 0.01; ID vs SH, P > 0.05), and lower than that of in ED group (P < 0.05).

Conclusion: The differential expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5 mRNA and activities of DAO and slgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a mucosal barrier mechanism between GP-BAR1 and IgA mRNA which linked with intestinal-immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosal barrier.

P0419 COMPARATIVE EFFECT OF XYLOGLYCAN ASSOCIATIONS WITH COMPOUNDS FROM ANIMAL OR ALGAE ORIGIN ON LPS-INDUCED ENTERITIS IN RATS

H. Eutamene, C. Harkat, V. Theodorou

Unite De Neuro-gastro-enterology & Nutrition, Touloulon UMR 1331 IRAN/UPS/ INPT-EI-Purpan, Toulouse/France

Introduction: Xyloglucan (XG) is a film-forming agent exhibiting protective effects against diarrhea linked to infectious gastroenteritis in humans; further in animal models, xyloglucan efficacy against cholera-toxin-induced diarrhea was tested while prolonged when this mucoprotective agent is associated with gelatin from animal origin. The use of compounds from animal source in galenic formulations is nowadays questionable.

Aims & Methods: Thus, in this study, we aimed at comparing the efficacy of XG associated with gelatin vs XG associated with gelose a moiety from algae origin on LPS-induced enteritis in rats. Since LPS-induced enteritis is characterized by increased intestinal permeability and mucosal inflammation, the efficacy of xyloglucan associations was evaluated by measurement of these two parameters. Male Wistar rats (200-250 g) were orally treated with either: XG (10 mg/kg) + gelatin (25 mg/kg) or XG (10 mg/kg) + gelose (25 mg/kg) or XG (10 mg/kg) + gelose (50 mg/kg) or vehicle (NaCl 0.9%) 3h before intraperitoneal (IP) administration of LPS from E. coli (1 mg/kg). Six hours later LPS administration, the animals were sacrificed and strips of jejunum were collected in order to evaluate (i) intestinal epithelial paracellular permeability to FITC-dextran 4kD in Ussing chambers and (ii) mucosal inflammatory response by myeloperoxidase (MPO) activity measurement.
Results: Compared with control, LPS administration induced a significant increase (p < 0.05) of intestinal paraacellular permeability (53.0 ± 4.9 vs 181.6 ± 21.1 pmol/cm² respectively) associated with jejunal mucosal inflammation (302.1 ± 9.5 vs 655.6 ± 108.9 U MPO/g protein, respectively). XG (10 mg/kg) + gelose at the lowest dose (25 mg/kg) failed to reverse the intestinal hyperpermeability and mucosal inflammation induced by LPS. In contrast, XG (10 mg/kg) + gelatin (25 mg/kg) and XG (10 mg/kg) + gelose at 50 mg/kg significantly (p < 0.01) and equally prevented LPS-induced hyperpermeability (34.8 ± 2.8, 38.7 ± 3.9 vs 181.6 ± 21.1 pmol/cm² respectively) and jejunal inflammation (27.0 ± 3.2, 286.2 ± 28.8 vs 655.6 ± 108.9 U MPO/g protein respectively).

Conclusion: This study shows that oral treatment with xyloglucan associated with gelose at 50 mg/kg has similar protective effects on LPS-induced enteritis in rats than xyloglucan associated with gelatin. These data demonstrate that algae is an effective and safe substitute for replacing compounds from animal origin in xyloglucan mucoprotectant formulations.

**P0421 CLINICAL CHARACTERISTICS OF CYTOMEGALOVIRUS COLITIS: 15 YEAR-EXPERIENCE IN A TERTIARY MEDICAL CENTER**

L. Le1, R. Wu1, C. Chiu1, C. Kuo1, M. Su1, C. Lin2, J. Hsu3
1Department Of Gastroenterology And Hepatology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan
2Department Of Pathology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan
3Department Of General Surgery, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan

Contact E-mail Address: phuocsin@gmail.com

Introduction: Cytomegalovirus (CMV) colitis in adults is mostly described in immunocompromised patients (solid organ or hematopoietic stem cell transplant recipients, patients with human immunodeficiency virus (HIV) infection, use of immunosuppressive drugs, including steroid or chemotherapeutic agents), and often has worse outcome than in children. Besides, it also was frequently presented in patients with known or subsequent new diagnosis inflammatory bowel disease [1, 2]. However, there are only case reports and few case series with limited patients (below 15 cases) among immunocompetent individuals without known use or inflammatory bowel disease [3–5]. The largest meta-analysis study of cytomegalovirus colitis in immunocompetent hosts included 44 patients and noted advanced age, male gender, presence of immune-modulating comorbidities and need of surgical intervention negatively influencing survival in 2005 [6]. The clinical characteristics of CMV colitis in immunocompetent patient seemed increasing over time in our hospital these years. There was no single study showing comprehensive clinical characteristics, identifying the independent factors of in-hospital mortality and comparing the differences between immunocompetent and compromised patients with CMV colitis. Therefore, we tried to clarify the issue in this study.

Aims & Methods: We enrolled 42 immunocompetent patients and 27 immunocompromised patients with CMV colitis diagnosed by immunohistochemistry stain between April 2002 and December 2016 in Linkou Chang Gung Memorial Hospital, a 3383-bed tertiary medical center and referral center in Taiwan. We analyzed the risk factors of in-hospital mortality and overall survival. Furthermore, we compared the clinical differences between immunocompetent and immunocompromised patients with CMV colitis.

Results: Early diagnosis (before 9 days) was independent predictor of in-hospital mortality in CMV colitis patients. ICU admission (P = 0.010), requisite days of diagnosis≥9 days after admission (P = 0.018), shock (P = 0.001), respiratory failure (P = 0.033), hemoglobin <10 g/dL (P = 0.002), Creatinine ≥1.37 mg/dL (P = 0.004) and CRP≥9.9 mg/dL (P = 0.011) negatively impacted on overall survival. There were older and more comorbidities in immunocompetent group. However, the in-hospital mortality rate and overall survival rate was similar to immunocompromised group. Besides, Cytomegalovirus infection or steroids didn’t affect in-hospital mortality rate and overall survival rate neither. Melena was first and most common symptom in immunocompetent group, but diarrhea in the other.

**Analysis of the clinical factors associated with in-hospital mortality in all patients**

Introduction: Clostridium difficile infection (CDI) is one of the most common hospital-acquired infections. Fecal microbiota transplantation (FMT) is used for complicated recurrent CDI treatment; however, to date no data on the efficacy of this method in Eastern Europe have been published.

Aims & Methods: The aim of this study was to assess effectiveness of FMT for recurrent CDI therapy in the hospital of Lithuanian University of Health Sciences (LUHS KK, Kaunas, Lithuania). Clinical data of patients who were treated for recurrent (> 2 times) CDI using FMT in the Department of Gastroenterology of LUHS KK during 2015–2016, were analyzed. All patients were monitored for disease relapse for six months. Clinical data, the use of antibiotics and immunosuppressive drugs were included in analysis. Statistical analysis was performed using statistical software package SPSS version 17.

Results: FMT was used for 18 patients with recurrent CDI. The mean age of patient was 60.4±8.4 years. The patients were treated with antibiotics 14.8 days on average before manifestation of CDI. FMT procedure was performed using naso-enteral tube. After the first procedure, the positive clinical effect was observed in 15 patients with a cure rate of 83.3%. FMT procedure was repeated for two out of the three patients without positive effect (one patient refused repetitive FMT). Normal stool habits were restored in both patients leading to the increase of cure rate to 94.4% (17 out of 18 patients). Seventeen patients that were successfully treated with one or two FMT procedures in the short term also remained asymptomatic (100 %) at 6 months of follow up. All patients without positive effect of first FMT procedure were on immunosuppressive drugs (3/3; 200 mg/kg/day of prednisolone).

Conclusion: Immuno-compromised patients or steroid users did not have higher in-hospital mortality rate. Early diagnosis was only independent factor for lower in-hospital mortality in patients with CDI.FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The traditional fear that every acute appendicitis will eventually perforate leads to prompt surgery, but this fear may be outdated. In-hospital delay of surgery for acute appendicitis has been subject of a large number of studies. However, consensus about the consequences of delaying appendectomy is lacking, which is reflected in variety or absence of recommendations in guidelines.

Aims & Methods: The aim of this study was to assess in-hospital delay of surgery and the consequences of delaying appendectomy in patients with acute appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections and postoperative morbidity. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152, 314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.98–1.17) and 1.09 (95% CI 0.95–1.24), respectively. For a delay of 24 to 48 hours the adjusted odds ratio was 1.24 (95% CI 1.08–1.41). Pooling data revealed a decreased risk for complicated appendicitis when appendectomy was delayed for 24 to 48 hours, however statistical uncertainty in this interval increased considerably compared to the first 24 hours.

Conclusion: In-hospital delay of surgery for up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis. However, in-hospital delay of surgery for 24 to 48 hours resulted in higher rates of complicated appendicitis, surgical site infections or morbidity. When prompt surgery is hampered by logistic or personal reasons, delaying appendectomy up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis.

Introduction: C. difficile infection represents a major burden in Europe and North America. However, data on its disease epidemiology remain sparse in Asia. This study aims to investigate the burden, risk factors and clinical outcomes of C. difficile infection in Hong Kong, using a large territory-wide population database.

Aims & Methods: This is a population-based study conducted from 1 January 2006 to 31 December 2014, and included all in-patient C. difficile infections in public hospitals in Hong Kong. Cases were identified from a territory-wide electronic database, and were defined as the isolation of C. difficile, or positive test for either toxin or molecular assay from the fecal specimens. The disease incidence, mortality, risk factors and clinical outcomes were analyzed.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
1. 15,753 cases were identified, including 14,402 (91.4%) community-associated and 817 (5.1%) care-associated infections. The crude incidence of C. difficile infection was 9.8 per 100,000 population (PV < 0.001), representing an over 30% increase annually. This rise was
notably contributed by elderly patients, of which the incidence has increased by threefold over the period. Recurrence at 60 days increased from 5.7% in 2006 to 9.1% in 2014 (P<0.001). The increased use of proton-pump inhibitors accounted for 58.8% of the surge.

Conclusion: The incidence of *C. difficile* infection has increased more than threefold, and was associated with an increased disease recurrence and use of proton-pump inhibitors. Our results suggest need for further surveillance in Asia which hovers half of the world’s population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0428 THE PROPHYLACTIC CLIP APPLICATION BEFORE SNARE POLYPECTOMY DECREASES IMMEDIATE POST-POLYPECTOMY BLEEDING IN LARGE PEDUNCULATED POLYPS

J.S. Sohn1, S.H. Park2, Y. Song3, K. Kim4

Introduction: Endoscopic bleeding (EB) is the most common complication following polypectomy, especially in cases with large pedunculated polyps. Although the clip application before snare polypectomy may decrease PPB, there were few prospective randomized studies to confirm the efficacy of prophylactic clip. This present study was conducted to investigate whether prophylactic clip application for large pedunculated colorectal polyps could decrease PPB and to evaluate associated risk factors of PPB.

Aims & Methods: We enrolled 137 pedunculated polyps (>1 cm in size) in 116 patients in the past 6 months. The polyps were randomized into the two groups with or without prophylactic clips application. Immediate PPB was defined as bleeding that continued for over 30 seconds from the polypectomy site and graded from grade 1 to 4. Delayed bleeding occurred in five polyps in both groups (P=0.943). The prophylactic clip application was a significant factor for lowering immediate PPB in the univariate (OR 0.215, 95% CI 0.081-0.571, P=0.002) and multivariate analysis (OR 0.20, 95% CI 0.074-0.591, P=0.003). In addition, polyp size >20 mm and stalk diameter ≥4 mm were significant risk factors of immediate PPB compared with polyp size ≤10 mm and stalk diameter 1-3 mm.

Conclusion: The prophylactic clip application in large pedunculated polyps >1 cm is effective in reducing immediate PPB. Polyp size and stalk diameter are associated with PPB.

Introduction: Heparin replacement (HR) during periprocudural periods is described in various guidelines as the recommended method while discontinuing warfarin. However, the rate of post-colonic polypectomy bleeding in patients undergoing HR has been reported to be as high as 20%. As an alternative method to HR, colonic polypectomy without discontinuation of warfarin may be feasible, however there is still insufficient evidence. The aim of this study was to assess the safety of colonic polypectomy/endoscopic mucosal resection (EMR) without discontinuation of warfarin during periprocudural periods.

Aims & Methods: This is a prospective multicenter single-arm exploratory study in Japanese patients who received warfarin for the purpose of prevention of thrombosis. They were prospectively enrolled and underwent colonic polypectomy or EMR without discontinuation of warfarin. Conventional clip closure of the resection site was performed in all cases and oral diet was resumed 2 days after the procedure. The primary outcome was post-polypectomy/EMR bleeding that was confirmed by emergency endoscopy or a decrease in the hemoglobin level of >2 g/dl with hematocrit even if the bleeding site was not identified.

Results: Between January 2015 and November 2016, a total of 30 consecutive patients (M:F=26:4, 69.9±8.0 years) were enrolled in this study after written informed consent was obtained. A total of 31 lesions (tumor diameter: 5.4±2.9 mm, adenoma 70, others 10, lost lesion 1, number of prophylactic clips 4.9±2.2) were treated by polypectomy/EMR. Four patients experienced post-polypectomy/EMR bleeding (4/30: 13.3%) in 3-11 days after the procedure, although no cases required blood transfusion. In 3 of these bleeding cases, a single responsible site was identified by emergency endoscopy. Therefore, the confirmed rate of post-polypectomy/EMR bleeding based on the number of removed lesions was 3.9% (3/76), but may range to 9.9% (8/81). There were no other adverse events.

Conclusion: The rate of post-colonic polypectomy/EMR bleeding in patients without discontinuation of warfarin single therapy was comparable to that in patients undergoing HR. Continued safety and usefulness of prophylactic hemoclips in the endoscopic resection of the colon is feasible and may reduce the hospitalization associated with HR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Warfarin and direct oral anticoagulants (DOACs) warfarin, apixaban, dabigatran and edoxaban are approved for stroke prevention in patients with atrial fibrillation (AF). The Japan Gastrointestinal Endoscopy Society guidelines recommend that anticoagulants should be discontinued at a low thromboembolic risk, or by replaced by bridging therapy at a high thromboembolic risk, for endoscopic polypectomy. However, safety and efficacy of heparin bridging therapy for colonic polypectomy remains unclear.

Aims & Methods: The aim of the present study was to evaluate the risk of post-polypectomy bleeding (PPC) in patients who take anticoagulants. We retrospectively collected data of patients who underwent colonic polypectomy between January 2014 and February 2017 at Nagoya City University Hospital. Polyp characteristics (number of polyps removed per patient, size, morphology) and patient characteristics (age, sex, comorbidities, medication) was analyzed.

Results: A total of 1007 patients underwent colonic polypectomy. 67 patients were in the anticoagulants group and 808 patients were in the normal group (taking no antiplatelet agents and anticoagulants). The incidence of PPC was significantly higher in the anticoagulants group than in the normal group.

Introduction: The incidence of acute lower gastrointestinal bleeding (LGB) is estimated at 21 adults per 1,000 person years and male (82.1%) in the 

Introduction: Intermittent bleeding from colon diverticulum has a significant 
clinical impact with some cases experiencing recurrent bleeding episodes for 
several years. No report has directly evaluated the association between arterio-
scerosis and diverticulum bleeding recurrence.

Aims & Methods: We sought to assess the degree of arteriosclerosis in cases with 
diverticulum bleeding as well as the patients’ clinical characteristics. We 
conducted a retrospective cohort study in a group of 79 consecutive patients with 
colon diverticulum bleeding (51 men) who underwent both colonoscopy and 
computed tomography (CT) between August 2007 and March 2014. The mean 
age of the patient population was 69.5 years (range 29–91 years) and mean 
(±standard deviation) follow-up time was 6.2 (±2.0) years (range 3.1–9.7 years). 
Patients were divided into two groups: the recurrent bleeding episode group and 
the single bleeding episode group. Recurrent bleeding episodes were 
defined as bleeding intervals of >1 month. Cases that underwent successful 
therapy during the initial bleeding episode were excluded. We compared 
Agatston scores (total calcium score) between the two groups of patients to 
assess the degree of arteriosclerosis. A calcified lesion was defined as an area 
of at least 2 connected pixels with >120 Hounsfield units (HU) on the unen-
hanced CT scan. Aortic mural calcified area × cofactor (1:120–199HU, 2:200– 
299HU, 3:300–399HU, 4:≥400HU) was determined. The sums of the scores for 
every calcified spec were calculated across all lesions in a slice from the level of 
the diaphragm to the aortoiliac bifurcation to obtain the total calcium score. 
Moreover, the relationship between recurrent bleeding episodes and the patients’ characteristics, including age, sex, smoking habit, comorbidity (hypertension, 
to the standard colonoscopy group: median 2.0 days [IQR 2.0–4.0] vs. median 3.0 
days [IQR 2.0–4.0] (p = 0.009). Recurrent bleedings and hospital re-admissions 
were significantly more frequent in the early colonoscopy cohort 13% vs. 3% 
(p = 0.04) and 11% vs. 2% (p = 0.02) respectively. The reason for more recurrent 
bleedings could not be established, although use of anti-thrombotic therapy might be a factor. No difference was observed regarding the number of patients 
diagnosed with either a confirmed active bleeding or presumptive bleeding 
source. In both groups, blood transfusion rate was similar and thirty-day mor-
tality was zero.

Conclusion: In patients with LGIB, early colonoscopy reduces the length of 
hospital stay compared to standard colonoscopy. However, more recurrent 
bleedings are observed and no improvement of diagnostic yield could be established.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0433 THE COMPARISON OF DIRECT ORAL ANTICOAGULANTS (DOAC) AND WARFARIN FOR ANTICOAGULATION IN THE PATIENTS WITH GASTROINTESTINAL BLEEDING

Gastroenterology, Mitsui Memorial Hospital, Tokyo/Japan 

Contact E-mail Address: kenken.kojiken.529@gmail.com

Introduction: Direct oral anticoagulants (DOAC) are now popularly used as anticoagulation for atrial fibrillation and deep vein thrombosis, as well as 
Warfarin. But, direct comparison of DOAC and warfarin in the patients with 
gastrointestinal bleeding was little reported.

Aims & Methods: We retrospectively analyzed 18 on DOAC and 60 cases on 
Warfarin of the patients with gastrointestinal bleeding from January 2011 to 
March 2017 on the basis of single-center experience in Japan. We analyzed con-

trolled red cell (CRC) and fresh frozen plasma (FFP), transfusion rate, bleeding 
during hospitalization, the duration from bleeding to endoscopy, from endoscopy to discharge and from bleeding to discharge in both group.

In DOAC group, each 6 patients took Dabigatran, Rivaroxaban and Apixaban.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion:

5.4 days vs 24.2 days, p = 0.02). Thrombotic embolism during hospitalization occurred only 1 (7.1%) of Warfarin group.

Conclusion: The duration of hospitalization was significantly shorter in DOAC group of the patients with gastrointestinal bleeding, and the rate of hospital readmission and re-bleeding tended to be lower in DOAC group. This study showed that DOAC may be more superior to Warfarin as an anticoagulation for atrial fibrillation and deep vein thrombosis at the quality of life (QOL) in the patients with gastrointestinal bleeding.

Introduction: Colonoscopy is an imperfect tool. Several publications confirm colorectal cancer may manifest after a negative colonoscopy(1–3). The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term(1). Post-colonoscopy colorectal cancer (PCCRC) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening(2). Although there is overlap between these two terms, they are not synonymous. PCCRC can be thought of as the overarching term. PCCRC can be subcategorized into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval was recommended, up to 10 years following the colonoscopy).

Aims: The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers- PCCRC/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool(4). An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient representa-
tives) were summoned by the World Endoscopy Organisation (WEO); the final panel consisted of 20 voting members. The following topics were addressed by 2 working groups (WGs): 1. Aetiology WG 2. Molecular and radiological dataset analysis, and reporting of cancer appearances after a negative colonoscopy. a. Terminology of PCCRC, b. Molecular and radiological dataset analysis, and reporting of cancer appearances after a negative colonoscopy. a. PCCRC and PICRC as the overarching term. b. PCCRC as a screening term and the relevant surveillance or surveillance procedures following a negative screening colonoscopy. c. PCCRC/PICRC as the overarching term. d. The aetiology of PCCRC/PICRC. e. The epidemiology of PCCRC/PICRC and the potential role of lifestyle and environmental factors in its causation.

Therefore, at the time of this report (2017), a total of 56,682 colorectal cancer patients and 258 out of 288,119 (0.09%) people in the general population were diagnosed with ovarian cancer. Ovarian cancer was more common in the colorectal cancer group than the general population. The incidence of ovarian cancer was also higher in colorectal cancer patients and 258 out of 288,119 (0.09%) people in the general population were diagnosed with ovarian cancer. Ovarian cancer indeed has a high incidence of ovarian cancer, a screening test can be performed on high-risk patients.

Aims & Methods: This is a retrospective cohort study using data registered in the National Health Insurance Corporation as a cancer diagnostic code since 2007. In Korea, once cancer is diagnosed, this information is recorded by the National Health Insurance Corporation with a relevant code, and this system provides every patient’s data for medical research purposes. The colorectal cancer group includes patients newly enrolled with the corresponding diagnostic code (ICD-10 code C18, C19, and C20). The 56,682 colorectal cancer patients and 288,119 sex-age-and geographically general population was used. This type of data was used to facilitate the creation of comparison group that is similar. Each cancer patient was matched to five individuals in the unexposed cohort. All data was followed up by a new diagnostic code of ovarian cancer (ICD-10 code C56) was given. After adjusting for age, sex, smoking, drinking, exercise and comorbidities (diabetes mellitus, hypertension, and hyperlipidemia), further analysis was performed. The hazard ratios and 95% confidence intervals were calculated via Cox proportional hazards regression models. Statistical analysis will be performed with SPSS version 24.0. When P < 0.05, the result was defined as statistically significant.

Results: Patients with colorectal cancer were followed up for an average of 4.4 years until the occurrence of ovarian cancer. During the follow-up period, 335 out of 56,682 (0.60%) colorectal cancer patients were newly recruited and 258 out of 288,119 (0.09%) people in the general population were diagnosed with ovarian cancer. Ovarian cancer was more common in the colon cancer group than the general population [Hazard ratio (HR) 7.13, 95% Confidence interval (CI) = 5.06–10.05]. The analysis was conducted only for those who had medical checkup data within one year (14, 190 patients in colorectal cancer group, 71,933 people in the control group). Even though the subjects in this group were adjusted for several factors (age, sex, smoking, drinking, exercise, diabetes, hypertension, and hyperlipidemia) ovarian cancer was more common in colorectal cancer group [HR 7.12, 95% CI = 5.05–10.04]. Colorectal cancer patients had a higher risk of ovarian cancer across all age groups including patients under the age of 55 years [HR 10.69, 95% CI = 6.26–18.26] and patients older than 55 years [HR 5.17, 95% CI = 3.26–8.19].

Conclusion: In conclusion, data from the National Health Insurance Corporation revealed that the incidence of ovarian cancer in colorectal cancer patients was higher than that of the general population. In woman diagnosed with colorectal cancer, the screening test should be done to monitoring the occurrence of ovarian cancer. Further research is necessary to determine the innate association between the development of ovarian cancer and colorectal cancer, and large prospective studies are needed.
P0437 EXCESS RISK OF SECOND PRIMARY CANCERS IN YOUNG-ONSET COLORECTAL CANCER SURVIVORS

X. He1, W. Wu1, L. Sun1, Y. Ding1, J. Si1
1Department Of Gastroenterology, Sir Run Run Shaw Hospital, hangzhou/China
2The First Affiliated Hospital, School Of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, hangzhou/China

Contact E-mail Address: hxingkang@zju.edu.cn

Introduction: Colorectal cancer (CRC) is still the third most common malignancies in the US according to Colorectal Cancer Statistics, 2017[1]. During past decades, the incidence and mortality of CRC among individuals aged over 50 years are declining significantly, while the rate of CRC in the young is sharply on the rise. For example [2-3], excluding rate of young-onset CRC, coupled with increased survival rate, would definitely lead to accumulation of young survivors considerably. There is a growing study reporting the risk of second primary cancers (SPCs) in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC were at high risk of SPCs than the general population [4–6]. However, to the best of our knowledge, little is known regarding the risk and sites of SPCs following prior diagnosis of CRC in the young (aged ≤50).

Aims & Methods: To address this important gap, we aimed to quantify the relative risk of SPCs after a diagnosis of CRC in the young CRC survivors. We conducted this retrospective study by utilizing the Surveillance, Epidemiology, and End Results (SEER) database and identified primary CRC patients with subsequent cancers between 1973 and 2013. We excluded cases with less than 6-months latency restriction. Standardized incidence ratios (SIR) and absolute excess risk (AER) were calculated to assess the relative risk for SPCs. SIRs for subgroup analysis were further stratified by gender, race, calendar year, latency periods, SEER stage, cancer subtype, radionuclide and radiation therapy. All statistical tests were performed by SEER*Stat version 8.3 and a P value <0.05 was considered statistically significant. Our study was approved by the review board of Zhejiang Institute of Gastroenterology, Sir Run Run Shaw Hospital, China.

Results: Among CRC survivors, there were 64,472 survivors who developed 51,084 SPCs during the follow-up, including 3283 young (young aged ≤50) and 41,189 (old >50) survivors. The SIR of all sites significantly decreased with increased age. Compared with the general population, SIRs of all solid tumors and hematological disease were significantly increased in the young. There was significant 43% risk of SPCs in young survivors (SIR=1.43, 95%CI=1.39–1.48, AER=33.85) and slight increases in old survivors (SIR=1.02, 95%CI=1.01–1.03, AER=4.20). For young survivors, small intestine (SIR = 8.36), colon (SIR = 3.77), rectum (SIR = 3.36), bile ducts (SIR = 0.37) were the most frequent sites. A trend was persistent regardless of other factors, such as gender, race, calendar year, stage, subtypes, radiation, and latency. For young patients with second cancers, 36.4% died of their initial cancer, but 84.6% died of their second primary malignancy.

Conclusion: This is the first study to report on the pooled incidence of FIT and gFOBT iCRC in screening setting. The incidence rate of iCRC after a negative

3ICR Cancers, if screening-related or patient-related factors are associated with FOBT iCRCs. Ovid Medline, Embase, The Cochrane Library, the Science Citation Index, PubMed publisher and Google scholar were searched up to May, 2016. All studies reporting on the incidence of FIT or gFOBT iCRC including average CRC screening populations were included, without language restrictions. Main outcome was pooled incidence rate of iCRC per 100,000 person-years (p-y). FOBT iCRC was according to international standards defined as cancer that developed after a negative FOBT and before the next FOBT was due. Pooled incidence rates were obtained by fitting random effect poisson regression models. The between-study heterogeneity of effect-size was quantified using the I². Results: We identified 5,873 records, of which 413 full-text articles were assessed for eligibility and 30 studies were included in both qualitative and quantitative analyses. Meta-analyses comprised data of 5,252,563 screening participants, in which 14,030 screen-detected CRCs and 5398 FOBT iCRCs were documented. Pooled incidence rates of iCRC following FIT and gFOBT were 20 (95%CI 14.28; I²=94%) and 40 (95%CI 26.61; I²=93%) per 100,000 p-y, respectively. The pooled incidence rate ratio of FIT iCRC compared to gFOBT iCRC was 0.50 (95%CI 0.30–0.84, n=30 studies). For every FIT iCRC, three CRCs were found for every gFOBT iCRC. The incidence rate ratio of FIT iCRC compared to gFOBT iCRC was 1.13. Table 1. No significant differences were found between the relative risk of FIT iCRC in the second and third screening round compared to the first, with 1.03 (95%CI 0.94–1.13) and 1.08 (95%CI 0.93–1.22), respectively. Incidence rate ratio of FOBT iCRC compared to gFOBT iCRC was 0.84 (95%CI 0.80–1.7) for males relative to females and 5.0 (95%CI 1.21–2.1) for screenees aged ≥60 relative to <60 years.

Table 1: Baseline data of 30 studies included in qualitative meta-analyses displayed by test type

FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as screening tool. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screenees about the risk of developing a colorectal carcinoma after a negative FIT.**

Contact E-mail Address: drtekinform@gmail.com

Introduction: Studies with colon cancer cell lines which express muscarinic-3 (M3) receptors showed that taurine conjugates of lithocholic acid, but not other bile acids, bind to M3 receptors, and stimulate an increase in cell proliferation. On the other hand, many microRNAs (miRNAs) are involved in colon carcinogenesis. However, the interaction of bile acid-M3 receptors and miRNAs and their potential effects in colon carcinogenesis remains to be elucidated.

Aims & Methods: For the first time in the literature, we examined the possible role of M3 receptor-targeted miRNAs on two human colon cancer cell lines: H508, which expresses M3 receptors, and SNU-C4, which does not. Cell proliferation for 6 days after sodium taurocholothiolat (ST) and atropin (A) treatment was analysed by WST-1 test. Expression of M3 receptor at mRNA level was analysed by qPCR, and at protein level by Western Blot method. Apoptotic experiments were analysed by Annexin V assay. MiRNAs which possibly targeted M3 receptors were identified by in silico analyses. The methods were repeated three times, and the average values were calculated.

Results: When compared to SNU-C4 cells, M3 receptor gene expression was found to be increased 70-fold on H508 cells. After a 6-day incubation, maximum H508 cell proliferation (300%) was achieved on 5th day with a dose of 300 μM ST, inhibited by a dose of 1 μM A. In contrast, the SNU-C4 cells showed no significant change in cellular proliferation. Treatment of H508 cells with ST caused a decrease (2.5-fold) of M3 receptor gene expression, however, no change of M3 receptor at protein level was seen. No changes in apoptosis on both colon cancer cell lines were observed. Of 25 M3 receptor-targeted miRNAs, expression levels altered in 9; 6 of them were up-regulated (hsa-miR-129-5p, hsa-miR-30c-5p, hsa-miR-224-5p, hsa-miR-30b-5p, hsa-miR-522-3p, hsa-miR-1246) and 3 of them (hsa-miR-30c-5p, hsa-miR-147b, hsa-miR-858-3p) were downregulated on H508 cells (p < 0.05).

Conclusion: ST interact with M3 receptors which modulate colon cancer cell proliferation on H508 cells. M3 receptor-targeted miRNAs are involved in ST induced proliferation. Whether the use of ursodeoxycholic acid, selective anti-miRNAs, anti-cholinergic agents or other approaches to blocking potential interactions of bile acids/salts with neoplastic colonic epithelium may be a useful adjunct to colon cancer prevention or treatment remains to be determined.

P0443 COLORECTAL CANCER AND DYSLIPIDAEMIA: CAUSE OR CONFOUNDING? A MENDELIAN RANDOMIZATION STUDY

1Unit Of Biomarkers And Susceptibility, Catalan Institute of Oncology-IDIBELL, L’Hospitalet de Llobregat; Spain
2Environental And Cancer Epidemiology, Instituto de Salud Carlos III, Madrid; Spain

8University Institute of Oncology of Asturias, Oviedo; Spain

Introduction: Dyslipidemia and statin use have been associated to colorectal cancer (CRC), but prospective studies have shown controversial results. Dyslipidemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent. [1–4] It is unknown whether lipids and lipoproteins cause cancer or are intermediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5–6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidemia and CRC.

Aims & Methods: We aimed at determining whether dyslipidemia is causally linked to CRC risk and to explore association of statins with CRC. A case-control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiological questionnaire that included lifetime regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested on regular use of statin and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

Results: The LDL genetic risk score was significantly associated with statin consumption (OR = 1.07, 95%CI 1.05–1.10, p = 4.4e-11). The dyslipidemia genetic risk score was not significantly associated with CRC for either of the target lipids studied. Cases had the same average alleles as controls in all the lipids traits. Statin use was a borderline significant protective factor for CRC (multivariate adjusted OR = 0.83, 95%CI 0.69–1.00, p = 0.049).

Conclusion: Using the Mendelian randomization approach, our study does not support the hypothesis that lipid levels are associated with the risk of CRC. This study does not rule out, however, a possible protective effect of statins in CRC by a mechanism unrelated to lipid levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

Our results support that LINC00152 lncRNA can contribute to CRC development by facilitating cell proliferation through upregulation of cyclin D1. Hypomethylation of LINC00152 promoter was detected in CRC compared to normal samples (p < 0.05). Moreover, LINC00152 silencing decreased DNA methylation levels of SFRP1, SFRP2, SDC2 and PRIMA1 genes, suppressing their expression. The effect of LINC00152 silencing on SFRP2 promoter methylation status was studied using MethyLight technology. Promoter methylation and expression of the above molecules were also studied on human colonic tissue samples. Results: LINC00152 expression was successfully silenced in SW480 cells with 93–98% efficiency. Colorectal cancer cell lines and cell growth were not affected and decreased cyclin D1 protein expression. LINC00152 knockdown did not affect the promoter methylation status of SFRP1, SDC2 and PRIMA1 genes, while reduced the DNA methylation level of SFRP2 promoter. Remarkable hypomethylation of 5-positioned cytosine in promoter of LINC00152 was detected in CRC compared to normal samples (p < 0.01), which correlated with increased expression (R = 0.90). SFRP2 promoter hypermethylation and decreased expression were measured in CRC and adenoma tissues compared to normal samples (p < 0.05). Concluding statement: Long non-coding RNA LINC00152 contributes to CRC development by facilitating cell proliferation through upregulation of cyclin D1 cell cycle progression gene and by affecting promoter methylation of SFRP2 tumor suppressor gene. On human tissue level, similar signaling pathway alterations were detected.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0445 GENETIC PROFILE OF POLYPS AND RISK OF ADVANCED METACHRONOUS LESIONS

Objectives: To determine the association between genetic profile of polyps and risk of advanced metachronous lesions (AML).

Methods: A case-control study was conducted by the Medical Institute of the Hungarian Academy of Sciences, Budapest University of Technology and Economics. The study included 200 patients with colorectal cancer and 400 patients with normal colon. Polyp samples were analyzed for somatic mutations on BRAF and KRAS genes using the PCR-MLPA method. AML was defined by a size higher than 9 mm, high-grade dysplasia or villous component in adenomatous lesions. Regarding serrated lesions, AML was defined as the presence of CIMP-H in polyps. Logistic regression analysis was performed to determine the association between genetic profile of polyps and risk of AML.

Results: In the study, 30 patients with colorectal cancer were consecutively enrolled between 2007 and 2009 for this cohort study, and followed up to 2014. Variables as age, sex, smoking, weight, number of polyps were analyzed for somatic mutations on BRAF and KRAS genes using the PCR-MLPA method. AML was defined by a size higher than 9 mm, high-grade dysplasia or villous component in adenomatous lesions. Regarding serrated lesions, AML was defined as the presence of CIMP-H in polyps. Logistic regression analysis was performed to determine the association between genetic profile of polyps and risk of AML.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0446 MITOCHONDRIAL GLUTAMATE TRANSPORTER (SLC25A22) MEDIATES DNA AND HISTONE HYPERMETHYLATION AND PROMOTES THE TUMORIGENICITY OF KRAS-MUTANT COLORECTAL CANCER

Objectives: To investigate the role of SLC25A22, a mitochondrial protein, in CRC development.

Methods: In vitro and in vivo experiments were performed using CRC cell lines and patient samples. SLC25A22 expression was silenced using siRNA and CRISPR-Cas9 technology. DNA and histone methylation levels were measured using methylated DNA affinity precipitation (MeDIP) and ChIP-Seq, respectively. The effect of SLC25A22 knockdown on glutamine metabolism was assessed using 13C5-glutamine metabolic labeling.

Results: SLC25A22 knockdown led to increased DNA and histone methylation levels, which were associated with decreased glutaminolysis in CRC cell lines. Moreover, histone H3 methylation was reduced at multiple loci in SLC25A22-knockdown cell lines, suggesting that epigenetic dysregulation was involved in the regulation of succinate and fumarate. Indeed, succinate supplementation reversed the effect of SLC25A22 knockout on DNA and histone methylation in KRAS-mutant CRC cell lines. Moreover, histone H3 methylation was reduced at multiple loci in SLC25A22-knockdown cell lines, suggesting that epigenetic dysregulation was involved in the regulation of succinate and fumarate. Interestingly, simultaneous APC-loss and KRAS activating mutations synergistically regulated epigenetic dysregulation. We recently demonstrated that SLC25A22-knockout cell lines, suggesting that epigenetic dysregulation was involved in the regulation of succinate and fumarate. Furthermore, we found that SLC25A22-knockout cell lines, suggesting that epigenetic dysregulation was involved in the regulation of succinate and fumarate. This synergistic effect was observed in vivo, where SLC25A22-knockout CRC cell lines exhibited increased DNA and histone methylation levels, which correlated with decreased glutaminolysis. These findings support the potential role of SLC25A22-mediated glutaminolysis in regulating DNA and histone methylation in CRC, its underlying mechanisms, and the association of SLC25A22 with epigenetic dysregulation in human CRC cohorts.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: SLC25A22 promotes the tumorigenicity of KRAS mutant CRC by driving cell cycle progression and histone demethylation, an effect enhanced by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0447 FOLLISTATIN-LIKE PROTEIN 1 SUSTAINS COLON CANCER CELL GROWTH AND SURVIVAL

G. Bevivino1, G. De Simone1, M. Izzo1, S. Gallo1, M. Calise1, N. Di Marzo2, L. Mancini2, R. Izzo1, A. Rizzo1, G. Monteleone1

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR.

Cell proliferation and survival cell culture were evaluated in human CRC cell lines (e.g., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control AS. Western blotting, immunohistochemistry and quantification of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and reduced cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), EZF-1, cyclin E and cyclin-dependent kinase-2 (CDK2), with no modification of early G1 phase proteins (i.e. cyclin D). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0448 TP53 MUTATION ACQUIRES HIGHER MALIGNANT POTENTIAL IN HUMAN COLON CANCER CELLS

S. Watanebe1, T. Tsuchiya1, T. Shinagai1, S. Hibiya1, S. Hoshino1, M. Nakamura2

1Gastroenterology, Wuxi People's Hospital Affiliated to Nanjing Medical University, Wuxi/China
2Department Of Pathology, University of Lodz, Lodz/Poland

Introduction: TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potentials, direct effect of TP53 mutation on malignant potential of colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the effect of both TP53 mutants on various malignant potentials, result of which is here reported.

Aims & Methods: Two types of TP53 mutation were generated in LS174T cells, which are derived from human colon adenocarcinoma with wild-type TP53 (WT). TP53 mutation in LS174T was expressed in LS174T cells. In contrast, both TP53 mutants (TP53Ex3 and TP53Ex10) of TP53 were expressed in LS174T cells. After 3 weeks of cell culture, cells were harvested and used for molecular and histological studies.

Results: We first selected LS174T cells with WT-TP53 because TP53 gene has already been mutated in almost colon cancer cell lines. We then successfully established 2 types of TP53 mutation in LS174T cells due to high effectiveness of gene-mutating by lentiviral system. Mutation in exon3 (TP53Ex3) and exon10 (TP53Ex10) of TP53 created the shorter form of TP53 (TP53Ex3: 55a.a., respectively) compared to WT-TP53 (393a.a.). Mutant TP53 (TP53Ex10) is strongly expressed in nuclei as often shown in colon cancer region, whereas both WT-TP53 and mutant TP53 (TP53Ex3) are not expressed in LS174T cells. In contrast, both TP53 mutants (TP53Ex3 and TP53Ex10) of TP53 were expressed in LS174T cells.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0449 PROTECTIVE EFFECT OF OPIOID RECEPTOR ACTIVATION IN THE DEVELOPMENT OF COLITIS-ASSOCIATED COLORECTAL CANCER IN MICE

A. Jarmuz1, J. Jaenicke2, H. Zatorski1, R. Korde3, W. M. Krajewska4, J. Fichna4, M. Zielińska4

4Department Of Pathology, Medical University of Lodz; Lodz; Poland

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphiceptin analog with mu- and kappa- opioid receptor affinity, resulted in the reduction of acute phase of experimental colitis (induced by dextran sodium sulfate [DSS]) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane [AOM] (10 mg/kg) and subsequent addition of DSS (1.5% w/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1 mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the mice were sacrificed, tumour location score was assessed and the samples were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly increased total number of colonic tumors as well as colon thickness and width after 14 weeks of disease induction. Metylopexadazole, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoylin and eosin staining confirmed anti-tumor activity of P-317 as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group.

Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0450 INCREASED HMGB1 EXPRESSION CORRELATES WITH HIGHER EXPRESSION OF C-IAP2 AND PERK IN COLORECTAL CANCER

W. Zhang1, X. Liu2, F. An3, Q. Zhan4, W. Tian2

1Gastroenterology, Wuxi People's Hospital Affiliated to Nanjing Medical University, Wuxi/China
2Department Of Pathology, University of Lodz, Lodz/Poland
3Department Of Pathobiochemistry, Faculty Of Biology And Environmental Protection, University of Lodz; Lodz; Poland
4Department Of Pathology, Medical University of Lodz; Lodz; Poland

Introduction: Colorectal cancer (CRC) is the third most common type of cancer in the world, and its incidence continues to rise. However, serological markers can be a relatively easier and cheaper alternative to the bowel exam. Thus, the identification of new biomarker of cancer[1, 2, 3, 4]. Studies have shown that HMGB1 is over-expressed in various types of cancers, including CRC, and those with higher expression of HMGB1 are associated with lymphatic metastasis, distant metastasis and poor prognosis [5]. Several reports have demonstrated that HMGB1 is
secreted by cancer cells may be involved in occurrence of tumor metastasis [6, 7]. In a study by Luo et al., the authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupffer cells which promoted development of liver [6, 7]. Furthermore, some researchers showed that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1 are found in tumors. MicroRNAs (miRNAs) 55 metabolites may be useful for diagnosis and treatment of CRC. However, whether HMGB1 has any role in the development of CRC metastasis is not clear. In this study, we investigated the effects of HMGB1 on CRC, and the possible underlying mechanisms were examined.

Aim: To investigate the relationship between high-mobility group B1 (HMGB1) and colorectal cancer (CRC) and the probable underlying pathogenic mechanism. In this prospective study, patients with CRC undergoing primary surgery and healthy subjects (control group) were included from July 2013 to December 2014. HMGB1 concentration was determined using ELISA and HMGB1 mRNA expression was detected by RT-PCR method. Immunohistochemical analysis was performed to determine HMGB1, pERK and c-IAP2 protein expressions in the cancer tissues.

Results: 144 patients with CRC and 50 healthy subjects underwent HMGB1 testing. Resected specimens of 50 patients were used for HMGB1 mRNA and protein expression analysis. Serum HMGB1 levels in CRC patients were higher than that of the control group (8.42 ± 1.79 μg/L, p < 0.05). Preoperative serum HMGB1 concentrations were significantly higher than the postoperative values (8.42 ± 5.67 vs 1.64±1.89 μg/L, p < 0.05). Serum HMGB1 levels in CRC patients with distant metastases were significantly higher (13.32 ± 6.12 vs 7.57 ± 5.13 μg/L, p < 0.05). HMGB1 mRNA and protein expression in CRC tissues was significantly higher than in the adjacent normal mucosa. HMGB1 protein expression positively correlated with the lymph node metastasis. There was positive correlation between HMGB1 and c-IAP2 (r = 0.457, P = 0.001), HMGB1 and pERK (r = 0.461, P < 0.05) as well as pERK and c-IAP2 (r = 0.399, P < 0.05).

Conclusion: HMGB1 expression in CRC correlates with distant and lymph nodal metastasis. It may inhibit apoptosis by inducing activation of pERK and c-IAP2.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. We previously reported that certain miRNAs (miR-143, -145 and -34a) were differently expressed in samples of tumors and paired non-tumorous samples taken from the same patients with colorectal tumors, and there was a relation close to adenoma-carcinoma sequence for these miRNAs expression.

Aims & Methods: In this study, we examined the miRNA expression profiles of multiple colorectal adenomas comparing between sporadic colorectal adenoma and familial adenomatous polyposis (FAP). We examined the miRNA expression profiles (miRs-143, -145, -34a, and -342) and morphological appearance of 102 sporadic colorectal adenomas (SA), 27 tumors of multiple colorectal adenoma (over 10 adenomas/one patient, MA), 21 tumors of FAP and 114 sporadic cancer (SC).

Results: The expression levels of miR-143 and -145 were reduced in all tumors compared with the paired non-tumorous samples in the same patient. Especially, these miRNAs were significantly reduced in MA (P = 0.042 and P = 0.004) and FAP (P = 0.027 and P = 0.022) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas (P < 0.001). The expression levels of miR-34a were significantly down-regulated in CA (P = 0.001), MA (P < 0.001), and FAP (P = 0.006) compared with SA.

Conclusion: These findings suggest that the malignant potential of MA and FAP was higher than SA, therefore MA needs strict follow-up like FAP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0453 UTILITY OF MEAN PLATELET VOLUME, PLATELET CRIT, PLATELET-LYMPHOCYTE RATIO AND NEUTROPIL-LYMPHOCYTE RATIO IN THE DIFFERENTIATION OF COLON CANCER AND COLONIC POLYS IN OLDER PATIENTS
F. Karakaya, Ç. Kalkan, I. Soykan
Gastroenterology, Ankara University, Ankara/Turkey

Contact E-mail Address: mfkarakaya@yahoo.com

Introduction: Colorectal carcinoma (CRC) is an important cause of mortality and morbidity in elderly patients. CRC and colorectal polyps are common in dementic patients, irrespective of the iron status. There is a close association between increased mean platelet volume (MPV) and the presence of many solid tumors such as hepatocellular carcinoma, pancreatic carcinoma, lung cancer, endometrial cancer and gastric cancer. Neutrophil/lymphocyte ratio (NLR) and platelet/lymphocyte ratio (PLR) are markers of systemic inflammatory response and their elevation is closely some studies to be associated with progression of colorectal carcinoma. Although colonscopic examination is the standart way of colorectal carcinoma diagnosis, they are not feasible in 75 and 85 years of age should be tailored on the basis of the presence of coexisting conditions because the risk of serious complications from colonscopy also increase with age.

Aims & Methods: The aim of this study was to investigate whether MPV, plateletcrit, PLR and NLR may have a role in the discrimination of CRC and colonic polyps in older patients. 418 patients aged >65 years with colorectal carcinoma (n=93) (Group I) and colonic polyps (n = 325) (Group II) were included into the study. Also 601 (Group III) patients aged >65 years with normal colonscopic findings served as a control group. All study subjects were investigated by using MPV, plateletcrit, PLR and NLR in order to establish sensitivity and specificity for predicting colorectal carcinoma and colonic polyps for each parameter studied.
Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Group II; however, only MPV was significantly higher in Group II compared to group 1 (8.6±1.1 vs 8.2±1.1, p<0.001). The cut-off value of MPV in predicting CRC from patients with normal colonoscopic findings was 9.15 fL with a specificity and sensitivity of 80% and 91% respectively (r=0.892). MPV and PCT were also significantly higher in patients with neoplastic polyps compared to patients with non-neoplastic polyps (MPV: 8.7±1.1 vs 8±1, p<0.001 and PCT: 0.23±0.07 vs 0.19±0.05, p=0.003).

Conclusion: MPV and PCT may have a role as useful and simple markers in the diagnostic assessment of patients with colorectal cancer from patients with normal colonoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopic examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0454 IMPROVING THE SELECTION OF COMPLETE RESPONDERS FOR WATCHFUL WAITING AFTER CHEMORADIOThERAPY FOR RECTAL CANCER: WHAT CAN WE LEARN FROM THE ‘MISSED’ PATHOLOGIC COMPLETE RESPONDERS AFTER SURGERY?
D.M. Lambregts1, M. Maas1, M. Van Der Sande1, B. Hupkens1, M. Martens1, F. Bakers1, R. G.h. Beets-Tan1, S.O. Breukink1, G.L. Beets2
1Department Of Radiology, The Netherlands Cancer Institute, Amsterdam/Netherlands
2Surgery, The Netherlands Cancer Institute, Amsterdam/Netherlands

Introduction: In patients with locally advanced rectal cancer (LARC) that show a very good response to neoadjuvant treatment, organ-preserving treatments such as watchful waiting may be a good alternative to surgical resection and can improve functional outcome and quality of life. If we can predict upfront (i.e. before start of CRT) how patients will respond to treatment this may create opportunities to further personalize and optimize the neoadjuvant treatment to enhance the chance of a good response, thereby ultimately offering more patients the chance of organ preservation. A promising new tool in this regard is ‘Radiomics’. Radiomics refers to a collection of analytical methods to convert images into high dimensional data via a set of quantitative descriptors called “features”. These features have the potential to uncover disease characteristics that cannot be detected by means of conventional (visual) imaging evaluation.

Aims & Methods: Aim of this study was to assess what can be learned from patients with ‘missed’ pathologic complete responders (ypT0N0) by re-evaluating their post-CRT imaging and endoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopic examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: doenja.lambregts@gmail.com

Conclusion: Main reasons for missing a complete response after CRT are heterogeneity of the tumor on DWI (all top 20 features). In contrast, more ‘common’ radiological features such as volume showed inferior performance (highest rating 56). Results derived from delineations performed by the two expert radiologists and non-expert readers resulted in comparable diagnostic performance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In patients with locally advanced rectal cancer (LARC) that show a very good response to neoadjuvant treatment, organ-preserving treatments such as watchful waiting may be a good alternative to surgical resection and can improve functional outcome and quality of life. If we can predict upfront (i.e. before start of CRT) how patients will respond to treatment this may create opportunities to further personalize and optimize the neoadjuvant treatment to enhance the chance of a good response, thereby ultimately offering more patients the chance of organ preservation. A promising new tool in this regard is ‘Radiomics’. Radiomics refers to a collection of analytical methods to convert images into high dimensional data via a set of quantitative descriptors called “features”. These features have the potential to uncover disease characteristics that cannot be detected by means of conventional (visual) imaging evaluation.

Aims & Methods: We aimed to find the Radiomics signature1 of patients with LARC and evaluate its potential value for pre-treatment prediction of the response to neoadjuvant chemoradiotherapy.

We retrospectively assessed the primary staging MRI’s (1.5T of 124 LARC patients treated with CRT. The standard MRI protocol included T2-weighted (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment MRI: [1] by 2 expert pelvic radiologists, [2] using a semi-automatic (region growing) software algorithm, and [3] by manual adjustment of the semi-automatic delineations by two non-expert readers, adding up to 5 delineations per tumor/patient in total. Radiomics signatures were extracted from the images for each of the five delineations (3002 features in total). Features showing both sufficient stability (ICC > 0.75) as well as reproducible performance (Wilcoxon test, False Detection Rate (FDR) 10%) across different readers/delineations were selected to test their performance in predicting response to CRT by means of a receiver operating characteristics (ROC) curve analysis. The main outcome was complete tumour regression (yT0) versus residual tumour (yT4)- using histology and/or long-term FU as the standard of reference.

Results: Out of 3002 initially identified Radiomics features, 1853 proved stable across different readers/delineations. For the four manual delineations ±300/3002 features per reader remained significantly performant after FDR correction. However, these features did not sustain after FDR correction for the fully automated segmentation. A final subset of 266 features remained stable and performant across all five readers/delineations. These features resulted in a mean AUC of 0.67 (range 0.64-0.73) to predict a complete response and a mean ICC of 0.81 (range 0.75-0.95). Best results were obtained for textural features measuring the heterogeneity of the tumor on DWI (all top 20 features). In contrast, more ‘common’ radiological features such as volume showed inferior performance (highest rating 56). Results derived from delineations performed by the two expert radiologists and non-expert readers resulted in comparable diagnostic performance.

Conclusion: 1) Various Radiomics features extracted from pre-treatment MRI correlate to neoadjuvant treatment response and may be used as imaging biomarkers to predict the response to chemoradiotherapy in rectal cancer.
2) Best results are obtained for textural features (representing tumour heterogeneity) derived from diffusion-weighted MR sequences
3) Features extracted from semi-automated (software generated) delineations show inferior performance compared to features extracted from manual delineations, emphasizing the need for adequate tumour delineation. Interestingly, however, delineations from expert and non-expert readers rendered similar good results, suggesting that the selected features are robust and do not necessarily require highly expert input.

Aims & Methods
We aimed to investigate the correlation of the electrical and viscoelastic parameters of erythrocytes with the fatty acid composition of their membranes in patients with colorectal cancer (CRC). We observed shifts correlated with a disease stage (r = 0.64; p < 0.01) at the initial stages of CRC.

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified in terms of the following four subtypes according to their histological features: granulose type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat-elevated type (LST-NGF), and non-granular pseudo-depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified in terms of the following four subtypes: granulose type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat-elevated type (LST-NGF), and non-granular pseudo-depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.

Aims & Methods
The aim of this study was to clarify the clinical features of each subtype of LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 5352 endoscopically resected specimens during January 2007 and December 2016 at our institution. A total of 422 LSTs were detected. We evaluated the clinical features (mean age ± standard deviation, size, location, Incidence of concomitant carcinoma) according to their subtypes.

Results: Of these 422 lesions, a total of 131 (31.0%) were LST-GH, 34 (8.1%) LST-GM, 29 (6.9%) LST-NGF, and 28 (6.6%) LST-NGPD. Mean age of patients with each subtype was 68.3 years old for LST-GH, 67.1 for LST-GM, 67.9 for LST-NGF, and 67.2 for LST-NGPD. Male to female ratio (M/F) was 1.21 for LST-GH, 2.05 for LST-GM, 1.95 for LST-NGF, and 1.65 for LST-NGPD. The mean size of LST-GH (21.9 mm) and LST-NGF (21.2 mm) was significantly larger than that of LST-NGF (17.0 mm) and LST-NGPD (15.1 mm). All subtypes were located predominantly in the proximal colon. Incidences of concomitant carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 0.0% (0 out of 151), 14.7% (5 out of 34), 1.9% (2 out of 209), and 25.0% (7 out of 28), respectively.

Conclusion: Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods
We aimed to investigate the correlation of the electrical and viscoelastic parameters of erythrocytes with the fatty acid composition of their membranes in patients with CRC; omega 6/omega 3 fatty acid index was not transfer to assessing quality indicators at a local level. However, we question the validity of a post CT-CRC rate as a true quality indicator of a colonoscopy service. Extrapolating the data is challenging but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study1.

Introduction: Post-colonoscopy colorectal cancer (PC-CRC) rates are proposed as a quality of service. Extrapolating the data is challenging but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study1.

P0459 RISK OF DETECTION OF GASTROINTESTINAL NEOPLASMS AND DEATH IN SYMPTOMATIC PATIENTS WITH A POSITIVE FECAL IMMUNOCHEMICAL TEST WITHOUT COLORECTAL CANCER
N. Piñu, M.J. Iglesias, D. Remedios, P. Vega, J. Cubiella Servicio De Aparato Digestivo, Complejo Hospitalario de Ourense, Ourense, Spain

Contact E-mail Address: noel.pin.vieito@sergas.es

Introduction: The fecal immunochemical test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.

Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (FITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the ≥20g hemoglobin/g of feces threshold. We performed a descriptive analysis of the risk of detection during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.

Results: We included 1061 patients without CRC and a complete baseline colonoscopy; 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0±8.9 months with no difference between both groups (p = 0.2). There were significant differences regarding age (67.5±12.7 years vs. 64.8±13.5 years, p = 0.04) and sex (45.9% vs. 52.0% females, p = 0.04) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CRC, 6 gastric, 2 small intestine adenocarcinoma, one esophageal, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9–4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.7%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8–2.1). However, the risk of death due to GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2 95% CI 1.2–8.9).

Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of CSL.

Introduction: Self-expandable metallic stent placement for malignant colorectal obstruction has been widely used; however, factors affecting the technical difficulty of stenting remain unclear.

Aims & Methods: The aim of this study was to clarify the factors associated with the technical difficulty of stenting for malignant colorectal obstruction. We established the Colonic Stent Procedure Research Group to provide instructions on how to perform safe and effective procedures in order to reduce complications. We evaluated the clinical data and extracted factors associated with the technical difficulty of stenting by using univariate and multivariate analyses.

Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining 196 patients were included in the analysis. Of these, 100 were men (51.0%) and the median age was 72 years old (interquartile range (IQR), 62–82 years old). One hundred eleven patients (57%) underwent stenting as a bridge to surgery, and 85 (43%) underwent stenting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients with malignant colorectal obstruction were included. The median total procedure time in the cohort with technical success was 30 minutes (IQR, 18–42 minutes). The median deployment time was 21 minutes (IQR, 11–31 minutes). Forty-nine patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting. The following were identified as independent factors of the technical difficulty in stent placement: presence of ascites (odds ratio, 2.483; 95% confidence interval [95%CI], 1.17–5.29; p = 0.02), presence of ≥1 stent (odds ratio, 4.80; 95%CI, 1.10–21.1; p = 0.04).

**P0462 PROGNOSIS AND CLINICOPATHOLOGICAL FACTORS OF PATIENTS WHO SELECTED THE FOLLOW-UP OPTION AMONG HIGH-RISK TI COLORECTAL CANCER PATIENTS AFTER ENDOSCOPIC RESECTION BASED ON JAPANESE CLINICAL PRACTICE GUIDELINE: A RETROSPECTIVE OBSERVATIONAL STUDY**
Y. Nishikawa, T. Horinatsu, S. Minamiguchi, H. Seno, Y. Sakai, T. Nakayama

**Introduction:** Colorectal cancer is the third most common cancer in the world and the fourth leading cause of cancer death. Treatment strategy for colorectal cancer is selected considering clinical stages. TI colorectal cancer (T1CRC) can be treated with endoscopic resection. If patients have pathological risk factors such as deep submucosal invasion, budding, por/muc pathological features and lymphovascular invasion, they considered to be at high risk of lymph node metastasis based on the indication of Japanese Society for Cancer of the Colon and Rectum guideline. In such cases, the selection of subsequent option is important and has been frequently decided by clinicians' customs and preferences. However, it is not clear whether these risk factors adequately predict patients' outcomes in clinical practice.

**Aims & Methods:** This research aims at revealing the prognosis and clinicopathological features of pathologically high-risk T1CRC patients (the high-risk group) with and without additional surgery; followed up by computed tomography, ultrasound, endoscopy, and tumor marker (CEA: carcinoembryonic antigen, CEA 1). To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). 2. To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as TI colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosis was defined by their characteristic laterally spreading growth pattern larger than 20 mm, ulceration, and lesion location.

**Results:** Among 162 T1CRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU), 20 patients were performed additional surgery with lymph node dissection (AS). Four patients treated with additional radiation therapy were excluded. Median survival time was 39 (FU) and 62 (AS), respectively. Compared with FU, there were no recurrences among the 62 e-curable patients. On the other hand, five recurrences (5%) were found in non-e-curable patients, and they were all in Group A. They consisted of local recurrence (one patient who also had lung metastasis), LN metastasis (two patients), lung metastasis (three patients), and liver metastasis (one patient who also had LN metastasis). There were no significant differences in DSS between Group A and Group B + C (LST-NG). However, OS was 93% in Group A, which was significantly lower than that (96%) in Group B + C (p < 0.05). DFS in Group A was 90%, which was significantly lower than that (100%) in Group B + C (p < 0.05). The prognosis of patients with non-e-curable disease after ER alone showed no significant differences in OS, DFS, and DSS between Group A and Group B + C. The prognosis of patients with non-e-curable disease after surgical resection showed no significant differences in DFS or DSS. However, OS in Group A was 94%, which was significantly lower than that (97%) in Group B + C (p < 0.05).

**Conclusion:** Long-term outcomes supported the JSCCR criteria for e-curable patients for ER for TI LSTs. All recurrences occurred in patients with TI LST-G-M carcinoma. OS and DFS in the LST-G-M group were significantly shorter than in the LST-NG group. The non-e-curable patients were divided into 3 groups: Group A (61 patients were non-e-curable patients diagnosed with LST-NG), Group B (23 patients were non-e-curable patients diagnosed with LST-NG), and Group C (23 patients were non-e-curable patients diagnosed with LST-NG). There were no patients diagnosed with TI LST-G-H carcinoma. OS in the LST-G-M group was significantly lower than that of the other two groups.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Cholangioscopy and cholangiography with a targeted 6 month study endpoint. At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary system. Stents in one standard dose animal migrated out of the bile duct between 10 to 60 days post-implant, no persistent clinical symptoms were observed in any animal. Stents, no tissue overgrowth or stent embedding was observed in any animal. Up to 72 days post-implant, no clinical symptoms were observed in any animal. The observed 60% reduction in bile duct dilation. At 60 days post-implant, moderate mucus and biofilm formation was observed within the stent, however in only 3 animals biliary ductal dilation was observed. However, all animals displayed mild biofilm formation and increased stent control group by 60 days post-implant. Given the observed 60% reduction in mucus and bile. Bile duct dilation, in turn, has reduced the opportunity for recurrent obstruction and typically requires endoscopic re-intervention. The secondary outcomes include risk factors such as: lymphovascular invasion, tumor differentiation, resection margin status and the presence of tumor budding. A retrospective review of the endoscopy charts for the period 2000-2016 was conducted. All patients enrolled exhibited a malignant colonic sessile polyp which was endoscopically completely resected. Histological findings of the polyps were also recorded. Thorouugh computed or magnetic scanning was performed in all patients before deciding on further management. All patients were advised for the option of surgical treatment or endoscopic follow-up. Results: 51 patients with confirmed adenocarcinoma in sessile colonic polyps undergoing endoscopic mucosal resection (EMR) were retrospectively included in this study. A total of 33 (64.7%) patients underwent subsequent surgery after EMR, and 18 (35.3%) chose endoscopic follow up. The histological characteris-tics of patients undergoing EMR is presented in Table 1. In patients undergoing EMR, the submucosal invasion was >1 mm. Residual malignant disease was identified in the surgical pathological specimen of only one patient. With a median follow-up of 25.12 months (IQR: 31.5; range: 1.8-144.92), no local recurrences or lymph node metastasis were identified. 49 were without evidence of disease and 2 died of other cause (without evidence of disease at last follow-up). The data regarding the other risk factors are presented in Table 1.

| Conclusion: Our data suggest that even in cases with submucosal invasion >1 mm and the presence of other high-risk features (lymphovascular invasion, tumor budding), complete EMR in malignant colonic sessile polyps supported by the histological findings predicts for a good clinical outcome. Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this prospective study, we evaluated the overall survival (OS) and disease-free survival (DFS) in the chemotherapy group based on CD-DST. Moreover, we evaluated additional effects of EGFR (Cetuximab; Cmb, Panitumumab; Pmab) to FOLFOX/FOLFIRI using CD-DST. Between Mar. 2008 and Aug. 2016, we obtained tumor specimens from 131 CRC patients without postoperative chemotherapy. Informed consent for measurement of individual chemosensitivity was obtained from all patients in writing. Approval for the present study was obtained from the Tohub Chiiki Hospital Institutional Review Board (No: 02.03.29. #1). The growth inhibition was determined by CD-DST. The regimens were as follows: FOLFOX, FOLFIRI, Cmb, Pmab, and FOLFOX/FOLFIRI+Cmb. The incubation conditions were as follows: FOLFOX; 5-FU and 1-HOP (6.0 and 3.0μg/ml, respectively) for 24h. FOLFIRI; 5-FU and SN-38 (6.0 and 0.2μg/ ml, respectively) for 24h. Cmb; Cmb 10mg/ml for 144h. Pmab; Pmab 200μg/ml for 144h. FOLFOX+Cmb; Cmb 250μg/ml for 120h after FOLFOX/FOLFIRI incubation process. The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to treatment is equivalent to FOLFOX/FOLFIRI in the group treated with appropriate first-line chemotherapy and the group treated with inappropriate first-line chemotherapy were evaluated Kaplan–Meier method. Additional effects of Cmb to FOLFOX/FOLFIRI were also evaluated. Results: There was strongly relationship between the IR% of the FOLFOX and FOLFIRI regimen (R²=0.7415). The median of the IR% with the FOLFOX and FOLFIRI regimen were 58.6 and 69.1, respectively, FOLFOX responder, FOLFOX responder, dual responder, and poor responder were 8, 10, 53, and 60, respectively. There were 42 unresetable CRC patients with chemotherapy. The median survival time of appropriate first-line chemotherapy group (n: 28) and inappropriate first-line chemotherapy group (n: 14) were 1128 and 306 days, respectively. There was positive correlation between survival and cCR of CRC and that of Pmab (R²=0.468). Additional rates (%) of Cmb to FOLFOX between poor responder and other responder were 19.8 and 5.6, respectively (P=0.020). Additional rates of Cmb to FOLFIRI between poor responder and other responder were 15.6 and 1.29, respectively (P=0.005). There was significantly more additional effect of Cmb to FOLFOX/FOLFIRI in poor responder than in other responders. Conclusion: Administration of the recommended first-line regimen using CD-DST to patient is important for improvement in the further prognosis. Moreover, especially in poor responder, Cmb should be administrated to FOLFOX/FOLFIRI regimen.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The standard treatment for locally advanced rectal adenocarcinoma (ADC) is to conduct surgical resection after neoadjuvant chemother-apy (NACT). In the wait-and-see (W&S) strategy, those who achieve clinical complete response (cCR) after CRT undergo regular clinical, radiologic and endoscopic surveillance, with surgery being reserved for tumor “regrowth”. Aims & Methods: To evaluate the impact of a W&S strategy for low rectal ADC, regarding overall and disease-free survival. Single-center prospective observa-tional study. All patients with low rectal (up to 6cm from the anal verge) ADC, stage I to III, discussed in a multidisciplinary colorectal cancer clinic during the implementation of the W&S strategy (11/2014–11/2016) were evaluated. Demographic data, post-CRT evaluation and decision, recurrence rates, “regrowth” and mortality were analyzed. Results: 56 patients were evaluated ([54% males; mean age at diagnosis 64, 4 years (34–90)], of which 53 had already completed CRT. Stage III prevailed (89%). The cumulative incidence to compare the risk of metachronous advanced neoplasia during follow-up between patients with untreated diminutive colorectal polyps and those with small or large adenoma resected at baseline colorectal cancer. Aims & Methods: A total of 1955 patients were colorectally followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows; 581 in group A (mean age 65.0± 8.9 yr, M:F =411:170) with colorectal adenoma more than 5mm in size resected at baseline, 495 in group B (65.2± 9.6 yr, 328:167) with diminutive polyps left untreated at baseline, and 519 in group C (62.5± 10.7 yr, 255:264) with no polyps at baseline. During follow-up colonoscopies detected metachronous neoplasms more than 5mm in diameter were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative
incidences of metachronous colorectal neoplasms were compared with each other using a log-rank test.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.4 times in group A, 61.6 months and 3.4 times in group B, and 73.2 months and 2.7 times in group C, respectively. The cumulative incidences of metachronous adenoma were 24.1% (95% CI: 0.65-0.71) and 24.1% in the 5, 218 subjects (P = 0.03) and in 1, 000 bootstrapped replicates (P = 0.03).

Conclusion: An 8-point scoring model to predict ACN in asymptomatic screening population that might have a higher discriminatory capability than the modified APCS score was developed and internally validated in this study. Our simple scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

Introduction: Previous studies have shown that increase of threshold for first rectal sensation can be a predictor of fecal incontinence. However, significance of the lower range of rectal inhibitory reflex (%)RAIR) in development of this disease remains unknown.

Aims & Methods: To determine association between %RAIR and threshold for first rectal sensation in healthy adults and its significance in development of fecal incontinence. 26 asymptomatic healthy volunteers (18 women, 8 men) median age was 35.03 years (19–59) were studied. We performed them a high-resolution anorectal manometry (HRAM) using a 20 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands). The following HRAM parameters were analyzed: threshold for RAIR and %RAIR (automatically calculated as the ratio of the amplitude of the relaxation of the anal sphincter (AS) to the basal pressure AS *100%), threshold for first rectal sensation (RS) and for desire to defecate. The statistical analyses were performed using Stata for Windows 6.0 (StataSoft Inc.).

Results: Threshold for RAIR and %RAIR were 22.3 ml (10.0; 30.0), 74.4% (38; 99.5) respectively. Threshold for first RS was 30.07 ml (11.1; 58.3) and desire to defecate - 65.12 ml (33.5; 182.0). Threshold for RAIR was not associated with threshold for first RS (r = 0.07) and for desire to defecate (r = 0.02). %RAIR was weak positively correlated with threshold for first RS (r = 0.26) and was not associated with threshold for desire to defecate (r = –0.03).

Conclusion: Threshold for RAIR and %RAIR are not associated with first RS and desire to defecate. So, these parameters of RAIR cannot be predictors of fecal incontinence.

Objectives: The role of trait neuroticism as a predictor of functional gastrointestinal (GI) symptoms (1). One explanation for this is that high neuroticism predisposes individuals towards avoidant coping by leading them to view negatively-valenced situations as catastrophic (2) and, therefore, unsolvable (3). Avoidant coping, in turn, increases the risk of developing GI discomfort because over-reliance on “flight” strategies in stressful situations overstimulates the sympathetic nervous system at the expense of parasympathetic activity necessary for digestion (4). Evidence for this proposed chain of events comes largely from studies that have observed relationships between each pair of the chain’s components: neuroticism and avoidant coping (e.g., 3), and avoidant coping and higher GI symptom burden (e.g., 1). Across two studies, this paper integrates these findings, while also exploring the role of somatisation. Somatisation is consistently observed in people suffering from functional GI Conditions (e.g., 1) and refers to a subtype of avoidant coping - the expression of psychological stress through complaints about bodily symptoms (6). Should evidence emerge that somatisation is an intermediary between avoidant coping and GI symptom burden in the relationship between neuroticism, coping styles and GI symptom burden, the dominant explanation for how avoidant coping and GI symptoms are connected would need to be expanded to
predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages the use of biological ion channels (7).

Aims & Methods: In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidant styles such as denial and disin- engagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pool N = 250), the variables investigated in Study 1 were measured alongside hypochondriasis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test a priori hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate with both neuroticism and GI symptom severity were included (see Results table). Coping styles were assumed to covary, and the model in Study 2 assumed a covariance relationship between somatisation and hypochondriasis.

Introduction: This study aimed to investigate the regulatory effects of corticotropin-releasing factor (CRF) on the permeability of human intestinal epithelial cells through CK8-mediated tight junction.

Aims & Methods: The expression of CRFR1 and CRFR2 on HT29 cell surfaces were measured by immunofluorescent-RT-PCR, and the cell response to treatment with 100 nM CRF for 72 h, the transmission of FITC-labeled Dextran was measured by using a transwell chamber; the structural changes of tight junctions were observed under transmission electron microscopy; the expression of the junction protein occludin and Claudin-1 were detected by immunoblotting and immunofluorescence. The activity of RhoA was detected by immunoprecipitation. Furthermore, effects of CRF on intestinal epithelial permeability were examined in CK8-silenced HT29 cells, which were constructed by shRNA intervention.

Results: CRF treatment increased FITC-labeled Dextran permeability, caused opening of tight junctions, induced increased fluorescence intensity of CK8 and decreased intensity of ZO-1, claudin-1, and occludin, together with structural changes of tight junctions, occludin and Claudin-1 were downregulated. RhoA activity peaked at 30 min after CRF treatment. The increased permeability and the downregulation of claudin-1 and occludin induced by CRF treatment were not blocked by CK8 silencing. Nevertheless, CK8 silencing blocked the effects of CRF with regard to decrease in the expression of F-actin and ZO-1 and increase in RhoA activity.

Conclusion: CRF may increase intestinal epithelial permeability by upregulating CK8 expression, activating the RhoA signaling pathway, promoting intestinal epithelial actin remodeling, and decreasing the expression of the tight junction protein ZO-1. Other CK8-independent pathways may lead to decreased expression of claudin-1 and occludin, which also contributes to increased intestinal epithelial permeability.

Introduction: Diarrhea-predominant irritable bowel syndrome (D-IBS) is a chronic functional gastrointestinal disease. Its clinical manifestations are characterized by diarrhea and abdominal pain or discomfort in the absence of demonstrable pathology. The diagnosis of D-IBS is based on symptom assessment and the Rome III Diagnostic Criteria. According to an epidemiological study, D-IBS mainly affects young adults of 20–40 years old, and the quality of their lives is seriously affected. The pathogenesis of D-IBS has not been clearly clarified. Consequently, the usual treatment of the disease in Western medicine involves symptomatic therapy, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients’ symptoms and quality of life, increasing numbers of patients have begun to seek treatment with TCM.A series of randomized, double-blind, placebo-controlled trials had shown that Tongxie- Yaofang(TXFY) formula can significantly improve the clinical symptoms, such as diarrhea and abdominal pain or discomfort, of patients with IBS and improve the quality of their lives. However, the specific mechanism of it has not been completely elaborated. The purpose of this paper is to observe the regulating effects of TXFY-formula on colonic epithelial secretion via relevant ion channels.

Aims & Methods: We aimed to investigate the pharmacological effect of Tongxie-YaoFang (TXFY) formula, a Chinese herbal formula, on Diarrhea-predominant irritable bowel syndrome (D-IBS) rats with neonatal maternal separation plus restraint stress (NMS+RS) model of D-IBS, male Sprague Dawley rats were randomly divided into two groups (NMS+RS group and TXFY-formula group) with no handlings were used as controls (NH group). Starting from postnatal day 60, rats, TXFY-formula group were administered TXFY-formula (4.92 g/100 g bodyweight) orally twice a day for 14 consecutive days while NH group and NMS+RS group were given distilled water. Using short-circuit current technology, we observed 5-HT-induced changes of current across ion channels, such as cystic fibrosis transmembrane conductance regulator (CFTR) Cl channel, epithelial Na channel (ENaC), Ca2+-dependent Cl channel (CACC), Na+-K+-2Cl co-transporter (NKCC), and Na+-HCO3 co-transporter (NBC), in the colonic epithelium of three groups after exposure to drugs and specific blockers with a Power Lab System (AD Instruments International).

Results: Under basal conditions, the changes of short-circuit current (DSC, mA/cm2) induced by 5-HT were similar in NH group and TXYF-formula group, and both higher than NMS+RS group (70.86 ± 12.32mA/cm2, 67.67 ± 16.68mA/cm2 VS 38.8 ± 7.25mA/cm2, P < 0.01, respectively). When CACC was blocked by DIDS, 5-HT-induced DSC was smaller in NMS+RS group than in NH group and TXFY-formula group with no handlings were used as controls (NH group). Starting from postnatal day 60, rats, TXFY-formula group were administered TXFY-formula (4.92 g/100 g bodyweight) orally twice a day for 14 consecutive days while NH group and NMS+RS group were given distilled water. Using short-circuit current technology, we observed 5-HT-induced changes of current across ion channels, such as cystic fibrosis transmembrane conductance regulator (CFTR) Cl channel, epithelial Na channel (ENaC), Ca2+-dependent Cl channel (CACC), Na+-K+-2Cl co-transporter (NKCC), and Na+-HCO3 co-transporter (NBC), in the colonic epithelium of three groups after exposure to drugs and specific blockers with a Power Lab System (AD Instruments International).

0.035); 34.4 ± 2.4 vs. 23.2 ± 1.1 ± 1.2 mL; p
0.05). One hour after the
the last WAS session a significant increase of the fecal output in
related abdominal pain experienced in chronically stressed rats. Further, the effect of diosmectite treatment on IBS visceral hyper
sensitivity has never been investigated.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. Visceral hypersensitivity was randomized to one of four groups: diosmectite (500 mg/kg), diosmectite (500 mg/kg, WAS procedure), water (0.5 ml/ rat) or water (0.5 ml/rat, WAS procedure). Treatment was for 5 days, with the WAS procedure conducted once daily. The test apparatus consisted of a Plexiglas tank with a block affixed to the center of the floor. The tank was filled with fresh room temperature water to within 1 cm of the top of the block. Rats were placed on the block for a period of 1 h every day. For both conditions (basal and after WAS), intestinal transit was evaluated by fecal output measurement Visceral sensitivity was evaluated by colonic distension. This study adds relevant evidence to the use of diosmectite treatment to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silticlay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhea but also the functional abdominal pain experienced in chronic IBS.

Results: Under basal conditions, chronic oral treatment with diosmectite did not modify visceral sensitivity in response to CRD (20 ± 2 vs. 23 ± 1 cajays/5 mm for vehicle at 0.6 ml; 24 ± 2.4 for vehicle at 1.2 mL; p = 0.97 and p = 0.75 respectively) or intestinal transit in comparison with control group (p = 0.3). WAS treatment significantly increased the number of abdominal contractions at both 0.8 and 1.2 ml of CRD vs vehicle values (30.1 ± 2.5 vs. 17.9 ± 2.8 ± 0.8 mL; p
0.035); 34.4 ± 2.4 vs. 23.2 ± 1.1 ± 1.2 mL; p
0.05). One hour after the beginning of the last WAS session a significant increase of the fecal output in comparison with vehicle non-stressed rat (6.3 ± 1.1 ± 0.3 vs 0.3; p < 0.05) was observed. Chronic administration of diosmectite significantly (p < 0.05) reduced the number of abdominal contractions (a visceral sensitivity index) induced by WAS: the number of abdominal contractions at 0.8 and 1.2 ml of CRD in comparison with vehicle was (30 ± 3 vs. 24 ± 2 contractions at 0.8 mL; 34 ± 2 vs. 27 ± 2.2 contractions at 1.2 ml). Diosmectite also tended to improve stress-induced intestinal transit acceleration (6.3 ± 1.1 vs 4.9.4 ± 12 number of faces for 1 h; p = 0.38).

Conclusion: For the first time, these data illustrate in wistar rat, that diosmectite treatment is able to suppress WAS-induced visceral hypersensitivity to colorectal distension. This study adds relevant evidence to the use of diosmectite treatment in the management of IBS.

Introduction: Stressful life events may trigger the symptoms of irritable bowel syndrome (IBS). Preclinical chronic stress models have been developed in animals to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silticlay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhea but also the functional abdominal pain experienced in chronic IBS. Further, the effect of diosmectite treatment on IBS visceral hyper sensitivity has never been investigated.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. Visceral hypersensitivity was randomized to one of four groups: diosmectite (500 mg/kg), diosmectite (500 mg/kg, WAS procedure), water (0.5 ml/rat) or water (0.5 ml/rat, WAS procedure). Treatment was for 5 days, with the WAS procedure conducted once daily. The test apparatus consisted of a Plexiglas tank with a block affixed to the center of the floor. The tank was filled with fresh room temperature water to within 1 cm of the top of the block. Rats were placed on the block for a period of 1 h every day. For both conditions (basal and after WAS), intestinal transit was evaluated by fecal output measurement Visceral sensitivity was evaluated by colonic distension. This study adds relevant evidence to the use of diosmectite treatment to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silticlay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhea but also the functional abdominal pain experienced in chronic IBS. Further, the effect of diosmectite treatment on IBS visceral hyper sensitivity has never been investigated.

Results: Under basal conditions, chronic oral treatment with diosmectite did not modify visceral sensitivity in response to CRD (20 ± 2 vs. 23 ± 1 cajays/5 mm for vehicle at 0.6 ml; 24 ± 2.4 for vehicle at 1.2 mL; p = 0.97 and p = 0.75 respectively) or intestinal transit in comparison with control group (p = 0.3). WAS treatment significantly increased the number of abdominal contractions at both 0.8 and 1.2 ml of CRD vs vehicle values (30.1 ± 2.5 vs. 17.9 ± 2.8 ± 0.8 mL; p
0.035); 34.4 ± 2.4 vs. 23.2 ± 1.1 ± 1.2 mL; p
0.05). One hour after the beginning of the last WAS session a significant increase of the fecal output in comparison with vehicle non-stressed rat (6.3 ± 1.1 ± 0.3 vs 0.3; p < 0.05) was observed. Chronic administration of diosmectite significantly (p < 0.05) reduced the number of abdominal contractions (a visceral sensitivity index) induced by WAS: the number of abdominal contractions at 0.8 and 1.2 ml of CRD in comparison with vehicle was (30 ± 3 vs. 24 ± 2 contractions at 0.8 mL; 34 ± 2 vs. 27 ± 2.2 contractions at 1.2 ml). Diosmectite also tended to improve stress-induced intestinal transit acceleration (6.3 ± 1.1 vs 4.9.4 ± 12 number of faces for 1 h; p = 0.38).

Conclusion: For the first time, these data illustrate in wistar rat, that diosmectite treatment is able to suppress WAS-induced visceral hypersensitivity to colorectal distension. This study adds relevant evidence to the use of diosmectite treatment in the management of IBS.

Introduction: We have recently shown that postprandial sensations correlate with changes in circulating metabolites after a meal ingestion; however this phenomenon was demonstrated with a meal load up to the level of tolerance which involved an unpleasant fullness sensation. We have shown to be effective to treat functional dyspepsia. Recently, it has also been suspected to improve gastrointestinal motor function.

Aims & Methods: The aims of this study was to assess the effect of DA-9701 on colonic transit time (CCT) and symptoms of functional constipation. We prospectively enrolled 33 patients with functional constipation based on the Rome III criteria. The patients received 30 mg DA-9701 three times a day for 24 days. CCT was estimated initially and at the end of treatment. We also analyzed symptoms such as spontaneous bowel movements (SBMs), straining, stool form, feeling of incomplete emptying and anorectal blockage, abdominal discomfort and pain, overall defecation satisfaction, and incidence of adverse events.
Results: Twenty-seven patients completed the study. DA-9701 was associated with a reduced CTT from 34.7 to 21.0 hours (P < 0.001). Segmental CTT also significantly decreased after treatment (right CTT: from 14.0 ± 8.2 to 7.5 ± 7.4 hours, P < 0.001; rectosigmoid transit time: from 14.2 ± 11.9 to 9.5 ± 10.9 hours, P = 0.021). In addition, all constipation-related subjective symptoms, including SBM frequency, significantly improved compared to those before treatment. Serious adverse events did not occur.

Conclusion: DA-9701 accelerates colonic transit and safely improves symptoms in patients with functional constipation. Therefore, we suggest that this novel agent could help to treat patients with this condition.

P0485 PERFORMANCE OF A DIAGNOSTIC ALGORITHM FOR FUNCTIONAL GASTROINTESTINAL DISORDERS
E. C. Linedale1, A. Mikocka-Walus2, P. R. Gibson3, J. M. Andrews4
1Department Of Medicine, The University of Adelaide, Adelaide/Australia/SA
2School Of Psychology, Deakin University, Melbourne/Australia
3Gastroenterology, Monash University, Melbourne/Australia/VIC
4Department Of Gastroenterology & Hepatology, Royal Adelaide Hospital - SA Health, Adelaide/Australia

Introduction: Non-urgent referrals to specialist gastroenterology exceed capacity, resulting in long waiting lists and poor patient outcomes. New models of care are needed to translate specialist knowledge of functional gastrointestinal disorders (FGID) into primary care practice.

Aims & Methods: This study aimed to evaluate the safety and performance of an algorithm-based approach to the diagnosis and management of FGID. Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over a 2 year period with non-specific GI symptoms (no alarms) were randomised to waitlist control or intervention (2:1). Intervention patients were screened for alarms and abnormal blood/stool tests without an in-person consultation, to exclude organic disease (full blood count, C-reactive protein, biochemistry, thyroid function tests, iron studies, coeliac serology, +/- H. pylori serology, +/- faecal calprotectin and elastase) and classified according to the Rome III criteria. Information from patients with clinical alarm symptoms was captured on a gastroenterology consult tool, where judged appropriate, a prompt GE appointment offered. Elsewise patients received a letter stating FGID diagnosis and management options. Referrals were analysed for quality according to current triage practices.

Results: 89 intervention patients (61.5% female, mean 42, [SD 14]) and 21 control (75.6% female, mean 42, [SD 16]) patients completed intake. 35 intervention patients warranted prompt GE review after active screening. Organic disease was diagnosed in 10 (diagnosed: 19 FGID, 2 IBD, 1 neoplasm, 1 pancreatic insufficiency), 1 reflux oesophagitis, iron deficiency 1, 7 did not attend), and 4 had additionally clinically significant findings (polyps, iron deficiency). 45 were diagnosed with a FGID (9 had another non-urgent diagnosis). At follow up (mean 2.7 yrs [SD 6.5yrs] post-referral), none of the 45 patients diagnosed with FGID received a gastroenterology consult based on the original referral (six received a specialist appointment via duplicate referrals within the system). Confirmation of diagnoses at follow up was received by patients and/or referring doctors in 42/45 cases (three no longer contactable). The majority of patients (37/42, 88%) had received no alternate diagnosis to account for their gastrointestinal symptoms since the study. Whilst two had additional diagnoses (FGID plus diverticulitis, FGID plus prostatitis), and two – incidental yet clinically significant findings (FGID plus polyps).

Conclusion: The quality of referrals of patients with clinically suspected FGIDs was insufficient to allow the safe triage of patients according to urgency, with a third warranting more urgent review. Organic disease was diagnosed in a significant proportion of patients who would otherwise were unlikely to have been seen in primary care. Use of this specialist-independent diagnostic algorithm in primary or tertiary care may facilitate more timely and accurate diagnosis of organic gastrointestinal disease, and improve patient care.

P0486 SCOTTISH GUT MOTILITy DISORDER CLINIC: REVIEW OF ACTIVITY OVER 1-YEAR PERIOD
F. Moroni1, M. P. Eugenio2
1University of Edinburgh, Edinburgh/United Kingdom
2Gastroenterology, Western General Hospital, Edinburgh/United Kingdom

Contact E-mail Address: francesca.moroni@ibs.net

Introduction: IBS is common worldwide. In UK it exceeds the 20% of the popula- tion. 1 Burden of Irritable Bowel Syndrome (IBS) on UK healthcare has been estimated around 1800£per patient per year2. NICE guideline3 IBS provides a systematic approach to symptoms and therapies available to GPs and general gastroenterologists. This creates a good asset to minimize referrals to tertiary centres and address costs.

Aims & Methods: We retrospectively reviewed, via electronic records, all the patients seen at the Scottish Gut Motility Disorder Clinic between January and December 2016 included, focusing on original referral, diagnosis and treat- ment to evaluate the need for specialist input.

Results: In 2016, 378 patients attended the Motility Clinic; total of 459 visits; 333 females. Mean age was 51.4 (age range: 16 to 95 years), 60% of referrals originated via secondary care (40% GI, 50% Surgery, 10% other disciplines). The commonest reason for referral was IBS (40%); IBS-Conspisation (58%), IBS-Diarrhoea (21%) or IBS-MixedType (21%). 16% were referred with faecal incontinence and 37% with chronic constipation. 35% of patient didn’t receive any therapy at time of referral. 44% were prescribed treatment but not followed up for assessment of successful response to therapy prior to referral to the specialist clinic. In 28% of patients the diagnosis changed following Motility clinic assessment. Diagnosis at clinic based on Rome III questionnaire, depression and anxiety score, thorough history taking and physical examination (including per rectum exam), ad hoc pharmacy input and referral to specialist investigation. In 30% of patients referred with chronic constipation the diagnosis was changed to IBS-Constipation. 8% changed from IBS-D to IBS-M, 8% referred with faecal incontinence had Obstructive Defecation Syndrome, 6% referred as IBS-M were diagnosed with IBS-C, 5% referred as IBS-D were diagnosed as IBS-M, 3% referred with IBS-D had bile acid malabsorption. 56% of patients underwent specialist investigations including unorectal physiology (70%), 33% of patients attending the Specialist clinic received 1st line therapy and life style advice, albeit 57% of them, who received 2nd -line treatment, having failed 1st-line management.

Conclusion: The above data indicate the need for education and expansion of resources available in primary care to optimise patients’ management. Furthermore, it highlights the necessity for the introduction of a formal Neurogastroenterology curriculum in the general Gastroenterology training.

Introduction: Irritable bowel syndrome (IBS) affects 5–15% of adults in the general population, and is characterized by chronic recurrent abdominal pain and discomfort and associated with altered bowel habits. The pathophysiology of IBS is complex and not fully understood. Hence, treatment is often based on symp- tomatology rather than underlying physiological aberrancies.

Introduction: Most colonic diverticulitis can be conservatively treated, but some need surgical intervention due to intestinal complications. Risk factors associated with complications of diverticulitis have been reported mainly from Western countries, but few from Asian countries including Japan.

Results: Of the 282 patients, 183 (64.9%) patients had right-sided diverticulitis, and 70 (24%) had complications; perforation (n = 53), fistula (n = 8), abscess (n = 5) and stenosis (n = 4). The rate of complication was highest in sigmoid colon (88.6%) when compared with other locations; ascending colon (10%), transverse colon (1.4%), and descending colon (0%). Multivariate analysis identified the location of sigmoid colon (odds ratio 62.2, 95% confidence interval 2.66–9.39) as a significant independent factor for complications of diverticulitis. Among 70 patients with complicated diverticulitis, 55 (78.6%) patients underwent emergent surgery; most of them (54 patients, 98.2%) were with diverticulitis in the sigmoid colon.

Introduction: Colonic diverticulosis is one of the most common gastroenterological disorders. Though diverticulosis is typically benign, many individuals develop diverticular disease (DD). DD is thought to stem from a complex interplay of environmental, dietary and genetic factors; however, the exact pathogenesis remains unknown.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagen of the connective tissue in the development of diverticulosis. Genetic polymorphisms COL3A1 (rs3134646, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulosis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs3134646, rs1800255 and rs1800012 were associated with diverticulosis. After multivariate logistic regression analysis, they were not linked to the risk of developing colonic diverticulosis in general; when selectively analyzing genders, the minor allele (AA) in rs3134646 remained significantly associated with diverticulosis in men (p = 0.037).

Conclusion: Our study shows that a variant of COL3A1 rs3134646 is associated with risk of developing colonic diverticulosis in Caucasian men, while COL3A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

Introduction: Although symptoms occur in only 20% of patients harbouring diverticula, Diverticular Disease (DD) of the colon DD represents the 8th disease as burden in USA. Several treatment are currently advised in managing those patients, but their impact on the burden of the disease is unknown. The recent DICA endoscopic classification has been developed and validated for the classification of DD, founding that treatment of DICA 1 and DICA 3 patients did not impact significantly in terms of acute diverticulitis occurrence/recurrence and surgery occurrence. Our aim was to assess the impact of using DICA classification on the burden of DD in Italy.

Aims & Methods: We assessed retrospectively the overall and the cost/year of treatments (or rifaximin, or any other treatment, including probiotics, fibers, systemic antibiotics and spasmolitics) in DICA 1, DICA 2 and DICA 3 population. Analysis of diverticulosis prevalence was estimated according to data population provided by Italian Institute of Statistics (ISTAT). Cost of treatments was calculated according to data on drugs’ consumption collected during the DICA study.

Results: According to 2015 ISTAT population data, we estimated that >8 million of Italian people >60 years may have diverticulosis. According to our estimate, it is estimated that about 75% of diverticular population are on DICA 1, about 30% on DICA 2, and about 13% on DICA 3. According to the drugs’ consumption recorded during our study, we estimated that overall about 679 million of euros could be spent in Italy in treating those patients. In particular, >587 million of euros are spent in DICA 1 population, >205 million of euros in DICA 2 population, and >88 million of euros in DICA 3 population. Considering that medical treatments did not show any significant advantage when treating DICA 1 and DICA 3 patients in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence, we can estimate that >475 million of euros could be spent in Italy without any significant benefit for DD population.

Conclusion: DD has a significant burden for National Health System in Italy. DICA endoscopic classification may have a significant impact of this burden, helping to select DD people who effectively need treatments in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence.

Introduction: Fecal microbiota and metabolome may be altered in patients with Symptomatic Uncomplicated Diverticular Disease (SUDD). In particular, we found that Akkermansia muciniphila species were significantly increased in SUDD patients when compared with asymptomatic diverticulosis and healthy people, as well as PLS-DA analysis of NMR-based fecal metabolomics showed significant discrimination between HC and AD patient. Our aim was to assess the effect of current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

Aims & Methods: Thirteen consecutive female patients, living in the same district and suffering from SUDD, were studied. Patients were treated with a 2-week course of 30/day fiber supplementation (3 patients), 1,6 grams/day of mesalazine (3 patients), 900 billion day of probiotic mixture VSL#3 (currently available in Europe as VimoMixx) 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microorganisms. High-resolution proton magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.

Results: The overall bacterial quantity did not differ before and after treatment (p=0.449). The overall analysis showed that Akkermansia muciniphila species was significantly reduced at T1 (p = 0.017) and T2 (p = 0.026), while at T3 it became similar to that of T0 (p = 0.09). The amount of Lactobacilli group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. All treatments showed the same results except for probiotic group, who had a higher and persistent amount of Lactobacilli up to T3. PLS-DA analysis of NMR-based fecal metabolomics showed significant changes at T1 and T2, while at T3 it became similar to that of T0. All treatment were showed the same behaviour in influencing fecal metabolome except for rifaximin group, in which we did not find any metabolic change neither at the end of treatment nor during the washout period.

Conclusion: This preliminary study confirms that Akkermansia muciniphila may play a pathogenetic role in the occurrence of SUDD. We found also that current treatments for SUDD patients are able to influence metabolic activity in those patients except for rifaximin.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0493 5-YEARS ITALIAN REGISTER OF DIVERTICULOSIS AND DIVERTICULAR DISEASE (REMAID): A LOW PROGRESSION RATE INTRODUCTION: FECAL MICROBIOTA AND METABOLIC PROFILING DURING THE FIRST YEAR OF FOLLOW-UP

Introduction: Natural history of colonic diverticulosis and diverticular disease (DD) is poorly known, and available data derived mostly from retrospective cohort studies.
Introduction: In the vast majority of patients colonic diverticula remain asymptomatic (vulgar diverticulosis), while about 20% develop recurrent abdominal symptoms (symptomatic uncomplicated diverticular disease, SUDD) or complications (diverticulitis), with subsequent impact on quality of life (QoL). To date, clinical features associated with each subgroup are not fully understood.

Aims & Methods: Aim of this study was to assess, in a cohort of patients with colonic diverticula, the clinical features and QoL scores associated with each subgroup of patients. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Registry of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of two months. Inclusion criteria were: informed consent; age ≥18years and endoscopic/radiological-confirmed colonic diverticula. Outpatient/telephone visits were scheduled every 6 months. The clinical data [patients' characteristics and habits (diet, characteristics of DD, comorbidities and therapies) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients' features associated with new occurrence of SUDD and diverticulitis.

Results: Overall, at baseline 1217 [556 (45.7%) female, median years 67 (28–95), BMI 25.6kg/m² (16.2–43.4)] patients were enrolled: 707 (58.1%), 300 (24.7%), and 210 (17.3%) with diverticulosis, SUDD, and PD, respectively. At 12 months, 922 patients (53.1%, 29.8%, and 17.1% with diverticulosis, SUDD, and PD) were followed, and 27.4% of patients were lost at follow-up. In the 12 months follow-up, 33 (6%) and 4 (0.7%) of diverticulosis patients developed SUDD and acute diverticulitis, respectively; 4 (1.6%) of SUDD patients developed acute diverticulitis, and in 14 (9.4%) of PD patients a new episode of acute diverticulitis occurred after 1-year of follow-up. Overall, only 3 patients developed a complication, without need of surgery. One year of follow-up logistic regression, showed that only female gender was associated with subjects who changed subgroup from diverticulosis to SUDD (OR 2.26, 95%CI 0.97–5.22). No specific features associated with recurrence of diverticulitis could be identified.

Conclusion: These preliminary data suggested that, during an observation period of one year, progression from diverticulosis to SUDD occurred in less than a tenth of patients, and was associated with female gender. Overall incidence of diverticulitis was 2.3%, whereas incidence of diverticulosis was uncommon. This observational study suggested, that although the vast majority of patients did not show progression of disease, in those who progressed one in tenth remained to be followed during follow-up.

Introduction: Patients with symptomatic uncomplicated diverticular disease (SUDD) and those with diverticulitis share similar clinical patterns characterized by abdominal pain or change of bowel habits. In clinical practice, differential diagnosis between the two conditions may be useful in the diagnostic approach and therapeutic management.

Aims & Methods: Our aim was to assess the features of abdominal pain in patients with SUDD and PD. Patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. T test was used to compare QoL scores. Logistic regression was performed to identify patients’ features associated with the presence of subtypes of DD. A p value <0.05 was considered statistically significant.

Results: 1217 [556 (45.7%) female, age 66.1 ± 9.9y] consecutive patients were enrolled in the study. 300 (24.7%) and 210 (17.3%) fulfilled criteria for SUDD and PD, respectively. Among them, 223 patients with SUDD (74.3%) and 154 patients with PD (73.3%) accepted to fill in short-lasting pain questionnaire, whereas 156 patients with SUDD (52.0%) and 140 patients with PD (66.6%)
filled in long-lasting pain questionnaire. Abdominal pain lasting <24h was reported in patients with SUDD (86.5%) and 119/154 with PD (77.3%) (p < 0.026). Symptom severity score was higher in PD group than in SUDD group, but this difference was not statistically significant (5.5 ± 2.4 vs 5.1 ± 2.2 cm; p = 0.130). Patients with PD had short-lived pain located more frequently in left lower abdomen (56.6% vs 30.6%; p = 0.002), whereas SUDD patients presented a homogenous increased Coll1 expression, decrease in SMC with no alteration in AD.

Conclusion: Long-lasting pain was more frequently located in left lower abdomen in patients with PD (53.6% vs 23.7%;< p < 0.001), whereas more frequently was diffuse in SUDD patients (17.3% vs 71.5%; p < 0.001). Moreover, in patients with PD, pain lasting >24h was more often associated with fever (28.8% vs 5.4%,< p = 0.002), confinement to bed (35.7% vs 18.6%; p = 0.02), medical consulta tion (38.6% vs 23.7%;< p = 0.001), need for therapy (42.9% vs 19.2%;< p < 0.001), and hospitalization (26.8% vs 8.3%;< p < 0.001).

Disclosure of Interest: Both AD and PD patients show some peculiar clinical features of abdominal pain. SUDD patients frequently complained abdominal diffuse and short lasting pain. In contrast patients with PD frequently complained pain located in the left lower abdomen lasting for more than 24h. Our results suggest that these features are useful indicators to distinguish patients with SUDD and PD and should be carefully assessed in clinical work-up of diverticular disease.

Introduction: Colonic diverticulitis, as well as diverticular disease, is a multifactorial disease characterized by neurovascular alterations, impaired contraction, inflammation and fibrosis. Mesenchymal smooth muscle cells (SMC) are able to switch from a contractile phenotype to a less mature synthetic phenotype, characterized by a loss of differentiation with decreased expression of contractile markers as well as synthesis and release of several pro-inflammatory cytokines. Different organ specific pathways have been demonstrated to induce this mesenchymal transition. Renal fibrosis is driven by transforming growth factor-β (TGF-β) through inverse regulation of Smad2 and Smad3 fibrosis by PDGF-β, ending in downregulation of marker gene Tbr3 expression.

Aims & Methods: Aim of this study was to determine, both in human uninvolved and involved tracts of asymptomatic diverticulitis (AD) and diverticulosis and complicated diverticular disease (CDD), the alterations intrinsic to smooth muscle. Circular and longitudinal smooth muscle strips and cells (SMC) were isolated separately from surgically specimen of 18 patients (5-year-old with age > 80 years) submitted to surgery for cancer (6) (CTR). Contraction was tested in response to carbachol and relaxation in response to VIP. qPCR analysis, expressed as Relative Quantification, was performed for transcription of mRNA encoding for TGF-β, inflammasome components (NLRP3, ASC, CASP1, IL-1β) and for SMC phenotypic switch molecules (Collagen I, Sma, TGF, PDGF-β, Tbr3, Smad2/3). Data were normalized to β-actin mRNA and expressed as mean ± SE. In addition, the activation of inflammasome complex was indirectly tested trough quantification of IL-1β secretion by commercial ELISA kit.

Results: In both muscle layers, AD and AD SMC, compared to CTR, showed an overall increase in inflammatory gene expression, with a trend of decrease from AD to AD SMC, the lowest expression been observed in CDD. This inflammation was associated with an increase in IL-1β secretion in SMC medium compared to CTR and a progressive inhibition of contraction to carbachol, already in AD in circular strips and SMC. In contrast relaxation in response to VIP resulted significantly decreased only in AD both on strips and SMC with no alteration in CDD. Peculiarity of circular SMC was a progressive increase in Coll1 expression from AD to CDD compared to CTR (3 hundred fold increase) parallel to about 50% decrease in the contractile protein α-SMA. Differenti ally, longitudinal SMC, both in AD and CDD, presented a homogenous increased Coll1 expression, decrease in α-SMA and reduction of contraction. VIP-induced relaxation was significantly decreased in CDD. Phenotypic switch was only observed in CDD, driven in circular layer, by a TGF-β-dependent pathway (increased expression for TGF-β: 2.88 ± 0.6 and Smad2/3 reduced Smad2/3: 0.12 ± 0.12 and longitudinal layer by PDGF-β-dependent pathway (increase of PDGF-β: 2.27 ± 0.44 and parallel decrease of Tbr3: 0.58 ± 0.13).

Conclusion: Intrinsic myogenic alterations are present in colonic asymptomatic diverticulitis and complicated diverticular disease, both in the circular and longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticular disease, ended in a muscular synthetic pro-fibrotic switch.

Introduction: Aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysregulated Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH1-4 in GC were achieved from online available dataset. The mRNA and protein expression of NOTCH3 was examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, monolayer colony formation, cell migration and invasion assays through siRNA-mediated knockdown. The prediction of miRNAs which potentially target NOTCH3 was performed by www.microRNA.org and TargetScan. The regulation of NOTCH3 by putative miRNAs was confirmed by qRT-PCR, Western blot and dual luciferase activity assays through ectopic overexpression of miR-491-5p and miR-875-5p. The functional downstream targets of NOTCH3 were identified by gene expression microarray.

Results: NOTCH3, but not NOTCH1, 2, 4, is uniformly up-regulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MKN28 cells exhibited significant anti-oncogenic effect in vitro. NOTCH3 downregulation suppressed cell proliferation, reduced monolayer colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown or miR-491-5p/miR-875-5p overexpression in primary GC samples and re-expression of NOTCH3 rescued the inhibitory effect of miR-491-5p and miR-875-5p. Pleckstrin Homology Like Domain Family B Member 2 (PHLDB2) is identified as the functional downstream of NOTCH3 in GC. Concordantly, PHLDB2 knockdown significantly inhibited cell proliferation and promoted apoptosis, which phenocopied NOTCH3 knockdown or miR-491-5p/miR-875-5p overexpression. In primary GC samples, the expression of PHLDB2 and NOTCH3 showed positive correlation in The Cancer Genome Atlas (TCGA) cohort. Thus, the miR-491-5p/miR-875-5p-NOTCH3-PHLDB2 oncogenic cascade was constructed.

Conclusion: NOTCH3 is over-expressed and plays an oncogenic role in gastric carcinogenesis through its downstream PHLDB2. The activation of NOTCH3 in GC is partly due to the silence of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. Enforced overexpression of miR-491-5p and miR-875-5p in GC cells also exerted tumor-suppressive function by inhibiting cell proliferation and inducing apoptosis. More importantly, the expression of miR-491-5p showed negative correlation with NOTCH3 mRNA expression in primary GC samples and re-expression of NOTCH3 rescued the inhibitory effect of miR-491-5p and miR-875-5p. Pleckstrin Homology Like Domain Family B Member 2 (PHLDB2) is identified as the functional downstream of NOTCH3 in GC. Concordantly, PHLDB2 knockdown significantly inhibited cell proliferation and promoted apoptosis, which phenocopied NOTCH3 knockdown or miR-491-5p/miR-875-5p overexpression. In primary GC samples, the expression of PHLDB2 and NOTCH3 showed positive correlation in The Cancer Genome Atlas (TCGA) cohort. Thus, the miR-491-5p/miR-875-5p-NOTCH3-PHLDB2 oncogenic cascade was constructed.

Introduction: We found that tumor suppressor gene FOXF2 was silenced in gastric cancer (GC) through promoter hypermethylation. Restoration of FOXF2 suppressed GC tumorigenicity through inhibition of canonical Wnt
Conclusion: The rare FIGC syndrome is caused by germline co-occurrence of moderate-risk alleles and represents a polygenic, rather than a classical monogenetic disease. Therefore, this study aimed at dissecting the germline and somatic landscapes of the largest FIGC cohort ever studied. Constitutional and tumour DNA from probands of 53 families, fulfilling clinical criteria of FIGC, were screened for 55 candidate gastrointestinal cancer-associated genes with Illumina's MiSeq-platform, and classified according to the American College of Medical Genetics and Genomics (ACMG) guidelines. Somatic second hits, such as second mutation, loss of heterozygosity and promoter methylation, were searched for in FIGC tumours at potentially causative genes by PCR-Sequencing.

Results: Twenty-five out of 53 (47%) FIGC families harboured germline variants, and co-occurrence of germline moderate-risk alleles was found in ten families. From these ten families, seven harboured one pathogenic or likely pathogenic variant combined with one or more unclassified novel variants. The remaining three families carried solely clusters of novel unclassified variants. Moderate-risk alleles of BRCAl, MAP3K6, MSH6, SMRI, SDHB and SDHD were the most frequently found in this cohort. In addition, tumours arising in these 10 families were enriched in somatic variants within DNA repair genes and often display microsatellite instability phenotypes.

Conclusion: The clinical homogeneity and relatively high number of FIGC families herein allowed supporting the hypothesis that FIGC may be a genetic syndrome caused by moderate-risk alleles in gastrointestinal cancer-associated genes. This work is funded by: 1) FEDER COMPETE, FCT/MEC/FEDER/PT2020 and FCT funds (projects "PEst-C/SAU/LA0003/2013"; project 007274 (UID/ BIS/13019/2019); 2) ON.2-O-Novo Norte FEDER/EREN (projects NORTE-07-0162-FEDER-000118 and NORTE-07-0162-FEDER-000067); 3) No Stomach for Cancer Foundation; 4) FCT Fellowships (SFRH/BPD/89764/2012 to PO; FCT/MEC/115804/2015 to MC); 5) ICSUM (projects NORTE-07-0162-FEDER-000118 and NORTE-07-0162-FEDER-000067); 6) gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS), and familial intestinal gastric cancer (FIGC). Whilst germline defects at the CDH11 and APC genes have been found for HDGC and GAPPS families, respectively, FIGC remains genetically unexplained.

Aims & Methods: We hypothesised that the rare FIGC syndrome is caused by germline co-occurrence of moderate-risk alleles and represents a polygenic, rather than a classical monogenetic disease. Therefore, this study aimed at dissecting the germline and somatic landscapes of the largest FIGC cohort ever studied. Constitutional and tumour DNA from probands of 53 families, fulfilling clinical criteria of FIGC, were screened for 55 candidate gastrointestinal cancer-associated genes with Illumina’s MiSeq-platform, and classified according to the American College of Medical Genetics and Genomics (ACMG) guidelines. Somatic second hits, such as second mutation, loss of heterozygosity and promoter methylation, were searched for in FIGC tumours at potentially causative genes by PCR-Sequencing.

Results: Twenty-five out of 53 (47%) FIGC families harboured germline variants, and co-occurrence of germline moderate-risk alleles was found in ten families. From these ten families, seven harboured one pathogenic or likely pathogenic variant combined with one or more unclassified novel variants. The remaining three families carried solely clusters of novel unclassified variants. Moderate-risk alleles of BRCAl, MAP3K6, MSH6, SMRI, SDHB and SDHD were the most frequently found in this cohort. In addition, tumours arising in these 10 families were enriched in somatic variants within DNA repair genes and often display microsatellite instability phenotypes.

Conclusion: The clinical homogeneity and relatively high number of FIGC families herein allowed supporting the hypothesis that FIGC may be a genetic syndrome caused by moderate-risk alleles in gastrointestinal cancer-associated genes. Introduction: Enzymic submucosal dissection (ESD) is widely accepted to treat large superficial esophageal neoplasms. However, esophageal stenosis after ESD has become a key complication. To prevent such stenosis, we developed new regenerative therapies that suppress contracture and stenosis. About two weeks post-ESD, autologous oral mucosal epithelial cell sheets were fabricated from the patient’s own oral mucosal tissue. The cell sheets were then endoscopically transplanted onto the ulcer surface immediately after ESD. To date, this cell sheet treatment, which resembles cultured epidermal cell sheet transplantation in severe burn cases, has been clinically applied, and successful outcomes have been obtained at several institutions in Japan and Sweden. In addition to preventing stenosis by the simple dressing of the ulcer’s surface area, anti-inflammatory and wound-healing promoting functions of the cell sheets were expected. Furthermore, the culture supernatant obtained immediately before the transplantation, were analyzed with a cytokine array.

Results: Histological and morphological analyses revealed that tissue-engineered stratified epithelial cell sheets have an apical-basal polarity, and that the junctions between the basal cell of the sheets were significantly loose, due to dissociating desmosomes, which were also fewer in numbers. IHC showed that the expression levels of E-cadherin and desmosomal cadherins were downregulated in the epithelial cell sheets, but mesenchymal markers (N-cadherin, vimentin, and fibronectin) were upregulated. Taken together, these findings implied that epithelial mesenchymal transition (EMT) was induced in the basal cells. The results of the cytokine array showed that the cell sheets secreted EGF and growth factors (progranulin and epiregulin), and anti-microbial proteins (b-defensin).

Conclusion: The EMT of the basal cell layer of epithelial cell sheets may contribute to the improved engraftment after cell sheet transplantation. The secretion of antibacterial peptides and various growth factors from the cell sheets would exhibit anti-inflammatory effects, and promote wound-healing compared to reinforcement of esophagus with absorbable synthetic materials such as polymer membrane of polyglycolic acid and polyactic acid.

Introduction: Obestatin, a 23-amino acid peptide derived from the ghrelin peptide precursor, was originally isolated from stomach and characterized to bind selectively to the ghrelin-receptor (GPR39). Recently, we have described the expression of obestatin/GPR39 system in healthy human stomach as well as in a human gastric adenocarcinoma. In healthy human stomachs, obestatin expression was observed in the neuroendocrine cells and GPR39 expression was localized mainly to the chief cells of the oxyntic glands. In human gastric adenocarcinomas, the reported data strongly suggest the involvement of the obestatin/GPR39 system in the pathogenesis and/or clinical outcome, and highlight the potential usefulness of GPR39 as a prognostic marker in gastric cancer (5). However, the physiological role of the obestatin/GPR39 system in healthy stomach remains unknown.

Aims & Methods: To investigate the implication of the obestatin/GPR39 system in the regulation of pepsinogen secretion. GPR39, obestatin and pepsinogen I (PGI) expression was determined in the AGS cell line by immunocytochemistry; and in endoscopic biopsies of healthy human stomachs by immunohistochemistry and immunofluorescence. PGI secretion was measured after exogenous administration of obestatin (hemoglobin method, immunoblot) in AGS cells and in an in vitro explant culture of human stomach tissues obtained from surgical specimens after bariatric surgery. The influence of the acute GPR39 activation on PGI secretion was studied using obestatin (hemoglobin method, immunoblot).

Results: AGS cells expressed obestatin, GPR39 and PGI. In these cells, exogenous administration of obestatin (200 nM, 40 min) stimulated PGI secretion (60% over control). This effect was exerted via the GPR39 receptor. In the human healthy stomach, GPR39 expression was detected mainly in the chief cells of the oxyntic glands but also in a few cells of the neck section (pre-chief cells). This expression co-localized with PGI expression in both cell types. The mucous neck cells were positive for PGI and negative for GPR39. Obestatin also exerted a dose-dependent stimulatory effect on PGI secretion in the in vitro explant culture of human stomach, being significant for 100 and 200 nM compared to the control sample at 20 min (39% and 66% over control, respectively), for 200 nM at 40 min (51% over control) and 100 nM at 60 min (64% over control).

Conclusion: The obestatin/GPR39 system is physiologically involved in the stimulation of pepsinogen secretion in the healthy human stomach.

Introduction: Endoscopic variceal band ligation (EVL) is an effective procedure to control and prevent variceal bleeding in patients with liver cirrhosis. Although EVL has some complications, yet these complications are related to post-EVL ulcers. Few data exist regarding therapy of post-ligation ulcer and treatment been mostly empirical with drugs used for peptic ulcer disease.

Aims & Methods: We aimed to compare the efficacy of rebamipide, sucralfate and pantoprazole in treatment of post banding variceal ulcers. Seventy-five patients with esophageal varices eligible for elective band ligation represented the population of the study. The patients were allocated into three groups; rebamipide group, they received rebamipide 100 mg 3 times daily; pantoprazole group, they received pantoprazole 40mg/day orally at morning; sucralfate group, they received sucralfate 1 gm every 6 hours, for 14 days beginning at the next day of band ligation. Subjects underwent EGD 14 days after banding.
Primary outcomes included the size and number of ulcers and the subjects’ reported pain, dysphagia, chest pain and vomiting.

Results: At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient was statistically significant less in rebamipide group when compared to paniprazol and sucralfate (P < 0.01). Chest pain, dysphagia and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebamipide is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with no significant effect on post banding ulcer formation. Rebamipide can be used routinely in settings of post-EVL as a good alternative to pantoprazole and sucralfate.

P0505 MULTICENTRE EVALUATION OF FIRST-LINE ENDOSCOPIC TREATMENT WITH THE OTSC IN ACUTE NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING AND COMPARISON WITH THE ROCKALL COHORT - THE FLETROCK-STUDY

E. Wedi, A. Fischer, J. Hochberger, C. Jung, H. Richter-Schrag
1Gastroenterology And GI Oncology, University Hospital Göttingen, Göttingen/ Germany
2Department Of Medicine II, University of Freiburg, Freiburg/Germany
3Department Of Gastroenterology, Vivantes Klinikum in Friedrichshain, Berlin/ Germany

Contact Email Address: edris1@web.de

Introduction: The over-the-scope-clip (OTSC) overcomes limitations of standard clips and reduces delayed rebleeding in non-variceal upper gastrointestinal bleeding (NVUGIB). The study aims to evaluate mortality, rebleeding and mortality after rebleeding in patients in whom the OTSC was used as first-line endoscopic treatment (FLET) of NVUGIB. Data on OTSC use for NVUGIB in high-risk patients is currently limited.

Aims & Methods: In total, 118 patients (FLET cohort) with a median age of 73.5 years (range 29–93 years; mean ±SD 71.39 ± 12.39 years) were included. The distribution of patients with respect to risk category revealed a median Rockall score (RS) of 7 (range 3–10; mean ±SD 7.25 ± 1.51). For hypothesis testing, the FLET cohort was categorized into 3 risk groups taking into account the Rockall score: low risk (Rockall risk category (RRC) ≤ 3), moderate risk (RRC > 4), and high-risk (RRC ≥ 5). Event rates (mortality, re-bleeding and mortality after rebleeding) were compared to predicted event rates (Rockall cohort) using Fisher’s Exact Test.

Results: Primary successful haemostasis (PSH) was achieved in 92.4% either by FLET alone or in combination with an additional haemostatic technique in 1.7% (SCS = secondary clinical success). In 7.5% of the FLET cohort PSH couldn’t be achieved. Mortality in the FLET cohort was in the high-risk group (RRC ≥ 8) lower compared to RRC prediction, but no significant difference. However, mortality after re-bleeding was significantly reduced from 27.9 % to 19.9 % in the high-risk group (RRC ≥ 8) treated with FLET (p < 0.01). Furthermore, occurrence of re-bleeding or continued bleeding was significantly lower in the moderate risk group (RRC ≥ 7) with 4.9 % as well as in the high-risk group (RRC ≥ 8) with 21.4 % compared to RCC 24.9 % and 55.2 %, respectively, as predicted by the Rockall scoring system (p < 0.001).

Conclusion: Our study shows that OTSC is superior to standard clipping techniques and FLET of OTSC reduces significantly re-bleeding and re-bleeding associated mortality in NVUGIB and it is for this reason we recommend FLET for NVUGIB in high-risk patients.

Introduction: Proton pump inhibitors (PPIs) have been widely used for the treatment of endoscopic submucosal dissection-induced gastric ulcers. However, post-operative bleeding is still one of the most important adverse side effects.1, 2 Vonoprazan (VPZ), a potassium-competitive acid blocker, is a new class of acid-suppressing agents, and it is expected to reduce bleeding after gastric endoscopic submucosal dissection (ESD) by strongly inhibiting gastric acid secretion compared with PPIs.3

Aims & Methods: We compared the incidence of bleeding after gastric ESD between subjects treated with VPZ and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the EPZ group, 9 in the VPZ group) were excluded for simultaneous resection of two or more sites. A case in which active bleeding or exposed vessels were observed on the bottom of ulcers with hematemesis, melena or a drop of not less than 2 g/dl of Hemoglobin within 4 weeks after ESD was defined as ‘post-ESD bleeding’. In addition, we perform second-look endoscopy on the day after ESD. A case in which hemostasis was needed with hemorrhage of Forrest IIa or more when we underwent second-look endoscopy was defined as ‘next-day hemostasis case’. We investigated retrospectively post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Results: Gender, age, resected specimen diameter, oral antithrombotic drug administration, and dialysis were not significantly different in both groups. Two of the 19 patients in the VPZ group (10.5%) and 6 of the 70 patients in the EPZ group (8.6%) had Post-ESD bleeding (Table). In addition, 6 patients in the VPZ group (31.6%) and 37 patients in the EPZ group (52.9%) had next-day hemostasis. There was no significant difference in both groups regarding Post-ESD bleeding (p = 0.678) and next-day hemostasis (p = 0.197). However, next-day hemostasis was somewhat higher in the EPZ group than that in the VPZ group. That is possibly because EPZ or VPZ was first administered mostly from 1 to 14 days after the initial endoscopy. There was no prior use of anticoagulation in any of these patients. There were no reported immediate or delayed complications from the treatment.

Table: Incidence of post-ESD bleeding and next-day hemostasis

<table>
<thead>
<tr>

P0510 OUTCOMES FROM AN INTERNATIONAL MULTICENTRE REGISTRY OF PATIENTS WITH GASTRIC BLEEDING UNDERGOING ENDOSCOPIC TREATMENT WITH HEMOSPRAY

A retrospective cohort study was conducted. We reviewed the medical records of patients received clogoprazin with aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.

Contact E-mail Address: Dr.worapoth@gmail.com

Introduction: Current guidelines suggest dual antiplatelet therapy (DAPT), clopidogrel or ticagrelor with aspirin, for patients with acute coronary syndrome. Other indications of DAPT include recurrent ischemic stroke and percutaneous vascular disease. Gastrointestinal bleeding (GIB) is one of the most common adverse effects of DAPT, potentially causing hospital admission and death. Scanty information regarding safety of DAPT in Thailand is available.

Aims & Methods: The objective was to determine cumulative incidence and risk factors of GIB in patients received DAPT, clopidogrel with aspirin and ticagrelor with aspirin among Thai patients.

A retrospective cohort study was conducted. We reviewed the medical records of patients received clopigrelor with aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.

Contact E-mail Address: alzoubaidi@ucl.ac.uk

Introduction: Acute gastrointestinal bleeding (AGIB) can carry poor outcomes unless prompt endoscopic haemostasis is achieved. Hemospray is a novel proprietary mineral blend that forms a mechanical barrier over the bleeding site when applied endoscopically.

Aims & Methods: The primary aim of this international multicentre registry is to collect data on the successful cessation of GI bleeding following application with Hemospray. Secondary outcomes of recurrent bleeding (within 72 hours), 30 day mortality, disease and procedure specific outcomes were also collected.

Data was collected prospectively (January 2016 – April 2017) on the use of Hemospray in acute upper and lower GI bleeding, from 3 initial centres in the international registry. The use of Hemospray in GI bleeding was at the endoscopist’s discretion at the time of endoscopy. Hemospray use was either as monotherapy, dual-therapy with standard endoscopic techniques or as rescue therapy once standard methods had failed.

Results: To date 56 cases have been recruited (39 male and 17 female). The Forrest Classification of the bleeding lesions were in 5 (9%) cases Forrest Ia bleed, 41 (73%) Ib, 3 (5%) Ha, 4 (7%) Ib and 3 (5%) Forrest III bleed. Sources of GI bleed included Peptic ulcer disease 24 (43%), post endoscopic therapy 9 (16%), malignancy 11 (20%), inflammation 3 (5%), Mallory Weiss tear 2 (4%), angiodysplasia 1 (2%), bleeding polyph 2 (4%), duodenal diverticular bleed 1 (2%), oesophageal varix bleed 1 (2%), portal radiation 4 (7%) and bleed post NGT insertion 1 (2%). A total of 48 patients (86%) achieved immediate haemostasis after Hemospray endoscopic therapy, 8 patients did not achieve haemostasis. 2 managed conservatively, 1 treated by radiological intervention and 5 died. Hemospray was used in 25 patients (45%) as monotherapy [haemostasis achieved in 22/25 (88%)], in 22 patients (39%) in combination with other modalities [haemostasis achieved in 17/22 (77%)] and in 9 patients (16%) used as rescue therapy where other modalities failed [haemostasis achieved in 9/100%]. There were 6 cases of delayed re-bleeding of which 1 occurred in less than 24 hours post initial endoscopy, 2 at 24–72 hours, 1 at 4–7 days, 1 at 7–14 days and 1 more than 14 days after the initial endoscopy. There was no prior use of anticoagulation in any of these patients. There were no reported immediate or delayed complications from the treatment.

Conclusion: Early data from our registry show a high rate of immediate haemostasis (86%) with Hemospray and an excellent safety profile. The imminent expansion of this registry to other centres in Europe will provide invaluable data on the efficacy of Hemospray in various disease and patient types over the coming years.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Results: A total of 201 patients received clopidogrel with aspirin and 199 patients received ticagrelor with aspirin were recruited. Mean ± standard deviation age was 66.2 ± 11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs.100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 vs. 251.3 days, respectively (p = 0.216). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44% in clopidogrel group vs. 66.7% in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 (95% confidence interval [CI] 0.9-3.7, p = 0.093). By multivariate logistic regression analysis, duration of DAPT ≤ 180 days (RR 3.28; 95% CI 1.89–5.69, p < 0.001) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04-17.71, p < 0.001).

Conclusion: Risk of GIB is almost two times higher among patients received clopidogrel with aspirin compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT ≤ 180 days and previous GIB might be minimized the risk of GIB event after receiving DAPT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test turned negative in 53% of chemosensitive patients (p = NS) in capsaicin negative patients. After long-term capsaicin ingestion, the symptoms scores after capsaicin ingestion were reduced by 5.4/11.7 compared in capsaicin positive and negative patients at baseline (NS).

Aim & Methods: The aim of the study was to determine clinical characteristics of FD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. N = 49 outpatients with confirmed FD received an oral sensitivity test with 0.75 mg capsaicin at two occasions, before and after ingestion of the capsaicin capsule test (Hammer et al, NGM 2008). Sensations induced by gastric capsaicin are distinct from sensations induced by stimulation of mechanoreceptors (Hammer & Vogelsang, NGM 2007).

Results: 53% of FD patients had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily average upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4/11.7) than in capsaicin negative patients (6.6; 4.1/8.1) (p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms scores were comparable in capsaicin positive and negative patients at baseline (NS).

After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by −3.3 (−4.9;−1.9; p = 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by −1.0 (−1.8;−0.1; p < 0.05) in capsaicin positive but not significantly altered (−0.6;−1.7;+0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of chemosensitive patients (p < 0.01).

Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.

Contact E-mail Address: zaheernabi1978@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) has emerged as an efficacious treatment modality for achalasia cardia (AC). Prior treatment (PT) may affect the outcomes of subsequent. The impact of prior treatment on technical and clinical success of POEM is not well known. Small studies with short follow-up indicate that POEM is safe and feasible in PT failure cases. However, there is paucity of large studies with long-term follow-up.

Aims & Methods: In this study we aim to compare the safety and efficacy of POEM in treatment naïve (TN) cases versus prior treatment (PT) failure cases. The data of consecutive patients with AC who underwent POEM at a single tertiary care center from (January 2013 to November 2016) was analysed retrospectively. A comparative analysis was performed between TN and PT failure cases. Technical and clinical success, adverse events (AE), operative time (OT) for POEM were compared between TN versus PT failure cases.

Results: Overall, 502 patients with AC underwent POEM during the study period. 260 patients (51.8%) were TN and 242 (48.2%) patients had PT. Type II AC was the most common subtype in both the groups (TN -63.5% vs PT – 57.8%) followed by type I and type III. There was no significant difference with regards to AC subtypes between the two groups. The distribution of patients according to prior treatment history is as follows – PHD (205), LHM (23), LHM and PBD both (7), botulinium toxin injection (4) and POEM (3). Significantly more patients in the PT group had sigmoid oesophagus (47% vs 18). Mean OT was significantly more in the PT group when compared to the TN group (PT vs TN - 74.9 ± 30.6 vs 67.9 ± 27.1 min; P = 0.002). On multivariate analysis- type of AC, dilated esophagus (> 6 cm) and type of knife used were significant predictors of OT. Technical (98.1% vs 97.1%, P < 0.05) and clinical success (94.9% vs 91.9%) of POEM were similar in TN and PT cases. Gas related events and mucosotomies were equal in both groups (TN-35.7% vs PT-33.1%; p=0.57). Objective evidence of gastroesophageal reflux was found in 17/53 patients (32.1%) in PT group as compared to 11/44 (25%) in TN group (p=0.50).

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: rengara@wustl.edu

Introduction: Both EGJ and esophageal body motor abnormalities are found on esophageal HRM in reflux disease, and contribute to reflux burden assessed using acid exposure time (AET) on ambulatory reflux monitoring. Measurement of pH and 24-hr integrals is the gold standard. However, the role of the EGJ and esophageal body function in the pathogenesis of gastroesophageal reflux disease (GERD) is not well defined.

Aims & Methods: The aim of this study was to assess the role of EGJ and esophageal body function in GERD pathogenesis by performing HRM in patients with and without GERD.

Results: A total of 30 patients (15 with GERD and 15 without GERD) were included in the study. HRM was performed using a 18-channel manometric catheter and patients were classified into 2 groups based on the presence of reflux symptoms (ERD: 15 and non-ERD: 15). GERD group had significantly higher percentage of time spent in the integrated acid reflux zone (IARZ) (23.7% ± 10.8% vs 11.3% ± 4.2%, p = 0.003). Similarly, the percentage of time spent in the total reflux zone (TRZ) was also significantly higher in the GERD group (18.4% ± 8.5% vs 8.5% ± 3.2%, p = 0.005). In the GERD group, the percentage of time spent in the total acid reflux zone (TARZ) was also significantly higher (14.8% ± 7.4% vs 5.6% ± 3.1%, p = 0.005). The percentage of time spent in the total integrated acid reflux zone (TIARZ) was also significantly higher in the GERD group (11.0% ± 6.2% vs 3.9% ± 1.7%, p = 0.003). The percentage of time spent in the total integrated non-acid reflux zone (TIARZ) was also significantly higher in the GERD group (15.0% ± 10.1% vs 6.7% ± 2.8%, p = 0.005).

Conclusion: EGJ and esophageal body motor abnormalities are associated with increased reflux burden in patients with GERD. Further studies are needed to validate these findings and to determine the role of EGJ and esophageal body function in the pathogenesis of GERD.

achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (±13) mmHg to 13 (±5) mmHg (p < 0.0001). The presence of post-prandial peristalsis recovery was neither associated with normalization of IRP (IRP normalized in 17/26 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, p = 0.25), nor with overall treatment success of POEM (Eckardt score <3).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophageal contractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Medical treatments, endoscopic balloon dilatation, Botox and Heller myotomy are treatment modalities for managing achalasia. Recently per-oral endoscopic myotomy (POEM) has become a new option for achalasia patients and since 2010 it has become widespread. Earlier, anterior myotomy was used in this technique but in the last few years there are studies reporting that posterior myotomy is more effective. However, there are limited numbers of publications comparing anterior and posterior myotomy. This study aimed to investigate the effect of myotomy site on POEM, to our knowledge it is the first time in Europe and our country.

Aims & Methods: Between May 2014 and January 2017, POEM was performed to 225 achalasia patients at the gastroenterology clinics under general anesthesia by an endoscopist experienced at endoscopic submucosal dissection and trained for POEM. Demographic data, previous history for balloon dilatation and results of the procedure were recorded prospectively. Patients with anterior myotomy were grouped as “group A” and those with posterior myotomy as “group B”, and the results were compared.

POEM is an effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 80% at 3 years.

Conclusion: POEM is effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 81% at 3 years. Generally mild reflux esophagitis and abnormal esophageal acid exposure are diagnosed in about 40% of patients 3 months after POEM but are successfully manageable with proton pump inhibitors. Occurrence of reflux esophagitis tends to decrease with time.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peroral endoscopic myotomy (POEM) has gained trust by proven safety and short-term efficacy and at present, it is considered to be a standard method for treatment of esophageal achalasia. However, long-term data concerning the efficacy and safety especially with regard to post-POEM reflux are still awaited.

Aims & Methods: The aim of this prospective single-center case series was to assess the long-term clinical outcome of POEM with emphasis on post-POEM reflux evaluated by pH monitoring, endoscopy findings, reflux symptoms and use of proton pump inhibitors (PPIs). Since 2012, a total of 192 patients with achalasia underwent 202 POEM procedures. Follow-up visits at 3, 12, 24 and 36 months were completed in 160, 116, 70 and 27 patients. Upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring were performed 3 months after POEM, endoscopy was then repeated between 24-36 months. Main outcomes were treatment success defined as Eckardt score < 3, recurrence rate and post-POEM reflux.

Results: At 3, 12, 24 and 36 months, treatment success was achieved in 97% (95% CI: 94-100), 95% (CI 91–99), 88% (CI 82–95) and 81% (CI 69–93) of patients. A total of 14 patients experienced treatment failure (n = 5) or recurrence (n = 9). The recurrences occurred most often in patients with HRM type I achalasia (4 out of 26, 15.4%) followed by type II (3 out of 113, 2.6%) vs. none in type III achalasia (0 out of 10, 0%); p = 0.022. At 3 months, reflux esophagitis was diagnosed in 63/160 patients (39.4%; severe esophagitis LA C or D in 8 patients). Abnormal acid exposure on pH-metry studies was detected in 58/146 (39.7%). At 24–36 months, endoscopy was performed in 41 patients and reflux esophagitis was present in 9 patients (21.9%; none of the patients has been treated with PPIs). At 3 and 24 M, a proton pump inhibitor was administered to 33.5% and 31.4% of patients.

Conclusion: POEM is effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 81% at 3 years. Generally mild reflux esophagitis and abnormal esophageal acid exposure are diagnosed in about 40% of patients 3 months after POEM but are successfully manageable with proton pump inhibitors. Occurrence of reflux esophagitis tends to decrease with time.

PO0524 BEER EFFECTS ON POSTPRANDIAL DIGESTIVE SYMPTOMS AND GASTROESOPHAGIC PHYSIOLOGY

B. Serrano Falcón, M. Megia Sánchez, A. Ruiz De León, E. Rey
Gastroenterology Department, Hospital Clínico San Carlos, Madrid/Spain

Introduction: Beer has been related to gastrointestinal reflux (GER) and dyspepsia (1, 2), based on its alcohol and gas content. Main objective was to evaluate if moderate regular and non-alcohol beer consumption is related to postprandial

Contact E-mail Address: blan.serrano.falcon@gmail.com

Introduction: Beer has been related to gastrointestinal reflux (GER) and dyspepsia (1, 2), based on its alcohol and gas content. Main objective was to evaluate if moderate regular and non-alcohol beer consumption is related to postprandial
dyspeptic symptoms after a controlled meal. Secondary objectives were to evaluate its relation with postprandial GER and gastric accommodation and to evaluate its relation with daily digestive symptoms under real conditions.

**Aims & Methods:** Healthy people over 18 years old, free of frequent digestive symptoms (<once a week) and GERD disease (GERD), were included. Basal symptoms were assessed through PAGI-SYM(3) and QOLRAD (4) questionnaires, both validated to Spanish. Study was divided in two substudies based on the study intervention: 33 cl of regular beer (substudy 1) and the same amount of non-alcohol beer (substudy 2). Mineral water (33 cl) was the control intervention in both substudies. Each participant was its own control. The study lasted two weeks (control study week and intervention study week). Each week started with a visit to the laboratory at 7:30 am, when a pHelimeter calibrator was placed and taken off 24 hours later. Gastric accommodation was assessed through the maximum tolerated volume during a nutrient drink test (ENSURE® HI, 500 ml) in a rhythm of 15 ml/minutes, after the ingestion of beer (intervention) or water (control). It was defined as the volume after which the test finished or the participant reported the maximum pH to any dyspeptic symptoms (early satiety, bloating, epigastric pain and nausea), which were asked every 5 minutes. The mean age and 5 minutes had the highest perception. GER was evaluated in the postprandial period and during 24 hours through pH impedance register. Weekly symptoms evaluation was made through a diary adapted from PAGI-SYM questionnaire and sum of symptoms was used for analysis. Data were collected daily through email. Variables were compared between both visits and weeks in both substudies using a non-parametric test for matching data. Participants should drink 33 cl of beer before lunch and dinner during the intervention week. Other alcohol drinks were prohibited during the study.

**Results:** Ten participants were enrolled in substudy 1, mean aged 24 years old (SD 4, 118–32); 80% were men. Twenty participants were enrolled in substudy 2, mean aged 23.4 years old (SD 5.5 (20–38)); 65% were men. No significant differences were detected in the increase of symptoms during the nutrient drink test between control and intervention visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies. Reflux episodes after nutrient drink test and reflux episodes registered in 24 hours did not show significant differences between control and study visits. The sum of weekly symptoms did not show any difference between control and intervention weeks in both substudies.

**Conclusion:** Moderate beer consumption (regular and non-alcohol beer) does not cause an increase of dyspeptic symptoms and reflux in healthy people. It has been shown in a controlled situation (nutrient drink test and pHel impedance register) as well as real life (diary weekly symptoms). Gastric accommodation and reflux episodes have either shown to be affected by moderate beer consumption.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

PO056 DUODENAL PATHOLOGY IN PATIENTS WITH RUMINATION SYNDROME: EOSINOPHILIA AND INTRAEPITHELIAL LYMPHOCYTOSIS

M. Halland1, N.J. Tulley2, J.A. Murray1, R. Cameron1, M. M. Walker3

1Gastroenterology And Hepatology, Mayo Clinic, Rochester/United States of America

2University of Newcastle Faculty of Health PVC Office, Callaghan/Australia

3School Of Medicine And Public Health, The University of Newcastle Australia, Callaghan/Australia/NWSW

**Contact E-mail Address:** halland.magnus@mayo.edu

**Introduction:** Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea.1–3 Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD.1–3 Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might also occur among patients with rumination syndrome.

**Aims & Methods:** We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophageal high resolution impedance manometry (HRIM) and/or fulfilled Rome II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4–6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom we obtained 4–6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent within 30 days) intake of NSAIDS and pregnant and/or lactating females were excluded. Duodenal biopsies obtained were routinely processed to formalin fixed paraffin-embedded tissue blocks which were cut at 3µm, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm² in sections. Individual sections were also assessed for the presence of Brunner’s glands (BG) and intraepithelial lymphocyte counts (IEL) 100 enterocytes. This was done in order to distinguish the first part of the duodenum (D1) and the second part generally without BG (D2) and intraepithelial lymphocyte counts (IEL) 100 enterocytes.

**Results:** Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. The mean eosinophil counts/biopsy fragment (+/− Brunner’s glands (BG)) and intraepithelial lymphocyte counts (IEL) 100 enterocytes. Results: Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. The mean eosinophil counts/biopsy fragment (+/− Brunner’s glands (BG)), showed no difference in counts in the sections +/− BG (D1 vs D2), p=0.8. No overt pathology was noted, but IEL counts were significantly higher in rumination patients (mean 15, range 8–29, and 2 cases had lymphocytic duodenitis) vs controls (mean 11, range 11–18, p=0.02. Compared to controls, there was a significant increase in the mean eosinophil count among the patients with rumination syndrome rumination, 26 per mm² (range 16–42), vs 18 mm² (range 10–28), p=0.006. Conclusion: These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome compared to controls have not previously been described. Therefore, a potential role of duodenal immune mechanisms in the pathophysiology of rumination syndrome warrants further enquiry.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0527 CHRONIC POSTSTROKE OROPHARYNGEAL DYSPHAGIA IS ASSOCIATED WITH IMPAIRED CORtical ACTIVATION TO PHARYNGAL SENSORY INPUTS

O. Ortega1, C. Cabib1, N. Vilaridel1, L. Mundel1, P. Clavé2, L. Rofes2

2Centro De Investigación Biomédica En Red De Enfermedades Hepáticas Y Digestivas., Instituto de Salud Carlos III, Barcelona/Spain

Contact E-mail Address: oortega@csdm.com

Introduction: The role of afferent sensory pathways in the pathophysiology of post-stroke oropharyngeal dysphagia (OD) is not known [1]. We hypothesized that chronic post-stroke patients with OD (PSD) would show impaired sensory cortical activation in the affected hemisphere.

Aims & Methods: We studied 28 chronic unilateral post-stroke patients (17 PSD and 11 nondysphagic [PnD]) and 11 age-matched healthy volunteers (HV). Electrophysiological measures used to assess event-related sensory evoked potentials to pharyngeal stimulation (pSEP) and sensory thresholds with a naso-pharyngeal catheter with two electrodes passed through the nostrils 14-15 cm until the pharynx (Galectec Ltd, Dunvegan, Scotland) [2]. We analyzed pSEP peak-latency and amplitude (N1, N2, P2, N2-P2) and neurotopographic stroke characteristics from brain MRI.

Results: HV presented a highly symmetric bi-hemispheric cortical pattern of brain activation at centro-parietal areas (N1-P1, N2-P2) to pharyngeal stimuli. In contrast, an asymmetric pattern of reduced ipsilesional activation was found in PSD (N2-P2; p = 0.026) but not in PnD. PSD presented impaired safety of swallow (Penetration-Aspiration score: 4.5 ± 1.6) and delayed laryngeal vestibule closure (360 ± 70 ms), and higher NIHSS (7.0 ± 2.3 vs. 1.9 ± 1.4, p = 0.001) and Fazekas scores (3.0 ± 1.4 vs. 2.0 ± 1.1; p = 0.05) than PnD. pSEP showed a unilateral delay at stroke site exclusively for PSD (peak-latency inter-hemispheric difference vs. PnD: N1, 6.5 ± 6.7 vs. 1.1 ± 1.0 ms; N2, 32.0 ± 15.8 vs. 4.5 ± 4.9 ms, p = 0.05).

Conclusion: Chronic post-stroke OD is associated with stroke severity and degree of leukoaraiosis. Impaired conduction and cortical integration of pharyngeal sensory inputs at stroke site is a key feature of chronic PSD. These findings highlight the role of afferent pathways in the pathophysiology of post-stroke OD and offer a potential target for future treatments.

Introduction: Reduced sleep quality has been linked to gastrointestinal reflux disease (GERD) and functional gastrointestinal disorders. It is unknown whether GERD, functional dysphagia (FD) and irritable bowel syndrome (IBS) are more prevalent in subjects with significant sleep disturbance (SD) than those without SD.

Aims & Methods: The aim of the study was to investigate gastrointestinal symptoms, clinical characteristics, and psychological factors in subjects with and without SD in a general population undergoing health checkups. We enrolled 2752 consecutive subjects who received upper gastrointestinal endoscopy and colono-scropy during their health checkups. All participants underwent an evaluation with questionnaires including Reflux Disease Questionnaire score, Pittsburgh Sleep Quality Index (PSQI), Taiwanese Depression Questionnaire, and State-Trait Anxiety Inventory before receiving endoscopic exam. Demographic characteristics and biochemical data were also recorded. FD and IBS were based on Rome III diagnostic criteria, and metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition. Sleep disturbance was confirmed when PSQI score was greater than 5. We compared the clinical and psychological factors between subjects with and without sleep disturbance.

Results: Among the study population (n = 2674), 956 (36%) individuals had SD. SD subjects had more female gender, older age, lower level of education, higher systolic blood pressure, higher serum high-density lipoprotein levels, and higher prevalence of FD and IBS than those without SD. In addition, SD patients also had more depression, more anxiety, more severe GERD symptoms, and higher prevalence of non-erosive reflux disease (NERD) (p < 0.001). Multivariate analysis revealed that female sex (OR = 1.75, p < 0.001), older age (OR = 1.03, p < 0.001), more severe GERD symptoms (OR = 1.03, p < 0.033), NERD (OR = 1.63, p = 0.023), IBS (OR = 1.48, p = 0.05), and depression (OR = 1.16, p < 0.001) were positive predictive factors for SD, whereas higher level of education (OR = 0.57, p < 0.001) was negative predictive factor for SD.

Conclusion: Our study demonstrates that SD is associated with female sex, older age, lower education level, greater GERD symptom burden, greater depression, and higher prevalence of NERD and IBS. Future studies will be needed to clarify the relationship between functional gastrointestinal diseases and sleep disorders.

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

Introduction: Esophageal symptoms compatible with a functional esophageal disorder are common in the Western population. Age and presence of other GI and non-GI symptoms are associated with reporting esophageal symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.
Several studies have provided information on the prevalence of different atopic conditions in pediatric and adult EoE patients. They compared the prevalence of several groups of control subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have varied and the selection process for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. Therefore, a systematic review of the literature and a meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both pediatric and adult EoE patients in comparison with the non-EoE control population.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently by two researchers (AA and AJL). A highly sensitive search strategy was devised to identify all relevant bibliographic databases (PubMed, EMBASE, and Scopus) for the period up to March 2016. The search was not restricted with regard to the language of publication. A predetermined protocol was used in accordance with the quality standards for reporting meta-analyses of observational studies in epidemiology. Four reviewers (JJ-C, AA, MM-CM, and AJL) independently extracted relevant information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary estimates, including 95% confidence intervals (CI), were calculated for each season and month, whenever possible.

Results: Of the 2945 references identified, data was collected from 21 studies including a total of 53,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls was not structurally considered in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with asthma, allergic rhinitis, eczema among EoE patients, and healthy subjects representative of the general population. Further research should clearly document and use standard definitions of allergic rhinitis, asthma (including its sensitization) when assessing and documenting concurrent allergic diseases in EoE patients regardless of endoscopic findings (32% vs. 68%; p = 0.02). Furthermore, patients with dysphagia or FBO demonstrated a significantly higher rate of absorption under fed compared to fasted conditions (38.6; p = 0.04). 31 patients had endoscopic biopsies taken at least 3 months post therapy. Those with index features of chronic disease were more likely to be associated with failure of the eosinophilia to normalize regardless of medical therapy. Univariate analysis and binary logistic regression was used to identify associations between patient characteristics, presentation, endoscopic findings, degree of eosinophilia and subsequent response to treatment. Associations were assessed by Fishers exact test, t-test and Mann-Whitney for nominal, continuous parametric and non-parametric variables respectively.

P0935 EOSINOPHILIC ESOPHAGITIS: RATIONALISING THERAPY

Department Of Gastroenterology, University College London Hospital, London/United Kingdom

Introduction: Eosinophilic esophagitis (EE) is a chronic condition of the esophagus with pathognomonic clinical, endoscopic and histologic features. We aimed to prognosticate which cohort of patients respond best to proton pump inhibitor (PPI) therapy versus other medical therapy or topical steroid treatment. Univariate analysis and binary logistic regression was used to identify associations between patient characteristics, presentation, endoscopic findings, degree of eosinophilia and subsequent response to treatment. Associations were assessed by Fishers exact test, t-test and Mann-Whitney for nominal, continuous parametric and non-parametric variables respectively.

Results: 1653 patients fulfilled the entry criteria. 544 with previous cancer, achalasia, post-operative strictures or Barrett’s esophagus were excluded. 95 patients had histological eosinophilia in keeping with EE, 85 with dysphagia and 10 with reflux as their presenting symptom (67 male, mean age 42±7 years). 31(32%) of these had at least one presentation with food bolus obstruction (FBO). There was a trend towards a higher eos/hpf in patients with presentation with FBO (47±21) compared to dysphagia (38±17) and reflux (38±17) (p = 0.073). Endoscopic evidence of chronic stricture disease was associated with a higher eos/hpf than those with no strictures (mean 50.3 vs 39.6; p = 0.04). 31 patients had endoscopic biopsies taken at least 3 months post therapy. Those with index features of chronic disease were more likely to be associated with failure of the eosinophilia to normalize regardless of medical treatment compared to those with acute changes (furrows, exudates) (33% vs. 0%; p = 0.03). 31 patients were treated with proton pump inhibitors. 20 demonstrated a reduced normalisation of eos/hpf following either steroid or PPI therapy compared to those not presenting with these symptoms at a minimum of 3 months (46% vs. 100%; p = 0.03). Overall, there were no significant associations between concurrent H2 blockers or PPI therapy and normalized eos/hpf. Both the other biopsies regardless of endoscopic findings, patients presenting with dysphagia and/or FBO demonstrated a higher response to steroids than those with reflux symptoms (50% vs 9% p = 0.018) who responded best to PPI (91%). 78 patients were contactable a minimum of 3 months following initiation of treatment. Patients with chronic EE findings at initial endoscopy were less likely to respond symptomatically to PPI monotherapy compared to those with normal or acute endoscopic findings (52% vs. 68%; p = 0.003) while they were more likely to respond...
to steroids (64% vs 36%); p = 0.002. Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. (p = 0.007).

Conclusion: A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histological one.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: clinical and histological remission in patients with esophageal eosinophilia with Proton Pump Inhibitor-response esophageal eosinophilia (REE) is an emerging condition characterized by a constellation of clinical, endoscopic, and histopathologic findings. We aimed to prospectively compare the effect of different PPIs in inducing endoscopic and histologic remission in patients with PPI-REE. These data, although obtained in a small sample of patients, suggest that the pharmacokinetic and pharmacodynamic differences among these drugs do not affect their effect on PPI-REE patients.

Disclosure of Interest: V. Savarino: Consulting fee from Malesci, Reckitt, AlfaWasserman, Abbvie E. Savarino: Consulting fee from Medtronic, Sofar, Takeda, Abbvie, MSD All other authors have declared no conflicts of interest.

Endoscopic and histologic features at baseline and after PPI therapy in PPI-REE are equally effective in inducing endoscopic and histologic remission in patients with proton pump inhibitor-response esophageal eosinophilia

P0536 THE « GARD » (GASTRO-ESOPHAGEAL ANTI-REFLUX DEVICE): A NEW ENDOSCOPIC MEDICAL DEVICE TO DIAGNOSE, MANAGE AND TREAT GERD

N. Godin
Private Practice, Geneva/Switzerland

Contact E-mail Address: dr.godin68@gmail.com

Introduction: The « GARD » (Gastroesophageal Anti-Reflex Device) is an anti-reflux tubular valve placed in the lower esophagus under endoscopic control allowing normal ingestion of food and beverages but blocking all gastro-esophageal refluxate mechanically (fluid, solids and gas).

Aims & Methods: The « GARD » has an upper ring sized to the diameter of the patient’s esophagus with an accessory called the « calibration device » placed through the 2.8 mm working channel of a standard gastroscope. The GARD is held in place by pressure. The upper ring holds an anti-reflux thin-walled tubular valve moulded in one piece under the ring. After placement of a standard guidewire, the « GARD » is placed through the patient’s mouth and is released in the lower esophagus. The procedure is performed under sedation on an ambulatory basis in about 15 minutes when experienced. The « GARD » was placed in the esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, there was no migration in the stomach and removal of the GARD with the developed accessories was easily achieved. Pigs have a strong lower esophageal sphincter and have no reflux so gastro-esophageal reflux could not be evaluated. In a human volunteer with very severe gastro-esophageal reflux who had previously failed anti-reflux surgery and had an unsatisfactory response to clinical and pH metric measurement under 80 mg of esomeprazole, the « GARD » was placed preoperatively. Hereafter are this patient’s pH metric results without PPIs (table 1), with the patient taking 80 mg/day PPIs (table 2) and after GARD placement and PPIs stopped for 10 days, table 3.

Introduction: Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients’ symptoms with characteristics of refluxes obtained by 24h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M ± d) 42 ± 4.8 yrs and 49 controls (22 men, 27 women, age (M ± d) 46 ± 6.7 yrs) were examined using 24-hours esophageal pH-impedance recordings (Ohmega, MMS, the Netherlands; 2pH-6 impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline esophagitis 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients’ symptoms were classified according to Montreal classification.

Results: Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (Table 1). However higher number of acid refluxes, higher GERD-Q score and DeMeester score were present in ERD. The total number of gastro-esophageal refluxes didn’t differ between ERD and NERD groups of patients.

Introduction: Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

Aims & Methods: Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 248 patients with erosive esophagitis (aged 46.5 ± 16.3 years) and 273 controls (aged 46.4 ± 16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors was also collected. Binary logistic regression was calculated to assess the association of erosive esophagitis and extra-esophageal symptoms.

Results: Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentariness and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9% respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all socio-demographic characteristics and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR = 3.1, 95%CI = 1.7–5.7), and even more so with laryngeal disorders (OR = 4.4, 95%CI = 2.6–7.4). In all models, the association of erosive esophagitis with extra-esophageal symptoms was strong and independent of the types of symptoms separately (fully-adjusted model: OR = 4.6, 95%CI = 2.9–7.3).

Conclusion: Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper endoscopy should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders.

P0540 ASSESSMENT OF EXHALED BREATH CONDENSATE FOR NON-INVASIVE DIAGNOSIS OF GASTROESOPHAGEAL REFLUX DISEASE IN CORRELATION WITH MII-PH AND PEPEST

1Internal Gastroenterology Clinic, FN Brno, Brno/Czech Republic
2Internal Gastroenterology Department, FN Brno, Brno/Czech Republic
3Department Of Pulmonary Diseases And Tuberculosis, FN Brno, Brno/Czech Republic
4Department Of Bioanalytical Instrumentation, CEITEC Masaryk University, Brno/Czech Republic

Contact E-mail Address: stefankonecny@gmail.com

Introduction: Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological anatomical mechanisms and is lead to esophageal and extraesophageal symptoms. But extraesophageal reflux (EER) is a condition where refluxate penetrate above the upper esophageal sphincter (UES) in to the oral cavity, pharynx, upper and lower respiratory tract and leads to pathological changes like e.g. chronic cough, globus pharyngis, laryngitis, pharyngitis, rhinosinusitis, otitis media, bronchial asthma, COPD, sleep apnea and noncardiac chest pain. Currently there is no suitable, non-invasive diagnostic method applicable for GERD in clinical practice. Exhaled breath condensate (EBC) and saliva were two easily accessible samples that could be advantageously monitored for GERD patients. We aimed to compare the prevalence of GERD patients with EBC between different groups of patients and healthy controls. The analysis of EBC allowed us to evaluate the potential of this method for GERD patients with EER symptoms in the future. This can provide specific markers, that could be promising to assess the disease in future.

Materials and Methods: A portable EBC sampler was used for collection of EBC. 10 μl sample aliquots of EBC were analyzed. For pH measurement, the CO2 from EBC with 0.1 M NaOH with Na2CO3 gas for fixation. The pH of EBC, butyric acid (BA) was the second most significant parameter that was significantly elevated (p < 0.01) in both patient groups with acid reflux (pH < 4) and healthy controls. The pH of EBC was significantly lower (p < 0.01) in both patient groups (acid reflux- mean BA 2.29 m), weakly acid reflux- mean BA 6.83–7.47) and in the group with weakly acid reflux (p < 0.01) in both patient groups (acid reflux- mean pH 7.57)) vs. healthy controls (6.8, (6.65–6.99)). Butyric acid (BA) was the second most significant difference in pH and selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can
potentially reduce the diagnostic cost and avoid unnecessary invasive MII-pH testing in future. Unlike the EBC, pepsep analysis using Pepsep did not provide any diagnostic value.

Introduction: Impedance-pH testing is actually considered the gold standard diagnostic tool for reflux assessment. In fact, it allows to characterize any type of gastro-esophageal reflux (GER), namely acid and non-acid, and therefore permits – in presence of typical reflux symptoms – to diagnose functional heartburn (FH) based on the lack of abnormal acidic or non-acidic refluxate (i.e. normal number of reflux episodes and negative reflux-symptom association). Gastrin-17 (G17) has been proposed as a non-invasive marker of GERD, due to the negative feedback between acidic output and this hormone. Indeed, preliminary data showed that intermediate values of G17, between very low to normal levels, may identify GERD subjects with abnormal non-acid reflux.

Aims & Methods: We aimed to correlate various patterns of refluxate (i.e. predominant acidic refluxate, predominant non-acidic refluxate and no reflux at all), as assessed by impedance-pH, with different levels of G17 in endoscopy-negative subjects with heartburn. Thirty-five consecutive patients (19F/16M, mean age 47 years, range 31–56 years), all reporting heartburn for 6 months according to at least 3 episodes/week, entered the study. All patients underwent upper endoscopy off-medication and in case of no lesions were classified as endoscopy-negative. In all subjects, impedance-pH was performed off-therapy and blood determination of G17 (Biohit Oji, Finland; normal values: 1–9 pmol/l) was evaluated on the same day of reflux monitoring. Impedance-pH tracings were blindly and manually analyzed to detect the distal acid exposure time (AET abnormal if ≥3.2% over 24 hours) and the number as well as the characteristics of reflux episodes (acidic/weakly acidic/weakly acidic). Patients were then divided in three groups according to the results of impedance-pH: a) Group A: subjects with increased number of acid refluxes or abnormal AET; b) Group B: subjects with increased episodes of non-acid reflux and normal AET; c) Group C: subjects without increased number of any kind of GER (Group C). In the Group A, the mean value of G17 was 0.9 pmol/l, in the Group B was 2.6 pmol/l, and, in the Group C was 5.1 pmol/l (p < 0.01). Very low G17 levels were significantly associated with increased acid reflux episodes or abnormal AET, confirming the background of the negative feedback between acidic output and G17 levels. Interestingly, when impedance-pH showed a feature of non-acid reflux pattern (Group B), levels of G17 were always low, but higher than in case of acid reflux pattern (Group A) (p < 0.05). Finally, when impedance-pH did not show any kind of abnormal reflux, suggesting a diagnosis of FH, G17 levels were always normal.

Conclusion: In this preliminary study, G17 levels well correlated with the three different categories of patients suffering of heartburn and included in the NERD umbrella (i.e. NERD patients with increased acid reflux episodes or abnormal AET, endoscopy-negative patients with increased non-acidic reflux and subjects with FH, suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

**P0542** ANTI REFUX MUCOSECTOMY (ARMS) FOR REFRACTORY GASTRO ESOPHAGEAL REFLUX DISEASE (GERD) - ARE WE THERE YET?

R. Shah, A. P. Maydeo, V. Dhir

Gastroenterology, Baldota Institute of Digestive Sciences, Global Hospital, Mumbai/India

Contact E-mail Address: rahullshah@hotmail.com

Introduction: As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve non-surgical control. Linx procedure, Stretta have been proposed as less invasive options.

Aims & Methods: We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap valve grading of 1 to 3. We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients indicative of severity of reflux All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

Results: Technique: Crescentic ARMS of the esophagogastric junctional (EGJ) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal valve at gastric cardia. All the patients who underwent ARMS had a significant reduction in the DeMeester score, with predominant decrease in the recumbent acid exposure. 7/12 patients were able to discontinue all the medical therapy. PPI dose reduction was possible in the other patients with a mean reduction of 50%, alginates were stopped in all patients and HRA were also discontinued.

Conclusion: Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardia opening, while preserving and/or re-creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost “mechanically-stitched” appearance. The mucosal flap is rebuilt and looks well-defined. Furthermore, the lesser curve side

</table>
of the EGI is shortened with scar formation, and greater curve of EGI (this angle sits further cephalad and therefore retains mucosal flexibility as a mucosal flap valve. The quantity of mucosa to be resected to induce appropriate (“not too tight and not too loose”) scar formation is a key issue in this procedure. Total circumferential resection causes strictureing as demonstrated in previous studies, while subtotal dissection, which we have termed crescentic, produces better results in this regard, while still resulting in symptom control. Mucosal flap valve grading is not only a good predictor of reflux in these patients but also is a prognostic marker of effectiveness of ARMS, i.e. higher the grade worse the outcome. Also, with the extent and type of mucosal resection (EMR vs. ESD) according to the mucosal flap valve grading may be a better predictor of outcome than a box standard procedure. This technique has a potential role in people with oesophageal dysmotility wherein Nissen’s fundoplication is relatively contraindicated.

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, bone mineral density (BMD), true fractional calcium absorption (TFCA), and parathyroid hormone were not statistically different vs DEX and 22% (8% vs. 11%) for ESO. No spontaneous fractures occurred during treatment; 1 traumatic foot fracture (DEX) and 1 humerus fracture (circumstance unknown; ESO) occurred during follow-up.

Conclusion: 26 wks of DEX or ESO therapy increased bone turnover markers, but did not reduce BMD, TFCA, or serum or urine mineral levels. ESO increased TFCA by <1%. Although bone turnover markers increased with PPI therapy, levels remained within the normal ranges. No clear explanation for an association between PPI therapy and fracture risk was found in this study.

Introduction: Ral-folding alginates can reduce the acidity of the stomach head and therefore inhibit gastroesophageal reflux; however, remains unexplored of effect on alginates on postprandial processes in the stomach.

Aims & Methods: 25 patients (17 F; age 23–69) with typical GERD symptoms, participated in this study. All patients were on a 3-hour combined gastroesophageal pH-impedance monitoring with standardized breakfast (muffin and coffee). To determine the effect of alginates on postprandial reflux and pH in the esophagus and stomach, all patients underwent a repeat of similar monitoring the next day after taking the respective alginate after breakfast. The difference in pH in the esophagus, in two parts of the stomach and the different types of gastroesophageal reflux (acid, low acid, alkaline, liquid, gas & mixed) was estimated. To evaluate the effects of ral-folding alginates on the severity of postprandial reflux in patients with GERD and for the postprandial stomach content.

Results: Monitoring with alginate showed significantly (P < 0.05) less number of acid [average values 5.42 ± 0.69 (M ± sd) vs. 3.33 ± 0.43 during 1st postprandial hour and 3.96 ± 0.8 vs. 1.82 ± 0.57 during 2nd postprandial hour] and gas [0.26 ± 0.06 vs. 0.08 ± 0.05 during 1st postprandial hour and 0.47 ± 0.35 vs. 0.05 during 2nd postprandial hour] gastroesophageal reflux, but increased of number low acid reflux [2.52 ± 0.46 vs. 3.91 ± 0.82 during 1st postprandial hour and 2.00 ± 0.42 vs. 2.16 ± 0.45 during 2nd postprandial hour; P > 0.05]. Also noted is a significant (P < 0.05) increase in the pH in the esophagus for 120 minutes after ingestion [average pH values 6.04 ± 0.27 vs. 4.86 ± 0.23 during 0–60 min., and 5.93 ± 0.25 vs. 4.15 ± 0.26 during 60–120 min.]. In the gastric cardia (a typical place of formation of postprandial acid pocket) showed significantly (P < 0.05) higher values for the first 60 minutes after intake of alginate [pH 4.3 ± 0.37 vs. 3.04 ± 0.25], during 60–90 min, pH values wasn’t significantly (P > 0.05) different [2.75 ± 0.45 vs. 2.43 ± 0.28]. In the stomach body no significant effect of the drug on pH was recorded [average values for stomach 2.56 ± 0.46 vs. 2.1 ± 0.18 during 1st postprandial hour and 2.29 ± 0.49 vs. 2.09 ± 0.18 during 2nd postprandial hour; P > 0.05].

Conclusion: Our findings demonstrate that ral-folding alginates is an effective method for the prevention of postprandial acid and gas reflux and to reduce the injurious effect of acid in the esophagus. At the same time alginate showed no effect on stomach content in the postprandial period, it means that the main mechanism of action is through the movement of postprandial acid contents from the lower esophageal sphincter, but not the neutralization of stomach acid, unlike non-folding antacids and PPIs.

Introduction: S-isomer (S) pantoprazole is more bioavailable and less dependent on cytochrome 2C19 than is racemic pantoprazole.

Aims & Methods: We aimed to evaluate the efficacy and safety of 10 mg S-pantoprazole for treatment of non-erosive reflux esophagitis (NERD). This study was designed as a multicenter, randomized, double-blind, placebo controlled trial.NERD was defined as reflux symptoms and normal endoscopy findings. Patients were allocated to take either 10mg S-pantoprazole or placebo once daily for 4 weeks, after which reflux symptoms were reassessed. Recurrence of symptoms was assessed at 4 weeks after cessation of medication. The efficacy endpoints were complete relief of symptoms, improvement of reflux symptoms, and safety. Results: Eighty-eight: patients were randomly assigned to the pantoprazole group (25 males, 43.7 years old) and 86 to the placebo group (32 males, 43 years old), and 163 patients were subjected to a per protocol analysis. A higher proportion of patients in the S-pantoprazole group had complete symptom relief (39% vs. 14%, P < 0.001). In patients under treatment, symptoms of heartburn, acid regurgitation and epigastric discomfort were 0.66, 1.82, and 0.57. The factors associated with poor symptom responsiveness to PPI were older age, female sex, greater body mass index and symptom severity in both groups.

Conclusion: S-pantoprazole (10 mg) was more efficacious than placebo in providing reflux symptom relief in patients with NERD, especially acid regurgitation.

Introduction: Refractory non erosive reflux disease (NERD) is defined by absence of clinical response to a 12-week course of proton pump inhibitors (PPI) at full dose in absence of esophagitis. It accounts for about 20% of all NERD cases. 24-hour multichannel intraluminal impedance (pH-MII) monitoring should give useful pathophysiological information about refractory NERD. Therefore, our aim was to assess whether this technique could be useful to guide a “tailored” therapy to refractory NERD patients.

Aims & Methods: We retrospectively recruited patients undergoing MII-pH mon-
itoring for refractory NERD. All patients had undergone upper endoscopy, and cases of esophagitis were excluded. No patient received PPI during MII-pH monitoring. Subjects were subgrouped into 3 categories according to Zerbib’s classification: i) Acid reflux (exposure to pH < 4 for at least 1.1% of record time), ii) Non acid reflux (symptom association probability to pH >4 reflux episodes >95%) and iii) Functional heartburn (no pathologic reflux, with symp-
tom association probability <50%). MII-pH guided therapy was performed as follows: patients with acid reflux received PPI at double dose, patients with non acid reflux PPI at full dose plus alginates and patients with functional heartburn levosulpride 75 mg/day for 4 weeks. A visual analogue scale (VAS) ranging 0–
100 was administered before and after such tailored therapy to evaluate overall symptom relief. Responders were defined by VAS improvement of at least 10%.

Results: Thirty-four patients with refractory NERD were selected (female:male ratio 20:14, mean age 47 ± 12.8). Twelve had acid reflux, 7 non acid reflux and 15 functional heartburn. Overall effectiveness of tailored therapy was 82.3% (28 out of 34), and it did not differ between subgroups (91.7% acid reflux, 71.4% non acid reflux, 80.0% functional heartburn, p = 0.31). At univariate analysis, therapy failure directly correlated with dysphagia (OR = 0.15, p = 0.10) and in combination with sensation of slow digestion (OR = 7.78, p = 0.005). However, at multivariate analysis, these parameters were not statistically significant. We found a mean VAS reduction of 30.2 ± 24.9, which was similar between acid reflux (36.7 ± 22.7), non acid reflux (30.0 ± 27.7) and functional heartburn (22.5 ± 26.0, p = 0.22).

Conclusion: A tailored approach to refractory NERD, guided by MII-pH mon-
itoring, demonstrated to be effective, independently from disease subtype. Therefore it should be advised to patients who complain of symptom persistence despite PPI therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Stem cells residing in the esophageal mucosa (e.g., in submucosal glands) or Barrett's esophagus (BE) is a metaplastic abnormality in patients with gastro-esophageal reflux disease in which the normal stratified squamous epithelium in the esophagus is replaced by columnar epithelium. BE predisposes for squamous cell carcinoma. One underlying mechanism of BE is that gut columnar stem cells residing in the esophageal mucosa (e.g., in submucosal glands) or Barrett's esophagus (BE) is a metaplastic abnormality in patients with gastro-esophageal reflux disease in which the normal stratified squamous epithelium in the esophagus is replaced by columnar epithelium. BE predisposes for squamous cell carcinoma. One underlying mechanism of BE is that gut columnar stem cells reside in the esophageal mucosa (e.g., in submucosal glands) or Barrett's esophagus (BE). These continuously replicate and form a columnar epithelium. Bone Morphogenic Proteins (BMPs) are a family of growth factors that control tissue architecture, homeostasis and stem cell differentiation. In BE, BMP4 is upregulated in columnar cells.

Conclusion: Gastric cardia gland epithelial cells in both human and mouse exhibit HOXA13 expression. All physiological upper gastrointestinal tract tissues are HOXA13 negative in line with HOX gene collinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett's metaplasia in the stomach and might be indicative of Barrett's not being a true transdifferentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0550 GASTRIC CARDIA GLANDS MANIFEST APPARENT BROAD DIFFERENTIATION POTENTIAL, AS EVIDENCED BY HOXA13 EXPRESSION, IMPLICATIONS FOR THE ORIGIN OF BARRETT’S ESOPHAGUS

Gastroenterology & Hepatology, Erasmus Medisch Centrum, Rotterdam, Netherlands

Contact E-mail Address: v.janmaat@erasmusmc.nl

Introduction: Metaplastic phenomena in the upper gastrointestinal tract are still poorly understood. A prominent theory is that Barrett’s esophagus originates from gastric cardia glandular epithelium. However, in absence of evidence that the gastric stem cell has broad differentiation potential, this theory remains controversial. The gastroesophageal junction is a high prevalence area for metaplasia and subsequent cancer. Characteristic of this area are the gastric cardia glands which are the most proximal part of the anatomic gastric cardia. Recent evidence from human and mouse studies has shown Barrett’s esophagus can originate from these gastric cardia glands.1-3 If it can be shown that gastric cardia glands contain elements associated with positional mispecification, this theory could be substantially bolstered. HOX genes are a family of transcription factors that convey positional information. The 3’ to 5’ sequence of HOX genes corresponds to the sequence in which they act along the anterior to posterior axes of the gut. This property is termed collinearity and links clustering to function. In gastrointestinal physiology, HOX4, a 5’ member of the HOX4 cluster, has an expression pattern restricted to the colonic epithelium. However, pathological metaplastic lesions of the esophagus and stomach are also characterized by HOX4A2 expression. This in parallel with the similarities of these lesions with physiological gastric epithelium. Hence, investigating HOX4 expression in gastric cardia glands appears a rational strategy in assessing the potential of this gastric cardia epithelium to serve as the origin of Barrett’s esophagus.

Aims & Methods: We aimed to determine HOX4A2 expression in physiological gastric cardia glands. Firstly, strips of tissue from surgical specimens containing squamous esophageal epithelium, gastric cardia glands, and oxyntic stomach glands, were collected. These were continuous strips, from proximal to distal, to preserve morphological information. Material from three patients was selected, they suffered from either a neuroendocrine tumor, or decompensated achalasia, or an adenocarcinoma. Antibodies against HOX4A2 were found not to be specific. Therefore, in situ hybridization by RNA-scope was performed to visualize HOX4A2 RNA. Secondly, a HOX4A2GFP x C57BL/6 J heterozygous mutant mouse model was used. In these animals, the cardiac glands showed nuclear GFP signal. Rectal squamous epithelium was negative as well as ileal epithelium, in accordance with HOX4A2 colinearity in mouse and human. A littermate negative for HOX4A2GFP was analyzed and showed no nuclear GFP signal in either gastric cardia gland or in ileal epithelial glands.

Conclusion: Gastric cardia gland epithelial cells in both human and mouse exhibit HOX4A2 expression. All physiological upper gastrointestinal tract tissues are HOX4A2 negative in line with HOX gene collinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett's metaplasia in the stomach and might be indicative of Barrett's not being a true transdifferentiation.

Introduction: We have demonstrated transcriptionally active high-risk HPV (hr-HPV) is strongly incriminated in Barrett’s dysplasia (BD) and oesophageal adenocarcinoma (OAC) using mainly fresh frozen tissue.1-4 This study aimed to identify biomarkers of active HPV infection in Barrett’s metaplasia (BM)/BD/OAC by immunohistochemical staining (IHC) of formalin-fixed paraffin embedded (FFPE) tissue for aberrations of p53 and the retinoblastoma (pRb) pathway which are targets for the viral oncoproteins, E6/E7 respectively.

Aims & Methods: Prospectively, BM (n=81) BD (n=72) OAC (n=65) FFPE specimens were subjected to IHC staining for pRb, p16INK4A, cyclin D1, p53 and RNA in-situ hybridization (ISH) for E6/E7 transcripts. HPV DNA was determined via PCR in fresh frozen specimens. Viral load measurement (real-time PCR) and Next Generation Sequencing of TP53 was also performed.

Conclusion: Of 218 patients, 56 were HPV DNA positive (HPV16 (n = 42), 18 (n = 13), 6 (n = 1)). Viral load was low. Transcriptionally active HPV (DNA+/RNA+) was only found in the dysplastic and adenocarcinoma group (n = 21). The majority of HPV DNA+/RNA+ BD/OAC were characterized by p16INK4A high (14/21, 66.7%), pRb low (15/21, 71.4%) and p53 low (20/21, 95%) and was significantly different to controls [combination of HPV DNA- RNA- (n = 94) and HPV DNA- RNA+ cohorts (n = 22)] p53low had the strongest association with DNA- RNA- lesions (OR = 23.5, 95% CI = 8.0, 65). Seventeen HPV DNA- RNA+ BD/OAC identified as p53low, were sequenced and all but one exhibited wild-type status. Seventeen HPV DNA+ RNA- BD/OAC identified as pRblow, showed nuclear GFP signal. RNA in-situ hybridization (ISH) for E6/E7 transcripts. HPV DNA was determined via PCR in fresh frozen specimens. Viral load measurement (real-time PCR) and Next Generation Sequencing of TP53 was also performed.

Introduction: Barrett’s Oesophagus (BE) is an acquired condition resulting from oesophageal reflux that causes gastric metaplasia. BE is known to progress to dysplasia and eventually to oesophageal adenocarcinoma. Although the incidence of oesophageal adenocarcinoma (EAC) continues to rise, recent findings show that the incidence of oesophageal squamous cell carcinoma (ESCC) is also increasing. This study aims to define the incidence of ESCC in BE patients, in order to identify any potential risk factors for ESCC in BE patients. Methods: BE patients undergoing endoscopy at our hospital were included in the study. Biopsies were taken from the esophagus and assessed for BE and ESCC. Results: A total of 1000 endoscopic procedures were performed on 800 patients, of whom 488 patients were included in the study. The incidence of ESCC in BE patients was found to be 1.28%, which is significantly higher than the incidence of ESCC in the general population. Conclusion: The incidence of ESCC in BE patients is significantly higher than in the general population. Further studies are needed to identify potential risk factors for ESCC in BE patients.

Introduction: Barrett’s oesophagus (BE) is characterized by the presence of columnar epithelium in the lower oesophagus. BE is associated with increased risk of esophageal adenocarcinoma (EAC). The aim of this study was to investigate the incidence of EAC in patients with BE.

Methods: A retrospective chart review was conducted of all patients with BE seen at a single tertiary care center from January 1, 2010 to December 31, 2018. The incidence of EAC in patients with BE was determined using the Surveillance, Epidemiology, and End Results (SEER) database.

Results: A total of 1000 patients with BE were identified. The incidence of EAC in patients with BE was 1.28%, which is significantly higher than the incidence of EAC in the general population.

Conclusion: The incidence of EAC in patients with BE is significantly higher than in the general population. Further studies are needed to identify potential risk factors for EAC in patients with BE.
as genotypic evolution. Patients with dysplasia also show a significant increase in gland phenotype diversity (Shannon) per biopsy in adjacent to dysplasia glands compared with patients who do not have dysplasia.

**Conclusion:** BE is phenotypically diverse with a range of glandular phenotypes that are clonally related. An increase in phenotypic diversity may be a potential biomarker for progression which patients with dysplasia are more likely to progress from BE to cancer with implications for diagnostic and surveillance policy.

**P0557 A DEDICATED BARRETT’S OESOPHAGUS ENDOSCOPY LIST IMPROVES THE ACCURACY OF ENDOSCOPIC REPORTING AND QUALITY OF BIOPSY**

H. Al-Hasani, T. Sharp, S.M. Ha, L. Matsuoka, N. Siddique

Gastroenterology, Queen Elizabeth the Queen Mother Hospital, Margate/United Kingdom

**Contact E-mail Address:** hannahalhas@gmail.com

**Introduction:** The importance of skilled endoscopic assessment of Barrett’s oesophagus (BO) has been clearly established and forms part of the British Society of Gastroenterology guidelines. Use of Prague classification when reporting on areas of BO improves standardisation, and adherence to the Seattle biopsy protocol (quadrant biopsies every 2 cm) when sampling Barrett’s mucosa is thought to improve dysplasia detection. In East Kent Hospitals NHS Foundation Trust we have created a dedicated nurse-led BO surveillance endoscopy list with the aim of improving compliance with guidelines and the quality of biopsies taken. Here we present a retrospective observational study of patients who underwent upper GI endoscopy on a general endoscopy (GE) list compared with the dedicated BO endoscopy (DBO) list.

**Aims & Methods:** We searched our endoscopy software for patients who had an indication for gastroscopy documented as BO and who had an endoscopy on a GE list from 2012–2013. The same search was performed for patients who were scoped on the DBO list from 2014–2016. Endoscopy reports were reviewed to assess the use of Prague classification and determine numbers of biopsies taken. Biopsy results were recorded on our electronic pathology database.

**Results:** One hundred procedures for BO surveillance on GE lists were audited, comprising 65% male patients with median age 68 years; 60% were performed by a consultant gastroenterologist and the remainder were performed by other operators including general and gastroenterology registrars. Of the 105 procedures on the DBO lists, 63% of patients were male, median age 70 years. Prague classification was used in 94% of endoscopy reports on the DBO lists compared with 5% on the GE lists. The Seattle biopsy protocol was observed in 70% of cases on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was similar in both groups: 8/105 (7.6%) on the DBO list and 6/100 (6%) in the GE group. All (100%) of the dysplasia detected on the GE lists occurred in procedures performed by consultant gastroenterologists.

**Conclusion:** Our comparison shows that observance of Prague classification is significantly higher on the DBO lists when compared with GE lists (94% vs 5%), and this compliance with the Seattle biopsy protocol is similarly higher (74% vs 30%) when compared. Both of these are indicative of higher quality endoscopic surveillance on DBO lists. However, this did not translate to a different dysplasia detection rate which appeared to be more influenced by the endoscopy operator since all of the dysplasia detected on the GE lists was identified by consultant gastroenterologists. We therefore recommend that all Barrett’s oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0556 THE EFFICACY OF ENDOSCOPIC MUCOSAL RESECTION IN MANAGING EARLY NEOPLASIA IN BARRETT’S EOSPHAGUS, EXPERIENCES OF A TERTIARY REFERRAL CENTER IN THE UK**

**E. Foria**1, C. Gordon1

1Gastroenterology, Royal Bournemouth Hospital, Bournemouth/United Kingdom

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplasia. Our objectives were to demonstrate EMR’s efficacy in removing early neoplasia within BO and its usefulness in obtaining comprehensive histological specimens to accurately stage the early neoplasia and effectively deliver therapy.

**Aims & Methods:** We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We analysed the resection margins for both en bloc and piecemeal EMRs. We compared the original histology from the resection endoscopy to the histology obtained from the EMR, to analyse any deviation and to demonstrate the importance of histological staging of the early neoplasia in BO. We also investigated the three-year survival in patients, who have had their EMR longer than 3 years ago, along with causes of death.

**Results:** Our study included a total of 99 patients underwent 134 EMR procedures and 250 EMR. 84% were male, the mean age at first EMR was 71 years (SD = 8.2). 24 patients underwent 2 EMR procedures, 2 patients underwent 3 EMR procedures and 2 patients underwent 4 EMR procedures. The median length of the circumferential and maximum extent of the BO segments were 2.8 cm and 4 cm, respectively. The median follow-up period was 7.6 years.

**Conclusion:** In this moderately sized retrospective study EMR has been proven to be an effective tool in managing early neoplasia within BO. It not only allows the potential complete resection of the visible early neoplasia (61.7% for en bloc and 51.4% for piecemeal EMR), but also gives a histological specimen with a more accurate grading of the neoplasia (upgraded in 57%, downgraded in 14% and unchanged only in 23 patients (28%). The EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 23 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO with clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). However the EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 23 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO with clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). However the EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 23 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO with clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). However the EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 23 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO with clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). SQUAMOUS CELL CARCINOMA VERSUS SURGICAL RESECTION FOR MM-SM1 ESOPHAGUS

P0561 LONG-TERM OUTCOMES OF ENDOSCOPIC RESECTION FOR IMMUNE-MEDIATED DYSPLASIA IN THE ESOPHAGEAL MUCOSA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Contact E-mail Address: croumans@erasmusmc.nl

Introduction: Barrett esophagus (BE) is a premalignant condition for esophageal adenocarcinoma (EAC), where recommended guidelines aim to reduce treatment variation and improve quality of care. Data on the extent to which level BE surveillance guidelines are followed are scarce.

Aims & Methods: The objectives of this systematic review and meta-analysis were to (1) summarize guidelines in BE surveillance and (2) identify factors that are associated with adherence. A systematic literature research was performed using EMBASE, MEDLINE, PubMed, and Web of Science up to September 2016. Studies reporting adherence in at least one of the following four domains were selected: surveillance interval, biopsy protocol, landmark identification and histopathological information. Relevant publications were assessed using the STROBE statement for observational studies (http://strobe-statement.org/). Adherence was considered a prevalence ratio and reported as a prevalence ratio for the associated factors were reported as odds ratios with analysis of heterogeneity (I² statistic).

Results: From a total of 373 studies, 49 were eligible for this meta-analysis. For BE surveillance in non-dysplastic BE patients a prevalence ratio for adherence of 54% (95% confidence interval (CI) 45%-63%) was found and 41% (95% CI 37%-45%) in patients with low-grade dysplasia, but with large heterogeneity (I² = 98% and I² = 100%). Adherence to the Seattle protocol was 47% (95% CI 33%-61%, I² = 100%), length of BE was reported according to the Prague classification in 34% (95% CI 23%-44%, I² = 98%) and in 51% (95% CI 27%-75%, I² = 99%) of patients with a dysplastic BE the histology samples were reviewed by a second pathologist. Shorter BE length, an academic practice setting, a younger age and the involvement of the clinical set-up incorporating a multifaceted intervention program were associated with better adherence. Endoscopists following the Seattle protocol detected more dysplasia.

Conclusion: Adherence to guidelines for the surveillance of BE is far from optimal and multifaceted intervention programs were associated with better adherence. Longitudinal studies are needed to determine the interval to development of esophageal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Squamous cell carcinoma in the esophagus confined to the muscularis mucosae (MM) or submucosa up to 200 μm (SM1) has a risk of lymph node metastasis, it is defined as relative indication for endoscopic submucosal dissection (ESD) by the Japan esophageal society guideline. Although additional surgical treatment after ESD is recommended, long-term outcomes of ESD compared with surgery has not been clarified.

Aims & Methods: This study aimed to evaluate the long-term outcomes of ESD and survival of patients with MM-SM1 ESD. Between 2006 and 2016, patients with relative indication lesions of ESCC treated endoscopically or surgically in Okayama University hospital were retrospectively analyzed. We evaluated risk factors for mortality using cox regression analysis, adjusted hazard ratios for ESD compared with surgery, the survival curves stratified with risk factor, and perioperative complication rate.

Results: 54 lesions in the ESD group and 51 lesions in the surgery group met the pathological criteria of relative indication for endoscopic resection. 10 patients underwent additional chemoablation in the ESD group. 8 patients underwent additional chemoradiation in the surgery group. Lymphovascular invasion, submucosal invasion, and ASA-PS was significantly associated with mortality using Cox analysis. Adjusted for lymphovascular invasion, submucosal invasion, and ASA-PS, propportional hazard ratio of mortality for ESD compared with surgery was not significantly different (hazard ratio [HR], 0.76; 95% confidence interval [CI], 0.26-2.2; P = 0.61). The survival curves for ESD and surgery stratified with each risk factor were not significantly different. Perioperative complication rate were significantly low in ESD compared to surgery (29.6% vs 49.1%; P = 0.047).

Conclusion: ESD dose not compromise the long-term outcome compared to surgery. Further large number randomized controlled trials are necessary to confirm these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

treated by endoscopic resection were prospectively recruited from 16 hospitals throughout Japan. This cohort study was approved by the institutional review board at each hospital, and we obtained written informed consent from all patients. Using Lugol chromoendoscopy, we evaluated the dysplastic squamous epithelium in the esophagus. Lugol voiding lesion (LVL) was graded into 3 categories (A = no lesion; B = 1 to 9 lesions; C = ≥ 10 lesions per endoscopic view). Endoscopic images obtained from eligible patients at study entry were centrally reviewed in a blinded fashion by three endoscopists to determine the grade of LVL. ALDH2 status was determined by questionnaire facial flushing after alcohol drinking (present and past flushing), inactive ALDH2 (never flushing = active ALDH2). Lifestyle surveys were conducted using a self-assessment questionnaire. Data collected between July 2000 and Dec 2001 from a different cross-sectional cohort (n = 1104; M/F = 610/432) were used as an historical control.

Results: Between Sep 2005 and May 2010, 330 patients (M/F = 278/52) were registered. The proportions of the different grades of LVLs were A = 50 (15.2%), B = 174 (52.7%), and C = 106 (32.1%). After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), and not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in inactive ALDH2 and moderate alcoholic drinkers compared to non-temperance group. OR of LVL grade C associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 358) than active ALDH2 (OR = 138) (p < 0.05).

Conclusion: The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

they were not recommended additional therapy. The remaining eight patients had synchronous or metachronous adjacent adenocarcinoma. In total 33 cases were treated only by ER without additional therapy. Besides 97% (32/33) of those cases had no recurrence except for one case with a lymph node recurrence, which was successfully treated by additional CRT. The other 12 cases with lymph node involvement or SM2 were recommended additional therapy. They underwent CRT (n = 4), radiotherapy (n = 3), or esophagectomy (n = 3). No recurrence was observed after the abovementioned treatments. At the end of the follow-up, the 3-year overall and disease-specific survival rates were 100% (95% CI: 0.977–1.000) and 100%, respectively. Considering ER alone for MM/MM1, 76% of all cases were completed their treatment only with ER, and 24% of high risk case for metastasis were treated appropriately with additional therapy.

Conclusion: Conclusions: Our study suggests that ER is a valid treatment for esophageal SCC with a preoperative predicted invasion depth of MM/MM1. Disclosure of Interest: All authors have declared no conflicts of interest.

P0566 TRIAMCINOLONE INJECTION AND SHIELDING WITH POLYGLYCOLIC ACID SHEETS AND FIBRIN GLUE FOR THE PREVENTION OF POSTOPERATIVE STRICTURE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION: A RETROSPECTIVE COMPARISON OF TWO PILOT STUDIES AND A HISTORICAL COHORT
Dept. Of Gastroenterology, University of Tokyo, Tokyo-Japan

Contact E-mail Address: sakaguchi-tky@umin.ac.jp

Introduction: Triamcinolone injection is an effective and widely used method for prevention of post-endoscopic submucosal dissection (ESD) stricture; however, deep infiltration and wide resection area especially for esophageal submucosal dissection (ESD) are a strong risk factor for postoperative stricture. The aim of our study was to evaluate the efficacy of combining this method with the shielding method with polyglycolic acid (PGA) sheets and fibrin glue, another novel and effective method for the prevention of postoperative stricture.

Aims & Methods: 2 consecutive single-arm pilot studies were performed, and retrospectively compared with the results of a historical control group. After approval by the Institutional Review Board and trial registry, we enrolled patients with a diagnosis of superficial esophageal squamous cell carcinoma covering over half the circumference of the esophagus. In study group A (UMIN000010158), performed July 2014 to September 2014, immediately after the endoppled patients underwent esophageal ESD, a total of 40 mg of triamcinolone acetonide was injected into the submucosal layer of the ESD defect, followed by adhesion of a PGA sheet to the post-ESD defect with fibrin glue. In study group B (UMIN000011058), performed July 2013 to September 2013, immediately after the enrolled patients underwent esophageal ESD, only adhesion of a PGA sheet to the post-ESD defect with fibrin glue was performed. As control, 11 cases at our institute who had undergone ESD for superficial esophageal squamous cell carcinoma covering over half the circumference of the esophagus during 2002 to June 2013 were extracted. After exclusion of patients who did not undergo follow-up for at least 3 months, and patients who underwent salvage surgery after non-curative ESD, statistical analysis was conducted on the incidence of postoperative stricture and required endoscopic balloon dilation (EBD) sessions in each of these 3 groups was performed.

Results: During the study period, 15 patients were enrolled in study A, 13 patients in study B, and 37 patients were extracted as group C. After exclusion, 11 cases in group A (2 circumferential, 9 semi-circumferential), 11 cases in group B (11 semi-circumferential), and 30 cases in group C (3 circumferential, 27 semi-circumferential) were analyzed. Although postoperative stricture occurred in all circumferential cases in group C, it was successfully prevented in 1 case of circumferential ESD and in 100% of semi-circumferential ESD. A sub-analysis comparing the semi-circumferential ESD cases was performed. There were no significant differences in tumor size (A: 34.9 ± 8.1, B: 31.5 ± 7.0, C: 34.8 ± 13.3 mm) and operation times (A: 95.4 ± 23.8, B: 108.2 ± 33.1, C: 112.1 ± 50.3 min) in the 3 groups. Group A demonstrated the most effective results in both the incidence of postoperative stricture (A: 11.0%, B: 36.4%, C: 55.6%), and the number of EBD sessions required (median A: 0, B: 35.0 mm in the ESD group (p = 0.013), resection by EMR (p = 0.001), piecemeal resection (p = 0.016), and microscopic positive margins (p = 0.044). In multivariate analysis, risks factors for recurrence were: resection by EMR (OR = 7.315; IC [1.685–31.762]; p = 0.008), piecemeal resection (OR = 2.635; IC [1.105–6.199]; p = 0.036). At 24 months, recurrence-free survival rate was 95.2% in ESD group, versus 59.8% in EMG group (p = 0.001). For infiltrating tumors ≥3 m, metastasis free survival rate at 24 months was 100% after complementary treatment by radiotherapy, and 62.2% without complementary treatment (p = 0.042).

Conclusion: Endoscopic resection of superficial esophageal SCC is safe and effective. According to our results, ESD should be preferred to EMR because it is associated with a higher curative rate and an increased recurrence free survival rate.

Introduction: Oesophageal squamous cell carcinoma (ESCC) with invasion into the submucosa up to the lamina muscularis mucosae (MM/MM1) has approximately 10% lymph node metastasis and is a relative indication for endoscopic resection (ER) as per the Japanese Esophageal Society (JES) guidelines. The consideration criteria for additional treatment of MM/MM1 ESCC are as follows: (1) lymph node metastasis, (2) SM1, (3) positive vertical margins, and (4) diffuse pattern of infiltration (INF). However, the clinical validity of the JES guidelines has not been established. We evaluated the curative conditions after ER for MM/MM1 ESCC based on long-term outcomes.

Aims & Methods: We recruited 98 patients with MM/MM1 ESCC who underwent ER between August 1992 and October 2013 and were followed up for more than 3 years at Hiroshima University Hospital. As per the JES guidelines, the e-curable group was characterised by en bloc resection lesions with pathological MM, tumour invasion infiltration pattern (INF) of 0, c1 (0 mm), V0, L0, and Y0. We evaluated the clinicopathological characteristics of patients and lesions over the rates of overall survival, disease-specific survival, recurrence-free survival, lymph node recurrence and local recurrence in the e-curable and non-e-curable groups.

Results: We enrolled 98 consecutive MM/MM1 ESCC patients (88 males; mean age, 67.9±9 years; e-curable group, 39 patients; non-e-curable group, 59 patients; mean follow-up period, 75.4±44 months). There were no significant differences in the clinicopathological characteristics of the patients and lesions between the 2

United European Gastroenterology Journal 5(5S)
groups. The proportion of patients with additional treatment after ER was significantly higher in the curable group (38%, 39/99) than in the e-curable group (23%, 9/39) (p < 0.05). Operation, radiotherapy, and chemotherapy were administered to 38%, 4 (10%), and 12 (5%) patients, respectively, in the e-curable group and to 7 (12%), 22 (37%), and 10 (17%) patients, respectively in the curable group. The 5-year overall survival rates in the e-curable and non-curable groups were 97% and 75% (p < 0.05), respectively. The overall survival rate was significantly higher in the e-curable group. Three deaths (10%) occurred due to primary cancer. The other reasons were as follows: other organ cancer (3 cases), heart failure, 4 cases; pneumonia, 3 cases; and others, 11 cases.

The 5-year disease-specific survival rates in the e-curable and non-e-curable groups were 100% and 98%, respectively. The lymph node recurrence rates in the e-curable and non-e-curable groups were 3% (1/33) and 7% (4/59), respectively. The local recurrence rate in the e-curable and non-e-curable groups were 0% (0/39) and 7% (4/59), respectively. The 5-year recurrence-free survival rates in the e-curable and non-e-curable groups were 100% and 87%, respectively. The recurrence-free survival rate was significantly higher in the group with INFa and no lymphovascular invasion than in the group with INPb, INFc or lymphovascular invasion.

Conclusion: Our data support the clinical validity of the curative conditions after ER for MM/M1 ESCC of the JES guidelines. However, MM/M1 ESCC with INFa and no lymphovascular invasion may have more possible curative conditions after ER without additional treatment.

or those in which the biopsies were still taken from the different anatomical areas were excluded. A total of 331 patients were enrolled. 214 patients were classified into four groups: Group A: Hp (-) PG (-), Group B: Hp (+) PG (-), Group C: Hp (+) PG (+) and Group D: Hp (+) PG (+). PG positive was defined as PG I ≥ 70 μg/L and PGR ≥ 70. According to the range and degree of atrophy/intestinal metaplasia, patients were divided into five groups on the basis of OLGA/OLGIM staging system. The levels of Hp infection rate, PG I, PG II and PGR were compared between groups. Group A and Group B both showed significant lower Hp infection rate (p < 0.001) and 1 of them were low-grade dysplasia. From 32 of patients with suspected endoscopic PCLS, the diagnosis was confirmed with histology in 26 patients (81.2%). A total of 72 patients had PCLS vs. 32 who were initially suspected (p = 0.001), with a total positive rate (CI 40.7-56.6, 95%).

Conclusion: Pre-malignant conditions and lesions of the stomach (PCLS) can show as normal mucosa or gastritis during endoscopic procedure. 39.9% of patients who underwent endoscopic procedure with presumptive gastritis had PCLS. PCLS may be under-diagnosed if random biopsies are not taken. Therefore, taking biopsies from areas without suspected PCLS causes a change in the clinical management of patients, both for the initial diagnosis and for the staging according to OLGA and OLGUM systems.

Introduction: Prognosis of GC has a noticeable relation with its clinical stage. Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recognized risk factors for intestinal type GC (GC). A large cohort study has confirmed that the annual incidence of GC were approximately 0.1% for patients with AG, 0.23% for IM and 6% for high-grade dysplasia, which were much higher than those in other tissues. In addition, long-term follow-up studies have shown that the extent/topography of mucosal atrophy parallels the risk of GC and it is on this ground that a system for staging gastritis, known as the ABC method, has been suggested as a predictive marker for patients with GC. We aimed to discuss the correlation between the combination of Helicobacter pylori antibody and pepsinogen and OLGA/OLGIM staging system in gastric precancerous lesions risk assessment. A total of 331 patients were enrolled after the examination of endoscopy at Endoscopy Center, the First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China.

Introduction: Endoscopic treatment of sporadic duodenal adenoma is mainly performed in tertiary centers because it is technically challenging and associated in multivariate analysis with major complications (perforation 15–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non ampullary sporadic duodenal adenomas (SDA) in two tertiary centers in a large series and to determine the predictive factors of outcomes with a long follow-up.

Aims & Methods: This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endoscopic treatment for SDA histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the endoscopic treatment by EMR for SDA histologically proven were included. Patients with a long follow-up.

Conclusion: Endoscopic treatment of sporadic duodenal adenoma is mainly performed in tertiary centers because it is technically challenging and associated in multivariate analysis with major complications (perforation 15–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non ampullary sporadic duodenal adenomas (SDA) in two tertiary centers in a large series and to determine the predictive factors of outcomes with a long follow-up.

Aims & Methods: This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endoscopic treatment for SDA histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the endoscopic treatment by EMR for SDA histologically proven were included. Patients with a long follow-up.

Conclusion: Endoscopic treatment of SDA appears to be effective and relatively safe in tertiary centers. Perforation is rare. Recurrence rate is frequent and associated with piecemeal resection but can be endoscopically managed.

Introduction: Additional surgery should be recommended in patients with non-curative endoscopic resection for early gastric cancer (EGC). However, this decision has been often hesitated according to patient condition such as advanced age or comorbidities. After the recognition of recurrence, the salvage surgery has been considered difficult. However, little has been reported on it.

Aim of this study was to clarify the results of salvage surgery for recurrence after non-curative ESD for EGC using data from multicenter retrospective study (EAST study)15. Of 15,785 patients who underwent ESD for EGC at 19 participating institutions from January 2000 to August 2016, 1,385 cases (11.3%) were included to meet the current curative criteria for ESD15 were retrospectively reviewed. Among 1,069 patients enrolled into EAST study, 1,064 patients underwent additional surgery, and 905 patients were observed without any additional treatment. We evaluated first site of recurrence, clinical course after salvage surgery, and long-term survival on non-treatment group. Recurrence was classified regional LNM, and distant metastasis.

Results: Over a median follow-up period of 64 months, recurrence was detected in 27 patients. Among them, 2 patients were excluded from this study due to missing data. The recurrences were only local site (intra-gastric recurrence in 7 patients, regional LNM 7), and distant metastasis 15 (60%). The first treatments for recurrence were endoscopic treatment 1, surgery 7 (28%), chemotherapy 6, and selective vascular embolization 1 patient. In the remaining 5 patients, recurrence was detected at 0, 2, 3, 5, 30 months after salvage surgery, and all of them died of gastric cancer. Median survival time of all 25 patients with recurrence was 31 months after salvage surgery. And one patient died of acute myocardial infarction just one month after salvage surgery. In the remaining 5 patients who underwent salvage surgery was only 7 months from salvage surgery.

Conclusion: More than half of recurrence after non-curative ESD without additional surgery were distant metastasis, and the survival rate after salvage surgery was quite poor.

Introduction: Since population-based screening for gastric cancer in Korea was implemented in 2002, endoscopic treatment of early gastric cancer (EGC) has been popularized. Most patients with early neoplasm have no alarming symptoms/signs. In addition, the strategy for detecting factors predicting curative endoscopic resection of EGC is becoming important because the general population is aging and considering the quality of life after treatment.

Aims & Methods: This study investigates factors affecting curative endoscopic resection of EGC in the era of population-based screening for gastric cancer. The subjects consisted of patients newly diagnosed with stomach cancer at Seoul St. Mary’s Hospital between May 2011 and May 2016. All patients completed questionnaires about symptoms, social history, family history, knowledge of national cancer screening program, the reason for screening, and the interval between endoscopy screening examinations for gastric cancer.

Results: Of a total of 469 patients, 147 (31.3%) had a curative surgical resection and 62 (13.3%) were in non-curative surgical resection or an inoperable state. The patients with curative endoscopic resection had minimal abdominal symptoms and few alarm symptoms/signs (a family history of gastric cancer, anemia, and clinically important weight loss), whereas alarm symptoms were more common in patients with advanced cancer. In multivariate logistic analysis, regular surveillance endoscopy was only the factor predicting the curative endoscopic resection [Odd ratio (95% CI) 6.099 (2.532–14.933), p = 0.000]. In addition, the proportion of curative endoscopic resection was significantly higher in the 1-year surveillance interval groups [Odd ratio (95% CI) 10.381 (4.081–26.405), p < 0.0000]. The 2-year endoscopy interval groups [Odd ratio (95% CI) 3.161 (1.106–9.035), p = 0.032] than patients who had no endoscopy within 2 years.

Conclusion: Most patients with the curative endoscopic resection have minimal abdominal symptoms and no alarming symptoms/signs. Regular surveillance endoscopy was the only factor predicting the curative endoscopic resection of gastric cancer. In addition, more frequent endoscopic surveillance could help to early detect gastric cancers with curative endoscopic resection.

Introduction: Endoscopic submucosal dissection (ESD) is not currently accepted as an alternative treatment to surgery in ulcerative type EGC due to relatively higher probability of lymph node metastasis (LNM). This present retrospective analysis examined the correlation of various histologic factors with the presence of lymph node metastasis in ulcerative type EGC.

Aims & Methods: A retrospective analysis on 200 patients with ulcerative type EGC who underwent radical gastrectomy with D2 lymph node dissection. Several clinicopathologic factors were investigated to identify predictive factors for LNM: tumor size, histopathologic type of tumor, lymphovascular invasion and death of invasion. Multivariate logistic regression analysis was performed to evaluate the risk factors for LNM.

Results: The total rate of LNM was 15.5% (31/200). The rate of LNM was 2.1% (2/95) in the lesions confined to the mucosa and 27.6% (27/105) in those that had infiltrated the submucosa. On univariate analysis, depth of invasion (p = 0.047) and lymphovascular invasion (p < 0.001) were significant associated with LNM. However, there was no significant association between tumor size, histopathologic type of tumor and LNM. On multivariate analysis, only lymphovascular invasion (p < 0.001) was significantly associated with LNM. There was no significant association between tumor size and lymph node metastasis in ulcerative type EGC.

Conclusion: Ulcerative EGC confined to the mucosa could be considered for candidate for curative ESD due to the low risk of LNM. This finding should be confirmed by more data from other centers, which focus on LNM after ESD in ulcerative type intramuscular EGC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0579 THE FEASIBILITY STUDY USING KUMC ROBOTIC MANIPULATOR IN ENDOSCOPIC SUBMUCOSAL DISSECTION

Introduction: Gastrointestinal cancers are one of the most common malignancy worldwide. Especially endoscopic submucosal dissection (ESD) for early gastrointestinal cancers have been considered as the current standard cancer treatment. However, lack of counter traction during ESD procedure is one of major difficulty. To overcome this problem, we developed new endoscopic technique using robotic manipulator and conducted study about efficacy and safety in vitro animal study.

Aims & Methods: A novel robotic suture manipulator is composed of control panel and a working arm, which grasp and move objects at the end of scope. A total of 10 porcine stomachs were used for the test. Porcine stomachs were assigned randomly to 2 groups and ESD was performed on mucosa of stomach using conventional technique and new endoscopic technique with robotic manipulator. Endoscopic experts and novice endoscopists performed ESD in 2 parts (antrum & body) of stomach. During procedure, robotic manipulator lifts up dissected tissue of stomach to make better visibility. Procedure time, complete resection rate, and complications such as perforation were recorded.

Results: The average procedure time for the robotic manipulator and conventional ESD was 42 minutes and 45.9 minutes. In novice endoscopists, the average procedure time using robotic manipulator is faster than conventional ESD group (p = 0.001). Both endoscopic experts and novice endoscopists completed the ESD procedure for an blee resection of target lesions using KUMC robotic manipulator. There was no difference in complete resection rates between two groups. No complication such as perforation was occurred in both groups during the procedures. There was no difference depending on resected location in stomach.

Conclusion: The robotic manipulator, which can perform ESD more easily showed feasible result comparing with conventional ESD. ESD using robotic manipulator could be helpful, especially in novice endoscopists. This research proposes a novel approach for safe and feasible method during ESD.

Introduction: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. An advantage of IRE is its ability to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Several clinical trials for applying IRE to human organs such as liver, pancreas and kidney are conducted and studies about IRE ablation for gastrointestinal tumors also have been conducted recently. Here, we developed new endoscopic IRE device, and studied about its effectiveness and feasibility in animal model.

Aims & Methods: Newly developed endoscopic IRE ablative cathether works with single channel of endoscope. A pair of dipolar electrodes consist of pre-shaped f 0.63 mm nitinol wire and the distance between each electrode is 10 mm. The electrodes are loaded within braided tube for stent delivery system then deployed within IRE cathether put in stomach through the endoscope. We performed endoscopy and IRE ablation was done on pig's stomach mucosa by using endoscopy with newly developed IRE cathether. We divided pig's stomach into 2 parts (antrum & body), and IRE ablation was applied on each part of the stomach. Pigs were sacrificed after 24 hours, and we collected their stomachs with surgical technique. Following fixation, tissues were stained with H&E.

Results: Ten male Yorkshire pigs and in vitro stomachs were used in this study. The tissue with H&E stain showed feasible result comparing with conventional ESD. ESD using robotic manipulator could be helpful, especially in novice endoscopists. This research proposes a novel approach for safe and feasible method during ESD.

BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. *Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency; five or more times/week, one to four times/week, less than one times/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004), < 500, 000, 500, 000-990, 000, 1, 000, 000-1, 490, 000, > 1, 500, 000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.
Consistent with the mechanism of action of IRE on the cell membrane only, there was complete collapse within the IRE lesions without intervening live cells. But there was no difference in histology depending on gastric part in which ablation was applied. During the study, no complication was observed in pigs in 24 hours after ablation.

Conclusion: The new endoscopic IRE device, which can perform IRE ablation on gastrointestinal tract using endoscopy showed safe and feasible result.

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up. The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastric Cancer, diagnoses of GIN are attributed, at least partly, to the small size of biopsy specimens. Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (StF) were used (April 2010-March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011-March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy (EGD). We counted the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., size, macroscopic appearance, and color tone), endoscopic experience level, biopsy sample size, and biopsy groups diagnosis at GIN. The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 5420 patients who underwent EGD in the first period, 2,584 (30.7%) underwent gastric biopsy with StF. Among the 15,908 patients who underwent EGD in the second period, 4,204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93% (205/2584) and 7.54% (317/4204) of the StF and SmF groups, respectively (P = 0.556). GIN was diagnosed in 2.98% (77/2584) and 1.94% (81/4204) of the StF and SmF groups, respectively (P = 0.048). The difference in significance was significant (P = 0.048). The two groups diagnosed as GIN did not differ significantly in terms of the patient characteristics, the lesion characteristics, endoscopic experience level, biopsy related hemorrhage. The mean minor-axis lengths of the biopsy samples were 1.50 ± 0.50 mm and 1.38 ± 0.40 mm in the StF and SmF groups, respectively. The SmF group samples tended to be shorter (P = 0.088). In both groups, 40% of the final diagnoses were epithelial neoplasias; no significant differences were observed. The SmF use may increase the rate of GIN. Thus, SmF use should be avoided with a standard caliber endoscopy.

P0583 THE ROLE OF STRESS AND NITROSAMINES IN THE DEVELOPMENT OF GASTRIC CANCER: A NEW MODEL OF ADENOCARCINOMA FORMATION WITH METASTASES IN RATS

Introduction: Stress is an important factor that may lead to the formation of cancer. The role of stress for the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. But, there is no clinical and epidemiological evidences that nitrosamines alone can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (over-population during 9 months); 2) the daily using of toluidine (2 g/kg) in food and water with nitrates (2 g/l); 3) the combined effects of stress + nitrosamines. The
upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

**Results:** Using upper gastroscopy, we studied the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucosa during the first 3 months. In the third month 35% (7 of 20) of animals demonstrated multiple small peptic ulcer (n = 11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (n = 21 and large, n = 9). Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa observed 4 months after the beginning of daily using of toluidine and nitrides in 75% of rats. These rats showed symptoms of atrophic gastritis. Other 25% (5 of 20) of animals did not develop any changes in gastric mucosa.

Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. A similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (n = 131 of 160). This tumor lesions was accompanied by the migration of metastatic tumor cells through the bloodstream in the liver. The number of metastatic nodes varied from 1 to 5.

**Conclusion:** Thus, in our research we clearly show that only combination of two factors, stress and nitrosamines, is able to cause development of gastric cancer with metastasis in the liver while the presence of these factors alone contribute mucosal injuries without oncological changes in the stomach.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 1). The 14 GJFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC. Particularly, leucine, threonine and serine are the most altered three GJFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than the combination of 3 AAAs 0.841 (95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-tRNA biosynthesis metabolism was excessively activated, which significantly responsible for the above alteration metabolomics in GC patients.

Contact E-mail Address: liujian-825@163.com

Introduction: It is reported that aromatic amino acids (AAAs) in gastric juice could be used as potential diagnostic biomarkers to screen gastric cancer (GC) [1–3]. However, the underlying mechanism remain elusive [4]. Our group had conducted explorations on the reasons to cause such phenomenon before. The candidate molecules: 1) L-type amino-acid transporter 1 (LAT1), which is involved in the enhancement transport of amino acids and the accumulation of AAAs near cancer foci; 2) intracellular amino-acid-metabolizing enzymes, such as imino acid 2, 3-dioxigenase (IDO) and monoamine oxidase (MAO); 3) proteins involved in intracellular protein degradation or autophagy, (e.g., SQSTM1/p62) had been examined [5]. However, because of the difference in the expression of the above proteins in different pathological classifications of GC tissues, it is impossible to explain the phenomenon that the elevation of AAAs’ levels in gastric juice in almost all types of GC patients.

Aims & Methods: To investigate the role of proteolytic enzymes matrix metalloproteinase-2/9 (MMP-2/9) in the abnormal elevation of AAAs’ concentrations in gastric juice of GC patients, gastric mucosal specimens and gastric juice samples were simultaneously collected from 29 GC patients, while MMP-2/9 was markedly overexpressed in non-neoplastic gastric disease (NGD) patients. The expression levels of MMP-2/9 and type IV collagen (Col IV) in gastric mucosal tissues were examined by immunohistochemical staining while the levels of AAAs in gastric mucosal specimens were determined by liquid chromatography-tandem mass spectrometry (LC/MS/MS). Furthermore, the association between them was evaluated by Spearman correlation analysis.

Results: On the one hand, the expression intensity of MMP-2/9 in GC group were significantly higher than those in NGD group, while Col IV was markedly lower than that in NGD group (P < 0.001 for all). Moreover, there was a positive correlation between the expression level of MMP-2 and MMP-9 (rho = 0.439, P < 0.01), but they were both negatively correlated with Col IV (rho = −0.454, P < 0.01; rho = −0.392, P < 0.01). On the other hand, significantly higher level of AAAs in gastric juice were observed in GC patients than those in NGD individuals (P < 0.001 for all). Ultimately, the expression levels of MMP-2/9 in gastric mucosal tissues were both positively correlated with the concentrations of AAAs in gastric juice (MMP-2: rho = 0.262, P < 0.05; MMP-9: rho = 0.293, P < 0.01 for all) and all correlation was significant (P < 0.001 for all). Moreover, all correlation was significant (P < 0.001 for all).

Conclusion: The overexpression of MMP-2/9 resulting in the degradation of Col IV in gastric juice and extracellular matrix may lead to the variation of AAAs’ levels in gastric juice of GC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several studies have demonstrated serum PGII level as a marker of the functional gastric mucosa, and a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, which provides a binding site for the transcription factor for the PG2 gene, in association with the PG2 circulating level and clinical parameters at risk for GC and in GC patients.

Aims & Methods: Gastric function of 180 patients (67 GC, 71 first-degree relatives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was assessed by gastropanel test. We investigated the PG2 TATA BOX polymorphism frequencies in relation to serum PG2 (sPG2) expression level, HP positivity and risk for GC. TATA BOX DNA fragments were amplified by PCR and analyzed by the capillary-electrophoresis (GeneMapper software). Association among clinical data and PG2 polymorphisms were estimated by Receiver operating characteristic (ROC) curve and linear regression analyses.

Results: After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL PG2 cut-off was 70.15% and 79, 65% sensibility and sensitivity, respectively. H. pylori positive sPG2 level for the PG2 gene, in association with the PG2 circulating level and clinical parameters in population at risk for GC and in GC patients.

Conclusion: H. pylori infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. H. pylori infection may play a pathophysiologic role in NAFLD development, indicating that H. pylori eradication might play a role in reducing risk of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0591 HELICOBACTER PYLORI INFECTION STATUS IN HUMAN IMMUNODEFICIENCY VIRUS-POSITIVE PATIENTS

Contact E-mail Address: seiya_wecke_0728@yahoo.co.jp

Introduction: Helicobacter pylori infects the gastric mucosa and causes chronic gastritis via the immunoreaction of the host. By contrast, the human immunodeficiency virus (HIV) infects CD4-positive T lymphocytes and destroys the immune system of the host. Some studies pointed out that the H. pylori infection rate is lower in HIV-positive patients. This is because in these patients, H. pylori is incidentally eradicated by the course of antibiotic therapy for HIV infection and because the supply of nutrients to H. pylori is prevented by the decrease in the number of CD4 lymphocytes.

Aims & Methods: We enrolled 290 HIV-positive patients who underwent esophagogastroduodenoscopy in our Hospital between January 2013 and September 2016. As end points of H. pylori infection examination, we retrospectively examined the presence of gastric mucosa atrophy, H. pylori infection, H. pylori eradication and comorbidity. As end points of HIV infection examination, we quantified the number of CD4 lymphocytes and the titer of HIV and investigated the presence of acquired immunodeficiency syndrome (AIDS). Based on these data, we examined the relationship between H. pylori and HIV infections.

Results: Of the 290 patients, 281 were men and 9 were women, whose median age was 46 years (range, 22–82 years). Ninety patients had atrophic gastritis or antral or duodenal ulcer, of whom 40 underwent examination for H. pylori infection. The median number of CD4 lymphocytes in the 21 H. pylori-positive cases was 505/μL (range, 15–998/μL). The titer of HIV ranged from non-detectable to 90, 900 copies/μL, and one patient had AIDS. Meanwhile, the median number of CD4 lymphocytes in the 19 H. pylori-negative cases was 331/μL (range, 15–998/μL). The titer of HIV ranged from non-detection to 1, 590, 000 copies/μL, and three patients had AIDS. H. pylori eradication therapy was applied in 18 of 21 H. pylori-positive cases. The success rate of primary H. pylori eradication was 37.5% (6/16 patients) and that of secondary eradication was 70% (7/10 patients). In addition, 2 (7.7%) of the 26 patients with stomach or duodenal ulcer needed urgent hemostasis. Five (6.7%) of the 74 cases of atrophic gastritis had gastric cancer, of which two were undifferentiated stomach cancers.

Conclusion: In our study, the number of CD4 lymphocytes was higher in the HIV-positive patients with H. pylori infection, implying that the high CD4 count was suggested to be associated with persistent H. pylori infection. In addition, the success rate of H. pylori eradication was shown to be insufficient in HIV-positive patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter Pylori infection reduces the risk of Barrett’s Dysplasia and is independent from the geographical location, a meta-analysis

B. Eross1, N. Farkas2, K. Márta3, P. Hegy1
1Centre For Translational Medicine, University of Pecs, Pecs/Hungary
2Institute Of Biomedical Informatics, University of Pecs, Pecs/Hungary
3Institute For Translational Medicine, University of Pecs, Pecs/Hungary

Contact E-mail Address: xeroibal@yahoo.fi

Introduction: European and Northern American populations a decreasing prevalence of H. pylori infection has been observed, along with an increasing prevalence of Barrett’s oesophagus and an increasing incidence and prevalence of the adenocarcinoma of the oesophagus and gastro-oesophageal junction cancers. Previous meta-analyses, H. pylori infection has been proven a protective factor against Barrett’s oesophagus, but some individual studies suggested the opposite.

Aims & Methods: Our aim was to scrutinise all data available on the relationship between H pylori infection and Barrett’s oesophagus prevalence, to see, if H pylori has a protective role for Barrett’s oesophagus and if it is dependent from the geographical location. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). We conducted a systematic search in PUBMED, EMBASE and COCHRANE databases from inception to December 2016, for the keywords of Barrett’s, Barrett’s metaplasia, Barrett’s oesophagus, Barrett’s oesophagus, Barrett’s oesophagus, H pylori. H pylori and Helicobacter. We also used information from the references of relevant publications to find further eligible studies. We have conducted a meta-analysis of the data from all studies included. We used the random effect DerSimonian and Laird model.

Results: We found 568 articles in PUBMED, 741 in EMBASE and 15 in COCHRANE databases. After exclusion of the articles without sufficient data on the prevalence of H pylori and Barrett’s oesophagus, we have identified 83 articles for the meta-analysis. The statistical analysis has included 98 665 patients with Barrett’s oesophagus and 720 800 patients without Barrett’s oesophagus. The statistical analysis from all 83 studies from five continents and 27 countries showed a protective effect of H pylori for Barrett’s oesophagus, but not in Africa, overall Odds Ratio = 0.63 (95% CI:0.55, 0.71). The OR and 95% CI values were 0.34 (0.17, 0.67) for Asia, 0.71 (0.55, 0.91) for Europe, 3.05 (0.59, 15.73) for Africa, 0.60 (0.51, 0.71) for North-America, 0.95 (0.56, 1.64) for South-America and 0.56 (0.39, 0.85) for Australia. The OR and 95% CI values were 0.84 (0.43, 1.64) for Eastern Europe; 0.68 (0.52, 0.90) for Western Europe and 0.71 (0.55, 0.91) for all of Europe, suggesting that the protective role of H pylori infection is not different across Europe.

Conclusion: This large meta-analysis has given further evidence, that Helicobacter pylori infection has a protective role for Barrett’s oesophagus and this protective role is independent from the geographical location, apart from Africa. In view of the decreasing prevalence of H pylori in developed countries and the epidemiological rise of Barrett’s oesophagus and adenocarcinoma, it would be important to conduct further large, prospective, multinational studies on the effect of H. pylori infection on Barrett’s oesophagus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Literature data involves Helicobacter pylori (HP) as a pro-inflamatory and pro-coagulant risk factor for ischemic coronary heart disease1, 2, but the benefit of the curative treatment against HP infection and its repercussions on heart function were not explored sufficiently.

Aims & Methods: We aimed to investigate the role of HP eradication therapy in patients with different stages of heart insufficiency (HI) and coronary heart disease (CHD), 290 patients with CHD admitted in Cardiology and Gastroenterology Departments of St. Andrew Apostole Constantin were explored for HP infection status and found positive. The infection was determined by HP- Ag in faces, urea breath test or endoscopic biopsy. The CHD was assessed by electrocardiography (ECG) and HI was staged according to NYHA classification. According to the implementation of eradication therapy for HP, we divided the patients in two equal groups: patients matched by age, gender, severity of HI, one group of 145 patients with treatment and the other group of 145 patients without eradication therapy. We compared the heart function improvement after treatment for HP in both groups. We also compared the evolution of PCR, fibrino- gen, IL-6 and other inflammatory markers.

Results: The eradication therapy for HP with one PPI and two antibiotics associated with cardiac treatment, improved the clinical status based on NYHA classification in 58 patients with HP compared with NYHA staging at the time of HP infection (p = 0.019, p = 0.037, p = 0.08, respectively p = 0.005, ss) and the state of CHD. The laboratory finding also revealed a favorable course of pro-inflammatory tests in treated patients compared with untreated patients, regarding protein C-reactive, leucocytes, IL-6 and fibrinogen.

Conclusion: HP should be one of the treatment targets when managing infected patients with CHD, the eradication therapy being along with cardiac treatment important steps to improve the cardiac function.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter pylori infection has become more and more resistant to conventional first-line treatment regimens. So, there is a considerable interest in evaluating new antibiotic combinations and regimens. Nitazoxanide is an anti-infective drug with demonstrated activity against protozoa and anaerobic bacteria including Helicobacter pylori.

Aims & Methods: This work is designed to evaluate the efficacy and safety of a unique triple Nitazoxanide containing regimen as a treatment regimen in Egyptian patients with Helicobacter pylori infection.

Methods: Two hundred and twenty four patients with upper Gastro-intestinal tract (GIT) dyspeptic symptoms in whom three-in-one capsule BQT (Pylera) has been prescribed in 322 patients (mean age 50 years) between 1/2013 and 12/2016. All patients were instructed in a standardized fashion and a prospective follow-up was planned. In a subgroup of patients, genotypic susceptibility testing for clarithromycin and levofloxacin by PCR was carried out on gastric biospies before treatment. Treatment outcome and the eradication failure were prospectively included in a study whose goal was to assess the response.

Results: The response to treatment was significantly higher in group 1 of Nitazoxanide treatment regimen than group 2 of traditional treatment regimen. Group 1 showed complete cure (95.6%) of 113 patients who completed the study in group 1 showed complete cure while only 63 cases (60.6%) of 104 patients who completed the study in group 2 showed the same response according to per-protocol (PP) analysis (p < 0.001). The regimen was well tolerated by all the patients enrolled in the study.

Conclusion: Nitazoxanide-containing triple therapy is a promising therapy for the eradication of Helicobacter pylori. (ClinicalTrials.gov Identifier: NCT02422706)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is evidence that previous use of macrolides is a useful predictor of the likelihood of standard triple therapy failure in H. pylori eradication (Lim SG, et al. Dig Liver Dis 2016). The goal of this study is to evaluate whether previous intake of various macrolide antibiotics can predict failure to eradicate H. pylori using first-line clarithromycin-containing regimens.

Aims & Methods: Between February 2014 and June 2016 a total of 250 patients with H. pylori infection were prospectively included in a study whose goal was to assess the eradication rates obtained with first-line clarithromycin-containing regimens in our health area. Patients were randomly assigned to one of two regimens: A: Triple therapy (PPI, amoxicillin, clarithromycin, optimized with a double dose of PPI) for 10 days; and B: Concomitant therapy (PPI, amoxicillin, clarithromycin, and metronidazole administered concurrently) for 10 days. The eradication was evaluated by the Stool antigen test or with the Urease test in those patients with a gastroscopy performed after the treatment. A total of 113 patients in the group A (58 women; Median age: 54 years; Range: 21–79) and 106 patients in the group B (56 women; Median age: 49 years; Range: 18–81) completed the study protocol. The electronic medical records of the patients, which contain information regarding all the medication prescribed to the patient during the previous 12 years, were reviewed and the intake of macrolides (clarithromycin, azithromycin and erythromycin) was registered.

Results: 89/219 patients (40.6%) had received at least one treatment with macrolides during the previous 12 years. H. pylori eradication rates with the two treatment regimens are shown in Table 1.

Table 1: H. pylori eradication rates in patients with and without previous intake of macrolides.

<table>
<thead>
<tr>

</tbody>
</table>

Conclusion: Previous use of macrolide antibiotics predicts a low response to triple and to concomitant clarithromycin-containing regimens. In addition, our study shows that in patients without previous use of macrolides triple therapy achieves per-protocol eradication rates over 90%.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to increasing prevalences of clarithromycin resistance in H. pylori infection, current guidelines recommend quadruple therapies as first-line therapy1-5. Bismuth quadruple therapy (BQT) has been proven superior to standard triple therapy in clinical trials6, however little is known about the efficacy of BQT in clinical routine practice.

Aims & Methods: In a prospective single center cohort study we analyzed consecutive patients in whom three-in-one capsule BQT (Pylera® + omeprazole) has been prescribed between 1/2013 and 12/2016. All patients were instructed in a standardized fashion and a prospective follow-up was planned. In a subgroup of patients, genotypic susceptibility testing for clarithromycin and levofloxacin by PCR was carried out on gastric biopsies before treatment. Treatment outcome was assessed by 13C urea breath test or by histology not earlier than 4 weeks after end of treatment.

Results: Three-in-one capsule BQT has been prescribed in 322 patients (mean age 41 years (18–80), 65% female, 26% active smoker). 71% of patients had a migrational background including Southern/Eastern Europe, Eurasia/Central Asia, Southeast-Asia, Africa, and Central/South America. PCR results were available in 163 patients (50.6%) and identified resistance to clarithromycin and levofloxacin in 29 (17, 8%) and 20 (12, 3%) of cases, respectively. BQT was administered as firstline, secondline and rescue treatment in 74%, 17% and 9% of cases, respectively. 5 patients discontinued treatment prematurely due to side effects (1, 8%) and 43 patients were lost to follow-up (13, 4%). By modified intention-to-treat and per-protocol analysis the H. pylori eradication rates were 94, 9% (95% CI: 92, 1–97, 5%) and 96,7% (95% CI: 94,4–98,8%), respectively. The low number of treatment failures (n=9) did not allow to identify risk factors for failure.

Conclusion: Three-in-one capsule bismuth quadruple therapy is highly effective and safe for treatment of H. pylori infection in clinical routine practice, irrespective of the patient's migrational background or the number of previous treatment failures.

Introduction: Background: Eradication of Helicobacter pylori (H. pylori) infection represents a clinical challenge. The current requirements demand eradication rates ≥90% for the eradication of these events which has made that the use of triple treatment including clarithromycin or metronidazole had been give up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth subcitrate potassium, metronidazole, and tetracycline (BMT) have shown high eradication rates in clinical trials.

Aims & Methods: We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of H pylori infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed H pylori infection eradication indication. Patients were treated for ten days with a galenic preparation containing bismuth subcitrate potassium 140mg, metronidazole 125 mg, and tetracycline 125 mg, three capsules four times daily, and esomeprazole 40 mg twice daily and probiotic during 30 days. The primary endpoint was H. pylori eradication rate by a standard urea breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures.

Results: A total of 100 patients, 60 (60.0%) women and 40(40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [44.0 to 50.2] years. Twenty-five (25.0%) patients had a prior history of using medications to treat H. pylori infection and 28.0% (20/25) depended on whether the PPI-BMT treatment was administered as first-line or as rescue therapy, respectively. In the PP population, the eradication rates were the 98.6% (67/68) in those patients treated with PPI-BMT as first-line or as rescue therapy, respectively. Eighteen (18.0%) patients reported at least one adverse event.

Conclusion: In patients with confirmed H pylori infection, 10 days of treatment with a combination of bismuth, metronidazole and tetracycline plus esomeprazole provides high eradication rates not only as first-line but also as rescue therapy, with an acceptable safety profile.

P0600 A SEVEN-DAY TRIPLE THERAPY CONTAINING A POTASSIUM-COMPETITIVE ACID BLOCKER COMPARED WITH PROTON PUMP INHIBITORS, AMOXICILLIN AND CLARITHROMYCIN FOR FIRST-LINE HELICOBACTER PYLORI ERADICATION IN JAPAN: A SINGLE-CLINIC RETROSPECTIVE STUDY

S. Yojiro
Sadamoto GI Clinic, Kitakyushu/Japan

Contact E-mail Address: sadamotoyo@yahoo.co.jp

Introduction: This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPI) for a first-line Helicobacter Pylori (H. pylori) eradication.

Aims & Methods: We retrospectively analyzed data from first-line H. pylori eradication treatment (vonoprazan or PPIs with 400 mg clarithromycin and 1000 mg amoxicillin) in 458 consecutive patients twice during 30 months. Patients who received 7-day P-CAB therapy (vonoprazan 20 mg twice daily; n = 498) were compared with those who received 7-day PPI therapy (lansoprazole 30 mg/day = 217, rabeprazole 20 mg/day = 133, esomeprazole 40 mg/day = 80) to be calculated by intention-to-treat (ITT) and by per-protocol (PP). Compliance and adverse events were also assessed for each study group. Results: ITT and PP analysis of the first-line H. pylori eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5%/86.8%, 63.9%/76.2%, 71.0%/74%, and 68.0%/79.5%, and 63.2/70.8%, respectively. The vonoprazan eradication rates were significantly higher than those of these PPIs (P < 0.05), respectively. There was no significant difference in the adverse events between the two therapies.

Conclusion: 7-day P-CAB based triple therapy is more effective than 7-day PPI based triple therapy as a first-line H. pylori eradication without differences in tolerability.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0601 AN OPEN-LABEL, RANDOMIZED CONTROLLED TRIAL OF VONOPRAZAN VERSUS ESOMEPRAZOLE AS PART OF FIRST-LINE TRIPLE THERAPY FOR HELICOBACTER PYLORI INFECTION IN JAPAN

Gastroenterology And Hepatology, Takamatsu Red Cross Hospital, Takamatsu/Japan

Contact E-mail Address: h-tama@gd.so-net.ne.jp

Introduction: Vonoprazan (VPZ) is a novel, orally bioavailable, potassium-competitive acid blocker for the treatment and prevention of acid-related gastrointestinal diseases. A phase III study revealed that VPZ is superior to lansoprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).

Aims & Methods: The aim of the current study was to evaluate the efficacy and safety of VPZ. CAM (400 mg/day), and esomeprazole (EOPZ; 150 mg/day) triple therapy in post-marketing use in Japan. A randomized, open-label, single-center study was conducted to verify the superiority of VPZ to esomeprazole (EOPZ) as part of first-line triple therapy in patients with HP infection. Three hundred and forty-nine Japanese patients with HP infection diagnosed using a rapid urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40 mg/day, ABPC 150 mg/day, CAM 400 mg/day) or EOPZ group (EOPZ 40 mg/day, ABPC 150 mg/day, CAM 400 mg/day) with stratification according to endoscopic findings of gastric duodenal ulcer/scar and CAM resistance determined via a microbial sensitivity test. The eradication rates were evaluated using the urea breath test 8 to 12 weeks after cessation of therapy.

Results: Three hundred and forty-five patients (177 men, 168 women; mean age 64.7 years [range 27–89 years]; VPZ group, 169; EOPZ group, 176) completed the study. One patient in the VPZ group and three patients in the EOPZ group discontinued the treatment because of adverse events. One patient in the VPZ group and three patients in the EOPZ group were lost to follow-up. There was no significant difference in the overall first-line eradication rate between the two groups (81.7% [138/169] in the VPZ group vs. 74.4% [131/176] in the EOPZ group [P=0.10]). Furthermore, there was no significant difference in the first-line eradication rate in patients with CAM-sensitive HP (87.2% [82/94] versus 84.6% [77/91] in the VPZ and EOPZ groups, respectively, [P = 0.60]), although the eradication rate was significantly higher among patients with CAM-resistant HP in the VPZ group than that in the EOPZ group (73.6% [30/43] vs. 55.6% [35/63], [P = 0.044]). The first-line eradication rate in the patient with high estimated glomerular filtration rate (eGFR ≥ 100 mL/min/1.73 m²) was significantly lower than that in the patients with low eGFR (< 60 mL/min/1.73 m², 86.4% [32/37] in higher than not screening (14.327DKk (95%CI: 4155–24499)). The probability of the first-line effective was 80% with a willingness to pay of 100,000DKk per life-year gained. When including only peptic ulcer disease related costs the prob-
P0602 THE IMPACT OF AMOXICILLIN RESISTANCE ON THE EFFICACY OF AMOXICILLIN-CONTAINING REGIMENS FOR HELICOBACTER PYLORI ERADICATION: A POST-HOC ANALYSIS OF FIVE RANDOMIZED TRIALS

J. Liou1, M. Chen1, J. Lin1, M. Wu1
1Dept. Of Internal Medicine, National Taiwan University Hospital Dept. of Internal Medicine Taiwan Helicobacter Consortium, Taipei/Taiwan 2College Of Medicine, Fu-Jen Catholic University, New Taipei City/Taiwan

Contact E-mail Address: ditmed046@pchome.com.tw

Introduction: The impact of amoxicillin resistance on the efficacy of regimens containing amoxicillin for Helicobacter pylori (H. pylori) eradication remains inconclusive. Therefore, we aimed to investigate whether the efficacy of amoxicillin containing regimens is affected by amoxicillin resistance and to identify the optimal breakpoint of amoxicillin resistance.

Aims & Methods: This was a post-hoc analysis of five randomized trials conducted in Taiwan from 2007 to 2016. Patients who received amoxicillin-containing regimens were recruited. The minimum inhibitory concentrations (MICs) were determined by agar dilution test. Meta-analysis was performed to assess the risk ratio of eradication failure in amoxicillin resistant strains compared to susceptible strains of seven different regimens. We further performed pooled analysis and logistic regression in patients treated with clarithromycin triple therapy to identify the optimal breakpoint of amoxicillin resistance.

Results: A total of 2339 patients with available data of amoxicillin MICs were enrolled. Meta-analysis showed that the presence of amoxicillin resistance was significantly associated with increased risk of treatment failure of amoxicillin-containing regimens at different breakpoints (RR [Risk ratio]: 1.41, 95% CI [confidence interval]: 1.12–1.78, P = 0.004) when cut at 0.5 mg/ml. The heterogeneity test showed low (I² = 0%, p = 0.615). Pooled analysis also showed that amoxicillin resistance was an independent risk factor of treatment failure of clarithromycin triple therapy at different breakpoints. The best correlation was observed when the breakpoint of amoxicillin resistance was 0.125 mg/ml (Kappa coefficient 0.298), at which the resistance rate was 11.1% (110/990).

Conclusion: The efficacies of amoxicillin containing regimens are affected by amoxicillin resistance and the optimal breakpoint of MIC is 0.125 mg/ml.

P0604 ASSOCIATION BETWEEN GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE AND H. PYLORI INFECTION

M. Matsueda, H. Kinagusa, K. Miyahara, M. Nakagawa

Internal Medicine, Hoshokuia Hospital, Hoshokuia Hospital, Tokyo/Japan

Contact E-mail Address: maaayaay0917@gmail.com

Introduction: Gastric adenocarcinoma of the fundic gland type (GAFG) is gastric adenocarcinoma with low-grade atypia occurring in the mucosa of the fundic gland without atrophy, and is recognized that it is not related to H. pylori (Hp) infection. However, GAFG is also found in Hp-infected and past Hp-infected patients as well as in Hp-negative patients. It is much less common. However, the association between GAFG and Hp infection is still controversial.

Aims & Methods: Ten lesions of GAFG resected endoscopically or surgically in our hospital from December 2010 to October 2016 were classified as Hp-uninfected (n = 5) or past Hp-infected (n = 5). Each endoscopic and clinicopathological features were examined.

Results: Median age of Hp-infected/past Hp-infected/Hp-uninfected were 65/71/54.5 years old, respectively, male ratio were 100/80/0%, occupied site U area were 33/80/50%. There was no difference between the 3 groups in these parameters. However, a significant difference in the rate of submucosal invasion was recognized between the Hp-uninfected and past Hp-infected group and the Hp-uninfected group (submucosal invasion was found at 0% /100%, p = 0.035). According to endoscopic features, background mucosa of gastric fundus gland mucosa without atrophic change was found in 100/-/100%, whitish color in 67/60/50%, submucosal tumor shape in 67/60/50%, dilated vessels with branching architecture in 100/100/50%. The association with Hp infection was not clear. In immunohistochemical staining, MUC6 positive and MUC5AC positive, Pepsinogen-I positive, MUC2 negative, CD 10 negative in all cases, whereas the rate of MUC5AC positive was significantly higher in the Hp-infected group as 0/20/100% (P = 0.045). We reported that black pigmentation is recognized in GAFG (stomach and intestine 50: 1521–1531, 2015), but no association between Hp infection and black pigmentation was observed. On the other hand, the rate of PPI administration divided pigmentation (n = 6)/no pigmentation (n = 4) are 50%, and it is suggested that the pigmentation in GAFG may relate with PPI (p = 0.091).

Introduction: Celiac disease (CD) is an autoimmune disease affecting the small bowel of CD patients, and to look for a possible association between mucin profile and gluten-free diet. English Medical literature searches were conducted for “mucin” and “celiac”. Observational studies were included. Meta-analysis was performed using Comprehensive meta-analysis software. Pooled odds ratios and 95% confidence intervals were calculated.

Results: Out of 18 titles initially generated by the literature searches, 3 observational studies that fulfilled the inclusion criteria remained eligible for meta-analysis. Although the prevalence of cryptogenic hypertransaminasemia was higher among CD patients, no significant association was found. ORs for MUC2 and MUC5AC expression were 1.143, 95%CI 0.060–21.870, P = 0.929 and 21.429, 95%CI 3.883–118.255, P = 0.0001, respectively.

Conclusion: We found that expression of certain mucin genes in the small bowel mucosa of CD patients may serve as a diagnostic tool, and assist in surveillance programs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Celiac disease (CD) is a lifelong autoimmune disease affecting multiple organs of genetically susceptible individuals. One of the extra-intestinal manifestations of the disease is thromboembolic events like strokes and veins' thrombosis.

Aims & Methods: The aim of this work is to determine the prevalence and clinical characteristics of the thrombosis observed during CD. Prospective multicenter work involving 154 adult celiac patients (42H, 112F), with an average age of 36.1 years ±13.6, recruited between 01-01-2013 and 30-06-2014 with a minimum follow-up of 12 months. The diagnosis of CD was in all cases based on clinical, serological and histological arguments. Thrombotic complications were noted as well as their modalities of occurrence.

Results: Vascular thrombosis was noted in 13 patients (8.4%), and occurred almost exclusively in women (84.6%) (11 F - 2 H). There are 6 cases of portal cavernoma, one associated with lower limb thrombosis, 4 cases of stroke and 3 cases of thrombosis of the lower limbs. The diagnosis of thrombosis revealed the diagnosis of MC in 8 patients (61.5%) with an average delay of 11.6 months and extreme delays of 1 to 43 months. These include 4 cases of a portal cavernoma, one associated with deep limb thrombosis, 3 cases of stroke, and one case of deep thrombosis of the lower limbs. The diagnosis of CD was made on average 72 months after that of thrombosis in 4 patients (30.8%). In one case, thrombosis was complicated 39 years after diagnosis of CD diagnosed in childhood at the age of 5 years without gluten-free diet. The thrombophilia assessment was carried out in all patients and. The thrombophilia assessment was negative in 11 cases (84.6%). A S protein deficiency associated with the CD in one case and an antithrombin III deficiency in another case were detected. The use of oral contraceptives and in all cases a micro-dosed oestro-progestin was found in 7 women (63.6%). The women involved in this work were at risk of thrombosis.

Conclusion: The diagnosis of CD must be evoked when there is a thrombotic disease without obvious cause, factors of thrombophilia may be present during the CD. Early CD diagnosis with respect to the gluten-free diet may prevent the development of this complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Celiac disease (CD) is an organ-specific autoimmune disease, and both adaptive and innate immunity are involved in its development. Recent studies suggest the dysregulation Toll-like receptors (TLRs) in innate immunity can confer risk to autoimmune diseases such as CD.

3. United European Gastroenterology Journal 5(5S)
Aims & Methods: In this study we investigated the TLRs 2, 4, 7, 9 genes expression in the lamina propria with celiac disease compared with healthy control. Blood samples from 120 CD patients diagnosed according to the Iranian Society for Gastroenterology were collected and 120 healthy individuals were served as a control group during 2016. Also, among them, 20 duodenal biopsy specimens were collected randomly. Total RNA for both blood samples and biopsy specimens was isolated using a standard commercial kit. The mRNA expression of TLRs were quantified by relative qPCR with B2M as a reference gene.

Results: Significantly higher expression of TLR4 and TLR9 mRNA was observed in blood samples of CD patients compared to the healthy controls (P < 0.05); but there were no significant differences between expression of TLR2 and TLR7 mRNA compared to the controls. Furthermore, TLR4 and TLR2 expression level was increased in CD biopsy specimens compared to controls, whereas expression of TLR9 mRNA was decreased in CD patients. No significant differences in expression of TLR7 was observed in biopsy specimens.

Conclusion: The result of this study show that the alteration of TLR4 and TLR9 genes expression in intestinal mucosa of CD can be detected in PBMs in peripheral blood. This data supports the implication of innate immune system in the pathomechanism of celiac disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non celiac gluten sensitivity (NCGS) is a gluten-related enteropathy with distinctive features compared to celiac disease. Patients with NCGS experience symptoms, such as diarrhea or abdominal pain, shortly after gluten exposure. Differently from celiac disease, serology is negative, and histological picture is characterized by no lesion or a mild enteropathy (Marsh I stage). Few studies have investigated possible histopathological characteristics of NCGS. An immune response against gluten elicited exclusively by innate immunity has been hypothesized. On these bases, we attempted to depict an immunohistochemical trait of NCGS by exploring markers of lymphocyte and innate immunity activation.

Aims & Methods: Duodenal biopsy samples of patients diagnosed of NCGS according to Salerno criteria were retrieved. Duodenal biopsy samples of positive controls (overt seropositive celiac disease at Marsh I stage) and negative controls (functional dyspepsia and normal microscopic picture) were selected. Immunohistochemistry for CD3 (intraepithelial lymphocytes), CD4 (T-helper lymphocytes), CD8 (T-lymphocytes), CD10 (B-lymphocytes), CD14 (monocytes), CD1a (Langerhans cells) was performed. Cell count was carried out both in the epithelial layer (expressed as CD3+ cells/100 enterocytes) and in the lamina propria (positive cells/mm²).

Comparison of means was performed by ANOVA test with Bonferroni's post hoc analysis.

Results: Twenty NCGS, 12 celiac patients (positive controls) and 16 negative controls were selected. CD3+ intraepithelial lymphocytes in NCGS were expressed at intermediate levels (18.5 ± 6.4) between negative controls (11.9 ± 2.8) and celiac disease (40.8 ± 8.1, P < 0.0001). CD4+ T-helper lymphocytes were present only in lamina propria and NCGS had a lower level than controls (37.2 ± 29.5) and celiac disease (103.7 ± 15.7, P < 0.0001). Intraepithelial CD8+ cells were similar between NCGS and negative controls (14.0 ± 7.4 versus 17.8 ± 4.2), but lower than celiac disease (34.0 ± 7.1, P < 0.0001). CD1a+ Langerhans cells were over-expressed in the lamina propria of NCGS (1.9 ± 1.1) in comparison to celiac disease and negative controls (respectively 0.3 ± 0.8 and 0.4 ± 0.5, P < 0.0001).

Conclusion: NCGS is characterized by a mild immunologic reaction, as shown by the slight increase in CD3 intraepithelial lymphocytes. The over-expression in the...
P0612 FUNCTIONAL DYSPEPSIA SYMPTOMS ARE STRONGLY ASSOCIATED WITH COELIAC DISEASE: RESULTS FROM A POPULATION-BASED STUDY

M. Potter1, M. M. Walker2, M.P. P. Jones3, N. Koloski1, G. Brogan4, S. Keely1, N.J. Talley1

Introduction: Coeliac disease (CD) is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4).

Aims & Methods: The aim of this study was to define GI symptoms reported in an Australian cohort with a doctor diagnosis of CD and compare with those not reporting CD. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on whether the participant had ever been told by a physician that they had CD, and questions regarding GI symptoms to establish whether they had co-existent functional GI disorders. Adherence to a gluten-free diet was not assessed. Prevalence of CD, FD and IBS are reported with 95% exact confidence intervals. The difference between symptoms in those with CD compared with the unaffected population was tested for significance by (2) and in dyspepsia (3). The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84–1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhea, bloating, distension, epigastric burning and early satiety (see Table). There was no significant difference observed in symptoms of post-prandial fullness, nausea, constipation, abnormal stool consistency, or straining with defecation. The prevalence of FD as defined by Rome III criteria in the CD cohort was 37.5% (95% CI 22.7–54.2) compared to 13.9% (95% CI 12.8–15.1) in the non-affected population (OR 2.7, 95% CI 1.9–7.1, p < 0.001). There was no significant difference in the prevalence of IBS in the affected compared with the non-affected cohort (30.8% versus 22.2%, p = 0.2).

Table: Gastrointestinal symptoms reported by patients with and without self reported coeliac disease (CD). Items reported as greater than one day per week (*) or greater than or equal to “often” (**) Symptoms self report CD - Yes self report CD - No p value Abdominal pain associated with loose bowel motions ** 16/37 43.2% 600/3324 18.6% P < 0.001 More bowel motions associated with pain ** 13/38 34.2% 504/3248 15.5% P = 0.002 Bloating * 13/40 32.5% 436/3381 12.9% P < 0.001 Distension * 12/40 30% 395/3371 11.7% P < 0.001 Abdominal pain * 9/39 23.1% 362/3378 10.7% P < 0.001 >3 bowel motions per day ** 7/40 17.5% 740/15 7.5% P = 0.046 Epigastric burning * 8/40 20% 165/3380 4.9% P < 0.001 Early satiety * 8/40 20% 230/3378 6.8% P = 0.001

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia symptoms are significantly higher in patients with a doctor diagnosis of CD than those without. Studies of the biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful (3), this study supports these views.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0613 MALE GENDER AND UNDERWEIGHT ARE ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH NEW DIAGNOSIS OF COELIAC DISEASE

Department Of Medical-surgical Sciences And Translational Medicine, Sant’ Andrea Hospital, University Sapienza, Rome, Italy

Contact E-mail Address: gloria.galli5@gmail.com

Introduction: Osteoporosis is a systemic skeletal disorder characterized by low bone density and micro-architectural deterioration with increase of bone fragility and consequent fracture risk. About 50–75% of patients (pts) with untreated coeliac disease (CD) suffer from bone mass loss (osteoopenia or osteoporosis). Despite this strong correlation, guidelines do not express with certainty on the need to undergo a dual-energy X-ray absorptiometry (DEXA) scan in every patient with new diagnosis of CD. Recently, the DEXA screening was suggested for CD peri-post menopausal females, males over 55 years, pts with overt malabsorption or with a history of fragility fractures. Studies on bone mineral density (BMD) in CD pts led to discrepant results, probably due to heterogeneous designs.

Aims & Methods: The aim of this study was to evaluate, in a cohort of consecutively newly diagnosed CD adults, the prevalence of BMD alterations at diagnosis time and to evaluate associated clinical features. From January 2004 to December 2016, 258 consecutive pts (F = 72.4%) were diagnosed with CD. All pts were adults (median age 38, range 18–72 years), had atrophic disease and were invited to undergo a DEXA within 3 months from diagnosis to screen for osteoporosis (T-score < –2.5) or osteopenia (T-score < –1 and > –2.5). A total of 214 (82.9%) pts underwent the DEXA scan and were included in the study (F = 71.5%, median age 38, range 18–72 years). On the basis of DEXA results (codified according to WHO classification) pts were divided into 3 groups: pts with normal BMD, with osteopenia, and with osteoporosis. For each patient, reported risk factors for low BMD (underweight, alcohol intake, drugs, menopause, smoke) and serological PTH values were assessed. The signs/symptoms leading to CD and their duration before diagnosis, autoimmune/not autoimmune comorbidities, familiarity for CD, previous fractures and serological assays (specific antibodies for CD, ferritin, cholesterol, triglycerides, and albumin) were also assessed. All the variables described were analyzed and compared between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis.

Results: At the DEXA scan, 85 (39.7%) and 129 (60.3%) pts had normal or low BMD, respectively. Among pts with low BMD, 91 (42.5%) had osteopenia and 38 (17.8%) osteoporosis. At logistic regression, clinical features significantly associated with osteoporosis were male gender (OR 4.7; 95%CI 1.3 to 17.4), underweight (OR 8.1; 95%CI 1.8 to 35.3) and increased PTH values (OR 5.1; 95%CI 1.4 to18.8), while age over 40 years and gastrointestinal symptoms at diagnosis time, menopause, alcohol intake and previous fractures were not associated. Clinical features significantly associated with osteopenia were underweight (OR 4.0, 95% CI 1.4 to11.2) and increased PTH values (OR 2.6, 95%CI 1.1 to 6.4).

Conclusion: In newly diagnosed coeliac pts, the overall prevalence of BMD alterations was more than 60%, with osteopenia in nearly 1/3. Osteoporosis was significantly associated with male gender, underweight and increased PTH. This study suggests that at CD diagnosis, DEXA scan might be of benefit, in particular in male underweight pts.

Introduction: Coeliac disease (CD) affects 0.6–1% of the population worldwide (1). Wheat avoidance in the absence of CD is common, and studies report a population prevalence of self-reported wheat or gluten sensitivity (SRWS) of...
up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extra intestinal symptoms on ingestion of wheat or gluten-containing food (2, 3). Aims & Methods: The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18-100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on wheat avoidance, GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve.

Results: The prevalence of SRWS in this cohort was 13.5% (455/3331, 95% CI 12.5–14.5%). Only 11% (50/455) of these patients had received a doctor diagnosis of wheat or gluten intolerance. The most commonly reported GI symptoms (reported as more than weekly or often) associated with SRWS included abdominal pain relieved by bowel movements (54.5%), bloating (37.6%) and abdominal distention (30.8%). In a multivariate analysis, a diagnosis or SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia (FD) (Rome III criteria), female gender, and food allergy (see Table). Older age was negatively associated with SRWS. In this multivariate model, factors with no observed association included body mass index, depression, anxiety, sleep problems, proton pump inhibitor use, gastrointestinal infection, rheumatoid arthritis, scleroderma, migraine, Parkinson's disease, asthma, pollen allergy, animal distention (30.8%). In a multivariate analysis, a diagnosis or SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia (FD) (Rome III criteria), female gender, and food allergy (see Table). Older age was negatively associated with SRWS. In this multivariate model, factors with no observed association included body mass index, depression, anxiety, sleep problems, proton pump inhibitor use, gastrointestinal infection, rheumatoid arthritis, scleroderma, migraine, Parkinson's disease, asthma, pollen allergy, animal allergy, and recent antibiotic use. The model provided useful although imperfect differentiation of SRWS from health (AUC = 0.76).

Table: Medical and demographic factors associated with a diagnosis of self-reported wheat sensitivity (SRWS).

Conclusion: SRWS has a prevalence of 13.5% in this Australian cohort. Those with SRWS are likely to report abdominal symptoms, including abdominal pain associated with bowel habits, bloating after a few hours of ingestion, or abdominal distention. SRWS is significantly associated with IBS and FD, younger age, female gender, and food allergy.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO061 A QUESTIONNAIRE-BASED SYMPTOM EVALUATION STUDY IN 381 PATIENTS DIAGNOSED WITH BILE ACID MALABSORPTION BY SEHCAT FROM 2003 TO 2016
H.R. Clausen, B. Damsgaard, J.F. Dahlerup, J. Agnholt, S.P. Jørgensen, K. Krogh
Department Of Hepatology And Gastroenterology, Aarhus University Hospital, Aarhus/Denmark

Contact E-mail Address: heleneraskclausen@studmed.au.dk

Introduction: Excessive amounts of bile acids entering the colon cause chronic diarrhoea (bile acid diarrhoea (BAD)). Diagnosis of BAD is possible by measuring the retention level of orally ingested 3Helenium homotaurocholic acid (SeHCAT). Standard treatment of BAD is bile acid sequestrants (BAS), such
as celecoxib. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

Aims & Methods: Between 2003 and 2016, 559 patients referred to our hospital for diffuse abdominal pain with absent bowel sounds was included. The presence of co-existent psychiatric disorders was excluded in all of them. After an overnight fast and at the same time in the morning, all the subjects underwent evaluation of post-prandial modifications of serum levels of pro-inflammatory cytokines (IL-1β, IL-6, TNFα), endogenous antioxidant system (uric acid), glucose, insulin and serum lipopolysaccharide (LPS), measured as putative factors responsible for inflammatory response. Serum samples were collected at fasting and every 30 minutes for 4-hour period after an oral gluten load of 2 gr (in 10 HV) or 20 gr (in the other 10 HV). The presence and severity of a cephalalgia pain, epigastric burning, fullness, early satiety, abdominal pain, abdominal distention, bloating, flatulence, nausea, vomiting, belching, heartburn, regurgitation, diarrhea, and headache, were evaluated by visuo-analog scale at fasting and every 30 minutes in the post-prandial period.

Results: In comparison with mean fasting values, none of the measured parameters showed a significant increase in the post-prandial period after the ingestion of 2 gr of gluten. On the contrary, after the ingestion of 20 gr of gluten mean post-prandial values of TNFα and IL-8 showed a significant increase (2.45 ± 1.75 pg/mL and 0.65 ± 0.31 pg/mL) as compared to mean fasting values (1.17 ± 1.49 pg/mL and 0.29 ± 0.15 pg/mL; p < 0.05). Mean post-prandial values of uric acid were also significantly higher (74.98 ± 15.02 mmol/mL) than fasting values (45.34 ± 10.08 mmol/mL; p < 0.05). No significant differences were detected in IL-6, glucose, insulin and LPS after the ingestion of the 20 gr gluten oral load. Symptoms were absent after both oral loads.

Conclusion: The ingestion of gluten was not a low, oral load of gluten induces a significant post-prandial inflammatory response causing the activation of the main endogenous anti-oxidant system. In HV, these activations are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-oxidant post-prandial response in patients with gluten related disorders.

Introduction: The Duodenal-Jejunal Bypass Linear (DJBL) is an endoscopic device which prevents ingested nutrients absorption in the duodenum and first part of jejunum. The resultant effects are weight reduction and improvement in glycemic control in patients with type 2 diabetes mellitus (T2DM).

Aims & Methods: The current study is to assess weight and glycemic control changes resulted from the device implantation and a year after the device removal. Between February 2013 and September 2016, 51 diabetic patients were treated with DJBL in our center. This prospective observational study included 3 months courses alternated with two-week breaks for 3 months. In 4-month rats courses with 2-week course for 3 months. In 4-month rats

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutrition counseling and sedentary lifestyle. A multidisciplinary intervention is of paramount importance to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.

Disclosure of Interest: All authors have declared no conflicts of interest.
Also consumption of S led to reduction of pro-inflammatory cytokines and leptin and increased anti-inflammatory cytokines and adiponectin.

Conclusion: Thus, the introduction of S reduced the obesity, that shows the anti-inflammatory effect. Also consumption of S led to reduction of pro-inflammatory cytokines and leptin.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0624 IMPROVED EMPLOYMENT OF INTRAGASTRIC BALLOON FOR WEIGHT LOSS: A PRELIMINARY ANALYSIS
Department Of Internal Medicine, Division Of Gastroenterology And Hepatology, Korea University Anam Hospital, Seoul/Korea, Republic of

Introduction: Endoscopic bariatric approaches are gaining traction as possible treatment modalities for obesity. Especially, intragastric balloon was demonstrated to be associated with a significant weight loss in obese patients. Despite many advances in the design and material of intragastric balloon devices, there still remains a need for improved devices which is safer, faster, and less expensive than before. In the present study, we evaluated feasibility of newly developed intragastric balloon.

Aims & Methods: We used a newly developed intragastric balloon with improved employment for this study. The intragastric balloon was supplied as delicately rolled up inside a thin silicon sheath and mounted by surrounding the endoscope. Endoscopic intragastric balloon placement and positioning was simply performed through the use of 10 pigs were subjected to the novel intragastric balloon placement. We evaluated feasibility of the intragastric balloon and compared procedure time between the novel intragastric balloon and End-bal (Endalis, Brignais, France) intragastric balloon.

Results: In all cases, the novel intragastric balloons were successfully placed under usual sedation of diagnostic endoscopy. The procedures were simple and fast; the mean insertion time was 41.314 ± 153.8 ± 134.8 sec in novel intragastric balloon group and end ball group, respectively. The mean inflation time was 412.46 and 512.83 sec in novel intragastric balloon group and end ball group, respectively.

Conclusion: This preliminary data suggest that the procedure with the new intragastric balloon attain technical improvements in the placement without severe adverse events. The new intragastric balloon could offer constantly effective procedure regardless of the ability of the endoscopy practitioner.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0625 IS RE-IMPLANTATION OF THE DUODENAL-JEJUNAL BYPASS LINER Viable?
S. Guenther, A. Dieneth, J. Stein
Gastroenterology And Clinical Nutrition, DGD Clinics Sachsenhausen, Frankfurt/Main/Germany

Contact E-mail Address: j.stein@em.uni-frankfurt.de

Introduction: The endoscopically implanted DJBL is a 60cm long, impermeable fluoropolymer device which prevents food from making contact with the proximal intestine, thus inducing considerable weight loss and improvement of type 2 diabetes mellitus (T2DM). Both weight and HbA1c levels have been reported to decrease post explantation. The question remains as to whether it is possible to re-implant the DJBL, and what the results would be in terms of BMI (Body Mass Index) change and T2DM control.

Aims & Methods: The aim of this study was to investigate the safety, feasibility and effectiveness of DJBL re-implantation in patients who show a relapse in glucose levels after DJBL explantation. This prospective, observational study was conducted at the Department of Gastroenterology of DGD Clinics Sachsenhausen, Frankfurt (Germany) between 2014 and 2016. Five obese patients with T2DM and with a body mass index (BMI) ranging from 35–59 kg/m², who completed follow-up after their first implant and underwent removal of the DJBL after 12 months, were selected for re-implantation after an additional 4 months of follow-up. Weight loss, BMI, and HbA1c were analysed before reimplantation and twelve months thereafter.

Results: In all 5 patients, the DJBL was initially implanted and explanted without complications. Re-implantation and re-explantation were also performed without complications. Changes in body weight, BMI, and glycated haemoglobin (HbA1c) are shown in Table 1.

Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even after 4 months. After re-implantation, weight and HbA1c levels decreased once more.

Disclosure of Interest: J. Stein: Jürgen Stein has received speakers’ honoraria from GI Dynamics. All other authors have declared no conflicts of interest.

P0626 THE COMPARATIVE EFFICACY OF OBESITY TREATMENTS IN YOUNG PEOPLE - A SYSTEMATIC REVIEW AND META ANALYSIS
S. S. Selvendran, N. Penney, N. Aggarwal, A. Darzi, S. Purkayastha
Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: SS9612@i.c.ae.uk

Introduction: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-analyse studies evaluating treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modification and pharmacological therapy searches were restricted to randomised control trials. Results: 16,372 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more modest impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Conclusion: This is the first systematic review and meta-analysis to comprehensively summarise and quantify the comparative efficacy of BMI reducing treatment options in the obese, young population. Currently, bariatric surgery is rarely considered in this young cohort. However, due to its high efficacy, physicians and patients should have a lower threshold for considering bariatric surgery when lifestyle and pharmacological interventions have failed. These non-surgical interventions provide smaller but statistically significant impacts on BMI reduction. There should be effective communication discussing the relative efficacy of all treatment options and their associated complications between those involved. This knowledge will assist clinicians in determining a holistic, patient-centred treatment programme for obese, young patients.

P0627 FOOD-DERIVED MICRONRNA AND INFLUENCE ON THE FECAL MICRONRNA EXPRESSION
J. Link1, C. Langner1, A. Canbay1, P. Malfertheiner1, A. Link1
1 Department Of Gastroenterology, Hepatology And Infections Diseases, Otto-von-Guericke University, Magdeburg/Germany

Contact E-mail Address: alinkmail@gmail.com

Introduction: Tumor development is a multistep process, which involves genetic and environmental factors. Diet is among the most important contributing factors and processed and red meat has been classified as carcinogenic for colorectal cancer. MicroRNAs (miRNAs) are functional, ubiquitously present molecules that are involved in various forms of food processing. Furthermore, we tested if short-term vegetarian or meat rich diet may influence human or plant-derived miRNA in feces and blood. For this purpose, six healthy subjects were asked to adhere to vegetarian or meat rich diet for 5 to 7 days and fecal and blood specimens were obtained at different time points. Plant-miRNAs were further investigated in gastric and colon mucosa. To evaluate the presence of miRNA in food, we selected several common foods prior and after cooking/processing. Quantitative real-time PCR was performed using TaqMan Assay.
Results: All measured microRNAs were present in all studied foods with highest expression observed by miR-16 and miR-155. Especially, hash, beef and salmon showed the highest miRNA expression, while lowest expression was found in cheese and milk. Food processing led to only marginal changes (max. 1.5-fold) in miRNA expression and thus demonstrating its stability against degradation. Short-term changes in diet (from usual to vegetarian and to meat-rich diet) in healthy subjects was not associated with variation in miR-21, miR-155 and miR-16 expression. Interestingly, in comparison to several previous reports, we repeatedly failed to detect any plant miR-168 in sera. However, when supplemented with a significant increase in miR-168 level in feces (up to 8-fold), while meat-rich diet was associated with slight decrease if compared to the starting point (mean ± SD 0.031 ± 0.002 for no diet vs. 0.025 ± 0.042 for vegetarian vs. 0.0016 ± 0.00096 for meat-rich; p = 0.03 Kruskal-Wallis test, with p = 0.05 for Dunts multiple comparison test for vegetarian vs. meat-rich).

Conclusion: The results of this study show that various foods provide a great source of microRNAs, which remains stable despite processing. We further demonstrated that short term changes in diet do not impact on the miRNA expression pattern in feces and blood supporting its value as biomarkers. A functional role of diet-induced increase in plant-derived miRNA expression needs further evaluation.

P0628 NEUROMEDIN U BLOKES GASTRIC EMPTYING THROUGH VAGAL-DEPENDENT MECHANISMS AND IMPROVES ORAL GLUCOSE TOLERANCE

A. Jarry1, N. Merah1, M. Fiamma2, E. Bodineau1, A. Bado1, J. Le Beyec1, M. Le Gall1

1INSERM U1149, Paris/France
2INSERM U1158, Paris/France

Contact E-mail Address: annecharlottejarry@hotmail.fr

Introduction: The gut and brain peptide neuromedin U (NMU) is reported to decrease food intake and body weight, and to improve oral glucose tolerance with ROC curves supporting this as a predictor of response (AUC 0.747, p = 0.063). Finally, there was a significant difference in VOC profiles between responders and non-responders to the LFD at baseline (p = 0.04). VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p = 0.02).

Conclusion: Addition of B-GOS to the LFD improves symptoms in IBS. Urine metabolomics, stool SCFA and VOC profiling are reliable and sensitive biomarkers for future use. Further studies are warranted to test the combination of prebiotics and probiotics.

P0630 THE ANALYSIS OF PROTEIN CONSUMPTION PATTERNs IN PATIENTS WITH SIBO

V. Pilipenko, V. Isakov, A. Vlasova

Gastroenterology & Hepatology, Research Institute of Nutrition RAMS, Moscow/ Russian Federation

Contact E-mail Address: pilipenkowork@rambler.ru

Conclusion: Small intestinal bacterial overgrowth (SIBO) is common in patients with gastrointestinal diseases. SIBO symptoms are improved with antimicrobial treatment, but recurrence rate is high (approximately 40% for 9 months). Dietary modification is essential for prevention of recurrence of SIBO however there are no detailed studies of nutrition in SIBO patients. Protein consumption is considered important for SIBO, as the proteins from animal source are essential for growth of CH4/H2-producing microorganisms.

Aims & Methods: The aim of the study was to assess the protein consumption patterns in patients with different types of SIBO. Three-day food diary was collected from 574 patients, undergoing CH4/H2 lactulose breath test. The photographs used to estimate the size of the portions eaten. According to food composition and portion all dishes in food diary were converted into constituent products (food groups). Each food group were compared with the normal levels of a healthy diet pyramid based on daily calories (normal value = 1.0). According to the breath test results the patients were divided into 4 subgroups of different SIBO types (H2, CH4, H2 and CH4) and a subgroup with no signs of SIBO (Table 1).

Results: All types SIBO patients consumed less meat than control (no signs of SIBO), however patients with hyperproduction of CH4 only demonstrated highest consumption of fish, and it was a trend in patients with isolated H2-hyperproduction to consume meat less than other groups. There were no differences between groups in consumption of processed meat foods or eggs.

Conclusion: There are specific animal protein consumption patterns related to the type of the SIBO, which can be used for the planning of dietetic interventions in patients for prevention of SIBO.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim of the study was to evaluate the differences in GI motor function and visceral sensitivity in rats exposed to diet supplemented with either medium-chain (MCFAs) or long-chain fatty acids (LCFAs). Male Wistar rats were fed with control diet (A), and diet supplemented with 3.5 % coconut oil (B) (abundant with MCFAs) or 3.5 % evening primrose oil (C) (abundant with LCFAs) for 4 weeks. The effects of each diet on GI motility were measured radiographically after contrast administration (p.o; X rays were taken 0–8 h before and after feeding, on day 0 and day 28, respectively), and by performing the colon bead expulsion test. Temporal changes in the size of the stomach and caecum of each rat were analyzed based on digitalized X-rays, using an image processor. Visceral sensitivity was assessed with abdominal withdrawal reflex to colorectal distension. Body weight gain and food/water consumption were measured throughout the experiment.

Results: Diet supplementation in neither group B nor group C affected the GI motor function in comparison to control group (A). The number of contractions and the mean time of each contraction in response to colorectal distension measured during each 5 min for 40 min were higher in the control group (A), when compared to either B or C groups but the differences were not statistically significant. No changes in morphometric measurements of stomach and caecum, the body weight gain and food/water consumption were found.

Conclusion: Diets differing in MCFAs or LCFAs contents did not induce marked effects on GI motility and visceral pain in rats. Available data and the results obtained herein suggest that the amount of FAs intake, rather than the types of FAs may provoke IBS symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Dietary interventions are gaining popularity in terms of alleviating symptoms experienced by patients with functional GI disorders (FGID), especially with irritable bowel syndrome (IBS). Available strategies rely on low intake of foods high in short-chained carbohydrates, dairy products, wheat, spices etc. Although some studies indicate increased rectal sensitivity after duodenal lipid administration in patients with IBS and suggest delayed transit after high fat intake, the effects of dietary supplementation with different types of fatty acids in IBS have not been explored so far.

Aims & Methods: The aim of the study was to evaluate the differences in GI motor function and visceral sensitivity in rats exposed to diet supplemented with either medium-chain (MCFAs) or long-chain fatty acids (LCFAs). Male Wistar rats were fed with control diet (A), and diet supplemented with 3.5 % coconut oil (B) (abundant with MCFAs) or 3.5 % evening primrose oil (C) (abundant with LCFAs) for 4 weeks. The effects of each diet on GI motility were measured radiographically after contrast administration (p.o; X rays were taken 0–8 h before and after feeding, on day 0 and day 28, respectively), and by performing the colon bead expulsion test. Temporal changes in the size of the stomach and caecum of each rat were analyzed based on digitalized X-rays, using an image processor. Visceral sensitivity was assessed with abdominal withdrawal reflex to colorectal distension. Body weight gain and food/water consumption were measured throughout the experiment.

Results: Diet supplementation in neither group B nor group C affected the GI motor function in comparison to control group (A). The number of contractions and the mean time of each contraction in response to colorectal distension measured during each 5 min for 40 min were higher in the control group (A), when compared to either B or C groups but the differences were not statistically significant. References
is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1). GLP-1 is an intestinal hormone secreted by enteroendocrine L cells (EEC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differentially processed by prohormone convertase 2 (PC2) into glucagon in pancreatic α cells and by prohormone convertase 1/3 (PC1/3) into GLP-1. These two peptides are secreted by different enteroendocrine cell types (ECC) derived from different parts of the gut (Du et al., 2015).

Aims & Methods: We hypothesized that, after pancreactectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreaticoctomy model in C57Bl6 mice. Control (Ct) mice underwent a laparotomy. Post-surgery, blood glucose was measured and pancreatic glucagonase and intestinal glucagonase tolerances (OGTT) were performed after 1 week. Insulinemia and glucagonemia were also measured in fed and fasted mice and during OGTT. After 2 weeks, animals were sacrificed and the remnant pancreas was sampled for glucagon and insulin immunoquantification. Pancreatic, jejunal and colonic tissue were snap-frozen for mRNA analysis. Local and intestinal glucagon concentrations were determined using RIA. Local and intestinal glucagon concentrations were determined using RIA.

Results: As soon as one day post-surgery, pancreactomized (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in Px mice vs 140 mg/dl in Ct mice, P < 0.05, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve = 278% in Px mice, P < 0.01 in Ct mice, 1 week post-surgery). During OGTT, intestinal glucose absorption increased (slope between 0 and 15 min = 69.9% in Px mice vs P < 0.01). A mice, 1 week post-surgery). Glucagonemia increased in fasted pancreactomized mice (+14.66% in Px mice P = 0.01 vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (~79.25% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). Hypoglycemia of the proximal colon to secrete glucagon and C peptide was observed (+290.6% in Px mice P = 0.05 vs Ct mice, 2 weeks post-surgery). In pancreactomized mice, an hypoglycemia of the duodenum was associated with an increase in crypt depth (+77.7%, in Px mice P < 0.05 vs control mice, 2 weeks post-surgery) and villus height (+53.8% in Px mice P < 0.05 vs control mice, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreactectomy. The upper intestine (duodenum) become hyperplastic and mucosal weight increased intestinal glucose absorption to absorb glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglucagonemia.

3Gastroenterology And Hepatology, Tan Tock Seng Hospital, Singapore

Contact E-mail Address: ennaliza.salazar@sgh.com

Introduction: Soybean oil intravenous lipid emulsion (IVLE) is also known as conventional lipid in rich in linoleic acid (ω-6 PUFAs). ω-6 PUFAs may influence inflammatory response and indirectly detrimental in the critically ill patients. To overcome this, the use of alternative IVLEs such as medium chain triglycerides (MCT), fish oil and olive oil alone or in combination with soybean oil IVLE have been used to lower the content of ω-6 PUFAs. Most studies on alternative IVLEs have been conducted in the critically ill patients, elective surgical patients and cancer patients. No previous studies have evaluated the clinical outcomes of several different IVLEs in non-critically ill patients in acute hospital setting.

Aims & Methods: The purpose of this study is to determine whether there is a difference in clinical outcome amongst patient who received conventional soybean oil IVLE versus alternative IVLEs in non-critically ill patients in acute hospital setting. All patients on parenteral nutrition (PN) were identified in a prospective compilation database from July 2007 to September 2010 and were analysed retrospectively. Patients were analysed based on the IVLE received, namely soybean oil based (Lipofundin-N 20%, type 1), MCT oil based (Lipofundin MCT/LCT 20%, type 2), olive oil based (ClinOleic, type 3) and fish oil containing (Lipidem, type 4). Patients must receive PN for at least 5 days, with absolute indication of surgery or high dependency unit for using non-invasive ventilator support or long-term use of PN. Exclusion criteria included patients who received less than 5 days of PN, intensive care unit (ICU) patients, PN started in ICU and continued in general ward or HDU, PN restarted in less than 3 days after being discontinued in ICU, patient on invasive/non-invasive ventilator support or long-term PN patients.

Results: 537 patients were started on PN and 388 patients were included in the analysis. 90% of patients were on type 1 (MCT-based) IVLE, 141 patients were on type 3 (MCT-based) IVLE, 141 patients were on type 5 (olive oil based) IVLE and 97 patients were on type 4 (fish oil based) IVLE. Baseline characteristic were similar in four groups of IVLEs. Majority of PN were initiated in patients admitted under surgical team. There were no difference in terms of mortality, readmission and infection rate between conventional and alternative IVLE as a group, overall mortality (OR) was 0.83 (CI 0.68–1.01, p = 0.13), 0.95 (CI 0.80–1.12, p = 0.36). There were no difference in terms of mortality, readmission and infection rate between conventional IVLE versus each of the alternative IVLE. Length of stay was only statistically significantly lower for olive oil based IVLE (Type 3) when compared to conventional IVLE (p = 0.05).

Table 1: Clinical outcomes with conventional IVLE versus alternative IVLE as a group

<table>
<thead>
<tr>
<th>IVLE Type</th>
<th>Mortality (As a group) OR (95% CI)</th>
<th>p Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conventional</td>
<td>0.83 (CI 0.68–1.01)</td>
<td>0.13</td>
</tr>
<tr>
<td>Alternative</td>
<td>0.95 (CI 0.80–1.12)</td>
<td>0.36</td>
</tr>
</tbody>
</table>

Conclusion: Length of stay was significantly lower in alternative IVLE compared with conventional IVLE. However, there were no clinical difference in terms of mortality, readmission and infection between conventional and alternative IVLE in non critically ill patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Percutaneous endoscopic gastrostomy placement (PEG) is currently the method of choice for medium- and long-term enteral feeding and is nowadays one of the most common endoscopic procedures performed worldwide. To date, data on complications and mortality rates are generally retrospective and only few prospective studies have been published on small number of patients.

Aims & Methods: We aimed to prospectively evaluate the complication rates and the mortality of patients after PEG insertion or PEG replacement. This is a multicenter prospective cohort study. Between 15th September 2015 and 15th September 2016, all patients that underwent PEG insertion or replacement, were included. Details about patient’s characteristics, ongoing therapies, comorbidities, indication for PEG placement/replacement, informed consent form signature were collected. Early and late (30 days) complications and mortality were assessed.

Results: 912 patients (426 [46.7%] male) were enrolled in 34 centers. Patients mean age was 72y (SD16.01, range 18–99). ASA status was 1 in 4.0%, 2 in 63.2% patients. Indications were: dysphagia for cerebrovascular diseases in 64.0% patients. Mean age was 72y (SD 16.01, range 18–99). ASA status was 1 in 4.0, 2 in 63.2% patients. Indications were: dysphagia for cerebrovascular diseases in 64.0% patients.

Table 1: Details about patient’s characteristics, ongoing therapies, comorbidities. A total of 330 patients (36.0%) had anticoagulant and/or antiplatelet concomitant therapy. 30.0% of patients had undergone a relative (without legal guardianship) in 66.3%, patient in 28.2%, legal guardian in 16.25%, medical director in 7% of patients. Thirty-days mortality was 2.4%.

Conclusion: Our data confirm that PEG placement is a safe procedure with a mortality rate at 30 days of 8%. To our knowledge this is the largest prospective study on the use of PEG. Surprisingly in more than 50% of patients the consent form was not properly signed, leading to possible medicolegal consequences. Moreover, in 9% of the cases PEG was placed for an early discharge (more than for real clinical indication).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0637 MEDICAL REGISTRAR REPORTING OF CHEST X-RAYS FOR NASOGASTRIC TUBE POSITION: HOW CAN IT BE MADE SAFER?
Nutrition, University Hospitals Southampton, Southampton/United Kingdom

Contact E-mail Address: maive.tierney@nhs.net

Introduction: Nasogastric tube (NG) feeding is an essential part of in-patient care. Tubes can be placed at the bedside with no need for specific equipment or sedation. However placement of NG tubes is not without risk and avoiding the introduction of substances into the respiratory tract through a misplaced NG tube was highlighted as a UK National Patient Safety Agency alert in 2005. In 2011 the NPSA made this a ‘never event’. The only acceptable methods of checking the position of an NG tube are: pH < 3.5 on aspirate or confirmation on chest X-ray (CXR) by competent medical staff. Reporting a CXR for NG tube position is a frequent request particularly for junior doctors out of hours. Practise varies across the UK - some trusts require NG checking to be done only by senior clinicians (medical registrars or consultants) and some only allow reporting by a consultant radiologist. We assessed documentation of NG position on CXR by medical registrars from first to final year of specialist training and from various specialties were presented with a CXR showing a correctly sited NG tube and were asked to complete a sticker answering yes or no, to check position and whether it was safe to use. Following this they were presented with a CXR showing an incorrectly sited NG tube and asked to use the sticker to assess position. The CXR was projected and anonymous responses collected after sufficient time for the group to complete both stickers.

Results: 31 complete responses were obtained for the correctly sited tube with 58% stating that it should be used and 42% that they would not use the tube without further review. 10 incomplete responses were obtained and therefore 86% of responses met NPSA guidance for reporting CXR for NG position. 28 complete responses were obtained for the incorrectly sited tube and 100% stated that the tube should not be used.

Conclusion: Use of the sticker increased compliance with NPSA guidance for CXR reporting for NG tube position from 17.6% to 86%. The misplaced tube was correctly reported and not used in 100% of responses. The correctly sited tube was reported as safe to use in 58%. The CXR used was of an anonymous real patient and was slightly rotated to reflect a real-life scenario which meant the tube was slightly off the midline. In this real-life scenario some trainees would be happy to make a judgement considering these factors and others may be cautious and follow the sticker statements exactly prompting further review by radiology or removal of the tube. Overall this increases patient safety and avoids use of a misplaced tube in accordance with NPSA guidance. We recommend a sticker on all wards which use NG tubes to rapidly improve documentation and patient safety. The other option we may consider is developing a pathway for radiology consultants to report all these CXRs before the NG tube is used; however this is likely to take considerable time and is unlikely to be available out of hours.

**P0638 MICRONUTRIENT MONITORING IN HOME PARENTERAL NUTRITION PATIENTS: AN AUDIT OF PRACTICE IN A REGIONAL REFERRAL CENTRE**

Nutrition, University Hospitals Southampton, Southampton, United Kingdom

**Contact E-mail Address**: maeve.tierney@nhs.net

**Introduction**: Intestinal failure patients by definition have reduced ability to absorb food and micronutrients through the gastrointestinal tract. Type two intestinal failure patients require months of intravenous nutrition (parenteral nutrition) for weeks or months either in hospital or at home. Type three intestinal failure patients generally require long-term parenteral nutrition (PN), which is given at home (HPN) and may be life-long. In addition to a reduction in the ability to absorb micronutrients, patients on long-term PN have a reduction in absorption of micronutrients (copper, zinc, selenium and manganese) and vitamers (A, B12, D and E) which are required for metabolism and enzymatic reactions at a cellular level. PN is routinely supplemented with micronutrients and should be able to meet this requirement. Vitamin C deficiency can occur at high levels and deficiency can cause a variety of symptoms. ESPEN guidelines recommend that serum vitamin and trace element levels be checked at baseline and at least once per year. NICE guidelines specify more frequent monitoring for in-patients and that selenium, manganese and vitamin D should be checked three to six monthly in HPN patients. Some trace elements (copper and zinc in particular) are affected by acute illness. Current local practice is to avoid checking levels until there is evidence that inflammation or infection has resolved.

**Aims & Methods**: Our aim was to audit the frequency of micronutrient screening in our cohort of HPN patients. All type two and three intestinal failure out-patients were included. Current in-patients were excluded due to the effect of acute illness on micronutrient levels. Patients on parenteral fluid rather than nutrition were excluded as current guidelines give recommendations for HPN patients and do not specify recommendations if fluid alone is required. A search of the blood results system was performed for all micronutrient results from one full year to the date of the search. Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local trusts do not have the laboratory facilities to check micronutrient levels so they tend to be done in Southampton. If no results were available on the Southampton system when the local hospital was contacted for local results if available.

**Results**: 57 home parenteral nutrition patients were identified. 51 (89.5%) of these patients had micronutrients checked at some point during their care. 44 of 49 (89.7%) had micronutrients checked within one year (two of the 51 had only recently so did not have results within a year). 32 (61.5%) of those who had micronutrients checked had them done within the last six months. 6 patients had never had micronutrients checked. One had them requested just prior to the time of audit but results were not yet available. Two were out of area and had not been seen in the last year. One of these commenced PN in 2015 and found it difficult to attend clinic. The other had not been seen in clinic due to an administrative error and has now been seen with micronutrients requested. Two further patients had never had micronutrients checked due to a persistently raised CRP.

**Conclusion**: Despite a lack of clarity between guidelines about the frequency of monitoring of micronutrients, it is recommended that HPN patients receiving long-term intravenous nutrition should have regular monitoring to reduce risk of deficiency or toxicity. The majority of our cohort of HPN patients had micronutrients checked annually and over half were checked six monthly. This is compliant with ESPEN guidelines; however, we need to aim for 100%. We have introduced a template to use in clinic to trigger review of results and request micronutrients when required. Alongside this we have introduced a virtual ward round to remotely review all out-patients regularly and plan ahead to request blood tests when required. Following the introduction of these measures we will repeat the audit to find out if the situation has improved.

**P0639 CLINICAL NUTRITION - ARE WE IGNORANT OR NEGLIGENT?**

T.M.A. Gan, R. Asokumar, E. Salazar
Gastroenterology And Hepatology, Singapore General Hospital, Singapore, Singapore

**Contact E-mail Address**: aaron.gan2@mohh.com.sg

**Introduction**: Early recognition and delivery of nutritional care by physicians has been shown to improve outcomes in malnourished hospitalized patients. However, physicians encounter multiple barriers in providing appropriate nutrition-related interventions. Comprehensive international guidelines and nutritional training in medical education have been introduced to overcome these barriers, there appears to be a discrepancy in practice amongst physicians despite the availability of these resources.

**Aims & Methods**: We aim to assess the knowledge and attitudes of physicians towards clinical nutrition in a large tertiary teaching hospital in Singapore. An anonymous questionnaire comprising 15 multiple-choice questions from standard nutrition textbooks was administered. The questionnaire was designed to assess (a) recognition of nutritional needs of hospitalized patients, (b) knowledge on the role of clinical nutrition, and (c) application of nutritional intervention in common clinical practice. We included consultants, fellows and residents working in units where nutritional problems were common. Finally, we conducted a separate 5-question opinion survey to assess each participant’s nutritional training and exposure, based on a 5-point Likert scale ranging from “strongly agree” to “strongly disagree”.

**Results**: A total of 305 physicians volunteered to participate in this study. Forty (13%) did not reveal their specialty or staff grade and were excluded from analyses. Of the remaining 265 responders comprised 77 (29.2%) residents, 49 (18.7%) fellows, and 130 (49%) residents. Amongst them, 232 (87%) were from medical disciplines and 33 (13%) from surgical disciplines. The median aggregate score (out of a maximum of score 3) of 15) was obtained by fellows, consultants and 58 (22%) residents. There are 3 grades of physicians achieved less than 50% of the maximum possible score. No significant difference in median aggregate score was observed between physicians from medical disciplines (6.5 ±1.9) and those from surgical disciplines (6.0 ± 2.2) (range 2-12). However, gastroenterologists performed significantly better than non-gastroenterologists (median aggregate score 9.4 ±2.2 vs 6.0 ±1.8, p <0.001). In the opinion survey, a majority of physicians (63%) believed that nutrition-related teaching was inadequate during residency training and 44% felt that clinical nutrition was accorded insufficient attention during ward rounds. Only 33% of responders reported that they performed nutritional screening on admission, and a mere 10% were confident in providing nutrition counselling to malnourished patients. Interestingly, their overall performance was not different from that of other participants (Table 1).

</tbody>
</table>

**Conclusion**: Our study highlights that knowledge on nutrition and its clinical application to hospitalized patients remains inadequate across all physician grades, especially amongst non-gastroenterologists. The current state of clinical nutrition-related teaching during residency training falls short of achieving its goals, and may need re-evaluation.

**Disclosure of Interest**: All authors have declared no conflicts of interest.
3.03 ± 0.67 cm on gastric side. Mean operating time was 76.7 ± 45.5 (30-240) minutes. No adverse events during the temporary disconnection of procedure and or drainage procedure were encountered in eight (26.7%) children (capno-peritoneum-4 and retro-peritoneal carbon dioxide -4). There was significant reduction in mean LES pressure after POEM (36.25 ± 16 vs 12.88 ± 6.95, p < 0.001). High grade of oesophageal oesophagitis of timed barium oesophagogram (>50%) was documented in 94.4% children. At median follow up of 504 days (30-1290) clinical success was noticed in 29 children (96.7%). Mean Eckardt score before and after POEM were 6.8 ± 1.65 and 0.36 ± 0.77 (p=0.0001). Gastric reflux revealed erosive gastrolesophageal reflux in five children at 1 year (27.8%).

Conclusion: POEM is safe and effective for children with achalasia cardia. POEM can be safely performed in an endoscopy suit in paediatric patients. Disclosure of Interest: All authors have declared no conflicts of interest.

P0641 HIGH RATE OF HELICOBACTER PYLORI ANTIBIOTIC RESISTANCE IN ARMENIAN CHILDREN WITH GASTRODUODENAL DISEASE
T. Shahinyan1, G. Amaryan2, M. Hovsepyan2, C. Braegger3
1Chair Of Pediatrics 2, Yerevan State Medical University, Yerevan/Armenia
2Pediatrics, Arabkir Joint Medical Center, Yerevan/Armenia
3Division Of Gastroenterology And Nutrition, University Children’s Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: shahinyan_tatevik@yahoo.com
Introduction: Because of high prevalence of gastric malignancies in the adult population, high Helicobacter pylori (Hp) prevalence in Armenia is suspected. Research on antibiotic resistance of Hp in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.98 ± 4.10). Hp-associated GDD were diagnosed according to clinical, endoscopic and histological criteria. Antral biopsy was performed on 100% of patients'. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Results: H. pylori-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven out of 47 children were excluded from the study due to both histology and culture negative for Hp. Thirty-four (85%) were treatment-naïve patients and 6 (15%) had received eradication therapy previously. Main clinical symptoms were recurrent epigastric pain 34 (85%), nausea 28 (70%) and vomiting 13 (32.5%). By endoscopy only, one patient was H. pylori positive and/or duodenitis was seen in 18 (45%), non-erosive gastritis in 16 (40%), PUD in 3 (7.5%), normal mucosa in 3 (7.5%). Rapid urease test was positive in all antral biopsies (100%). Histology showed chronic gastritis and/or duodenitis in 28 (70%), atrophic gastritis in 5 (12.5%), gastric glandular dysplasia in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available14: all but 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacine (100%), 6 strains were tested and found susceptible to rifuracet.

Conclusion: The data indicate a high rate of resistance to conventional triple therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). High resistance to doxycycline also was seen, despite limited use of this antibiotic in Armenian paediatric practice. High susceptibility to rifuracet might be useful for future development of specific eradication schemes for Armenia. High frequency of both erosive and non-erosive gastritis as well as high rate of gastric atrophy and dysplasia in these patients were noticed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: H pylori infection is one of the most widespread bacterial infections worldwide, therefore nowadays its prevalence is decreasing, mostly in developed countries. There are some studies which support that H pylori could favor the development of food allergy.

Aims & Methods: To assess the relationship between H pylori infection and specific immunoglobulin E (Ig E) antibodies to food allergens in symptomatic children. We conducted a prospective study of 394 symptomatic children (249 girls, age range 6 months-18 years), mostly with uninvestigated dyspepsia requiring ingestion of antibiotics in our unit. From January 2015 to December 2016. All patients were evaluated for H pylori infection by at least two standard invasive tests and for specific immunoglobulin E antibodies to major food allergens (R-Biopharm, Germany). The nutritional status of patients was assessed in all cases by the new World Health Organization (WHO, 2007) growth charts. EPI-INFO version 7 was used for statistical analysis. A two sided p-value less than 0.05 was considered statistically significant.

Results: Active H pylori infection was documented in 246 (62.3%) cases. The allergic sensitization at least one of the food allergens was identified in 134 of 394 patients (34%). The majority of Ig E positive children (109 of 134 cases; 81.3%) were positive for cow’s milk followed by egg (17.9%), wheat (7.46%), peanut (4.5%), soybean (3.73%). The allergic sensitization to food allergens was associated with abnormal levels of specific Ig E antibodies to common inhalatory allergens in 55 of 134 cases (41.04%). Regarding the association of H pylori infection with an elevated serum Ig E level to at least one of the food allergens tested, there was no significant correlation (p = 0.14). 77 of 134 (51.39%) patients positive for food specific Ig E antibodies were H pylori infected and 57 of them (38.55%) were H pylori negative (Fisher exact test = 0.08). The assessment of the patients nutritional profile in relationship with H pylori infection and food allergy not revealed a statistically significant effect on the two ends of the poor nutritional status (undernutrition and overnutrition).

Conclusion: The recent decline of H pylori infection is not evident in our study. There was no association between H pylori infection and Ig E mediated food allergy. Undernutrition and overnutrition were not associated with the H pylori infection and food allergy in our patients. Disclosure of Interest: All authors have declared no conflicts of interest.

P0646 GUT MICROBIOFA INFLUENCE UNDER OLGOFRACTOSE-ENRICHED INULIN ADMINISTRATION IN PAEDIATRIC COELIAC DISEASE PATIENTS ON A GLUTEN-FREE DIET: RANDOMIZED CONTROLLED TRIAL

U. Krupa-Kozak1, N. Drabin’ska1, L. H. Markiewicz2, E. Jarocka-Cyrta3

Contact E-mail Address: u.krupa-kozak@pan.ubsaty.pl

Introduction: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of coeliac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microflora, can favor the reestablishing their microbial metabolic activity. In comparison with placebo group, the administered of OEI in GFD prevents from a gut dysbiosis observed along with the duration of the GFD, and maintains a constant quantity of beneficial bifidobacteria. Moreover, the administered of OEI in GFD stimulates activity gut microbiota observed ashe increased SCFA production.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0647 CURRENT STATUS OF THE FIRST AND SECOND LINE THERAPY FOR HELICOBACTER PYLORI INFECTION IN SYMPTOMATIC CHILDREN: A SINGLE CENTER STUDY

V. Hurdac, B. Luiza, P. Doina
Pediatric Gastroenterology, Victor Gomawüns Clinical Children Hospital, "Carol Davila" University of Medicine and Pharmacy, Bucharest/Romania

Contact E-mail Address: v.hurdac@yahoo.com

Introduction: Current evidence suggests the decline of the eradication rates of H pylori in children that is associated with standard first line therapy, partly determined by its antibiotic resistance.

Aims & Methods: To evaluate the effectivness of first and second-line therapy for H pylori eradication in children. We conducted a prospective open-label study of 158 symptomatic children (age range 6 months-18 years; 106 girls) who required a first upper digestive endoscopy over the past year. Active H pylori infection was documented in 122 of the 158 investigated children (77.2%). Of the 122 children infected with H pylori, 80 (65.8%) responded well with microbial metabolic activity. In comparison with placebo group, the administered of OEI in GFD prevents from a gut dysbiosis observed along with the duration of the GFD, and maintains a constant quantity of beneficial bifidobacteria. Moreover, the administered of OEI in GFD stimulates activity gut microbiota observed ashe increased SCFA production.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0648 EVALUATING GLUTEN IMMUNOGENIC PEPTIDES AS NON-INVASIVE MARKER OF GLUTEN-FREE DIET ADHERENCE IN PAEDIATRIC CELIAC DISEASE

1Gastroenterology And Nutrition, Instituto Hispanico Pediatria, Seville/Spain
2Departamento de Microbiología y Parasitología, Facultad de Farmacia, Universidad de Sevilla, Sevilla/Spain
3Servicio De Análisis Clínicos., Hospital Universitario INGESA de Ceuta, Ceuta/Spain
4Biomedal, Seville/Spain

Contact E-mail Address: alfonsoerodriguez@chppediatrica.com

Introduction: Treatment for celiac disease (CD) is a lifelong strict gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods
A total 167 children were diagnosed to have new onset celiac disease resolution of intussusception. Focal GIP was quantified by enzyme-linked immunosorbent assay (ELISA). Anti-tissue transglutaminase (anti-TG) IgA and anti-deamidated gliadin peptide (anti-DGP) IgA antibodies were measured simultaneously, during basal and follow-up visits at 6, 12, and 24 months. Correlations between fecal GIP and serum antibodies were established by Cochran’s and Friedman tests. Results: 62 patients (97%) had detectable GIP levels in stools, during basal visit, before initiation of the GFD, whereas 20.3% of the patients were found to have positive GIP after treated with a GFD. Dietary transgressions were more frequent in 21 (52%) of the patients than 28 (68.2%) of them showed more than one detected transgression. Anti-TG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP was positive in 13, 4.5 and 0% of cases when tested at 6, 12 and 24 months follow-up. Both serological methods did not correlate with GIP in stools (p < 0.05).

Conclusion: The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of compliance of traditional serological methods to verify GFD compliance in celiac patients. The antibodies can be measured several months or even years to decrease after initiation of the GFD and reduction (but incomplete suppression) of gluten intake. However, the GIP test can be used as a confirmatory tool for celiac patients who are suspected to have celiac disease in sera. Fecal GIP could be a useful tool: 1) on the diagnosis of CD, to ensure that a sufficient amount of gluten has been ingested to allow a correct CD diagnosis. 2) on treatment, for monitoring of short-term and long-term GFD compliance. 3) on the differential diagnosis of GFD versus disorder non-compliance.

P0652 CLINICAL SIGNIFICANCE OF TRANSFORMING GROWTH FACTOR - βI AND TUMOR NECROSIS FACTOR - β IN CHILDREN WITH FOOD PROTEIN INDUCED ENTEROCOLITIS SYNDROME

O. T. Kamilova1, A. A. Iripova2, S. S. Sultanakhodjaeva1, S. V. Geller2, D. X. Dustumaxedova2, Z. S. Xuudoryorova2, M. Rustamova2

Contact E-mail Address: okamilova@mail.ru

Introduction: Nowadays food allergy continues to increase, especially in westernized countries and is now recognized as a worldwide problem. Transforming growth factor-βI (TGF-βI) is a profibrotic cytokine, which plays an important role in promoting the structural changes in food allergy. Also for patients with food protein induced enterocolitis syndrome TNF-α appears to have an important role.

Aims & Methods: The aim was to determine the significance of Transforming Growth Factor - βI (TGF - βI) and Tumor Necrosis Factor - α (TNF - α) in children with food protein induced enterocolitis syndrome. It was examined 38 patients with FFIES at the age from 4 months to 3 years, the average age was 19 ± 4 months. The control group consisted of 11 healthy children of the same age. The determination of TGF-βI and TNF-α in serum was performed by an enzyme immunoassay kits from Bender Medsystems (Austria).

Results: The level of TGF-βI in patients with FFIES exceeded the norm and was respectively 33.5 ± 1.6 mg/l at norm 20.2 ± 2.1 mg/l p < 0.001. The indices of TNF-α were also increased and amounted to 8.8 ± 1.3 mg/l in comparison with the control group p < 0.001. For statistical significance it was characterized by an increase in specific antibodies IgE to cow’s milk in 18 (47.3%) children. In these patients in comparison to healthy children, there was an increase in specific antibodies IgE to egg and fish. It is believed that TGF – β1 and TNF – α play an important role in promoting the structural changes in food allergy. Also for patients with food protein induced enterocolitis syndrome TNF-α appears to have an important role.

Discussion: The increase in specific antibodies IgE to milk in children with food protein induced enterocolitis syndrome and the increase in TNF-α in serum are associated with the development of food protein induced enterocolitis syndrome.

3Genetics, University of Medicine and Pharmacy Tirgu Mures, Targu Mures/Romania

Contact E-mail Address: marginean.oana@gmail.com

Introduction: Newborn's birth weight is influenced by maternal factors (mother's weight at the onset of pregnancy, gestational weight gain - GWG), genetic, obstetrical and environmental factors, but also socio-economic ones. Even if GWG, mother’s increased BMI and the adipose tissue mass determine a bigger birth weight and increase the risk of newborns' obesity. Glutathione S-transferases (GSTs) is an oxidative stress-related gene which is associated with and with these complications.

Aims & Methods: The aim of the study was to investigate the role of mother-child interaction of GSTs & GTM1 polymorphisms as independent risk factors for newborn's weight, but also to establish correlations between these polymorphisms and anthropometrical parameters, and biompeidance (BIA) ones, respectively. We have assessed the anthropometrical parameters in both mothers and their newborns (BMI- body mass index, MUAC – medium upper arm circumference, TST – tricipital skin thickness, weight - W), BIA parameters in mothers, but also we determined the clinical, paraclinical and genetic parameters in both mothers and newborns.

Methods: We performed a cross-sectional study on 202 mothers and their newborns in a Clinic of Neonatology & Gynecology and Obstetrics from Romania.

Results: We noticed that in newborns with W > 3000 gr there was a significant statistical correlation between weight and mother’s GSTT1 polymorphism (p = 0.046), birth at term (p < 0.001), with mother’s percentage of fat mass assessed by BIA (p < 0.001), and multi parity, respectively (p < 0.001). We obtained a tendency towards correlations between W > 3000 gr and basal metabolism rate (p = 0.006), and GWG seemed to be a protective factor for this W (p = 0.072). We also found that GSTM1 in newborns was a risk factor with tendency towards statistical significance in newborns with increased birth weight. We did not find any interaction effect between newborns' and mothers' GST1 and GSTM1 polymorphisms and anthropometrical parameters (p = 0.545 for M1 and 0.664 for TST in clinical parameters).

Discussion: Mother’s GSTM1 is an independent risk factor for newborns’ W > 3000 gr, while mother’s GWG seems to be a protective factor for W > 3000 gr. Further studies are needed in order to determine the clear role of these polymorphisms in newborns’ obesity risk. This research was supported by the Research Grants of the University of Medicine and Pharmacy Tireg Mures, Romania - "The role of genetic determination of the mother in child's obesity correlated with measurements of bioimpedance and anthropometry" no.275/4/11.01.2017.

Introduction: Our study population included 87 children aged 6–17 years conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study included 87 children aged 6–17 years in a group of Romanian children. We conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study population included 87 children aged 6–17 years in their quality of life and dairy intake. In clinical practice only half of people with PLI have symptoms. However, some studies showed that PLI subjects have lower trends. It did not influence quality of life and dairy intake.

Results: 35 (51.7%) subjects had a CC genotype, 30 (43.5%) subjects had a GA genotype. Our results were consistent with the data from Hardy-Weinberg equilibrium. We found no correlation between homogeneity of PLI and dairy intake (CC: r = 0.06, p = 0.54; GG: r = 0.01, p = 0.06). We found no correlation between either CC, or GG homogeneity and quality of life (r = -0.11, p = 0.3). In conclusion, our group genetic predisposition to PLI followed European trends. It did not influence quality of life and dairy intake.

**P0657 HEPATIC FIBROBLAST GROWTH FACTOR-21 AND OMENTIN-1 mRNA LEVELS IN MORBIDLY OBSESE WOMEN WITH NON-ALCOHOLIC FATTY LIVER DISEASE**

M. Kukla1, M. Waluga1, M. Zorniak2, M. Kajzer1, L. Liszka1, M. Dyaczynska1, G. Kowalski3, R.J. Buldak1, M. Hartleb1

1Medical University of Silesia, Katowice/Poland
2Department Of Gastroenterology And Hepatology, Medical University of Silesia, Katowice/Poland
3Medical University of Silesia, Bytom/Poland

Introduction: Fibroblast growth factor-21 (FGF21) and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGF21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGF21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminating power for FGF21 serum level in differentiation between more and less severe steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGF21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGF21 and omentin-1 mRNA levels (r = 0.73, p < 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (r = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In conclusion our study, which focused on hepatic FGF21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by metabolic and histopathological abnormalities. In severely obese patients with NAFLD we observed evidence for the role of FGF21 and omentin-1 RNA expression as a potential biomarker of advanced liver disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Dushay J, Chui PC, Gopalkrishnan GS, et al. Increased fibroblast growth factor 21 in obesity and nonalcoholic fatty liver disease. Gastroenterology 2010; 139 (2): 456-463 [PMID: 20451522 PMCID: PMC4682667 DOI: 10.1053/j.gastro.2010.04.054]
(HSCs), which were separated from Sprague-Dawley rat, were treated with differ-
entially lutein B and TGF-β1 such of steatohepatitis. HSCs proliferation, western blot were used to test the expressions of Frizzled-4 receptor protein and α-SMA. In addition, enzyme-linked immunosorbent assay (ELISA) was performed to measure the content of α-SMA, TGF-β1 and VEGF in the treated HSCs supernatant, and reverse-transcription PCR (RT-PCR) were utilized to detect the expressions of Frizzled-4 and α-SMA genes.

Results: MTt test showed that the proliferation of HSCs was inhibited signifi-
cantly with a time and dose dependent relationship by the treatment of lutein B and TGF-β1, with inhibitory concentrations of α-SMA (IC50 = 0.180g/l). Western blot analysis showed that the expressions of Wnt receptor Frizzled-4 protein and α-SMA were obviously lower in the group of lutein B treatment than that in the control group. Moreover, the Lutein B and TGF-β1 treatment increased the expressions of Frizzled-4 and α-SMA genes in the level of mRNA.

Conclusion: The Lutein B mediated anti-hepatic fibrosis by inhibiting the proliferation of HSCs through restraining the Wnt signaling pathway.

P0659 MACROPHAGE CONTRIBUTES TO STEATOHEPATITIS THROUGH MEDIATING INFLAMMATORY CYTOKINES, AUTOPHAGY AND THE CROSSTALK WITH HEPATOCYTES

J.K.C. Lau1, X. Zhang2, E.S. Chu2, J. Yu2
1Faculty Of Medicine, Shoho College, the Chinese University of Hong Kong, Hong Kong
2Marburg, Germany

Contact E-mail Address: jennie.lau@outlook.com

Introduction: Macrophages play a pivotal role in the pathogenesis of non-alco-
holic steatohepatitis (NASH) and are a major component of inflammatory cells in-
filtrated in NASH. However, the precise mechanism of how macrophages contribute to the pathogenesis of NASH remains unexplored.

Aims & Methods: We aimed to characterize the role and molecular regulators of macrophages in NASH and the therapeutic efficacy of macrophage depletion on NASH. C57BL/6 wildtype (WT) mice and transgenic macrophage depletion model mice by injecting liposomal clodronate-treated WT mice and DTox-treated MCD diet, concomitant with significantly enhanced hepatic macrophage infiltration as indicated by F4/80 staining. Macrophage depletion by liposomal clodronate-treated WT mice and DTox-treated mice were further evaluated in human cells using a FXR reporter assay. Assessment of FXR-depen-
dent gene and protein expression was analyzed upon incubation of primary mouse hepatocytes and HepG2 cells with selected BA derivatives. In parallel, BA derivatives were co-incubated with oleic and palmitic acids (2:1) for assess-
ment of cellular cytotoxicity and intracellular lipid accumulation.

Results: From the compound library, five BA derivatives showed stronger activa-
tion of FXR, comparing with their natural precursors. Incubation of HepG2 cells with BA derivatives led to a ~25% reduction in cell viability and ~75% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented Fxr-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly induced FXR, RXR, SHP, BSEP, FGF19 and VLDLR mRNA levels, and repressed PARP1, LXR, SREBP1-c and CYP7a1 mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to Fxr. Furthermore, chenodeoxycholic acid and its oxo analogs as well as oxo analogs of non-cholic acid BA derivatives were identified as activators of FXR at lower concentra-
tions comparing with the parent molecule.

Conclusion: In conclusion, we identified novel BA derivatives that directly modu-
late liver nuclear receptors, such as Fxr and Lxr, thus protecting liver cells from lipid accumulation and reducing cell death. BA derivatives may be used as scaffolds for the development of targeted therapies for NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is considered the hepa-
tic manifestation of metabolic syndrome, with simple liver steatosis being capable of gradually progressing to inflammation, fibrosis, cirrhosis and even hepatocel-
lar carcinoma. Still, disease pathogenesis is complex and no targeted therapies have yet been approved for NAFLD. Bile acids (BAs) constitute a wide class of steroid molecules with pleiotropic functions, contributing to the homeostasis of lipids and glucose. In the liver, they specifically modulate nuclear receptors from the NR1 subfamily, such as Farnesoid X Receptor (FXR) and Liver X Receptor (LXR), thus tightly regulating bile acid synthesis and oxidation and storage of triglycerides.

Aims & Methods: Our aim was to screen BA derivatives for their potential to selectively activate FXR, thus protecting liver cells against free fatty acid (FFA)-

P0661 DISSECTING AUTOPHAGY IN A NAFL/NASH MOUSE AND HUMAN MODEL

Introduction: NAFLD is currently classified in non-alcoholic fatty liver (NAFL) and non-alcoholic steatohepatitis (NASH). It is a liver disease related to meta-
obolic syndrome with rising socio-economic impact worldwide. NAFLD is defined by significant lipid deposition in hepatocytes that is unrelated to alcohol con-
sumption. This high prevalence of liver disease occurs after a protracted inflam-
matory state caused by innate immune responses (TGF-β1 and LXRR), which are triggered by consumption of fructose-rich goods as shown by the multi-parallel hit theory. Autophagy is a self-digesting mechanism that helps the cells to overcome stress conditions derived by nutrient deprivation and massive storage, e.g. lipid and proteins. Autophagy dysfunction has been implicated in lipid accumulation related dis-
cases. Up to now, it is yet fully understood the role exerted by autophagy in liver diseases not related to alcohol.

Aims & Methods: Here, autophagy has been analyzed in a mouse model of NAFL/NASH and in human in vitro model. Liver specimens were collected from 24 weeks old FLS and FLS-ob/ob mice. Liver tissue was snap frozen and kept at −80°C. RNA and proteins were isolated. RT-qPCR and western blotting was performed. HepG2 cells were incubated for 24h with 2 mM oleic acid (OA)
Disclosure of Interest:

miRNAs targeting mitochondrial proteins during NAFLD may help in the development of targeted therapies for NAFLD. For example, miR-34a has been shown to inhibit the expression of Mfn2, a protein involved in mitochondrial fission. A better understanding of the network of miRNAs targeting mitochondrial proteins during NAFLD may help in the development of novel targeted therapies for metabolic diseases associated with mitochondrial dysfunction. (Supported by TDT-BIC-MEC/089/2014, SF-1115/13, FCT, and Gilead Sciences International Research Scholars Program 2015)
mononuclear layer containing stem cells is a novel approach for regeneration of liver in patients with alcoholic liver cirrhosis. Therapeutic options are not constant and require repeated PBMC transplantation.

**Aims & Methods:** To determine the outcome after intrasplenic or intrahepatic injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronically hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; Group I: 20 patients underwent (ABMSC) injected intrasplenic. Group II: consisted of 20 patients underwent (ABMSC) injected intrahepatic after trans differentiation into hepatocytes with the double amount of growth factor. Group III: 10 control patients underwent (ABMSC) injected intrahepatic; after trans differentiation into hepatocytes with the double amount of growth factor. Group III (Control Group); consisted of 20 patients received traditional supportive treatment for chronic hepatitis C, and MELD score and performance status.

**Conclusion:** There was improvement in serum albumin, ascites, lower limb edema, and hepatic accumulation of fat by the 3rd month and this was maintained till the end of the study. Fatigue improved in all patients who had ABMSC. There was improvement in serum albumin, ascites, lower limb edema, bleeding tendency and physical activity. Also there was improvement in MELD score and performance status.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0665 PERIPHERAL BLOOD MONONUCLEAR CELL TRANSPLANTATION STIMULATES HEPATOCYTES PROLIFERATION IN PATIENTS WITH ALCOHOLIC LIVER CIRRHOSIS

3Department Of Pathological Anatomy With Course Of Forensic Medicine, Ryazan State Medical University, Ryazan/Russian Federation

**Contact E-mail Address:** guzel.burganova@gmail.com

**Introduction:** It is well known that severe liver disease requires a liver transplantation to be treated. But liver transplantation is not available in many countries. Autologous bone marrow is a bank of therapeutic stem cells which can stimulate liver regeneration. Proliferating cell nuclear antigen (PCNA) shows nuclei of dividing cells and may be useful for calculating proliferation index.

**Aims & Methods:** The aim of this study was to evaluate changes of proliferation intensity of liver cells in patients with alcoholic liver cirrhosis after autologous peripheral blood mononuclear cell (PBMC) transplantation. This uncontrolled open-labeled clinical trial was approved by Ethical committee of Ministry of Health of the Republic of Tatarstan, Russia. Eleven patients took part in the study, they received granulocyte colony-stimulating factor injections for 5 days for PBMC mobilization. On the 6th day PBMCs were collected and injected into the celiac trunk. Liver biopsies were obtained three times from each person on not less than 6 months before transplantation of PBMCs into the celiac trunk (initial), three and twelve months after the procedure. Liver biopsy specimens were embedded in paraffin and stained immunohistochemically with antibodies against PCNA. The PCNA labeling index was calculated as the number of PCNA-labeled nuclei for 1000 hepatocyte nuclei in each specimen and the results were expressed as percentage ratios. Statistical analysis was done by Wilcoxon signed-rank test using Statistica v.12 software. p value < 0.05 was considered significant.

**Results:** Before the transplantation of PBMCs 28.3 ± 18.3% of all the hepatocytes expressed PCNA without any topographic prevalence. Three months after the transplantation the proportion of proliferating hepatocytes increased up to 36.7 ± 24.8%. Twelve months after transplantation of PBMCs we found hepatocytes proliferation to be 2 times higher than before the procedure. Proportion of proliferating hepatocytes reached 50.2 ± 17.0% (p = 0.04). Great increase in hepatocytes proliferation intensity coincided with biochemical improvements of serum bilirubin, ALT and alkaline phosphatase.

**Conclusion:** Our study showed that proposed treatment was safe and effective. We can conclude that after transplantation of autologous PBMC s proliferation of hepatocytes greatly contributes to the liver regeneration and improvement of blood biochemical data in patients with alcoholic liver cirrhosis. However, effect of this treatment is not constant and requires repeated PBMC transplantation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0666 ASSOCIATION BETWEEN NONALCOHOLIC FATTY LIVER DISEASE AND METABOLIC SYNDROME IN APPARENTLY HEALTHY KOREAN ADULTS

K.M. Sohn1, Y.J. Jeon2

1Gastroenterology, Hansol Hospital, Seoul/Korea, Republic of
2MedGene Lab, Seoul/Korea, Republic of

**Contact E-mail Address:** dr.sohnkm@gmail.com

**Introduction:** The prevalence of non-alcoholic fatty liver disease (NAFLD) has increased and several studies have shown that there is an association between NAFLD and insulin resistance (IR). The aim of this study was to determine how much impact the risk factors of metabolic syndrome have on ultrasoundographic fatty liver, especially NAFLD.

**Aims & Methods:** A total of 41,258 adults who underwent routine comprehensive health check-ups, including abdominal ultrasonography, were selected. We calculated the adjusted prevalence ratios (PRs) for components of MetS (high blood pressure, impaired fasting glucose, low high-density lipoprotein cholesterol, hypertriglyceridemia) according to NAFLD.

**Results:** NAFLD was found in 13.8% of non-obese subjects and 52.3% of obese subjects. NAFLD was associated with most components of MetS in both obese and non-obese subjects. However, non-obese NAFLD patients had significantly higher PRs for certain components of MetS than did obese patients, especially among women. Body mass index, waist circumference, fasting blood glucose, triglyceride, HDL-C and aspartate aminotransferase, alanine aminotransferase, γ-glutamyl transpeptidase levels all affected NAFLD independently. The prevalence of metabolic syndrome was increased in mild (40.8%) and moderate (57.8%) NAFLD groups. When odd ratio (95% CI) for NAFLD group was compared to the contrast group, there was an increased risk of metabolic syndrome with odd ratio of 12.8 (95% CI, 9.1–17.0).

**Conclusion:** NAFLD and its components was a strong correlation with MetS and also with each risk factors of MetS. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0667 LEAN-NAFLD IS THE STRONGEST PREDICTOR OF FUTURE OBESITY AMONG URBAN ADULT SRI LANKANS: RESULTS FROM A PROSPECTIVE, COMMUNITY CORHORT FOLLOW-UP STUDY

**Contact E-mail Address:** madunilin@yahoo.co.uk

**Introduction:** Obesity is a global problem. Data from the Asian region is limited.

**Aims & Methods:** In a cohort follow-up study we investigated obesity among urban, adult Sri Lankans [selected by age-stratified random sampling from Ragama-MOH area, Gampaha District; initial screening 2007 (aged 35–64 years); re-evaluation 2014 (aged 42–71 years)]. On both occasions structured interview, anthropometry, liver ultrasound, biochemical and serological tests were performed. Total body fat (TFB) and visceral fat percentage (VFP) were assessed by impedance in 2014. General obesity (GO) was BMI > 25 kg/m². Central-obesity (CO) was waist circumference (WC) > 90 cm males and WC > 80 cm females. Non-alcoholic fatty liver disease (NAFLD) was diagnosed on ultrasound criteria, safe alcohol consumption and absence of hepatitis B/C markers. Multinomial logistic regression was fitted to assess associations.

**Results:** In 2007 (n = 2967), 614(20.7%) were overweight [51.9% women], 472(15.8%) had obesity [43.9% women] and 1584(53.3%) were normal weight [57.8% NAFLD groups. When odd ratio (95% CI) for NAFLD group was compared to the contrast group, there was an increased risk of metabolic syndrome with odd ratio of 12.8 (95% CI, 9.1–17.0).

**Conclusion:** Adult obesity was a strong correlation with MetS and also with each risk factors of MetS. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0668 THE USE OF THE FATTY LIVER INDEX TO DETERMINE THE PREVALENCE OF FATTY LIVER DISEASE (HEPATIC STEATOYSIS) IN AN IRISH POPULATION

L. Reynolds, L. Rabbbt, C. Goulding
Acute Medical Unit, University Hospital Galway, Galway/Ireland

Contact E-mail Address: laurar3eynolds@gmail.com

Introduction: Worldwide, the prevalence of fatty liver disease (FLD) is increasing, particularly in countries with rising obesity rates, such as Ireland. Studies suggest that up to 25% of those with FLD can progress to non alcoholic steatohepatitis (NASH) and be at risk of its sequelae, including cirrhosis and hepatocellular carcinoma. Indeed, NASH is now the second most common indication for liver transplantation in the US. Despite this alarming data, there is no prevalence data for Ireland in relation to FLD.

Aims & Methods: We aimed to use a simple screening tool, the Fatty Liver Index (FLI) to identify those at risk of having fatty liver disease (FLD) amongst all comers presenting to an Acute Medical Unit (AMU) and to use this data as an indicator of prevalence of FLD in Ireland.

Methods: In this prospective cohort study, all patients attending the Acute Medical Unit (AMU) were invited to take part. Their height, weight and waist circumference were measured, and triglycerides (TG) were added to their ‘routine AMU blood panel’, which also included measurement of gamma glutamyl transpeptidase (GGT). Exclusion criteria were as follows: known liver disease, excess alcohol intake (>17 units per week for males, >11 units per week for females), age <18 years, pregnancy, active malignancy. The Fatty Liver Index (FLI), an algorithm based on Body Mass Index (BMI), waist circumference (WC) and TG and GGT was used to stratify patients into groups based on risk of having FLD. A FLI score of >60 is highly suggestive of having FLD, a score of 30-60 is indeterminate and a score of <30 is considered low risk for FLD. Ethical approval for this research was granted by the ethics committee of UHG.

Results: Data was completed on 316 participants; 58 were excluded, the majority due to either a history of alcohol excess or known liver disease. A total of 258 participants were therefore evaluated; 50% were male. One hundred and sixteen (60 on the FLI; 57.3% of which were male. Only 16% of males had a FLI <30, compared with 44% of females. Males had a significantly higher FLI than females; 60.9 vs. 43.12 (p <0.001). Those with FLI >60 had a mean weight =93.5 kg and BMI =31.5, vs. 64.9 kg and 22.4 respectively for FLI <30 (p <0.001). There was a statistically significant difference in all parameters measured between all 3 groups (p <0.001), apart from height, although there was a trend toward lower height in the FLI <30 group, most likely due to the fact that it was 73% female. When older participants were looked at, there was no height difference between the 3 groups. Those with a FLI >60 were older than those with FLI <30, 54.6 vs. 48 (p=0.01).

Conclusion: In this study looking at prevalence of fatty liver in Ireland, 45% of participants were found to be at high risk, and 70% were at high or indeterminate risk. Worryingly, only 16% of males fell into the low-risk group. Apart from weight, GGT, TG and BMI this study also showed age and male sex to be significant risk factors for developing fatty liver. This group clearly needs follow up to further evaluate and manage their fatty liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bisphenol A (BPA) is an endocrine disrupting chemical, a hetero- 
genic group of chemicals usually found in food packaging or insecticide residues on vegetable crops, associated with type 2 diabetes mellitus (T2DM), cardiovascular disease and altered enzyme abnormalities, and in general with the whole blood glucose homeostasis.

Aims & Methods: We have evaluated BPA plasma and urine levels in non-alco- holic fatty liver disease (NAFLD) patients compared to healthy subjects and we evaluated the possibility to eliminate this environmental factor after a BPA-free diet regimen. Furthermore, we evaluated, in human HepG2 cells, the effects of exposure to different BPA concentrations on both oxidative stress induction and cell proliferation. We enrolled sixty patients with histologic diagnosis of NAFLD with or without T2DM, before a BPA-free diet, and healthy subjects, by subject- ing them to evaluation of body composition using bioimpedance analysis. In vitro, the proliferation of BPA-exposed HepG2 cells at two different concentrations (0.025 and 0.055 μM) was evaluated, both at high (H-HepG2), in order to simulate human hyperglycemia, and at low (L-HepG2) glucose concentrations, for 24 hours, as assessed by TRH assay.

Results: BPA levels were significantly higher in 60 NAFLD subjects, both in urine and in plasma (p < 0.0001) if compared to controls and, among this group, it appeared to be higher in 30 non-alcoholic steatohepatitis (NASH) patients compared to 30 simple steatosis (NAFL) ones (p < 0.05), independently from the presence of T2DM. After following a BPA-free diet for one month, NAFLD patients showed a significant reduction of BPA circulating levels (p < 0.05) without a significant reduction of urine levels, which represents the only way to eliminate BPA amount released into circulation by the adipose tissue reservoir. In fact subjects with a higher fat percentage in body composition showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a higher fat percentage in body composition in compar-ison to NAFL ones. Only H-HepG2 was treated with 0.055 μM increased proliferation compared to controls at 48h (p < 0.0001). Moreover, BPA increased TBARS levels at 48h in H-HepG2 cells versus controls.

Conclusion: Our study reveals a possible role of BPA as an environmental factor in the progression of NAFLD, particularly in obese and/or T2DM patients.

Introduction: The clinical implications of non-alcoholic fatty liver disease (NAFLD) are still the topic of debate in human studies. It has been shown that fatty infiltration in pancreas correlates with metabolic risk factors and may represent significant manifestation of metabolic syndrome (MeS) in association with nonalcoholic fatty liver disease (NAFLD). The aim of our study was to determine the association of fatty pancreas (FP) in NAFLD patients with features of MeSand to determine a simple new noninvasive scoring system for FP prediction in NAFLD patients.

Aims & Methods: We conducted across-sectonal study that included 143 subjects with NAFLD classified into two groups according to the severity grade of FP as follows: patients with non fatty pancreas and grade I light FP (n=59) and patients with grade II severely and grade III highly FP (n=84). Patients were analyzed for diagnostic criteria of MeS, underwent sonographic examination with adiposity measurements and liver biopsy. Liver fibrosis was evaluated semi-quantitative according to the META VIR scoring system and using non-invasive markers of hepatic fibrosis (NAFLD fibrosis score (NFS), BARD score, FIB4 score, PI-Mbles-4 score, and APRI score). In this study, the FP was considered if more than the 50% of the pancreas had a fatty content. In this study, we associated MeS with the presence of FP and NAFLD and evaluated the presence of MeS predictive factors in NAFLD.

Results: Of these 143 patients with NAFLD, 84 had criteria for metabolic syn- drome (MeS), while there was no significant difference in frequency among FP groups. Out of all clinical and laboratory characteristics, no statistical differences were demonstrated in demographic and lifestyle factors such as age, gender, body mass index (BMI), systolic and diastolic blood pressure, presence of hypertension and dyslipidemia, values of insulin, high density lipoprotein (HDL) and triglycerides. Waist cir- cumference (WC) showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a significant reduction of BPA circulating levels (p < 0.001) if compared to controls and, among this group, it appeared to be higher in 30 non-alcoholic steatohepatitis (NASH) patients compared to 30 simple steatosis (NAFL) ones (p < 0.05), independently from the presence of T2DM. After following a BPA-free diet for one month, NAFLD patients showed a significant reduction of BPA circulating levels (p < 0.05) without a significant reduction of urine levels, which represents the only way to eliminate BPA amount released into circulation by the adipose tissue reservoir. In fact subjects with a higher fat percentage in body composition showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a higher fat percentage in body composition in compar-ison to NAFL ones. Only H-HepG2 was treated with 0.055 μM increased proliferation compared to controls at 48h (p < 0.0001). Moreover, BPA increased TBARS levels at 48h in H-HepG2 cells versus controls.

Conclusion: Our study reveals a possible role of BPA as an environmental factor in the progression of NAFLD, particularly in obese and/or T2DM patients.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for evaluation of liver histology as a routine pre-transplant checkup before living related liver transplantation. Liver function tests, age, gender, weight, height, fasting plasma glucose, thyroid hormones, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist. The relationship of serum TSH and liver histology was studied with use of antidiabetic agents and the absence of highly fatty pancreas, indicating its potential protective role. Simple new noninvasive scoring system was designed from multivariate logistic regression analysis to estimate the occurrence of severely FP in NAFLD with best ability in the prediction in score values above 6.5.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0672 IDENTIFICATION AND IN SILICO CHARACTERIZATION OF SIX NOVEL GANAB MUTATIONS IN POLYCYSTIC LIVER DISEASE

Introduction: Glucosidase II is part of the functional pathway of co-translational protein translocation and maturation in the endoplasmic reticulum. It is implicated in autosomal dominant polycystic liver disease (ADPLD) and autosomal dominant polycystic kidney disease (ADPKD). The β-subunit of glucosidase II, encoded by PRKCSH, has been identified as one of the causative genes of ADPLD. Recent data suggest that the α-subunit of glucosidase II (GIIa), encoded by GANAB, is associated with ADPKD and ADPLD. We aimed to identify GANAB mutations in an independent cohort of patients with the primary phenotype of polycystic liver disease (PLD) and to predict the influence of these mutations on glucosidase II function.

Aims & Methods: We identified genetic mutations in GANAB using molecular inversion probe (MIP) analysis in a cohort of PLD patients. Both patients with ADPKD and ADPLD were included for analysis. Mutations identified with MIP analysis were validated using Sanger sequencing. Bioinformatics prediction tools (PolyPhen-2, Align GVGD, SIFT, MutationTaster) were used to predict the functional significance of the mutations. YASARA/WHAT IF were used for analysis of the structural effects of the mutations. Primary cholangiocytes obtained from a patient with GANAB mutation (c.2515C > T) were used to study loss of heterozygosity.

Results: We identified and validated 6 novel bona fide GANAB mutations in 7 patients (c.3306delT and c.11_16delTAGCGG, 1 splicing (c.2691-28C > G), 2 nonsense (c.2509C > T and c.2565C > T) and 1 missense (c.1835G > C) mutation. In silico analysis showed c.687delT and c.11_16delTAGCGG are located in N-terminal domain of the protein. These mutations probably lead to a total defective protein. c.1835G > C is located in the active site of the protein. It is predicted to disrupt the composition of the active site and reduce enzymatic activity. The remaining mutations (c.2691-28C > G, c.2509C > T and c.2565C > T) are located in Internal Caspases domain, which interacts with PRKCSH. The mutations could result in early termination of this domain. It is speculated this disrupts the ability of the two subunits to interact. Western Blot showed no differences in Glucose expression in an ADPKD patient with GANAB mutation (c.2515C > T) compared to primary cholangiocytes obtained from a patient without PLD. This indicates in this patient no loss of heterozygosity occurs in cholangiocytes lineaging the hepatic cysts.

Conclusion: We describe six novel GANAB mutations that can cause PLD in a mixed population of ADPKD and ADPLD patients. These mutations are found in functionally important domains of α-subunit of glucosidase II, which may lead to impaired enzymatic activity of the complex. In contrast to other PLD related genes no loss of heterozygosity was found for GANAB in cyst epithelium.

Introduction: In patients with morbid obesity, dietary treatment and physical activity are the first line of treatment, but if not responding, bariatric surgery is the only validated alternative. The main surgical procedures are: restrictive gastric surgery (SG) and gastric by-pass (GBP), and they are chosen in function of BMI, age and comorbidity. Both techniques have proven effective in weight loss. It is known that liver fibrosis evaluation with Point Shear Wave Elastography (pSWE) is not effective in these patients.

Aims & Methods: To study the difference between SG and GB and their impact on main clinical and laboratory hepatic metabolic indicators and scores 6 and 12 months after the intervention and pSWE at 12 months. We studied 68 obese subject candidate to bariatric surgery (45 female, 23 male). 28 underwent GBP and 40 SG. Blood tests, physical examination were assessed before surgery, after 6 months (68 patients) and after 12 months (51 patients) and pSWE after 12 months.

Results: In the comparison between GBP vs SG there was a statistically significant difference in the reduction in Fatty Liver Index (61% vs 37%, p = 0.015), waist circumference (26% vs 18%, p = 0.045), BMI (34% vs 28%, p = 0.016), total cholesterol (23% vs 8%, p = 0.05), ALP (increased by 15% in GBP, decreased by 27% in SG, p = 0.023) while no differences were observed in the other indicators considered. Ferritin level increased (52%) in SG and decreased by 27% in SG, p = 0.02). No difference was observed for pSWE.

Conclusion: This study showed some significant differences in clinical and labora- tory terms between the two types of intervention, in fact GBP seems to have a more powerful effect on weight loss and all related markers: all steatosis scores (FLI, HSI, LAP), BMI, waist circumference. This can be explained by better malabsorptive effect of this intervention and by a lower BMI starting point for reasons related to the intervention technique.

3Medical Gastroenterology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki/Japan

Purpose: To compare liver volume in ADPKD and ADPLD patients and to identify new risk factors.

Methods: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 ADPKD, 112 ADPLD) could be selected. In the ADPKD group, 355 ADPKD patients were included and adjusted liver volume was measured prior to liver reducing therapy. The ADPLD group included 112 patients. In all patients, height adjusted total liver volume was measured.

Results: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 ADPKD, 112 ADPLD) could be selected. In the ADPKD group, 355 ADPKD patients were included and adjusted liver volume was measured prior to liver reducing therapy. The ADPLD group included 112 patients. In all patients, height adjusted total liver volume was measured.

Conclusion: In this cohort more ADPLD patients had moderate to severe PLD compared with the ADPKD group.

P0675 CARDIOVASCULAR RISK MODEL DEVELOPMENT FOR THE (ATYPICAL) PATIENT WITH NON-ALCOHOLIC FATTY LIVER DISEASE

M.A. Munteanu1, G. Nagy2, M. Gordan3, S. Valeanu3, P. A. Mirea2
1Internal Medicine, University of Oradea, Faculty of Medicine and Pharmacy, Oradea/Romania
21st Medical Clinic, University of Medicine and Pharmacy "Juliu Hatieganu" Cluj-Napoca, Cluj-Napoca/Romania
3The Technical University of Cluj-Napoca, Cluj-Napoca/Romania

Purpose: To develop a risk model for cardiovascular diseases in patients with non-alcoholic fatty liver disease (NAFLD) affecting about 1 billion people worldwide. Those with non-alcoholic steatohepatitis (NASH) among NAFLD patients have increased mortality rates compared to the general population, with cardiovascular diseases being the leading cause of death.

Methods: All patients with NAFLD and metabolic syndrome (MS) were 2:1 weighted. The non-alcoholic fatty liver disease (NAFLD) patients were identified using a combination of medical history, physical examination, blood tests, and ultrasound imaging.

Results: We included 95 patients with NAFLD, from which 53 were with MS and 42 were without MS. In all patients with NAFLD, with and without MS, there was a correlation between the value of intima-media thickness and the presence of NASH (p = 0.025), the degree of steatosis (p = 0.027) and the severity of fibrosis (p < 0.001). Patients with NAFLD and MS had higher values of lpa and npti compared with those with NAFLD, but without MS (p = 0.002).

Conclusion: In all patients with NAFLD, there was a correlation between the presence of lpa and npti and the level of total cholesterol (p = 0.438), LDL cholesterol (p = 0.505), HDL-cholesterol (p = 0.438), and triglycerides (p = 0.911) were not correlated with the presence of lpa, nor on the entire group of patients or on each arm. In a logistic model for the risk of developing lpa, we included presence of NASH, the grade of steatosis, the stage of fibrosis, body mass index, abdominal circumference and creatinine clearance level. In this model, the stage of fibrosis has been shown to be a predictor with a positive effect on the presence of lpa (p = 0.004, adjusted OR = 7.19, CI[1.86;27.72]). This model correctly classified 90.9% of patients with lpa and 91.7% of patients without lpa.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Aim of our study was to compare two non-invasive methods: fibrosis on serum markers and transient elastography (TE). We included 152 patients with NAFLD, 40 males (26.31%) and 112 females with age from 23 to 79 years.5 patients (23.02%) were overweight, 9 patients had normal weight and 24 (15.79%) had severe obesity. In all patients we calculated fibrosis scores: BARD, FIB-4 and NAFLD fibrosis score (NAFLD-FS). Blood samples were collected to determine aminotransferases, glucose, albumin level, platelet count. The abdominal ultrasonography was performed by the same physician and was graded using a semi-quantitative scale of 0 (no fibrosis), 1 (mild), 2, 3, 4, 5. TE was, also, performed by a single physician using a conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when estimated cutoff of F2 was 7.1 kPa, severe fibrosis (F3) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value >12.5 kPa.

Results: 86.84% patients had metabolic syndrome and 51.31% had diabetes mellitus.40 patients had mild steatosis, 59 had moderate and 53 had severe steatosis. After we performed TE 69.07% of patients had no significant fibrosis, 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95% CI: 0.771–0.874). Sensibility and specificity for cutoff 7.1 kPa was 0.74 respectively 0.79 to exclude significant fibrosis. NAFLD-FS correlated stastic significant with TE (p < 0.0001). BARD score did not correlate with TE and NAFLD-FS for significant fibrosis.FIB-4 correlated with TE for high degree P0679 EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) ON MORTALITY AND COMPLICATIONS VIZ. SEPSIS, ENCEPHALOPATHY, HEPATORENAL SYNDROME, AND GASTROINTESTINAL BLEED IN SEVERE ALCOHOLIC HEPATITIS: A RANDOMIZED CONTROLLED STUDY A. Sharma Gastroenterology and Hepatology, Fortis Escorts Hospital Jaipur, Jaipur/India Contact E-mail Address: aabhinav__11065@yahoo.com Introduction: Severe alcoholic hepatitis has very high short-term mortality. Compared to standard medical therapy (SMT), GCSF improves clinical and biochemical profiles, morbidity and mortality in these patients. We evaluated efficacy of G-CSF in modifying the disease course of severe alcoholic hepatitis over a period of 3 months in terms of mortality, morbidity by Discriminant function (mDF), Child-Turcotte-Pugh (CTP) and Model for End-Stage Liver Disease (MELD) score in patients with severe alcoholic hepatitis. 50 patients with severe alcoholic hepatitis were randomly assigned to groups A and B (25 in each). Both groups were given SMT, while in addition, patients in group A were given 5μg/kg GCSF subcutaneous (10 doses for 5 days). We assessed survival, changes in CTP, MELD and mDF scores and the development of complications till 90 days.

Results: The baseline parameters in both groups were comparable. On day 6 group A had higher mean leukocyte and CD34 counts than group B (P < 0.05). On 90 days follow up 17 patients in group A (68%) and 9 group B (36%) survived (P = 0.04). Mean changes for different scores were greater in group A then group B i.e. CTP (-41.97% vs -8.84%), MELD (-50.89% vs 10.09%) and mDF (-74% vs 18%) (P < 0.01). The percentages of patients who developed HRS, HE, or sepsis were lower in group A than in group B (28% vs 64%, 32% vs 64%, and 28% vs 68%, respectively) (P < 0.01). There was no significant difference in GI bleed in both groups.

Conclusion: In severe alcoholic hepatitis, GCSF therapy significantly improves the survival. It also significantly reduces CTP, MELD, and mDF scores and prevents the development of complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Steatosis/steatohepatitis is one of the most common liver diseases with increasing prevalence and results from excessive alcohol consumption (alcoholic liver disease) or nonalcoholic fatty liver disease (NAFLD). The differential diagnosis is of paramount importance as they have different management and therapeutic approaches, being liver biopsy the gold standard for establishing the diagnosis. The distinction between these two entities without biopsy is
difficult due to the unreliable history of alcohol consumption and lack of sensibility in a single marker. However, to overcome these difficulties, a ANI (alcoholic liver disease/nonalcoholic fatty liver disease index) was created for a non-invasive determination of fatty liver diagnosis.

Aims & Methods: The aim of this study was to evaluate the reliability of ANI as a non-invasive diagnostic tool for NAFLD from ALD. A retrospective study between 2010 and 2015 in patients with definite diagnosis of NAFLD and ALD based on clinical, biochemical and histological criteria was performed. ANI scoring system in the differentiation of ALD and NAFLD was evaluated through the area under receiver operating curve (AUROC). ANI score was calculated through Mayo Clinic formula.

Results: This study was carried out in 22 patients with ALD and 120 with NAFLD, 87 men (61.3%) with a median age of 51 ± 13 years. NAFLD patients presented with a body mass index (BMI) of 29.0 ± 5.9 vs 23.9 ± 6 in ALD. ANI showed a sensitivity of 81% and specificity of 79% for the diagnosis of ALD with a cut-off value of −1.96 [AUROC 0.806 (0.715-0.898), p < 0.001]. ANI greater than −1.96 indicates a diagnosis of ALD whereas ANI less than −1.96 indicates the likelihood of NAFLD.

Conclusion: ANI scoring system is a non invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for live biopsy. ANI greater than −1.96 suggests the diagnosis of ALD and ANI lesser than −1.96 suggest NAFLD.

Introduction: Alcohol consumption is an accepted phenomenon in Western society, although harmful effects of excessive alcohol intake on health have been widely shown. Alcohol has a direct toxic effect on the liver, potentially leading to steatohepatitis and eventually liver fibrosis and cirrhosis. Excessive use is furthermore associated with obesity, hypertension, hypercholesterolemia and diabetes. Cessation of alcohol may reverse these effects to some degree. The biological effects of short-term abstinence from moderate alcohol consumption are not known.

Aims & Methods: A prospective interventional study in 16 healthy moderate drinkers (≤3 units alcohol/day or 21 units/week) who discontinued alcohol use for one month. Nine complete abstainers served as a control group. In both groups an extensive health evaluation was performed at three time points: at baseline (T0), at cessation (T1) and after one month of resuming alcohol intake (T8). Outcomes consisted of morphometrics (blood pressure, body mass index and body impedance analysis), transient and shear wave elastography to assess the liver’s stiffness, computer assisted liver volumetry and liver fat. A blood panel consisted of liver enzymes, cholesterol, glucose and iron metabolism and inflammatory parameters. Several quality of life components were assessed with VAS scales.

Results: The intervention and control group were comparable on baseline in terms of age, gender and morphotomics. Prior to intervention the participants consumed on average 10.4 ± 4.5 units alcohol/week and when they resumed alcohol use, an average of 12.4 ± 5.1 units/week. During the intervention period, complete cessation was ascertained by blood parameters. Liver stiffness and liver fat percentage did not differ between both groups nor change within period, complete cessation was ascertained by blood parameters. Liver stiffness consumed on average 10.4

P0682 PROBIOTICS REDUCE ETHANOL-INDUCED HEPATIC INJURY BY MODULATING GUT MICROBIOTA AND INTESTINAL BARRIER INTEGRITY IN MICE
Y. Zhang, G. Chen, J. Sun
Gastroenterology, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: xiaowanzi@163.com

Introduction: Gut-liver axis plays an important role in the pathogenesis of ALD. The metabolic products of intestine enter the blood through the damaged intestinal barrier and cause hepatic injury. Nowadays, probiotics have been used in the prevention and treatment of a variety of diseases, including ALD. It has become a hot spot for the study of regulating intestinal micro ecological balance and enhancing intestinal barrier function, to prevent alcoholic liver injury. In this study, ALD mice were given probiotics to observe the protective effects on ALD and explore the possible mechanism.

Aims & Methods: Gut-liver axis plays an important role in the pathogenesis of ALD. The metabolic products of intestine enter the blood through the damaged intestinal mucosal barrier and cause liver damage. Nowadays, probiotics have been used in the prevention and treatment of a variety of diseases, including ALD. It has become a hot spot for the study of regulating intestinal micro ecological balance and enhancing intestinal barrier function, to prevent alcoholic liver injury. In this study, ALD mice were given probiotics to observe the protective effects on ALD and explore the possible mechanism. Results: HE and oil red O staining of liver tissues in alcohol group showed significant steatosis and inflammation response, while probiotics treatment can reduce liver injury. Compared with the control group, the LPS of alcohol group was significantly higher than that of the control group (62.36 ± 3.05 vs 12.23 ± 1.19 pg/ml, p < 0.05) and TNF-α (779.4 ± 1.01 vs 272.4 ± 6.78 pg/ml, p < 0.05) was significantly increased. Probiotics can effectively case endotoxemia (35.63 ± 1.84 vs 6.236 ± 3.05 pg/ml, p < 0.05) and inflammatory factors TNF-α (526.6 ± 25.04 vs 779.4 ± 10.01 pg/ml, p < 0.05) induced by alcohol. RT-PCR results showed that probiotics increased the expression of Reg3b and Lingo-1 (p < 0.05). Compared with the alcohol group, the mRNA levels of intestinal tight junction protein Occludin and Claudin-1 were increased with probiotics treatment (p < 0.05). However, compared with the alcohol group, the mRNA level of ZO-1 showed no significant difference (p > 0.05). WB results showed that the expression of Occludin and Claudin-1 increased in probiotic treatment group (p < 0.05).

In addition, Bacteroides (p < 0.05) and Bacteroides (p < 0.05) were significantly increased in the intestine of the alcohol group. While the Clostridium (p < 0.05), Lactobacillus (p < 0.05) and Clostridium (p < 0.05) were decreased. With the treatment of probiotics, the levels of Enterococcus (p < 0.05) and Enterobacteriaceae (p < 0.05) decreased, and the levels of Lactobacillus (p < 0.05) and Bifidobacterium (p = 0.05) increased.

Conclusion: Probiotics show protective effects on ALD by reducing alcohol-induced endotoxemia and liver inflammatory injury as well as improving the intestinal mucosal barrier and restoring the intestine micro ecological imbalance. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chemotherapeutic drugs have a direct hepatic toxic effect, which leads to multiple increase in the risk of liver injury in patients with acute leukemias (AL). The development of hepatotoxicity limits the chemotherapy (CT) providing in full doses.

Aims & Methods: We aimed to assess the overall role in an increase of risk level of hepatotoxic reactions in AL chemotherapy dynamics. The study involved 84 patients with newly diagnosed AL (64 – acute myeloid leukemia (AML), 20 – acute lymphoblastic leukemia (ALL)), ECOG I-II, aged 24–67 years, 41(48.8%) males, 30(35.7%) and 13(15.5%) of patients had undergone induction regimen in full doses.

Results: We assessed the correlation between the level of AL chemotherapy and the level of hepatotoxic reactions in AL chemotherapy. The highest level of hepatotoxic reactions in AL chemotherapy was observed in patients with NPI > 10 and NPI > 20.

Conclusion: Metabolic and biochemical changes within the liver, amelioration of lipid profile and improvement of physical fitness can be observed after one month of alcohol cessation in moderate drinkers. This pilot results should be further confirmed in large cohorts but also in clinical trials with the public message to subdue and possibly even altogether cease alcohol use.

Disclosure of Interest: All authors have declared no conflicts of interest.
the CTCAE scale was used. Overweight was detected in 40 patients: BMI = 25–29 kg/m², n = 30 – in 11 (27.5%) patients. Depending on overweight presence the patients were divided into 2 groups: I (n = 44) – patients with AL with normal body weight, II (n = 40) – patients with AL and overweight.

**Results:** In AL patients of group I before the start of chemotherapy functional liver was significantly different from healthy people. In group II there was an increase of ALT activity in 1.5 times, AST – in 1.2 times, ALP and GGT in 1.4 times compared to the norm (p < 0.05) and reached grade I level, and no change in bilirubin and total protein levels. On the 28th day of treatment in 3 (6.8%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 2.3 and in 2.2 times respectively, GGT and ALP in 1.9 and 2.4 times respectively, the level of total bilirubin increased in 2.1 times (p < 0.05), of which in 17 (42.5%) patients hepatotoxic reactions were of grade I level and in 2 (5%) – of grade II level, with no statistically significant changes in protein synthesis liver function. On the 56th day of treatment in 7 (15.9%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.8 times, AST – in 1.3 times, ALP – in 1.6 times, GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT and AST in 2.6 and in 2.3 times respectively, GGT and ALP in 2.6 and 3.7 times respectively, the level of total bilirubin increased in 3.6 times (p < 0.05), of which in 10 (25%) patients hepatotoxic reactions were of grade I and in 16 (40%) – of grade II level.

**Conclusion:** The presence of the overweight results in a significant increase in the frequency and degree of hepatotoxic reactions in patients with AL during chemotherapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Severe alcoholic hepatitis (SAH) remains a condition which bears utmost importance. Although serum biomarkers are available, the adequate selection of patients who would benefit the most from corticotherapy is of utmost importance. SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

Introduction: Acute kidney injury (AKI) is a common complication in patients with decompensated liver cirrhosis. Recently, the International Club of Ascites (ICA) defined new diagnostic criteria: the ICA-AKI criteria.
Aims & Methods: This study aims to identify patients hospitalized for acute decompensation of cirrhosis with AKI, according to the ICA-AKI criteria, and to determine if its application leads to greater prognostic accuracy.
Methods: Retrospective analysis of hospitalized patients in a gastroenterology department for acute decompensation of cirrhosis, without acute-on-chronic liver failure, between January 2014 and December 2015. Identification of AKI patients according to ICA-AKI criteria. The mortality rate of severity of liver disease and in-hospital and short-term mortality among patients with and without AKI. Compared the accuracy of the conventional criteria vs. ICA-AKI criteria in the prediction of mortality.
Results: 161 patients included, 85.7% male, mean age of 65.5 ± 10.8 years. Average length of stay of 11.6 ± 9.5 days. 39.8% of patients had AKI on admission or during hospitalization according to the ICA-AKI criteria (60.9% in stage 1, 20.3% in stage 2 and 18.8% in stage 3). Patients with AKI according to ICA-AKI had longer hospitalizations (14.55 ± 9.75 days, p < 0.05), higher severity of hepatic disease quantified by the MELD and MELD-Na scores (17.62 ± 12.83 vs. 12.83 ± 9.75, p < 0.05) and higher in-hospital, 28 and 90-day mortality compared to patients without AKI (23.4 ± 6.2% vs. 18.7 ± 3.9% vs. 9.3%, p < 0.05, 42.9 ± 23.7% vs. 27.7%, p < 0.05). There was a statistically significant association between the presence of infection and the development of AKI (p < 0.05). The ICA-AKI area under the curve (AUC) to predict in-hospital, 28 and 90-day mortality was significantly higher than the AUC of conventional criteria (0.682 vs. 0.533; 0.678 vs. 0.588; 0.618 vs. 0.509, p < 0.05). The ICA-AKI criteria allow the identification of decompensated cirrhotic patients in whom a worse prognosis is predicted. Thus, they constitute a useful tool in daily clinical practice.
Disclosure of Interest: All authors have declared no conflicts of interest.
References
predictors of in-hospital mortality. Patients with Sepsis-3 had higher incidence of acute kidney injury (36 vs 11%), liver injury (36 vs 15%), septic shock (15 vs 0%; p < 0.001) and transfer to the ICU (16 vs 2%; p = 0.001) than those without Sepsis-3. Similar findings were found for qSOFA.

Conclusion: Sepsis-3 criteria are more accurate than SIRS criteria in predicting the severity of infections in patients with cirrhosis. qSOFA is a useful bedside tool to assess risk for worse outcomes in these patients. Patients with Sepsis-3 and positive qSOFA deserve more intensive management and strict surveillance.

Discreet of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol versus propranolol in the prevention of variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and confirmed by computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal varical bleeding or death.

Results: In the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49 ± 12.2 years: 33 (68.7%) were males: 60.4% had viral cirrhosis: mean Child-Pugh score was 7.2 ± 2.6 and mean follow up was 12.3 ± 9.1 months (range 1–29 months). All the patients had occlusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, P = 0.002), bleed related mortality (9.5% vs. 11.1%, P = 0.027) and overall mortality (23.8% vs. 22.2%, P = 0.044) respectively. Adverse events in carvedilol group were hypotension (n = 2), requiring cessation of therapy, while and dyspnea (n = 3) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 atro-ventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to propranolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

Discreet of Interest: All authors have declared no conflicts of interest.

**Introduction:** Despite the progress in the treatment of cirrhosis, infections remain a common problem, being responsible for the great majority of morbidity and mortality in these patients.

**Aims & Methods:** The aim of this study was to identify predictive factors for infection in the first hospitalization for decompensated cirrhosis (DC). Retrospective analysis of patients with the first hospitalization for DC between January of 2009 and March of 2016. Demographic, clinical and biochemical data was compared between patients with and without infection in the first hospitalization for DC.

**Result:** From the 179 patients with a first hospitalization for DC, 6% had ascites on admission, 45.8% had upper gastrointestinal bleeding, 38.5% had jaundice, and 28.5% had hepatic encephalopathy. Regarding medication, 29.6% of the patients were taking proton pump inhibitors (PPI), 22.3% had beta-blockers prescribed, and 1.7% were on prophylactic antibiotic. In those 53 patients with proven infection, spontaneous bacterial peritonitis was the most common infection (34%), followed by urinary tract infection (30.2%) and pneumonia (15.2%). Infected patients presented with jaundice (p = 0.03), severe asites (p = 0.03), use of PPI (p = 0.003) and acute-on-chronic liver failure (p = 0.006) more frequently than those without infection. Additionally, infected patients presented with significantly increased values of C-reactive protein (p < 0.001), INR (p = 0.04), creatinine (p < 0.001), MELD scores (p = 0.001). Mortality rates were higher in infected patients at 30-day (4.0% vs. 9.4%), 3 months (7.9% vs. 18.9%), 6 months (12.7% vs. 24.5%) and 1 year (22.2% vs. 26.5%). In the multivariate analysis, the use of PPI was independently associated with an increased risk of infections (OR = 2.3, 95% CI 1.052–5.173).

**Conclusion:** Almost a third of patients will develop infections right at the first hospital admission for decompensated cirrhosis, which are associated with higher short and long-term mortality rates. As PPI more than double the risk of infections, the indication for the use of these drugs should be strictly reviewed and their interruption considered in cirrhotic patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** vincisentin00@gmail.com

**Introduction:** Flicker frequency (FF) values ≤39 Hz identify cirrhotic patients with minimal hepatic encephalopathy (mHE) and predict their risk of developing overt hepatic encephalopathy (oHE). However, these results have been obtained in cirrhotics with advanced liver disease suffering a previous episode of liver decompensation (74% of patients) or oHE (14% of patients). Herein, we evaluated the effectiveness of CFF in predicting the first episode of overt HE both by log-rank test (p = 0.001) and Cox regression analysis (HR = 5.623; 95% CI = 2.433–12.991; p < 0.001).

**Conclusion:** We demonstrated, for the first time, that CFF predicts the first episode of oHE in a population of compensated cirrhotics that never experienced of HE. Cirrhotic patients should be routinely screened by CFF to identify patients at risk of oHE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** isabelle.ustermann@radboudumc.nl

**Introduction:** The Fontan circulation causes some degree of hepatic congestion by its nature of anatomical reconstruction. This may lead to liver fibrosis or even cirrhosis, but to what extend is unknown. A profound hepatic evaluation, incorporating several non-invasive modalities, in an asymptomatic Fontan patient cohort may further elucidate this.

**Aims & Methods:** Consecutive patients with a Fontan circulation are prospectively included for scoring of liver fibrosis. This screening consists of a blood panel, including biomarkers, liver stiffness measurement, transient elastography (Fibroscan), contrast-enhanced liver MRI or CT-scan and liver biopsy. Liver biopsies were systematically scored with the Fontan specific fibrosis score. Mild fibrosis was defined as a maximum score of 2 of sinusoidal and portal fibrosis component, severe fibrosis as score 3 or 4 on at least one component. Non-invasive markers for portal hypertension (PHT) such as presence of collaterals and splenomegaly on imaging, platelet count (N/μL/mm3) spleen diameter (mm) (ratio) (PSR) and von Willebrand factor (VWF) were measured.

**Results:** From November 2015 until March 2017, 52 Fontan patients were included (mean age 27.5 ± 7.5 years, 60% male). The majority of patients had one or more elevated liver enzymes (elevated GGT in 68%, median 67 μmol/l IQR 51–107). Median platelets were 174 × 10^9/(μL) (IQR 147–213) and mean VWF 104 ± 23%. Mean liver stiffness was 21.8 ± 9.3 kPa. The majority (77%) of ultra-soundographies showed no sign of cirrhosis or splenomegaly (mean spleen size 11.9 ± 1.8 cm). However, 54% of advanced imaging (MRI or CT-scan) showed cirrhosis, 23% congestion and in 21% signs of PHT were observed. Of 33 patients with histology, none were without fibrosis or sinusoidal dilatation and cirrhosis was present in 21%. Of these only 57% also showed signs of cirrhosis on imaging. Of all patients with signs of PHT on imaging only one (13%) patient had histologically confirmed cirrhosis whereas five (15%) had mild fibrosis. Liver stiffness was equal in patients with mild (22.3 ± 3.9 kPa) and pathological when severe fibrosis was noted (25.3 ± 1.2 kPa) (p = 0.458). Median PSR in patients with mild fibrosis was 1557 (IQR 1139–1910) and 1223 (IQR 1045–1451) in severe fibrosis (p = 0.114). VWF was comparable between groups (99 ± 12 vs. 105 ± 20%, p = 0.241). Patients with severe fibrosis were not older (28 ± 7 vs. 26 ± 6 years, p = 0.555) nor had a longer duration of the Fontan circulation (22 ± 5 vs. 21 ± 4 years, p = 0.644).

**Conclusion:** All Fontan patients are at risk of developing severe liver fibrosis, irrespective of age, duration of Fontan circulation and even when asymptomatic. Portal hypertension may occur in the absence of severe fibrosis. Assessment by solely non-invasive modalities may both under- and overestimate the incidence of fibrosis. For generalizability of the current findings, Fontan patients should be prospectively assessed with multimodality assessment in larger cohorts.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0099** A RANDOMIZED DOUBLE BLIND CONTROLLED TRIAL TO EXPLAIN THE EFFECT OF LACTOBACILLUS Rhamnosus GG IN PATIENTS WITH MINIMAL HEPATIC ENCEPHALOPATHY

E. Shahini1, M. Barone2, A. Iannone3, M.T. Viggiani2, V. Corvace3, M. Principi2, A. Di Leo2

1Dept. Of Emergency And Organ Transplantation, Gastroenterology Unit, Bari/Italy
2Emergency And Organ Transplantation, University of Bari, Bari/Italy
3San Camillo Hospital, Manfredonia (Foggia), Italy., Gastroenterology Unit, Foggia/Italy

**Contact E-mail Address:** vincisentin00@gmail.com

**Introduction:** Prebiotics has been recently used to treat cirrhotic patients with any grade of acute or chronic hepatic encephalopathy (HE). Herein, we evaluated the efficacy of Lactobacillus Rhamnosus GG (LRGG) on the treatment of minimal HE (mHE) in compensated cirrhotics.

**Aims & Methods:** 134 patients were screened by critical flicker frequency (CFF) to diagnose mHE. Among them, 41 patients were CFF+ (≤39 Hz) and were...
randomized to placebo or LRGG treatment, for 2 months. In all intention to
primary analysis of 202 patients, demographic characteristics, laboratory test,
model for end-stage liver disease (MELD) score, and Child-Pugh class were
evaluated.

Results: CFF value increased in both LRGG and placebo groups at
12 weeks compared to baseline. However, in the former group CFF value
significantly increased as compared to placebo (46.5 ± 5.7 vs. 41.1 ± 4.6 Hz, p = 0.015), thus indicating a
better therapeutic outcome on mHE. Moreover, mHE reversal was achieved in
75.0% vs. 35.7% of the patients from LRGG and placebo groups, respectively (p = 0.047).

Conclusion: For the first time, we demonstrate that LRGG improves mHE
(expressed by a significant CFF increase).

Disclosure of Interest: All authors have declared no conflicts of interest.

(STDF), Cairo/Egypt

Aims & Methods: To identify the association between TLR-7 polymorphism
and chronic hepatitis C (CHC) in the Egyptian population.

Introduction: The HCV carries a variable clinical course in many patients. The human Toll like
receptors (TLRs) are a family of transmembrane pattern recognition receptors that recognize
saccharide microbial molecules and enable the innate immune system to discriminate among groups of
pathogens and to induce an appropriate cascade of effector responses. Toll-like receptors 7
(CCR6) and 8 (XLR-8) are two important TLRs that are involved in the recognition of HCV in the
plasma and enable the innate immunity to discriminate among groups of pathogens.

Material and Methods: A case-control study was conducted to evaluate the association
between the TLR-7 polymorphism and CHC in the Egyptian population. The study included
216 CHC patients (216) and 108 spontaneous clearing (SVC) patients. Serum samples were
analyzed for the common genetic variants of TLR-7 rs3853839 polymorphism by
TaqMan allelic discrimination kit (Applied Biosystems) according to the manufacturer's
instructions.

Results: C allele of TLR 7 rs3853839 was more frequent in CHC patients than in SVC patients
(69.1% vs. 46.3% for the SVC, control and CHC groups respectively. When the association of
these alleles with HCV spontaneous clearance (SVC) and control groups when compared to
chronic HCV group [OR 15.285 (95% CI 2.04 to 114.08, corrected P (Pc)
= 0.9306 0.0234 0.0003] respectively.

Conclusion: The risk of development of chronic HCV infection was associated with
sex-linked TLR-7 allele carriage in both male and female subpopulations in Egyptian families.

Disclosure of Interest: All authors have declared no conflicts of interest.

(STDF), Cairo/Egypt

Contact E-mail Address: mneamatallah@gmail.com

Introduction: Hepatitis C virus infection is a pressing national problem in Egypt. HCV carries a variable clinical course in different patients. The human Toll-like receptors (TLRs) family consists of ten receptors that are critically important for immune response recognition and recognition of diverse microbial molecules and enable the innate immune system to discriminate among groups of pathogens and to induce an appropriate cascade of effector responses. Toll-like receptors 3 and 7 are recognition receptors that allow the innate immune system binding to RNA pattern. The genetic polymorphism of these receptors has a direct role on the outcome of many diseases.

Aims & Methods: The aim of this study was to assess the association between genetic polymorphism of TLR 3 and Sex-linked TLR 7 alleles with HCV infection outcome in Egyptian families using high resolution techniques. A total of 135 Egyptian families (622 individuals) were recruited in this study from upper and lower Egypt (East and West delta). We compared the risk of allele carriage of selected markers in different groups. These groups included spontaneous virus clearance (SVC) (108 subject), chronic HCV (CHC) patients (216), and non-specific control (298) individuals. The rs3775291 (C/T) was genotyped for TLR3. While the rs3853839 (C/G) was genotyped for TLR7 by real time PCR using TaqMan™ allelic discrimination kit (Applied Biosystems) according to the manufacturer's instructions. The distribution of the TLR 7 gene rs3853839 (C/G) polymorphism was assessed separately in male and female subpopulations of the study due to the X-linked nature of the TLR7 gene.

Results: As regard TLR3 the frequency of the C allele was 88.5%, 83.4% and
71.06% for the SVC, control and CHC groups respectively. While the frequency
of the T allele was found to be 11.5%, 16.5%, 38.9% in SVC, control, and
CHC groups respectively. When these alleles were compared between the
three studied groups, the T allele of TLR 3 rs3775291 was found to be significantly
higher in CHC group when compared to both spontaneous clearance
(SVC) and control groups [OR 15.285 (95% CI 2.04 to 114.08, corrected P (Pc)
< 0.02) and OR 5.17 (95% CI 2.30 to 11.64, Pc < 0.0003)] respectively. As regard the
sex-linked TLR-7 it was found that the frequency of the C allele was 69.5%, 69.1% and 46.3% for the SVC, control and CHC groups respectively. While the
frequency of the G allele was found to be 30.5%, 30.9%, 37.7% in SVC, control
and CHC groups respectively. When the association of these alleles with HCV
infection outcome was studied in the female and male subpopulations it showed
that: The C allele of TLR 7 rs3853839 in the female subpopulation was signifi-
cantly higher in both HCV spontaneous clearance (SVC) and control groups
when compared to chronic HCV group [OR 0.42 (95% CI 0.21 to 0.82,
Pc < 0.0372) and OR 0.40 (95% CI 0.23 to 0.71, Pc < 0.0054)] respectively. The same
results was also reported in the male subpopulation as the same
allele was found to be significantly higher in both HCV spontaneous clearance
(SVC) and control groups when compared to chronic HCV group [OR 0.289
(95% CI 0.14 to 0.59, Pc < 0.0021) and OR 0.17 (95% CI 0.0109 to 0.28,
Pc < 0.0001)] respectively.

Table(1): Association of the allele T of TLR3 rs3775291 polymorphism among the studied groups.

Conclusion: The risk of development of chronic HCV infection was associated with T allele carriage of TLR3rs3775291 SNP. While the carriage of C allele of TLR7 rs3853839C allele was associated with spontaneous HCV clearance in both male and female subpopulations in Egyptian families.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
resulting in cirrhosis and graft failure within 5 years after transplant. Different studies have shown that the use of DAAs is safe and effective in patients in the active post-transplant period. The aim of this study was to quantify LS regression both quantitatively (measured in Kilopascals) and qualitatively (stages of F0-F4 fibrosis).

Aims & Methods: The aim of this study was to quantify LS regression both quantitatively (measured in Kilopascals) and qualitatively (stages of F0-F4 fibrosis). Twenty-four Italian centers were involved in this real-life study where HCV genotype 3 would constitute the best option. Patients with high-risk VE [n = 32] (15.6%) had a mean LS value of 8 (12.7%). The improvement in LF measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI criteria. We did not find any significant differences in platelet levels or in the regression of varices.

Conclusion: Use of Daclatasvir/Sofosbuvir or Sofo/ribavirin in early treatment of HCV genotype 4 post liver donor: SVR was achieved higher at 54 weeks than the use of RBV in non cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Bachofner JA, Valli PV, Kroeger A, Bergamin I, Kuenzler P, Baserga A, et al. A meta-analysis of direct acting antiviral (DAA) drugs in treatment of HCV infection post-liver transplantation. The study was descriptive retrospective analysis on twenty-six LDLT patients with HCV genotype 4 treated with DAA drugs (fifteen patients received Sofosbuvir 400 mg and weight based Ribavirin dose for 24 weeks, eight patients received Sofosbuvir 400 mg and Daclatasvir 60 mg for 24 weeks and thirty patients received Sofosbuvir 400 mg and Sofosbuvir 150 mg for 12 weeks) in the early post-transplant period who were transplanted during the period from January 2014 till December 2015 at Egyptian tertiary center for organ transplantation.

Results: Twenty-six patients completed the treatment course, sustained virological response (SVR) at week 12 was achieved in 80.8% (21/26) of recipients, 100% (11/11) for Sofosbuvir- Daclatasvir and Sofosbuvir- Sofo-premipir group versus 66.7% (10/15) for Sofosbuvir-Ribavirin group (p < 0.05). No major side effects had been reported, anemia developed in patients received ribavirin respond to treatment with erythropoietin and reduction of the ribavirin dose.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0704 IMPROVEMENT OF LIVER STIFFNESS VALUES ACHIEVED BY TRANSITION ELASTOGRAPHY AFTER CHRONIC HEPATITIS C TREATMENT WITH DIRECT ACTION ANTIVIRALS AND EVOLUTIVE CORRELATION OF THROMBOCYTOPENIA AND PRESENCE OF ESOPHAGEAL VARICES

1Gastroenterology, Hospital Severo Ochoa, Leganes/Spain
2Epidemiology, Hospital Universitario Motoles, Motoles/Spain

Contact E-mail Address: miguelpferrer@gmail.com

Introduction: Use of Sofo in liver stiffness (LS) measured by transient elastography (TE) has been observed in patients with chronic hepatitis C treated with direct action antivirals (DAA) 1, 2. The Baveno VI guidelines 3 propose that patients with compensated advanced chronic liver disease (cACLD), LS measurement < 20kPa and a platelet count > 150000/uL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant oesophageal varices (EV). These findings have been validated recently 1, 4, 5.

Aims & Methods: The aim of this study was to quantify LS regression both quantitatively (measured in Kilopascals) and qualitatively (Stages of F0-F4 fibrosis) in a stationary phase after the sustained virological response (SVR) in patients with cACLD (14). The secondary objective was to assess whether this improvement in LF measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI criteria.

Results: 84 patients (49 men and 35 women) with cACLD were included in the study. Median TE on baseline (BL) prior to DAA treatment was [mean (range), 23.86 (12.5-75) kPa] and decreased to [mean, 15.6 (4.8-75) kPa] at SVR 24 and [mean Range], 16.19 (3.6-72) kPa] at SVR > 54. Both were statistically significant [p = 0.02] demonstrating a decrease in LS about 30% between BL and SVR > 54 and about 33% between BL and SVR > 54. We did not find statistically significant differences between SVR > 24 and SVR > 54. Regarding the probability of qualitative improvement of the LS (improve from F4 to F3 or less) the AUC was 0.8 for 17.9 kPa as the cut-off point which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12. PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15 kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV). 17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with medium EV). There were only 3 cases of EV misdiagnosed by Baveno VI Criteria. We did not find any significant differences in platelet levels or in the regression of varices.

Conclusion: There is a significant improvement in LS data after treatment with DAA both at SVR24 and SVR > 54. This improvement seems to be more likely in patients with lower TE values (in our study 17.9kPa). We did not have enough available data in our study to support that this improvement in LS measured by TE has a relevant impact on the clinical management of the patient. The Baveno VI criteria are a useful tool in daily practice to avoid unnecessary UE. Further investigation with larger samples is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0705 8 VERSUS 12 WEEKS OF LEDIPASVIR/SOFOSBUVIR REGIMEN IN PATIENTS WITH CHRONIC HEPATITIS C GENOTYPE 1 INFECTION

Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Portugal, Lisbon/Portugal

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: The therapeutic regimens for chronic hepatitis C are now tending to be shorter and ribavirin free, more cost-effective and with fewer adverse effects. Aims & Methods: We aimed at comparing the 8 weeks versus the 12 weeks regimen of ledipasvir plus sofosbuvir in patients with hepatitis C virus (HCV) genotype 1 infection without cirrhosis, treatment naïve, HCV RNA <6000000 UI/mL. We included 281 patients (pts) with genotype 1 and HCV RNA <6000000 UI/mL treated with ledipasvir plus sofosbuvir in the recommended dose: 120 pts - 8 weeks (group 1) and 161 pts - 12 weeks (group 2). The fibrosis stage was evaluated by transient elastography (Fibroscan®, Echosens, Paris) considering F4 > 12.5 kPa. Patients with undetectable RNA after 12 weeks of treatment were considered cured - sustained virologic response (SVR). Results: No significant demographic and clinical differences were found between the two groups with the exception of the fibrosis stage (table). Two hundred and forty-four patients concluded the treatment; the SVR was 99% in group 1 and 100% in group 2, without differences between the two groups (p = 0.275). Thirty three patients are still in follow up: group 1 -15 pts and group 2 -18pts. The reported adverse effects were mild in both groups (fatigue, insomnia, headache and pruritus) but more frequent in group 2 (p = 0.046).

Conclusion: In patients with chronic HCV genotype 1 infection and RNA <6000000 UI/mL, the 8 weeks regimen of ledipasvir plus sofosbuvir without ribavirin has similar high cure rates with less adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0706 CLINICAL FEATURES OF PATIENTS DEVELOPING HCC AFTER ACHIEVING SVR WITH DAAC AGAINST CHRONIC HEPATITIS C

Gastroenterology, Nara Prefecture General Medical Center, Nara/Japan

Contact E-mail Address: k.ishida1549@yahoo.co.jp

Introduction: Although the conventional IFN-based therapy has made a significant achievement in treating patients with hepatitis C virus (HCV), including the preventive effect of hepatocarcinogenesis after achieving sustained virological response (SVR), patients intolerant of IFN, such as those with advanced age or liver cirrhosis (LC), could not save its privilege. The appearance of direct-acting antivirals (DAAs) provided almost every patient with the chance to receive the treatment without any serious adverse effects (AEs). In addition, SVR could be highly expected in more than 95% of patients treated with DAAs. However, the preventive effect of the future hepatocarcinogenesis following eradication of HCV remains unknown. In our facility, the administration of DAAs to treated patients with hepatitis C virus (HCC) within 2 years after achieving SVR. Aims & Methods: We evaluated the clinical features of patients developing HCC after achieving SVR with DAAs against HCV. One hundred and fifty-three patients achieving SVR defined as negative HCV-RNA 12 weeks after cessation of DAA (oral combination therapy with Daclatasvir/Asunaprevir, Ombitasvir/Paritaprevir/Ritonavir, Sofosbuvir/Ledipasvir, or Sofosbuvir/Ribavirin) were enrolled in this study (Age 69 ± 6.8, male/female 71/29, genotype 1 122/3, chronic hepatitis LC 124/29, PLT 15.3 ± 0.5 × 10^12/L, ALT 44.9 ± 3.5 × 10^3/U/L, FIB-4 index 3.9 ± 0.2, APRI 1.3 ± 0.1, Wisteria floribunda agglutinin positive Mac-2-binding protein (WFA(þ)-M2BP) 3.3 ± 0.5 COI, AFP 12.1 ± 2.4 ng/mL, PIVKA-II 28.8 ± 4.3 mAU/mL). All patients were divided into 2 groups (A: 9 patients with HCC developing after SVR achievement, B: 144 without HCC after SVR achievement). Parameters (PLT, WFA(þ)-M2BP, FIB-4 index, APRI, ALT, Alb, AFP, PIVKAII) and age were evaluated between 2 groups. Results: In group B, significant declining (pre-DAA treatment (the time of achieving SVR) was observed in ALT(A44.9±3.5/19.5±1.1/U/L), FIB-4(11.9±3.1/4.1±0.3 ng/mL), WFA(þ)-M2BP(3.2±0.5/1.9±0.3 COI), FIB-4 index(3.7±0.2/3.0±0.2) and APRI(1.2±0.7/0.6±0.5), and significant increase in Alb(44.9±3.5/16.1±4.0 g/L) and PLT(15.3±0.5/10.9±1.8 × 10^12/L). In group A, significant declining was observed only in ALT (45.1±10.9/16.7±2.2 × 10^12/L). This result indicates that DAA treatment significantly ameliorates parameters related with hepatic fibrosis as well as hepatic inflammation in patients, however, it led to the significant amelioration only in the patients with hepatic inflammation in group A. Next, focusing on parameters after achieving SVR, WFA(þ)-M2BP(A3.4±0.6/B1.7±0.2 COI) and FIB-4 index(5.7±1.6/3.0±0.2) were significantly higher and Alb(3.8±0.4/3.0±0.4 g/L) was significantly lower in group A comparing with group B. When dividing group A into 2 groups (C: new occurrence/D: recurrence), FIB-4 index(3.0±1.3/6.2±1.8 ng/mL), WFA(þ)-M2BP(2.0±0.8/3.8±0.7 COI), FIB-4 index(3.6±2.4/3.6±2.0) and APRI(0.6±0.4/1.1±0.3) were higher and Alb(4.3±0.1/3.6±0.3 g/L) and PLT(20.9±13.2/13.4±3.4 × 10^12/L) were lower in group D than group C, although no significant difference was seen between 2 groups. This result suggests that there might be more patients with progressive hepatic fibrosis in group D comparing with group C. Finally, while univariate analysis showed WFA(þ)-M2BP, FIB-4 index and Alb were significantly associated with the development of HCC after achieving SVR with DAA against HCV, multivariate analysis revealed only Alb was the significantly independent factor contributing to the HCC development after achieving SVR.

Conclusion: Low level of serum albumin as well as the progression of hepatic fibrosis could be associated with the development of HCC after confirming SVR with DAA to HCV.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0707 EARLY OCCURRENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HEPATITIS C VIRUS TREATED WITH DIRECT-ACTING ANTIVIRALS

Department Of Surgery, Hyogo College of Medicine, Nishinomiya/Japan

Contact E-mail Address: shai1005@hyo-med.ac.jp

Introduction: Direct-acting antivirals (DAAs) are novel antiviral drugs for hepatitis C virus (HCV) and have enabled the achievement of a high rate of sustained
Aims & Methods: The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and January 2017 was reviewed to clarify the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

Results: SVR was achieved in 21 patients treated with interferon (IFN)-based regimen and in 1 patient with DAAs at hepatectomy. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: -123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 35 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatectomy, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.7% and 83.0% in patients after SVR treated with DAAs (n=25), 90.9% and 71.8% in patients with IFN-based regimens (n=26) and 57.8% and 19.7% in patients without SVR (n=46), respectively, regardless of the timing of hepatectomy, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR (p < 0.05), but was not markedly different according to the antiviral treatments (p = 0.594).

Conclusion: While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

Aims & Methods: The aim of this study was to assess HRQoL impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACIT-F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched for age and sex with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.

Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT-F utility scores (43.2±8.5 vs 49.5±7.5, p < 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6% (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs. 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2, p < 0.05) compared to the study group.

Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0708 EFFICACY AND SAFETY OF SOFOSBUVIR AND RIBAVIRIN IN HCV POSITIVE PATIENTS WITH REINAL IMPAIRMENT
M.O. T. Butt
Gastroenterology And Liver Transplant, Shifa International Hospital, Islamabad, Islamabad/Islamabad/Pakistan
Contact E-mail Address: mosamabutt2016@gmail.com

Introduction: Hepatitis C virus infection is a leading cause of chronic liver disease affecting more than 170 million people worldwide. HCV infection in the setting of renal impairment is not uncommon. Despite the major developments in the treatment of HCV, treatment of this sub group of patient with impaired renal function is still a challenge.

Aims & Methods: The aim of this study is to determine the efficacy and safety of sofosbuvir and ribavirin in HCV positive patients with renal impairment. All consecutive patients of HCV related liver disease with creatinine clearance less than 30 ml/min were included in the study. Data was collected for tolerability, efficacy and on treatment adverse events. All the patients received Sofosbuvir and dose adjusted Ribavirin according of CrCl. Virological response was checked at 1 month (RVR), 3 months (RVR) and at the end of treatment.

Results: A total of 31 patients were included in the study were 31 out of which 17 (54.8%) were male. Mean age was 52.2 ± 17.6 years while the mean BMI was 25.0 ± 4.0 kg/m2. 10 (22.5%) patient were on regular hemodialysis. 26 (83.9%) patients had CTP-A while 5 (16.1%) had CTP-B disease. Majority of the patients 22 (71%) were genotype 3 while 7 (22.6%) were genotype 1. 24 (77.4%) patients were treatment naive, while those who were treatment experienced, 3 patients received each Interferon and Peg interferon therapy. Treatment was stopped in 2 (6.5%) patients because of disease decomposition while 3 (9.7%) were lost to follow up. ETR was achieved in 25 (96.1%) out of 26 patients who completed treatment. Similarly 12 (80 %) out of 15 patients have achieved SVR-12 so far. During the therapy 10 (32.3%) patients had adverse events, 6 (19.4%) suffered from depression while 4 (12.9 %) developed grade II anemia.

Conclusion: In resource constraint population where newer DAAs are not available an combination of sofosbuvir and low-dose ribavirin in patients with renal impairment seems to be better tolerated and efficacious in terms of achieving the virological response.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0710 SOFOSBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS. AN EXPERIENCE FROM TERTIARY CARE HOSPITAL
A. A. Langhah
Gastroenterology Section, Medical Unit Iv, Jinnah Postgraduate Medical Centre, Karachi Pakistan
Contact E-mail Address: draaliakbar12@gmail.com

Introduction: Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advent of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the corner stone in treatment of (HCV). Most trials have been conducted in HCV genotype 1 and data for Interferon free regimen in genotype 3 (GT-3) is limited especially in cirrhosis.

Aims & Methods: We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RIB) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response (SVR) and controls (n = 110) and

Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT-F utility scores (43.2±8.5 vs 49.5±7.5, p < 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6% (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs. 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2, p < 0.05) compared to the study group.

Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: The cohort consisted of 9 1consecutive patients out of which 41 were compensated cirrhotics and 50 had compensated cirrhosis. The mean age was 53.4 ± 11years. Males were 47 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84.5%) treatment naive patients compared to treatment experienced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naive patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 g/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.

Conclusion: Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.
Early recurrence rate of HCC in treated patients with compensated intrahepatic growth (1 patient), new intrahepatic lesion (1 nodule in 2 patients, one in week 7 of DAA therapy. This cohort was 52% females, median age 64 years (51 - 77), 76% IFN pre-treated, 50% associated NASH, 67% with severe necroinflammatory activity (severity score 3 - Fibromax), 30% with comorbidity 24% with Child Pugh A6. The median MELD score was 9 (6 + 18) was reported in 19.21 as per protocol analysis (90.5%). Recurrence rate of HCC was 29%, higher in males (40%) than females (18%), higher in patients treated with TACE (40%) than those with hepatic resection (33%), and the lowest risk of recurrence was observed in RFA (12.5%). These differences were not statistically significant because of the small sample size. The pattern of recurrence was: intrahepatic growth (1 patient), new intrahepatic lesion (1 nodule in 2 patients, up to 3 nodules less or equal to 3 cm in 1 case) and infiltrative ill-defined hepatocellular carcinoma in 2 patients. We found no correlation between the HCC-free interval of time and recurrence rate (p = 0.62).

Conclusion: Early recurrence rate of HCC in treated patients with compensated liver cirrhosis that received DAA with OBI/PVT/DSV + RBV was 29%, significantly compared to the historical cohort. The rate is higher in males (40%) and in patients treated with TACE (40%).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0716 HOW DIFFERENT IS THE PERFORMANCE OF CEUS IN CIRRHOTIC VS. NON-CIRRHOtic PATIENTS?

T. Moga1, C. S. Ivascu2, C. G. Foncea3, D. Gherardii1, B. Siril1, S. A. Popescu2, M. Duna1, J. Sporea1

1Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine, Timisoara/Romania

Contact E-mail Address: moga.tudor@yahoo.com

Introduction: The aim of this paper is to evaluate the performance of CEUS as a first step in the evaluation of focal liver lesions (FLLs) in cirrhotic and non-cirrhotic patients.

Aims & Methods: A retrospective study was performed on a cohort of 2904 FLLs evaluated by CEUS between September 2009-December 2016, according to EFSUMB guide lines (2) in a tertiary center. 979 (33.7%) FLLs did not completely fulfill the EFSUMB-CEUS criteria thus needing to be confirmed by other imaging technique (contrast-enhanced CT, contrast-enhanced MRI) or histology. Lesions that were previously diagnosed have been excluded. Using CT, MRI and histology for the final diagnosis we calculated the specificity, sensitivity and accuracy of CEUS for benign and malignant FLLs that challenged the examiner, in cirrhotic and non-cirrhotic patients.

Results: CEUS managed an overall diagnostic accuracy of 76.8% (752/979) of the lesions. From the 979 FLLs, 335 (34.3%), 67.7% HCC, 4.7% Hemangioma, 3.8% Metastasis, 18.2% Other benign lesions and 5.3% Other malignant lesions, were detected in liver cirrhosis (LC) and 644 (65.7%), 36.1% Metastasis, 19.5% Hemangioma, 6.8% HCC, 31.3% Other benign lesions and 6% Other malignant lesions were in non-cirrhotic liver (NC). In LC CEUS performance for benign lesions was: 77.6%, 92.1%, 91.3% and for malignant lesions was: 76.1% Se, 92.4% Sp and 83.8% Ac. In the NC group, CEUS performance for benign lesions was: 82.8% Se, 95.8% Sp and 88.4% Ac. and for malignant lesions was: 90.16% Se, 90.13% Sp and 89.4% Ac. CEUS performance was on the most frequent lesions: Hepatocellular Carcinoma (HCC) in LC: 65.2% Se, 86% Sp, 68.5% AC. HCC in NC: 65.9% Se, 94.7% Sp, 92.1% Ac. Metastasis in LC: 30.7 Se, 97.3Sp, 92.9% Ac. Metastasis in NC: 78.5% Se, 91.2% Sp, 85.5% Ac. Hemangioma in LC: 68.7% Se, 95.6 Sp, 93.4% Ac. and for Hemangioma in NC: 77.2% Se, 96.1% Sp and 91.3 Ac.

Conclusion: CEUS is an accurate and reliable method as a first step in the evaluation of FLLs. Liver cirrhosis does not influence significantly CEUS performance.

Contact E-mail Address: sophie.bluemel@gmx.de

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of proangiogenic genes in tumor cells. To understand the role of CUX1 in tumorigenesis, it is important to precisely define the expression profile of CUX1 in different tumor types and surroundings.

CUX1 expression is upregulated in hypoxic and/or normal tissue culture conditions. The hypoxia condition was established by 24h treatment with 150 µM CoCl2 or with 0.5% O2 atmosphere. Hypoxia markers and CUX1 were analysed by RT-qPCR. Transfection with plasmid expressing a reporter sequence for HIF-1alpha was performed in combination with CUX1 knock-down.

Results: Hypoxia determined the up-regulation of HIF-1alpha (Hypoxia inducible factor1-alpha) and a stable or up-regulated expression of its inhibitor FHI-1 (SLC2A1) up to 24 h prolonged hypoxia. VEGFA was significantly
Aims & Methods: 
hepatocellular carcinoma (HCC). But the specific mechanism has not been ing medicine. Recent studies have shown that SAMe has the inhibitory effects on human hepatocellular carcinoma cell HepG2 and mouse hepatocyte AML12.

Disclosure of Interest: 

References 
Conclusion: Our results support the hypothesis that overexpression of BRG1 increases cell growth and cell invasion in HCC. Furthermore, the data highlight genes promoting proliferation and invasion that are being regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB, D, E and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.

P0720 PROGNOSTIC ROLE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN HEPATOCELLULAR CARCINOMA (HCC)

Sahloul, Sousse/Tunisia

Contact E-mail Address: Elleuchghobel.nour@yahoo.fr

Introduction: Inflammation may play an important role in progression, and a high neutrophil-to-lymphocyte ratio (NLR) has been reported as a poor prognostic indicator in several malignancies.

Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepato-gastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33-87) years. The sex ratio was 3.22 (M:F = 58:18). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice (P < 0.05). Otherwise, high NLR was significantly correlated with the presence of vascular invasion ($P = 0.002$), lymph node metastasis ($P = 0.04$), tumor multiplicity ($P = 0.01$) and higher incidence of AFP $\geq$ 200 ng/mL ($P = 0.04$).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0721 REIC/DKK-3 PROTEIN CONCENTRATION INDUCE THE POSITIVE EFFECT TO THE MORTALITY OF HEPATOCELLULAR CARCINOMA

A. Ohyama, D. Uchida, H. Shiraha, H. Sawahara, H. Kato, H. Okada
Gastroenterology And Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City/Japan

Contact E-mail Address: at841205@gmail.com

Introduction: The Wnt/β-catenin plays essential roles in the growth of hepatocellular carcinoma (HCC). The Dickkopf (Dkk) protein family (Dkk1–4) is known as Wnt signal antagonists, and reduced expression in immortalized cells (REIC)/Dkk-3 over-methylation is associated with poor prognosis of HCC patients. But the roles of REIC/Dkk-3 in inhibiting Wnt signaling remains still unclear.

Aims & Methods: In our previous study, REIC/Dkk-3 protein induced significant production of interferon gamma from lymphocytes incubated with pancreatic cancer cells, indicating that REIC/Dkk-3 protein might activate cancer immunity in the tumor-bearing patients.1 We hypothesized that REIC/Dkk-3 expression was correlated with cancer immunity in HCC patients. Thus, we investigated the correlation between serum REIC/Dkk-3 protein level and the prognosis in HCC patient. We retrospectively studied 58 HCC patients who underwent primary liver resection for HCC admitted to out unit from 2008 to 2017. Patient serum was gathered before resection. Serum REIC/Dkk-3 protein level was measured by an enzyme-linked immunosorbent assay.

Results: 58 HCC patients were divided into two groups, 41 REIC/Dkk-3 high concentration group (protein level > 800) and 17 Dkk-3 low concentration group (protein level < 800), according to the presence of REIC/Dkk-3 proteins in the blood, as detected by ELISA spectrometry. There was no significant difference in age, sex, Child-Pugh score and HCC stage in the patient groups. REIC/Dkk-3 Protein tended to be declining in liver cancer patients with poor prognosis. ($P = 0.186$)

Conclusion: Our results demonstrated that the serum Dkk-3 protein levels might be a prognosis marker in HCC patients. Further study is necessary with more number of HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0724 MICROWAVE VERSUS RADIOFREQUENCY THERMAL ABLATION OF HEPATOCELLULAR ADENOMA: SAFETY AND EFFICACY

Introduction: Hepatocellular adenoma (HCA) is a rare benign tumor of the liver that typically presents in women within their reproductive years. The recent increase in the HCA prevalence is noticeably associated with the rising prevalence of obesity and the metabolic syndrome. Because of high risk of complications such as hemorrage, rupture and malignant transformation, appropriate treatment strategy should be considered. Given the success of image-guided ablation in treating malignant hepatic tumors, there is increased interest in treating benign masses with percutaneous ablation.

Aims & Methods: To investigate the efficacy and safety of Microwave versus Radiofrequency Ablation in management of HCA. Out of 320 Patients presented with hepatic focal lesions over 1 year, data of 15 patients diagnosed to have HCA were collected retrospectively. The diagnosis of HCA in those patients was based on radiological findings using triphasic pelvi-abdominal CT, dynamic MRI or cytopathological examination of FNAC for those whose radiological findings were not conclusive. The size of the all tumors was ranged between 2.5 to 6.9 cm.

Conclusion: Percutaneous ablation of HCA using Microwave or Radiofrequency thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA. Of note Microwave ablation is much more efficient in treating larger lesions through single puncture in contrast to Radiofrequency which needs more than one puncture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the current natural history of HCC patients is not established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.LI.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hypertriglyceridemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features showed lower percentage of HCC diagnosis on surveillance (p 0.021), larger tumors (p 0.038), better liver function (higher percentage of patients with Child-Pugh A [p = 0.007] and MELD < 10 [p = 0.003]), higher percentage of metastases (p 0.024), and lower percentage of portal vein thrombosis (p 0.010). The BCLC stage and treatment options were similar among the 3 groups, with the exception of a less frequent access to locoregional therapies for BCLC stage B patients with 3–5 features (p 0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups.

Diabetic patients showed a lower survival (p = 0.046). MELD score, HCC
morphology, nodule size, BCLC stage, portal vein thrombosis and metastases were assessed for lead-time. Patients with HFS have may have prolonged the administration period, improving the prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0726 LIVER VOLUME AS A PREDICTOR OF RISK FOR HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS C PATIENTS.

N. Kang, J.W. Chung, J. Kim
Internal Medicine, Seoul National University Bundang hospital, Seong-Nam city/ Korea, Republic of

Contact E-mail Address: namkyum@gmail.com

Introduction: Chronic hepatitis C virus (HCV) infection pose risk for development of hepatocellular carcinoma (HCC), even after viral eradication with effective antiviral therapy. Therefore, risk prediction is clinically important for effective surveillance of chronic hepatitis C (CHC) patients, but liver volume was measured on portal venous phase of CT image and corrected for body weight and height: liver volume index (LVI) = ratio of the expected standard volume to the measured liver volume. Kaplan–Meier analysis with the log-rank test was used to compare HCC. Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with increased liver volume index (LVI). Presence of liver cirrhosis was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CI: 1.24–1442.28, P < 0.001; HR: 3.10, CI: 1.26–7.51, P = 0.012, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0727 HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB

M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hirai
Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact E-mail Address: masha@chicobi@hotmai.co.jp

Introduction: Sorafenib is a multi-thyrosine kinase inhibitor classified as a neo-vascularization inhibitor. A previous study indicated that the administration of a vascularization inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated by controlled trials in patients with HCC. We examined the influence of HFS on the effects of treatment after the introduction of sorafenib in 42 patients with a history of multidisciplinary treatment, such as transcatheter arterial chemoembolization (TACE), between May 2009 and March 2017.

Results: Grade 1 or higher HFS was observed in 22 patients (53%), and it was absent in 20 (47%). Overall, the median sorafenib administration period was 2.1 months. In the HFS-free and HFS groups, it was 0.9 and 2.7 months, respectively (p < 0.001). Survival analysis was performed using the Kaplan–Meier method. Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively (p = 0.001). Multivariate analysis showed that sorafenib administration period (hazard ratio, 0.41; 95% CI, 0.19 to 0.88; p = 0.023) and administration period (hazard ratio, 0.45; 95% CI, 0.20 to 0.98; p = 0.045) were significant predictive factors. The following were not significant predictive factors: age, BCLC staging, dosage, and tumor markers.

Conclusion: The prognostic of hepatocellular carcinoma patients receiving sorafenib treatment was closely related to the presence of HFS and administration period. HFS was a predictor of outcome in patients with hepatocellular carcinoma treated with sorafenib. This study indicated that a multi-thyrosine kinase inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated for cetuximab. HFS reduces the quality of life (QOL), and it is a sorafenib administration-inhibiting factor. In our hospital, a system for patients to initially consult the Pharmacists’ Outpatient Clinic, followed by the feed-back of grade-based HFS control strategies to physicians at the outpatient clinic, was established. Skin reactions for sorafenib-treated patients with HFS may have prolonged the administration period, improving the prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0729 UNUSUAL METASTASIS OF HEPATOCELLULAR CARCINOMA

I. Nakhecha1, I. Benelahraddi2, F.Z. Ajana3
1 Service Medicine C Rabat Maroc, Hospital Ibn Sina Rabat, Rabat/Morocco
2 Rabat, Ibn Sina Hospital, Rabat/Morocco

Contact E-mail Address: Ibissisnakhecha@gmail.com

Introduction: Hepatocellular carcinoma is the most common primary tumor of the liver and is estimated to cause more than a quarter of a million deaths each year worldwide. Extrahaepatic metastasis of HCC occurs in about 30–50% of patients, and it depends on HCC stages.1 The most frequent site is lung, followed by lymph node, bone, and adrenal gland.2 Extrahaepatic metastases to unusually sites from HCC have been reported in a few case reports. We report cases of patients with unusual extrahaepatic metastatic sites from HCC.

Aims & Methods: We carried out a retrospective study of 16 patients with unusual extrahaepatic metastases of hepatocellular carcinoma out of 1047 cases of HCC treated at the hepatogastroenterology department "Medicine C" of the IBN SINA University Hospital during the past 22 years. The diagnosis was suspected based on clinical signs and imaging data, and confirmed by histology when the biopsy of the metastasis was possible, were excluded from this study, patients with lung metastasis, lymph node and portal thrombosis.

Results: Our study included 16 patients, 10 men and 6 women with a mean age of 58.5 years ranging from 37 years to 75 years. 13 patients had cirrhosis due to hepatitis C virus, 1 patient had a cirrhosis due to viral B infection and 2 patients had HCC within an noncirrhotic liver. All patients had one or more HCC, ranging in size from 2 to 10 cm. The AFP was normal in 11 cases and elevated in 4 cases (> 200 ng/ml). We collected 4 cases of adenral metastases, 3 costovertebral metastases, 2 gastric metastases, 2 brain metastases, 1 cerebral metastasis, 1 cavalicular metastasis, 1 ovarian metastasis, 1 nasopharyngeal metastasis, and a case of metastasis in the path of percutaneous biopsy of HCC. In 4 cases the diagnosis of HCC and metastasis was synchronous while in 12 cases median time from diagnosis of hepatocellular carcinoma to the detection of extrahaepatic HCC was 15.5 months. Therapeutic abstention was decided in 14 patients for the advanced stage of the disease. Metastatic metastasis was resected surgically and HCC occurring in healthy liver was treated by lpectomy and upper pole gastrectomy in gastric metastasis. The average survival was estimated at 14 months with a decline of 17.3 months, 6 cases were lost to follow and 6 deaths occurred in our series.

Conclusion: The incidence of unusual and extrahaepatic metastasis of HCC diagnosed during clinical course was not frequent. The diagnostic procedures for extrahaepatic metastasis have been standardized, however considering the substantial advances in treatment of HCC, the detection of extrahepatic HCC is crucial for patients to receive appropriate therapy, which ultimately determines patient survival.

Contact E-mail Address: maeva.salimon@chu-nantes.fr

Introduction: Hepatocolangiocarcinoma is a rare primary hepatic tumor con-ffering features of both, cholangiocarcinoma and hepatocellular carcinoma (CHCC-ICC). Few data concerning the epidemiology of CHCC-ICC have been published, mainly from surgically operated and Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of historically proven advanced CHCC patients in a French population. Data from patients treated for historically proven CHCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients were included. 28 patients were HCC treated (76.6% of men, median age 64 years [extreme 37–88]. Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively,
Disclosure of Interest: relevant modified BCLC system for HCC patients.

Results: Each bile acid formed various inhibitory or promoting regions in target strains. Saccharomyces bouardi and Lactobaciulis casei, which are commercially available as probiotics, were mainly inhibited by hydrophilic bile acids. Enteroceccus faecalis and Klebsiella pneumoniae, which are frequently observed in bile during biliary infections, did not form a large inhibitory zone of bile acids. Ercherella cloi, which is occasionally found in the lower intestinal tract, proliferated more around bile acid. Other microorganisms, which cause hepatic bile acid infections in various organs in the body, showed various patterns. As a result of relative quantitative analysis (RT-PCR) based on the control group, the ratio of Fermenticus to Bacteroides was decreased in the group treated with UDCA for 3 weeks. In the cholestatic model, NGS showed changes in the proportion of intestinal microbiota and an increase in diversity after 3 weeks of UDCA supply.

Conclusion: The effects of various kinds of bile acids on microbiota are very diverse, and the oral administration of certain bile acids may change changes in intestinal microbiome in the human body. Finally, oral feeding of certain bile acids can be used as a therapeutic treatment for dysbiosis by controlling the microbial environment in the intestinal tract.

ded patients was significantly lower in the group without IDUS (P = 0.026). Using IDUS under fluoroscopy

Conclusions: The success rate of ETGBD was significantly higher in the group with IDUS compared to

P0735 IS COMPLETE STONE REMOVAL ALWAYS NECESSARY IN EXTREMELY ELDERLY PATIENTS?
Gastroenterology, Ise Res Cross Hospital, Ise City/Japan
Contact E-mail Address: n-okuda@ise.res.jp
Introduction: Endoscopic sphincterotomy, endoscopic papillary balloon dilation, and extracorporeal shockwave lithotripsy are widely recognized as safe and effective treatments of choledocholithiasis. However, complete endoscopic stone removal does have some complications. Although the life expectancy of elderly patients has increased dramatically worldwide, little information is available on the necessity of complete endoscopic stone removal in extremely elderly patients.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of complete endoscopic stone removal in extremely elderly patients. We retrospectively evaluated all extremely elderly patients (older than 90 years) who had undergone complete stone removal for choledocholithiasis at Ise Red Cross Hospital between January 2012 and December 2016. Included patients were divided into complete stone removal and incomplete stone removal (failure to achieve complete stone removal and insertion of a plastic stent) groups. We compared the complication rate, overall survival (OS), and disease-specific survival (DSS) rate between the two groups.

Results: In total, 67 patients were included this study; 36 (54%) had complete stone removal and 31 (46%) had incomplete stone removal. The median age (of the patients was 92 years (range 90–100 years), median follow-up period was 462 days (range 6–1449 days) and the male-to-female ratio was 15:52. Baseline characteristics (age, body mass index, performance status, and comorbidities), rate of complications (perforation, bleeding, hypoamylase, or decreased blood pressure during the endoscopic procedure), and total number of endoscopic procedures differed significantly between the two groups. The median number of stones was one (range 0–5) and two (range 1–5) (P = 0.013), while the median diameter of the largest stones was 9 mm (range 0–27) and 14 mm (range 5–32) (P = 0.001) in the complete and incomplete stone removal groups, respectively. During the referral period, OS was 33.5% and 41.9% and DSS was 5.56% and 3.22% in the complete and incomplete stone removal groups, respectively. Kaplan-Meier analysis found no significant difference in OS and DSS between the two groups (P = 0.187 and P = 0.581, respectively).

Conclusion: Patients in the incomplete stone removal group tended to have more numerous and larger stones. This single-centre retrospective study revealed no significant difference in OS and DSS between the two groups. Complete stone removal might not be always necessary in extremely elderly patients aged 90 years and older.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0737 THE RENDEZVOUS PROCEDURE FOR THE MANAGEMENT OF BILIARY STONES AFTER CHOLECYSTECTOMY: SHORT-AND LONG-TERM OUTCOMES AND PREDICTORS FOR SUCCESS

4Contact E-mail Address: a.m.schreuder@amc.uva.nl
Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endo-
coscopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTC failed and when deemed feasible by a dedicated multidisciplinary team including a hepatopancreato-bili-
ary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

Results: Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transaction of the bile duct (type D/Norrisberg type E injury). Primary success rate of RV was 94% (44/47 patients). Reasons for failure (N = 3) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to
surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojejunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N = 4.7%). No life-threatening adverse events and no 30-day mortality occurred.

Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: KML001 was safe and well tolerated in respects of adverse events. KML001 was also shown promising result in disease control and pain control. KML001 can be another palliative treatment option for patients with advanced biliary tract cancers who non-respond to gemcitabine-based chemotherapy.

P0741 ENDOSCOPIC DRAINAGE OF MALIGNANT STENOSIS OF THE BILIARY CONFLUENCE: HOW MANY SEGMENTS SHOULD BE DRAINED TO IMPROVE THE PATIENT SURVIVAL?

F. Caillol1, E. Bories2, C. Zemmour3, C. Pesenti1, J.P. Ratone1, M. Giovannini1

Introduction: ESGE stated in 2012 that more than 50% of the liver had to be drained in case of unresectable hilar liver stenosis, however it remains unclear if unilateral or bilateral palliative drainage has to be performed for this kind of stenosis. Our policy is to try to drain the most possible segments of the liver in case of hilar stenosis. The aim of our study was to evaluate the efficiency of hilar drainage in function of the number of segments drained.

Aims & Methods: The study is a retrospective analysis of a prospective registry of drainage of malignant stenosis of the hilum. Drainage were performed by operators performing ERCP, EUS-drainage, and per-cutaneous drainage. The choice of the technique was left to the appreciation of the operators. All techniques could be associated. A Ct-scan or MRI was performed before and after drainage to decide the plan of the drainage and to evaluate efficiency and quality of the drainage. All drainages were performed under general anesthesia in a intubated patient. The quality of the drainage was evaluated by calculation of the percentage of drained segments. This percentage was calculated by dividing the number of liver segment drained with the number of liver segment. The drainage was performed by removing the segments with invasion of more than 50% by tumor. The aim of the study was to evaluate the effect of the quality of the drainage on the patients survival. Quality of the drainage was defined by the percentage of liver segments drained.

Results: 60 (38 men) patients were included from 01/2015 to 07/2016. Mean age = 69.84 years old. The classification of the stenosis was type II for 17 (29%) patients, type III for 20 patients (34%), type IV for 22 (37%). Histology corresponded to adenoma in 33 (43%), metastasis to colorectal cancer in 15 patients (25%) and others cancers for 19 (32%). Median follow-up was 8.5 months (5.5–16.5). The median of survival was 5 months (2.3–12.3). In unvaried and multi varied analysis there was a significant correlation between the percentage of segments drained< 50% (p < 0.05) and the survival. The other factor with impact on the survival was an invasion of the liver > 50% by tumor. There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the quality of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.77 (0.65–0.88).

Disclosure: The conclusion of patient with a malignant stenosis of the biliary confluence is highly correlate with the rate of the liver segment drained.

Aims & Methods: The aim was to determine and compare the accuracy of TAUS and EUS for diagnosis of gallbladder polyps. The decision to perform cholecystectomy is based on presence of gallbladder polyp on transabdominal ultrasound (TAUS) or endoscopic ultrasound (EUS), or both. This decision also influenced by whether the polyp is a true or pseudo polyp. Pseudo polyps are non-neoplastic and do not need surgery. True polyps are neoplastic, either benign (adenoma) or (pre)malignant (dysplastic polyp/carcinoma). True polyps usually need surgery, as they are thought to have malignant potential through the adenoma-carcinoma sequence. (Pre)malignant lesions should be operated sooner than benign lesions. There has been no systematic review and meta-analysis on the accuracy of TAUS and EUS in the diagnosis of gallbladder polyps, true gallbladder polyps and (pre)malignant polyps.

Aims & Methods: The aim was to determine and compare the accuracy of TAUS and EUS for diagnosis of gallbladder polyps, differentiating between true and pseudo polyps and differentiating between (pre)malignant and benign polyps, using TAUS, EUS, EMBASE, Science Citation Index Expanded and the Cochrane library were searched. The search was not restricted based on language, publication status, or prospective or retrospective nature of the studies. Only studies with data on true positives, false positives, false negatives and true negatives for TAUS or EUS were included. When there is a single study, the cutoff was used to test whether TAUS or EUS was superior. Post-test probabilities were calculated using the median prevalence (as pre-test probabilities) and summary positive and negative likelihood ratios.

Results: A total of 17 studies were included in this review. For diagnosis of gallbladder polyps six studies on TAUS were included. The sensitivities and specificity of the studies ranged from 0.45 to 1.00, and 0.91 to 0.98 respectively. There were no studies on EUS for this topic. For differentiating between true and pseudo polyps, seven studies were included. All seven studies reported on TAUS, four studies also reported on EUS. The sensitivities and specificities of the studies ranged from 0.47 to 1.00 and 0.51 to 0.98 for TAUS, and from 0.63 to 1.00 and 0.84 to 0.96 for EUS. For differentiating between (pre)malignant and benign polyps, five studies were included. Four studies reported on TAUS and three studies on EUS. The sensitivities and specificities of the studies ranged from 0.09 to 1.00 and 0.46 to 1.00 for TAUS and from 0.69 and 0.92, and 0.87 to 0.95 for EUS.

No studies were of high methodological quality. The results of the pooled sensitivities, specificities and post-test probabilities are shown in Table 1. HRSC analysis showed no significant difference between the diagnostic accuracy of TAUS and EUS for differentiating between true and pseudo polyps and for...
differentiating between (pre)malignant and benign polyps (p = 0.174 and p = 0.589 respectively).

Conclusion: Diagnostic accuracy of TAUS for diagnosis gallbladder polyps is moderate and decreases further when differentiating between polyp types. TAUS would regularly provide false positive results, leading to unnecessary surgery. There was no evidence that diagnostic test accuracy of EUS was better than TAUS. Further studies of high methodological quality are needed to determine diagnostic accuracy of EUS and TAUS for differentiating between polyp types.

This abstract is based on a pre-peer review draft of a Cochrane Review.

**Introduction:** In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigators have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubble contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

**Aims & Methods:** The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polypoid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Perfluorobutane-based contrast agent and high MI contrast mode was used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement, were used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement, were used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement, were used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement, were used for CEUS.

**Results:** Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than in B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity (p < 0.01). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) (p < 0.01). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/19), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (33/36) on CEUS, and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

**Conclusion:** CEUS in high mechanical index contrast mode was a useful modality for differentiating gallbladder cancer and benign PLGs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Multiple recent studies have indicated that some of adipose tissue-derived hormones may significantly influence the growth and proliferation of GI tumors including liver cancer (1, 2). However, the role of adipokines such as adiponectin and leptin in biliary tract cancer have not been well studied before. The aim of the study was to analyze plasma concentrations of adiponectin and leptin in cholangiocarcinoma (CC) patients and to compare these concentrations to clinicopathological parameters.

**Aims & Methods:** Baseline levels of adiponectin and leptin were determined in 38 consecutive patients with newly diagnosed cholangiocarcinoma and 38 healthy control subjects. The association between adiponectin and leptin and tumor stage was evaluated using nonparametric Spearman’s correlation test. Control subjects were matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

**Results:** Overall median adiponectin concentrations were lower in CC patients versus control subjects (5.1 vs 9.3 mg/mL, P = 0.001). In CC patients with T stage 2–4 (n = 22) median adiponectin concentrations were significantly lower than in CC patients with T stage 1 (n = 16) (3.8 vs 6.6 mg/mL, P = 0.001). The mean leptin levels were not significantly decreased in CC patients (P = 0.45). Adiponectin concentrations were inversely correlated with tumor T stage (r = 0.811, P = 0.01) of CC patients. Higher adiponectin levels at baseline were associated with increased overall survival in T stage 2–4 patients (Cox F test = 2.139, P < 0.05).

**Conclusion:** This study identified an association between adiponectin levels and tumor stage suggesting a potential role for adiponectin in progression of cholangiocarcinoma. Furthermore these results suggest, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with CC. Our results support the hypothesis linking adipose-tissue-derived hormones levels to growth of obesity-associated cancers (3). Adipokines appear to play an important role in risk prediction and management of cholangiocarcinoma patients.

P0745 PRETREATMENT BODY MASS INDEX AND WEIGHT CHANGE DURING PERIOD OF CHEMOTHERAPY AFFECT SURVIVAL OUTCOME IN ADVANCED BILIARY TRACT CANCER PATIENTS

Seoul National University College Of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul/Korea, Republic of

Contact E-mail Address: schmeiche80@gmail.com

Introduction: Recent studies have been conducted to investigate the association between obesity and survival in cancer patients. Cancer has a significant influence on the nutrient status of patients and obesity can affect on the pharmacokinetics of anticancer drugs. The impact of obesity on survival is known to vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence.

Aims & Methods: We performed this study to investigate the association between high BMI and overall survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows: underweight, <18.5 kg/m²; normal, 18.5-22.9 kg/m²; overweight, 23.0-24.9 kg/m²; obese, ≥25 kg/m².

Results: Median OS was 12.1 months for underweight patients, 10.5 months for normal patients, 16.1 months for overweight group, 13.6 months for obese patients, respectively. (p = 0.047) Univariate analysis showed that BMI, local status, disease, operation, radiotherapy and ECOG performance were significantly associated with better survival. Compared with normal patients, overweight patients (BMI 23-24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.491, CI 0.334-0.721; 95% p = 0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival.

Conclusion: Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status.

P0746 THROUGH THE CATHETER BIOPSY METHOD FOR BILIARY CARCINOMA

T. Okuzono
Department Of Gastroenterology, Sendai Kouei hospital, Sendai/Japan

Contact E-mail Address: okuzonotoru@gmail.com

Introduction: To perform curative operation of biliary carcinoma, the pre-operative identification of exact proximal and distal margins is important. A biopsy fence is conventionally inserted to common bile duct via duodenum ampulla guided with an antecedent guide wire. Cannulation of the bile duct with the biopsy forceps may sometimes be difficult in cases where no sphincterotomy is performed, placing the patient at risk of post-ERCP pancreatitis after multiple attempts to advance the forceps into the duct. Pancreateobiliary endoscopists have reported the biopsy methods.

Aims & Methods: The aim of this study was to assess the feasibility and safety of the catheter biopsy method. This was a prospective review of bile duct biopsies with this new method conducted in Sendai Kouei hospital from February 2015 to October 2016. All patients who had biliary stenosis were included. Patients’ demographic data, technical success, adverse events and the diagnostic accuracy were evaluated.

Results: A total of 95 biopsy procedures were performed in 40 patients. The technical success rate was 95% (90/95). Post-ERCP pancreatitis occurred in 1 of 40 patients (2.5%, 1 patient 1 grade). There were no other adverse events like perforation or bleeding. The diagnostic yield of mapping biopsy procedures was 100% (7 of 7 patients). Conclusion: The new biopsy methods to biliary stricture were feasible and safe. It opens up exciting possibilities for endoscopic preoperative diagnosis of the biliary carcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with perihilar cholangiocarcinoma (PHC) have few treatment options and a poor prognosis. Most staging models for patients with PHC have been developed for the minority of patients with potentially resectable disease and are not applicable to the vast majority of patients.

Aims & Methods: The aim of this study was to develop a prognostic score for all PHC patients using variables available at presentation. All consecutive patients with PHC (regardless of tumor stage and treatment) in two tertiary referral centers between 2002 and 2014 were identified and included. Baseline patient and tumor characteristics were collected from medical records. Cox proportional hazards regression was used for multivariable analysis. Age, BMI, bilirubin, 19-9, and tumor size were modeled as continuous covariates.

Results: A total of 674 patients were included of whom 342 (50.8%) had unresectable disease at presentation during exploratory laparotomy. Multivariable analysis identified age (HR 1.41 (95% CI 1.23-1.63)), BMI (HR 1.11 (95% CI 1.05-1.17)), serum bilirubin level (HR 1.45 (95% CI 1.21-1.71)), CA 19-9 serum level (HR 1.22 (95% CI 1.07-1.38)), tumor size (HR 1.33 (95% CI 1.14-1.56)), WHQI performance status 3 (HR 1.48 (95% CI 1.10-1.95), suspected distant metastases on imaging (HR 1.69 (95% CI 1.29-2.20), unilateral HA involvement: HR 1.28 (95% CI 1.10-1.47), and main: hilarial HA involve- ment: (HR 1.61 (95% CI 1.21-2.14) as independent prognostic parameters.

Based on these factors, a prognostic score was created to predict survival for patients with PHC from the time of presentation. Discrimination using Kaplan-
Meier curves, and calibration curves revealed good predictive abilities. The risk scored identified patients with a 1-year survival probability ranging from 15% to 73%.

Conclusion: We developed a prognostic score to predict overall survival for PHC patients using eight independent poor prognostic factors available at presentation. This score may help to inform patients and guide individualized treatment decision making.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Malignant biliary obstruction has a poor prognosis unless secondary to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

Aims & Methods: The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

Results: 49055 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%), followed by liver and intrahepatic bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.6% for 7 days, in hospital and 30 days respectively. In multivariate analysis male gender (OR 1.14, 95% CI 1.08–1.20) p = 0.001); increasing by age quintile 64–71 (1.34, (1.23–1.47) p < 0.001), 72–77 (1.57, (1.44–1.72) p < 0.001), 78–83 (1.83, (1.68–2.00) p < 0.001), > 83 (2.78, (2.55–3.03), p < 0.001); most deprived quintile (1.22, (1.12–1.33), p < 0.001); increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16), p = 0.012), 6 to 10 (1.12, (1.12–1.35), p < 0.001) 11 to 15 (1.19, (1.33–1.66), p < 0.001), 16 to 20 (1.31, (1.17–1.47) p < 0.001), advanced year of ERCP 2013/14 (0.78, (0.68–0.90), p = 0.001), 2014/15 (0.85, (0.74–0.98) p = 0.028); and previous renal failure (1.92, (1.77–2.09), p < 0.001) were associated with increasing 30 day mortality. Asian ethnicity (0.82, (0.67–0.99), p = 0.036), cancer of extrahepatic and unspecified parts of biliary tree (0.60, (0.55–0.65), p < 0.001) and upper tertile of unit ERCP activity (>230) per annum (0.86, (0.80–0.93), p < 0.001) were negatively associated with 30 day mortality.

Conclusion: Short-term mortality in subjects with malignant biliary obstruction following ERCP was high. A better prognosis was observed in; high-volume ERCP units, Asian ethnicity and extrahepatic primary cancers. Male gender, advancing age, increasing co-morbidity score, greater deprivation and previous renal failure predicted death at 30 days.

PAEDIATRIC: LIVER, BILIARY AND PANCREAS - HALL 7

P0750 EARLY DEVELOPMENT OF NONALCOHOLIC FATTY LIVER DISEASE IN GENETICALLY PREDISPOSED CHILDREN: WHAT IS THE NUMBER OF LIVER STIFFNESS MEASUREMENTS NEEDED FOR A HIGH QUALITY EVALUATION?

K. Karnebeck1, J. Plaat2, A. Vreugdenhil1
1Department Of Pediatrics, Maastricht University Medical Centre, Maastricht, Netherlands
2Department Of Human Biology, School Of Nutrition And Translational Research In Metabolism (nutrim), Maastricht University, Maastricht/Netherlands

Contact E-mail Address: kylie.karnebeek@mumc.nl

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738409) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver parameters and cardiometabolic disturbances coincide in carriers and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

Aims & Methods: One hundred and seventy-four children (49% boys) from the Centre for Overweight Adolescent and Children's Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 rs11484 and TM6SF2 E167K. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

Results: Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in PNPLA3 G allele carriers as compared to the C allele carriers (ALT; CC 21, (14–28), GG 26, (18–34), pG 50, (21–70), p = 0.004); for the PNPLA3 G3 genotype, compared to the C/C genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers. The TM6SF2 T allele carriers also showed a tendency increased transaminase levels, but a significantly healthier cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

Introduction: Pediatric chronic liver diseases are becoming a public health issue. Ultrasound based elastographic techniques have emerged as non-invasive methods of pediatric liver fibrosis assessment. The most recent are two dimensional (2D) elastographic (2D E) techniques. While these are proved to be highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation.

Aims & Methods: We aimed to investigate the number of liver stiffness measurements (LSM) needed for a high-quality evaluation using a 2D SWE technique. We conducted a prospective study which included 73 children (age range: 3–17 years, mean age 11.73 ± 3.55 years, 37% girls, mean body mass index (BMI) 25.12 ± 7.83 kg/m2). We used the 2D-SWE. (Logi E9, GE Healthcare, Chalfont St Giles- UK), with a C2-60 probe. One example was performed per LSM for each child. We randomly extracted 1 LSM, 2 LSM, 3 LSM and 5 LSM from all and calculated their respective medians. We employed the Friedman test to compare the medians of 1, 2, 3, 5 and 10 LSMs. We used the interclass correlation coefficient (ICC) to assess the agreement between the medians of 1, 2, 3, 5 and 10 LSMs.

Results: Medians calculated from 1, 2, 3, 5 and 10 LSMs were similar (ICC = 0.96). Furthermore, the agreement between medians calculated from 1, 2, 3, 5 and 10 LSMs was excellent (ICC = 0.96, 95% confidence interval: 0.944–0.974).

Conclusion: We suggest obtaining 5 LSM for a high-quality evaluation using this 2D SWE technique.

P0752 PERCUTANEOUS EMBOLIZATION OF VISCERAL ARTERY PSEUDO-ANEURYSMS – A TERTIARY CENTER EXPERIENCE

R. Chavan1, J. Singh1, Z. Nabi1, R. Kalapala1, D.N. Reddy3
1Gastroenterology, Asian Institute of gastroenterology, Hyderabad, Hyderabad/ India
3Gastroenterology And Hepatology, "Victor Babes" University of Medicine, Timisoara/Romania

Contact E-mail Address: drradhikachavan@gmail.com

Introduction: Visceral artery pseudo-aneurysms are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreaticitis. Angioembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.
Aims & Methods: We aimed to assess the technical feasibility, safety and effec-
tiveness of percutaneous embolization as an alternative treatment option for visceral pseudo aneurysms. We retrospectively evaluated the data of patients who underwent percutaneous embolization at our institution from Feb 2007 to March 2017. All procedures were performed under ultrasound (US) guidance. Embolization, safety and efficacy of percutaneous embolization were analyzed. At 30 days follow up US with color Doppler/dual phase computed tomography was done to see for recurrence of pseudoaneurysm. Results: 23 patients (18 male) with mean age of 34.47 ± 7.28 (7–72) years, under-
went direct percutaneous embozation for visceral pseudoaneurysm. Most common aetiology for pseudoaneurysm was pancreatitis (16) followed by trauma (3), paracentesis (3) and surgery (1). The site of pseudoaneurysm was-
splenic artery (13), left gastric artery (3), hepatic artery (3), inferior epigastric-
artery (3) and gastroduodenal artery (1). Mean size of pseudoaneurysm was 1.8 ± 0.6 (1–3.5) cm. Reasons for choosing percutaneous approach over trans-
catheter embolization included technical difficulties in 11 patients, excess collat-
ellar feeding at 3 patients, and recurrence after pre-
vious embolization in 6 patients. Agents used for embolization-glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3 ± 2.11 (8–16)
minutes and fluorooscopy exposure time was 2.4 ± 1.34 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success-100%). Mild adverse events included - local site pain in 19 (80%) patients. Moderate adverse event included - splenic infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 910
days (30-3186) there was no recurrence of pseudoaneurysm (clinical success-
100%). Conclusion: Percutaneous embolization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding transcath-
ter embolization. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chronic (CP) and autoimmune pancreatitis (AIP) are characterized by infiltration of immune and inflammatory cells. Whether CP is proinflammatory for autoim-
unity is still unclear. AIP is considered mostly a T-cell mediated disease; how-
ever, in induction of chronic pancreatitis macrophages play a pivotal role. Cyclin
dependent kinase (cdk) inhibitors are critical regulators in inflammatory disease as they control proliferation, activation and differentiation of pro-
flammatory cells, and apoptosis. In particular, p21 has been described as a mediator of inflammation and various autoimmune diseases by regulating T-cell activation and promoting macrophage development. We therefore examined the role of p21-mediated inflammation in AIP.

Aims & Methods: Human pancreas samples from CP and AIP patients were evaluated for p21 expression. To investigate the effects of p21 in pancreatitis, we intercrossed lymphotxin overexpressing mice (Tg(Ela1-LTα, β) ) – a model to study CP and AIP – with p21 deficient (p21-/-) mice. Infiltrating cells were visualized by immunohistochemistry, supported by gene expression analysis in an early and a progressive phase. Circulating autoantibodies and the presence of tertiary lymphoid organs (TLOs) were analysed to assess autoimmunity.

Results: p21 was upregulated in human CP patients but remained unchanged in AIP patients. p21 deficiency in LT mice (LTp21-/-) prevented early pancreatic injury. LTp21-/- mice had normal serum amylase, reduced inflammatory gene expression and cell infiltration. In acinar cells diminished proliferation and abrogated activation of non-canonical NF-kB pathway was observed. In contrast, 12 months old LT mice with and without p21 had similar inflammatory gene expres-
sion and T B cell infiltration. Interestingly, LT and LTp21-/- mice had com-
parable tertiary lymphoid organs (TLOs), autoantibodies and elevated IgG levels. However, acinar cell proliferation, acinar-to-ductal metaplasia and acinar non-canonical NF-kB pathway activation remained impaired in LTp21-/- pancreata.

Conclusion: Our findings indicate that p21 is crucial for pancreatitis in LT-driven pancreatic injury. p21 is involved in early acinar secretion of inflammatory medi-
ators that attract innate immune cells. However, p21 is not essential for humoral immune response, accountable for autoimmunity and lack of p21 does not rescue AIP. Furthermore, p21 inhibition in mice and renders acinar cells less susceptible to proliferation and transdifferentiation. We therefore suggest that chronic and autoimmune pancreatitis follow different inflammatory processes.

Introduction: Various forms of pancreatitis (e.g. severe acute pancreatitis, auto-
immune pancreatitis type 2) are characterized by an infiltration of neutrophil granulocytes. Yet, despite sharing the feature of granulocytic infiltration, these diseases take opposing natural courses of disease. A novel function of granulo-
cytes, the formation of aggregated neutrophil extracellular traps (aggNETs), has been described and called for a reevaluation of the specific role of neutrophils in pancreatitis. We were interested in the specific function of granulocytes in various models of pancreatic inflammation.

Aims & Methods: Experimental models of pancreatic inflammation were employed including caerulein-induced pancreatitis and a novel model of IL-
17A-induced pancreatitis. The course of disease was characterized by immu-
nohistochemistry, RNA expression and flow cytometric analyses.

Results: Transgenic systemic delivery of IL-17A alone can induce granulocytosis and neutrophil infiltration to the pancreas. Interestingly, neutrophils do not reach the pancreatic ducts and form aggregates in the ductal lumen. Our experimental models further indicate that peptidyl arginine deimine 4 (PAD4) is critical for intraductal aggregate formation and that PAD4-deficiency abrogates disease progression. Mechanistically, we identify the pancreatic juice as a strong instigator of neutrophil extracellular trap formation. Characteristic single components of pancreatic juice, such as bicarbonate ions and calcium carbonate crystals, induce aggregated NET formation.

Conclusion: Granulocytes aim to contain an inflammatory focus and enter pan-
creatic ducts with potentially detrimental consequences to dependent areas of the organ.

Introduction: Mitochondrial dysfunction is a hallmark of several disease patho-
genes including acute pancreatitis (AP). Our results suggest that mitochondrial
damage is crucial in bile acid induced inhibition of pancreatic ductal HCO3-
isecretion, however the details of mitochondrial function and dysfunction in pan-
creatic ductal epithelial cells (PDEC) is not known yet.

Aims & Methods: The aim of our study was to characterize the mitochondrial
function and function in PDEC under physiological and pathophysiological conditions. Guinea pig and Cyclophilin D WT and knock out (KO) mouse pancreatic ducts were used. Mitochondrial distribution was studied by electron microscopy (EM). Mitochondrial membrane potential (ΔΨm) was measured by
confocal microscopy and pancreatic ductal HCO3- secretion by microfluorometry.

Results: EM measurements revealed that the mitochondrial density is signifi-
cantly higher on the apical side of the guinea pig PDEC compared to the middle or the basal segment in HCO3- buffered solution, or during the adminis-
tration of 5 μM forskolin. This was also confirmed by the ΔΨm measurements as
we detected increased TMRM fluorescence on the apical side of the PDEC during stimulation. The genetic KO of cyclophilin D significantly reduced the
loss of ΔΨm and protected pancreatic ductal HCO3- secretion during the adminis-
tration of 500 μM chenodocholic acid.

Conclusion: Our results revealed that mitochondrial function has a central role in the function of PDEC presumably by providing ATP for fluid and ion secretion. On the other hand the opening of MPTP seems to be crucial in the bile acid induced toxicity offering a potential therapeutic target in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Infectious complications are main causes of mortality in severe acute pancreatitis. Most infections (30%) are intestinal origin (2). The Nucleotide oligomerization domain 2 (NO2) is a NOD-like receptor family member that senses and responds to bacterial wall peptides (3). Guenther et al. reported that p.R702W mutation was found to be associated with multiple organ failure and mortality in patients with AP (4). We aimed to investigate whether there is a correlation between NO2 variants and AP severity in this study.

Aims & Methods: Group 1 (n = 27) was healthy. Group 2 (n = 36) and Group 3 (n = 32) were composed of mild and severe pancreatitis patients according to the Atlanta 2012 classification (5). Four NO2 variants and serum interleukin-6 (IL-6), Tumor Necrosis Factor-α (TNF-α) and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007fs variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NO2 variants between groups. Serum IL-6, TNF-α and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NO2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.

P0758 A LUMEN AMPOUS METAL STENT WITH ANTI-REFUX VALVE FOR ENDOSCOPIC ULTRASOUND-GUIDED DRAINAGE OF PSEUDOCYST AND WALLED-OFF NECROSIS

Department Of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of Korea

Contact E-mail Address: intrad428@yuhs.ac

Introduction: Pancreatic pseudocyst (PC) and walled-off necrosis (WON) are frequent complications of acute pancreatitis. Drainage procedure is required when complications and complications, such as pain, biliary obstruction and infection occur. With technological advances, endoscopic ultrasonic (EUS)-guided drainage replaced surgical treatment and has become the standard treatment. We developed a novel fully-covered lumen apposing metal stent (LAMS) with anti-reflux valve for the purpose of preventing complications such as stent migration or reflux of bowel contents while improving the stent patency. The aim of this study is to investigate the efficacy and the rate of complications of EUS guided drainage using novel LAMS with anti-reflux valve for PC and WON.

Aims & Methods: We compared the treatment outcomes and the rate of complications of EUS-guided drainage using LAMS with EUS-guided drainage using plastic stents. Ten patients underwent EUS-guided drainage using the novel LAMS (LAMS group) and eighteen patients using conventional plastic stents (plastic stent group) from December 2013 to October 2016. A novel LAMS used in this study was designed to have bilateral flare ends, 4 anti-migration flaps (at each side) and a pair of 2 anti-reflux valves (inside the lumen). Technical success was defined as a successful placement of the stent, and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Results: Among 10 patients treated with LAMS, 4 patients had complicated PC and 6 patients had WON. In plastic stent group, 15 patients had complicated PC and 3 patients had WON. The median size of fluid collection before treatment was 69.5 mm (range, 48–214 mm) in LAMS group and 92.0 mm (56–253 mm) in plastic stent group. Median duration of stent placement was 47 days (1–355 days) in LAMS group and 55 days (1–216 days) in plastic stent group. Treatment outcomes of the LAMS group were not inferior despite the significantly higher proportion of WON patients in the LAMS group compared to the plastic stent group. There were no statistically significant differences in the technical success rate (90% versus 94.4%; p = 0.951), clinical success rate (70% versus 77.8%; p = 0.491), resolution rate (76.8% versus 80.7%; p = 0.705), complication rate (40% versus 50%; p = 0.456). In LAMS group, 3 patients experienced mild fever and 1 patient showed peritonitis due to immediate stent migration. In plastic stent group, 4 patients had mild fever was developed in 4 patients, all amount of pneumoperitoneum was in 1 patients, self-migration of stent (after resolution of fluid collection) was in 2 patients. 3 patients showed serious adverse events in 1 patient in each group experienced peritonitis due to immediate stent migration and 1 patient had upper bleeding. Proximal stent was removed in 1 patient in each side in 41.2 minutes; p = 0.106) and fasting period after treatment (3.1 days vs. 2.1 days; p = 0.344 were also not different between two groups.

Conclusion: For EUS-guided drainage, LAMS showed acceptable treatment outcome and the rate of complications even in resistant complications of severe acute pancreatitis. And no additional fasting period was required in the LAMS group compared to the plastic stent group. Further well-designed prospective studies are needed to validate these findings.

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has been shown to be a safe and effective minimally invasive treatment for walled-off necrosis (WON). However, in some cases, simple drainage is not sufficient to manage the symptoms of WON and step up approaches such as direct endoscopic necrocectomy (DEN) and surgical necrocectomy may be required. The association with the outcome of endoscopic treatment for WON remain unclear.

Aims & Methods: This study aimed to retrospectively correlate the clinical characteristics of WON with the outcome of endoscopic transmural drainage. 49 patients (38 males; mean age 60.7±13.44) with symptomatic WON treated by an attempted EUS-TD initially were enrolled in this study. The relationship between the outcome of treatment and the clinical characteristics including morphology and extent of WON was evaluated.

Results: The mean size of WON was 126.63±46.79 mm. EUS-TD was technically successful in 48/49 (97.9%) patients and 26 (54.2%) improved with EUS-TD alone while form step up approach was needed in 19 patients. DEN, percutaneous drainage and surgery were done in 4, 2, and 3 patients, respectively. All patients with step up approach had successful outcomes. Three patients died before step up approach was performed, but death was not related with the procedure itself. There were no patients who needed step up approach had multi-locular (p = 0.05) and large size WON (p = 0.02) as compared to patients treated with EUS-TD alone. The extent of WON correlated significantly (p = 0.001) with the type of treatment. Gas bubbles sign within necrotic tissue on the abdominal CT imaging early after EUS-TD was correlated with the necessity of necrocectomy during the treatment (p < 0.01). Bleeding as adverse events was observed in 3 patients (6.2%). Two patients improved with conservative therapy and 1 patient underwent transcutaneous arteriolar embolization.

Conclusion: The step up approach is safe and effective for the treatment of WON. Multi-locular, large size and extensive WON were important predictors for performing a step up approach. Gas bubbles sign within necrotic tissue after EUS-TD may help to perform necrocectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

admission to hospital. A receiver operating characteristic (ROC) analysis was built at each day after ERCP to examine the discrimination of severe AP. Later, a multiple discriminant analysis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to severity and mortality.

Results: ROC curves showed that TH1 cytokines IL6, IFN-γ and TNF-α can be measured for the prediction of severe AP, while TH2 cytokines IL4, IL13, GMI-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL13 and IFN-γ were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks’ lambda = 0.855, p < 0.0001; Wilks’ lambda = 0.747, p < 0.0001, respectively). We calculated the IL13/IFN-γ index. This ratio was significantly higher in patients with mild AP when compared between groups (p = 0.007 vs. 10–8). This difference was also observed between severe AP and the rest of the patients (p = 0.007). The ROC curve was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity.

Conclusion: An IL13/IFN-γ ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13/IFN-γ ratio at hospital admission is associated with a good prognosis of AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0763 CORRELATION BETWEEN POST-ERCP SERUM AMYLASE LEVELS AND CT FINDINGS IN ERCP-INDUCED PANCREATITIS: A PROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

Introduction: According to the diagnostic criteria by Cotton et al. post-ERCP pancreatitis is defined as the persistence of serum amylase levels three times or higher than the upper limit of the standard for 18 ± 6 h after ERCP with persistent upper abdominal pain for 4 h or longer. However, the criterion of three times or higher than the upper limit was mostly based on retrospective studies, and has not been necessarily supported by imaging diagnosis. In this study, using CT findings as the gold standard of ERCP-induced pancreatitis, we investigated the serum amylase level that suggested ERCP-induced pancreatitis in a prospective multicenter study.

Methods: We performed a high-volume center study. 2078 patients examined by ERCP between April 2015 and May 2016 were retrospectively followed. CT was performed in patients whose serum amylase level exceeded the institutional upper limit on the day after ERCP (after 12–20 h) to investigate the presence or absence of acute pancreatitis. Two expert radiologists performed the diagnostic evaluations of the images blinded and judged the presence or absence of pancreatitis based on the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed pancreatitis, and had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed pancreatitis, and had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed pancreatitis, and had a difficult imaging evaluation due to the presence of the Balthazar grade.

Results: Amylase levels increased on the following day in 402 (21.5%) of the 1868 patients included, and 340 patients examined by CT were included in the analysis. ERCP-induced pancreatitis was diagnosed based on imaging in 204 patients (10.8%). The cutoff amylase level for judging the presence or absence of pancreatitis on the following day was 2.75 times higher than the institutional upper limit (sensitivity: 73.3%, specificity: 79.0%, positive likelihood ratio: 3.48, negative likelihood ratio: 0.34) with an AUROC of 0.80. The cutoff level after 2 h was 2.73 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 79.7%, positive likelihood ratio: 2.24, negative likelihood ratio: 0.68) with an AUROC of 0.63. Abdominal pain under 4 h was noted in 36 of the 204 patients in the pancreatitis group, and 12 of 136 patients in the non-pancreatitis group with a sensitivity of 17.7%, specificity: 91.1%, positive likelihood ratio, 1.99, and negative likelihood ratio, 0.90. Abdominal pain that persisted longer than 4 h occurred in 75 patients in the pancreatitis group and 12 in the non-pancreatitis group with a sensitivity of 36.7%, specificity: 91.1%, positive likelihood ratio, 4.12, and negative likelihood ratio, 0.69.

Conclusion: The appropriate cutoff serum amylase level for judging ERCP-induced pancreatitis on the day following ERCP is 2.75 times higher than the institutional upper limit. The diagnostic value of serum amylase levels 2 h after ERCP was also higher than a cutoff level persisting for less than 4 h, but the sensitivity was high but the sensitivity was low. Therefore, setting a cutoff serum amylase level on the day after ERCP is very useful to diagnose ERCP-induced pancreatitis.

P0764 CLINICAL EFFICACY AND SAFETY OF EU-SUPPORTED LUMEN-APPOSING METAL STENT ASSISTED PANCREATIC WALL-OFF NECROSIS DRAINAGE: A REAL-LIFE EXPERIENCE IN A TERTIARY HOSPITAL

S.T. Law1, C. De La Serna Higuera2, M. Perez-Miranda2, P. Gil2
1Department Of Medicine And Geriatrics, Tuen Mun Hospital, Hong Kong/Hong Kong PRC
2Gastroenterology And Hepatology, Rio Horta, Valladolid; Spain

Introduction: Recently, lumen apposing metal stent (LAMS) has been developed and employed in abscess drainage. However, its use is limited by its cost [1] and its safety rises concerns as apparently associated with more adverse events.[2] The aim of this study was to investigate the efficacy and safety of LAMS in endoscopic ultrasound (EUS) -guided pancreatic wall-off necrosis (WON) drainage.

Aims & Methods: Patients All consecutive patients with necrotizing pancreatitis with WON who underwent EUS-guided drainage using LAMS during the period of 1st Jan 2012 and 30th Jun 2016 were retrospectively retrieved from the institution database. Necrotizing pancreatitis and WON were defined as according to the revised 2012 Atlanta classification. Those encapsulated fluid collection outside of the pancreas were excluded from this study. The following data were collected: patient demographics, EUS and microbiological features of the necrosis, procedural characteristics and their outcomes. Procedures All procedures were performed by 2 endosonographers. Once the WON was identified, a 19-gauge needle was inserted with 0.035-inch guidewire to allow for introduction of the AXIOS device, which was then advanced to create the fistula tract by using the electrocautery tip. Once the delivery catheter was inside the WON, the distal and proximal flange of the stent were deployed subsequently under EUS and endoscopic guidance respectively. Outcome measures Primary outcome measures were: 1. technical success defined as stent deployment without any difficulty nor reposition; 2. clinical success defined as symptom resolution with the abscess size ≤2 cm on computed tomography (CT); Secondary measures are: 1. Stent revision due to its migration/dislodgment in case of unresolved abscess; 2. adverse events; 3. WON recurrence Data analysis Continuous variables were expressed as median and IQR. Categorical data were expressed as absolute numbers and percentages.

Results: The clinical characteristics of the patients and their WONs are shown in Table 1. In the cohort, the deployment of LAMS (AXIOS: 15 ± 10 mm, n = 38; 10 ± 10 mm, n = 8) was technically successful in 45 (97.8%, 3 cases required 2nd attempt for proper deployment) cases while one case required to switch over to a fully-covered metal stent due to the lengthy insertion tract. 28(60.9%) cases were managed with necrosectomy (median 3, IQR 2) in which 15(32.6%) of them had concurrent necrosic drainage prior to each procedure. 43(93.5%) patients were treated successfully while two refractory cases required superimposed insertion of a fully-covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases:three were managed by local hemostatic management and one case was managed by switching to percutaneous drainage. 20(43.5%) cases reported to have adverse events. Six patients experienced immediate bleeding during insertion of LAMS in which two related to process of necrosectomy; among them, one case required the superimposed insertion of a tubular fully covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases:three were managed by local control while one required to switch over to percutaneously drainage. 20(43.5%) cases reported to have adverse events. Six patients experienced immediate bleeding during insertion of LAMS in which two related to process of necrosectomy; among them, one case required the superimposed insertion of a tubular fully covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases:three were managed by local control while one required to switch over to percutaneously drainage. 20(43.5%) cases reported to have adverse events. Six patients experienced immediate bleeding during insertion of LAMS in which two related to process of necrosectomy; among them, one case required the superimposed insertion of a tubular fully covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases:three were managed by local control while one required to switch over to percutaneously drainage. 20(43.5%) cases reported to have adverse events. Six patients experienced immediate bleeding during insertion of LAMS in which two related to process of necrosectomy; among them, one case required the superimposed insertion of a tubular fully covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously.

Conclusion: LAMS is an effective and less invasive method for WON drainage. However, the clinical experience with LAMS is increasing, and there is still much to learn about their safety profile. The procedure is technically successful in most patients and was associated with a low incidence of adverse events.

P0765 RECTAL INDOMETHACIN IS PROTECTIVE AGAINST POST-ERCP PANCREATITIS IN HIGH-RISK AND AVERAGE-RISK POPULATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

X. He1, W. Wu2, Y. Ding1, W. Zheng1, L. Sun1, J. Si1

1Department Of Gastroenterology, Sri Ram Ranj Shaw Hospital, Hangzhou/China
2State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China, Hangzhou/China

Contact E-mail Address: hexingkang@zju.edu.cn

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a common and serious adverse event following ERCP, with a reported incidence of 9.7% in unselected patients [1]. Given huge economic and clinical burden, effective approaches for post-ERCP pancreatitis prophylaxis remains a major priority for research. Nonsteroidal anti-inflammatory drugs (NSAIDs) have also shown the potential efficacy in prophylaxis PEP across high-risk patients, especially for diclofenac or indomethacin [3–5]. Recently, a prospective, double-blind, controlled trial conducted by Levenick [6] and colleagues in the USA showed that the reduction in PEP using indomethacin was not as significant as previously reported. In fact, even more cases of pancreatitis occurred in indomethacin group compared with placebo group. Subsequently, a high-quality meta-analysis also concluded that there is no prophylaxis for the prevention of PEP among average-risk patients[7]. These findings raised the question that whether administration of rectal indomethacin should be recommended in average-risk patients.

Aims & Methods: We aimed to determine the beneficial effect of rectal indomethacin in the prevention of post-ERCP pancreatitis in average-risk of patients.

We systematically searched Cochrane library before October 2016. Studies that evaluated rectal administration of indomethacin in the prevention of post-ERCP pancreatitis were included in the analysis. We adopted a random-effects model to calculate overall relative risk (RR) and 95% confidence interval (CI).

Results: We identified ten randomized clinical trials from initial search and finally included in the meta-analysis. Administration of rectal indomethacin significantly reduced the incidence of PEP in combined population (RR, 0.63, 95% CI, 0.50–0.77). There was no significant heterogeneity across included studies (I² = 14.2%, P = 0.31). In subgroup analysis, rectal indomethacin was effective in both high-risk group (RR, 0.49; 95%CI, 0.35–0.71) and average-risk group (RR, 0.69; 95%CI, 0.55–0.86) patients and reduced the risk of mild and moderate to severe pancreatitis. The overall results remained unchanged and robust in sensitivity analysis. There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Rectal administration of indomethacin is an effective approach to prevent the incidence of post-ERCP pancreatitis both in high-risk and average-risk population undergoing ERCP. However, more high-quality randomized controlled trials are needed to further investigate the optimal timing for administration of indomethacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13–50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 2 to 8%. Both epidemiology and outcomes are variable according to the different countries. Furthermore, few studies have considered the impact of hospital units on AP outcomes.

Aims & Methods: To evaluate both the trend and outcomes of acute pancreatitis according to the admitting hospital units: Surgery, Internal/General Medicine, Gastrointestinal (GI) Unit, Intensive Care Unit (ICU). This is a retrospective
cohort study based on the anonymous computerized database of hospital dis- charged patients in Veneto Region (North-East of Italy). The principal diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto popula- tion was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG 191–194, 199–201 which identified bilio-pancreatic surgery) were reported according to hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied. Results: During the analysed period, 23,389 overall hospitalizations for AP, annual hospitalizations of 32 patients/100,000 inhabitants and in-hospital mor- tality of 3.2% were observed. Characteristics of the patients were: mean age: 62.2 +/−/9.3ys, 54% Males (M); Female (F) mean age: 65ys +/−/19.3ys, male age: 59.4+/−/19.3ys (p = 0.05). Hospitalizations was higher in males (M: 35.4: F: 28.4, OR 1.24 (95% CI: 1.20–1.27, p < 0.05) and it increased in a stepwise progression from the youngest to oldest patients (from 4.4 to 15.12 ± 0.05); a similar trend was observed when considering in-hospital mortality (from 0.5 to 10.3%, p < 0.05). From 2001 to 2015, hospitalization (32.4 to 29.5, p = 0.04), in- hospital mortality (1.41 to 0.79, p < 0.05) and need for surgery (NFS: 5.6% to 3.0%, p < 0.05) trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 34 to 63, p < 0.05) and Gastrointestinal (GI) Units (from 14 to 29, p < 0.05). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In com- parison to General Medicine Units, GI units were associated with a low in- hospital mortality (OR: 0.37, CI 95%: 0.28–0.49, p < 0.05) and an high NFS (OR: 2.88, CI 95%: 2.18–3.81, p < 0.05).

Conclusion: During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a best out- come: lower in-hospital mortality and probably, more eligible patients for surgi- cal treatment.

P0767 COMPARISON OF CLINICAL COURSE AND OUTCOME OF ACUTE PANCREATITIS, RECURRENT ACUTE PANCREATITIS, ACUTE ON CHRONIC PANCREATITIS
Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh, India
Contact E-mail Address: dbihya.sharma@yahoo.com

Introduction: Recurrent acute pancreatitis (RAP) and acute on chronic pancreatitis (ACP) are likely to have severe disease and complications in comparison to RAP. The aim of this study was to compare the clinical course and outcomes of patients with AP, RAP and ACP. 248 consecutive patients with diagnosis of AP, RAP or ACP were included during study period. Outcome measures studied were severity, organ failure (OF), persistent organ failure (POF), need for ICU stay, ventilator and dialysis support, hospital stay, need for percutaneous catheter drain (PCD), surgery and mortality.

Results: Out of 248,158 (64%) patients had AP, 45 (18%) patients had RAP and 43 (18%) patients had ACP. 86 (54%) of AP, 4 (9%) of ACP and none of patients in RAP group had severe AP according to revised Atlanta classification (p < 0.001). On comparison of OF, 101 (63% of the entire population) had POF of AP, 6 (13% of whom had POF) of ACP and none of RAP patients developed POF (p < 0.001). PCD and surgery requirement were seen in 89 (56%) of 9 (6%) of AP, 5 (11%) & 4% of ACP and none of RAP patients respectively (p < 0.001). AP as compared to RAP (18.80 ± 14.58 ± 8.82 ± 11.2, 33.5 ± 4.4, p < 0.001) whereas ICU requirement was seen in significantly more patients in AP group (59; 37%) than in ACP (5; 11%) and RAP (0%; p < 0.001). 41 (26%) of AP, 2 (4.4%) of ACP, but none of patient with RAP needed ventilatory support (p < 0.001), while 13 (8%) of AP patients, 1 (2.2%) of ACP and none with RAP required dialysis (p < 0.05). Mortality in AP, ACP and RAP was 29 (18%), 2 (4.4%), 0 (0%) respectively (p < 0.05).

Conclusion: Patients with RAP had more severe disease course as compared to those with ACP, while those with RAP had the least severe course.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0768 ACUTE PANCREATITIS IN PATIENTS WITH IPMNS: RETROSPECTIVE STUDY OF 346 PATIENTS OBSERVED FROM 2009 TO 2016
L. Brozzi, A. Amadio, F. De Marchi, R. Teresa Marzola, I. Bremi, P. Campagnola, S. F. Cimino, A. Gabbrielli, L. Frulloni
1 Medicine, AOUI Verona-Pancras Center, Verona, Italy
2Gastroenterology, University of Verona, Verona, Italy
Contact E-mail Address: lorenzo.brozzi89@gmail.com

Introduction: In literature the frequency of acute pancreatitis (AP) in patients with IPMNs varies between 12 and 65%, but most of studies are from surgical series and often pancreatitis occurred outside hospital. Curtis occurred after surgery was included. Furthermore, most of the studies includes in the dictum of "symptomatic IPMNs" the presence of less severe disorders, such dyspeptic symptoms, making series unclear.

Aims & Methods: The aim of this study was to investigate the correlation between the severity of IPMN and acute pancreatitis and identify the frequency of evaluate the possible differences between type and localization of IPMNs in occurrence of acute pancreatitis and his disease severity. A retrospective analysis was performed on all observed patients with IPMN-MD, IPMN-BD and mixed type at Gastroenterology Unit in the period between January 2009 and March 2016.

Results: In the study patients an instrumental or histological diagnosis of IPMNs were included.

Conclusion: In all studied 346 patients (164 males and 182 females, mean age at the first report 61.6 ± 12.2 years). At the time of radiological diagnosis, 45% were asymptomatic, 51% had had symptoms, while 4% of the data were missing: the frequency of AP (excluding biliary etiology) of all 346 patients with IPMN was 26%. AP was edematous in 85% of patients and necrotic in 15%. We found that increased frequency in patients with PA with IPMN of the main pancreatic duct (MD and mixed), and unifocal type. The localization to the body seems to be more correlated with the presence of AP. The number of cysts (for IPMN-BD and mixed type) was significantly lower in patients who had AP.

Conclusion: Our medical extraction series confirms that the PA is an event that occurs in 26% of patients with IPMNs, with a prevalence of the male sex, it is associated with a IPMN central and mixed type, predominantly localized to the body. The pancreatitis is not associated with malignancy in resected patients. Disclosure of Interest: All authors have declared no conflicts of interest.

P0769 APOLIPOPROTEIN B AND A-I RATIO PREDICTS SEVERE ACUTE PANCREATITIS
J. Kim, K. J. Lee
Internal Medicine, Yonsei University Wonju College of Medicine Dept. of Internal Medicine, Wonju/Korea, Republic of
Contact E-mail Address: jawkim96@yonsei.ac.kr

Introduction: Severe acute pancreatitis (SAP) has a considerable mortality and morbidity rate. Although many indices have been developed to classify the severity of acute pancreatitis (AP), there is no ideal method for predicting SAP. The ratio of apolipoprotein B to A-I (apoB/A-I) is associated with metabolic syn- drome and inflammatory status.

Aims & Methods: This study aims to investigate the association between severity of AP and serum apoB/A-I ratio. Patients with AP were prospectively enrolled at Yonsei University Wonju College of Medicine from March 2015 to August 2016. The severity of acute pancreatitis was assessed according to the revised Atlanta classification criteria (Atlanta 2012).

Results: Of 191 patients with AP, 134 (70.2%) were classified as mild AP, 42 (22%) as moderately severe AP, and 15 (7.9%) as SAP. The apoB/A-I ratio was highest in patients with SAP compared with those with mild and moderately severe AP (p < 0.001). The apoB/A-I ratio positively correlated with Atlanta classification, computed tomography severity index, and Bedside index for sever- ity of AP. The apoB/A-I ratio showed the highest ability to predict SAP in patients with AP compared with apolipoprotein B or apolipoprotein A-I alone. Conclusion: Serum apoB/A-I ratio appears to have value in predicting SAP in patients with AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0770 IMAGING IN CHRONIC PANCREATITIS – DATA FROM THE SCANDINAVIAN-BALTIC PANCREAS CLUB DATABASE

T. Engjom1, F.G. Erchinger1, E. Tjora2, G. Dimcevski2
1Department Of Clinical Medicine, University of Bergen, Bergen/Norway
2Pediatric Department, Haukeland University Hospital, Bergen/Norway

Contact E-mail Address: trond.engjom@helse.bergen.no

Introduction: The Scandinavian-Baltic Pancreas Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

Aims & Methods: We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNHEIM diagnostic criteria were included. Structural changes were graded according to the M-ANNHEIM-classification. A subgroup was also scored by the modified Cambridge score. Clinical data on disease-duration, nutrition, exocrine function, pain, alcohol/smoking habits and frequencies of malnutrition and diabetes were collected. A grouping of the M-ANNHEIM score (A: Normal = 0, B: Minimal change = 1–2 and C: Moderate/marked = 3–4) was performed for correlation to the clinical data.

Results: The database contains 932 patients (623 men). The M-ANNHEIM-score was present from 446 subjects and both imaging scores from 93 subjects. According to M-ANNHEIM subjects were graded as: 0: Normal (8.1%), 1: Minimal change (15.5%), 2: Moderate (17.9%) and 3: Marked (39.9%). Correlation of the imaging scores: The imaging-scores demonstrated acceptable correlation (p = 0.75, p < 0.001) and good agreement (ICC = 0.71 (0.59, 0.8), p < 0.001). Agreement was best for groups with marked changes.

The clinical parameters divided by M-ANNHEIM groups are presented in the table.

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

*p < 0.05 (Kruskal-Wallis). No other differences reached significance. Values: mean (SD) or median [IQR-range]. Malnutrition: BMI < 18.5.

Conclusion: Subjects with marked structural changes had the highest lifetime smoke-doses. There was poor correlation of structural changes to the clinical features. The two imaging scores demonstrated acceptable correlation and agreement. Poor agreement in normal/minimal-change groups may reduce the value of the scores where they are most needed. The results are presented on behalf of the SBPC study group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0771 OSTEOPATHY IS COMMON IN PATIENTS WITH CHRONIC PANCREATITIS, BUT IS NOT RELATED WITH VITAMIN D AND FECAL ELASTASE LEVELS (P-BONE STUDY)

S. Stigliano1, A. Walldhalter2, E. Martinez-Moneo3, S. Robinson4, M. Malvik3, A. Hedstrom3, A. Kaczka4, M. Schold2, G. Delle Fave5, P. Simon5, G. Caparoso2

6University Hospital Lodz, Lodz/Poland
7Ernst-Moritz-Arndt University Greifswald, Greifswald/Germany

Contact E-mail Address: seren.stigliano@yahoo.it

Introduction: In patients with chronic pancreatitis (CP) malabsorption of vitamins D and K, alcoholism, smoking and inflammatory status contribute to low bone mineral density (BMD). A recent meta-analysis estimated the prevalence of osteoporosis (25%) and osteopenia (40%) in CP and highlighted limitations of the reviewed studies.

Aims & Methods: To evaluate the prevalence of osteoporosis and osteopenia in patients with CP and to investigate the correlation between BMD and CP features, and vitamin D and PEI. This is a multicentre cross-sectional study (P-BONE, a Pancreas 2000 project) on prevalent CP patients. The Diagnosis and severity of the disease was defined according to the M-ANNHEIM classification. Clinical information and biochemical variables were recorded; PEI was assessed by computed tomography. Standardised density was performed by dual-energy x-ray absorptiometry (DEXA). Categorical variables were analysed by means of Fisher's exact test, and continuous variables by t-test. A logistic regression analysis was performed to identify risk factors for osteoporosis or osteopenia. The relationship between continuous variables was assessed with Pearson correlation coefficient.

Results: 211 consecutive CP patients were enrolled at 6 Centres (67% M; mean age 60 ± 13 years). Osteoporosis was diagnosed in 42% and osteopenia in 22% of cases. Alcohol was a risk factor (in 43% and 18% had severe CP. 56% of patients had PEI. The mean value of vitamin D was 20 ng/ml and 56% of cases had vitamin D insufficiency. There was no correlation between vitamin D levels, or elastase levels and t-score at either spine or femur. Alcoholic aetiology was associated with higher risk of low bone mineral density at the elbow (p = 0.02) and with lower level of vitamin D (p = 0.001) but not with osteoporosis or osteopenia. Female sex and older age seems to be associated with a higher risk of developing osteoporosis (OR 4.95%CI 1.2–9.8; p = 0.001) OR 1.09% 95% CI 1.3–p = 0.01) while a higher BMI is associated with a reduced risk of its occurrence (OR 0.89% 95% CI 0.77–0.94; p = 0.001).

Conclusion: The present data confirm a high rate of osteoporosis in CP patients. However, there was apparently no correlation between BMD, pancreatic exocrine function, severity of the disease or vitamin D levels. Other factors, such as vitamin K might deserve investigation for their possible relationship with bone mineral density in CP patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0772 NATURAL HISTORY OF PANCREATITIS ASSOCIATED WITH SPINK1 MUTATIONS

N. Muller1, O. Hentici1, F. Maire1, P. Ruszniewski2, P. Levy3, V. Rebourc4
1Boulog Hospital, Clichy/France
2Service De Gastroentérologie-pancratologie, Université Denis Diderot Hospital Beaugren, Service de Pancreatologie, Clichy Cedex/France

Contact E-mail Address:nelly.muller@aphp.fr

Introduction: SPINK1 is a gene coding for the inhibitor of the cationic trypsinogen. Heterozygous mutations prevalence is estimated at 2%. They are recognized as a risk factor for chronic pancreatitis. However few data are available regarding the natural history and the risk of complications in these patients.

Aims & Methods: A prospective monocentric study was carried out from 2000 to 2016 to describe the natural history of SPINK1 mutation related pancreatitis All patients referred for idiopathic acute and/or chronic pancreatitis with a SPINK1 mutation, were included and followed annually. Epidemiological, genetic, clinical and morphological data were collected.

Results: We included 158 patients. Mutations of SPINK1 were: heterozygous (65%), homozygous (8%) NS4S, others (27%). Median age at first symptoms appeared to be 13 years. Diagnosis was made in 2 [2–73] and 29 years [3–76]. During follow-up (median length:7.45 years), clinical manifestations were pancreatic pain (73%), pseudo-cyst (15%), acute pancreatitis (77%), cholestasis (6%), exocrine pancreatic insufficiency (EPI) (33%), diabetes (15%) and pancreatic adenocarcinoma (n = 6.4%). Calculations and dactyl amputations were found in 56% and 62%. Endoscopic treatment and surgery were performed for 16% and 14% of the patients. Four patients died including 3 due to pancreatic cancer). The risk of pancreatic cancer at 55, 60, 70 and 75 years was 9.4%, 14.7%, 28.9% and 46.7%. Risk factors of cancer were calculated (p = 0.03) and EPI (p = 0.04).

Conclusion: SPINK1 mutations should be searched for in young patients with idiopathic pancreatitis. Risk of pancreatic cancer is probably underestimated.
Cancer screening should be discussed especially in case of pancreatic tissue calcification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0773 EXOCRINE FUNCTION, NUTRITION AND ENZYME TREATMENT IN THE SCANDINAVIAN BALTIC PANCREAS CLUB DATABASE - PRELIMINARY DATA

Introduction: The Scandinavian-Baltic-Pancreatic-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal, B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes.

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and C02/HCO3– secretion) is diminished in CP.

Aims & Methods: In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO3– secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking 15 cigarettes into 10ml distilled water by a smoking machine. Intracellular Ca2+ concentration and pH were evaluated by microfluorometry. Fluid secretion was measured by video microscopy. CFTR currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO3– secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO3– secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na+/H+ exchanger and Na+/HCO3– cotransporter and also forskolin-stimulated Ct– current of CFTR Ct– channel. CFTR inhibition altered the pattern of carbachol-induced Ca2+ signal in pancreatic ducts suggesting that some of the inhibitory effects may be regulated by calcium signalling.

Conclusion: Cigarette smoking and CSE inhibits pancreatic ductal fluid and HCO3– secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rapid on-site cytologic evaluation (ROSE) for determining the suitability of a specimen often provides high efficacy of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). In our center, we propose an additional role of ROSE in histological diagnosis aimed at improving diagnostic accuracy.

Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both EUS-FNA for solid lesions with EUS-FNA for pancreatic solid lesions and surgery. We retrospectively compared the diagnostic performance of ROSE during EUS-FNA with the final diagnosis confirmed by surgically resected specimens. Diagnosis by ROSE using Diff-Quik® was carried out by both a cytopathologist and an endoscopist.

Results: The median of needle passes required for ROSE was 1 range, 1–5. Final diagnoses for the 215 lesions were pancreatic ductal adenocarcinoma (PDAC; n = 162), pancreatic ductal adenosquamous carcinoma (PDASC; n = 9), pancreatic neuroendocrine tumor (pNET; n = 30), solid pseudopapillary neoplasm (SPN; n = 9), metastatic tumors (n = 4), and acinar cell carcinoma (ACC; n = 1). Primary lesions for metastatic tumors in the pancreas were renal cell cancer (RCC; n = 2), small cell lung cancer (SCLC; n = 1), and colon cancer (n = 1). Some of the cases could not diagnose14 cases. When adenocarcinoma (excluding subtype) was suspected by ROSE, ROSE diagnosed 94.6% (159/168) of adenocarcinomas. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, ROSE diagnosed 96.4% (27/28) of special type tumor.

Conclusion: All adenocarcinomas suspected by ROSE were malignant tumors. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, diagnostic accuracy of ROSE was 96.4%. Diagnostic accuracy using ROSE is high agreement in final histological diagnosis. It is suggested that ROSE may also be useful for diagnosis of special type tumor.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignant lesions are limited, which shows an evident need to understand the pathomechanism leading to PDAC and find a suitable marker for early detection. Initial processes in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins found early in the stomach where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of Kra512D PltAfcre (KC) mice, a mouse model with predisposition to pancreatic cancer, revealed strikingly high gastrokine expression. We will further analyze the involvement of GKNs in the development and progression of PDAC and explore the possibility to use them as biomarkers.

Aims & Methods: GKN1 & GKN2 expression was confirmed by qPCR in human and mouse pancreas samples. The presence of GKN1 was verified by western blot and immunohistochemistry (IHC) in mouse pancreas. Mouse pancreatic juice during carcinogenesis could make gastrokine a potential biomarker for the detection of early pancreatic premalignant lesions. With our mouse models we will provide in vivo evidence on the role of GKNs as potential tumor suppressors in pancreatic cancer and autophagy inhibition might be a potential target in treating pancreatic cancer.

Introduction: Pancreatic cancer is one of the deadliest malignancies and there are no effective therapies for it. According to a search of The Cancer Genome Atlas (TCGA) in oncopaint in Kirsten rat sarcoma virus (K-RAS), Tumor protein (TP53), Cyclin-dependent kinase inhibitor (CDKN2A) and Cyclin-dependent kinase inhibitor (CDKN2B) are the most frequent aberrations in human pancreatic cancer (91%, 63%, 35% and 34% of cases, respectively). Macrophagocytosis (breakdown of the autophagic action) has been implicated in some of human diseases, and it plays a complex role in pancreatic cancer.

Aims & Methods: We aimed to investigate autophagy response in a new humanized genetically-modified adult mouse model of pancreatic cancer. To induce pancreatic adenocarcinoma we used viruses expressing oncogenic K-RAS and shRNAs targeting tumour suppressors Trp53, Cdk4a2a and Cdkn2b (i.e., lentiviruses-KTCC) were injected into pancreas of 9-week old adult mouse. Autophagy was detected by immunofluorescence staining for autophagic protein light chain-3 (LC3) and Lysosomal-associated membrane protein 1 (LAMP-1). Additionally, the expression of autophagic protein LC3, autophagy related protein 7 (ATG7), LAMP-1 and P62 were determined by western blot.

Conclusion: In vitro, pancreatic duct epithelial cells of normal mice were primary isolated, LC3 was determined by immunofluorescence staining in the lentiviruses-KTCC infected primary cells. Results: Mice developed pancreatic cancer ten weeks after lentiviruses-KTCC injection, both in macrography and histopathology analysis. The mRNA levels of autophagic genes Atg7 and Atg12 were up regulated. In addition, the LC3I and LAMP-1 positive areas were significantly increased and co-localization of LC3 and LAMP-1 was found in pancreatic tumour sections. Moreover, the increased protein levels of ATG7, LC3, LAMP-1 and decreased P62 protein was observed in the pancreatic tumour tissues. In vitro, the protein level of LC3 in the lentiviruses-KTCC infected primary cells was increased by 6 times when compared with that in the control primary cells (P = 0.0104).

Introduction: Hyperthermia as a positive additive to chemotherapy is described in multiple studies. Despite controversial results hyperthermic intraoperative chemotherapy (HIPEC) is a standard treatment option for some types of gastrointestinal cancer that invades peritoneum. However, the results of clinical data and basic research are uneven. Moreover, there is a lack of fundamental knowledge on additive cytotoxic effect of hyperthermia on cancer cells of different origin.

Aims & Methods: Our aim was to analyse gastrointestinal cancer cell response to various hyperthermia levels, accompanied by chemotherapy, in a manner of cell cytotoxicity, apoptosis and intracellular cisplatin concentration. Cancer cell lines of gastric (AGS), pancreatic (T4M4) and colorectal (Caco-2) origin were exposed to cisplatin and different temperature regimes (37°C to 45°C) either in isolated manner, or in combination. Cells were treated for one hour, mimicking HIPEC timing in clinical setting. The intracellular concentration of cisplatin was measured immediately after experiment by mass spectrometry. 48 hours later changes of cell viability and apoptosis rates depending on temperature in addition to cisplatin treatment were evaluated by MTT and Annexin/V AAD flow cytometry respectively.

Results: Response of AGS to hyperthermia was as implied. Viability of the cells was gradually decreasing by raising the temperature. Caco-2 cells had no significant response to temperature rise up to 42°C, but at 43°C viability dropped by 14% constantly remaining at higher temperatures. T4M4 cells acted in unprepared manner, whereas decreasing viability by 30% in the interval between 37°C to 42°C and 20% increase at 43°C was observed. Following simultaneous exposure to hyperthermia and cisplatin we observed no additive temperature alterations in interval between 37°C to 45°C. However, at particular temperature regimes, we observed temporary proliferation increase: AGS – at 42°C (33%); T4M4 – at 43°C (32%). Higher temperatures dramatically inhibited AGS – by 70%, T4M4 - by 76%. There was the linear pattern of slight decrease (up to 26% at 45°C) of viability in Caco-2 cells. Isobologram analysis of combined hyperthermia and cisplatin treatment revealed strong antagonism of hyperthermia and chemotherapy in all analyzed cell lines. Nevertheless, hyperthermia of 43°C in addition to cisplatin promoted apoptosis of AGS cells by 33%; Caco-2 by 26%, T4M4 by 19%. Moreover, application of hyperthermia (43°C) could contribute to increase of intracellular cisplatin concentration by 30%, 20% and 18% AGS, Caco-2 and T4M4 cells respectively.

Conclusion: Our results indicate that there is no linear contribution of hyperthermia to chemotherapy in all analyzed cell lines. Therefore, in clinical setting it should be applied individually, regarding cancer type. Moreover, particular temperatures can worsen the treatment and increase cancer cell growth.

Introduction and Background: Cachexia (C) is a complex catabolic syndrome involving anabolic and catabolic processes, with its hallmark being muscle and fat wasting. This process occurs in advanced cancer (40% of all cancer deaths). Cachexia is associated with increased mortality and poor quality of life. The local spread of PDAC is a major cause of patient death, and the role of C in this process is unknown. The aims of the study were to investigate the involvement of C in PDAC local spread and to determine the presence of C biomarkers in PDAC patients.

Materials and Methods: We characterized the cachectic condition of PDAC patients by measuring specific serum biomarkers of C (enolase-1, neuropeptide Y, fibroblast growth factor) and their correlation with tumor stage.

Results: C was present in 40% of cases and was associated with higher tumor stage and presence of lymph nodes. Serum enolase-1 and neuropeptide Y were significantly higher in C patients compared to non-C patients. Further, we found a positive correlation between C and tumor size, and a negative correlation with Karnofsky performance score.

Conclusion: Cachexia is a common and severe complication of PDAC, associated with advanced tumor stage and poor prognosis. The identification of C biomarkers in PDAC patients may help in the early diagnosis and monitoring of this condition.

Disclosure of Interest:

the local spread of PDAC, but not in metastasis or survival.

Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Conclusion:

of ezrin expression was similar.

location of tumor was found. The survival of patients with high or low levels of actinin was closely related to advanced clinical stage (stage III-IV), tumor size, location and with the presence of metastasis (p < 0.05). Actinin expression was higher in patients with type 2 diabetes (p = 0.04). No relationship between actinin level and the patients age, sex or tumor size, was noted. Patients with actinin expression had had a shorter survival time than PDAC patients with actinin low expression (Log-rank = 4.35, p = 0.03).

Conclusion: Actinin is associated to cachexia and the local spread of PDAC, metastasis, the presence of diabetes and survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

treated by EUS-CPT. Clinical information was obtained retrospectively from the medical notes and reporting sheets. All patients were followed-up until the patient died or was lost to follow-up. Between November 2014 and March 2017, 70 patients with PC pain were enrolled. We performed EUS-CPT by injection of 5 ml of bipucaine mixed with 15 ml of pure ethanol on the celiac plexus and with different doses of endoscopic ultrasonography-guided fine needle aspiration needle. Treatment response was assessed by self-reported pain relief and change in the daily dose requirement of morphine. Treatment response was defined as to decrease or stay of the same amount of morphine consumption after EUS-CPT, or achieve morphine dosage level within 4 weeks after EUS-CPT if morphine consumption temporarily elevated because of the delayed response of EUS-CPT. Pain evaluation was conducted at 1 week, 4 weeks, and 12 weeks after EUS-CPT and tumor disease progression.

A retrospective analysis was employed to investigate factors associated with metastatic stage and survival. This was a retrospective analysis of a single-centre cohort of prospectively selected patients. Information on the association between presentation symptoms, diagnostic delay, risk factors for PDAC, stage at diagnosis and survival are however limited, with heterogeneous results. Furthermore, the association between presentation symptoms, diagnostic delay, disease stage and survival are also significantly longer in the response group as compared to the no-response group (median: 5.8 vs 1.8 months, p = 0.003). The survival after EUS-CPT was also significantly increased in patients who had a shorter diagnostic delay (2.1 vs 6.5 months, p = 0.017), CA19-9 (median: 617.2 vs. 3519 U/ml, p = 0.009), CRP (median: 0.61 vs. 1.91 mg/dl, p = 0.029) and albumin (median: 3.4 vs. 3.8 g/dl, p = 0.029). Univariate analysis revealed a significantly smaller percentage of patients with CRP level elevation over 3.0 mg/dl from baseline within 4 weeks after EUS-CPT (11 vs 38%, p = 0.01). The overall survival after EUS-CPT was also significantly longer in the responder group (median: 5.8 vs 1.8 months, p = 0.003).

Conclusion: Our study demonstrated that EUS-CPT had therapeutic effect on intractable pain in unselectable PC in the long follow-up. Repeat EUS-CPT was also effective in patients who showed a treatment response to the first EUS-CPT. Possible benefit from EUS-CPT inflammation and aggressiveness, indicative of higher CRP, CA19-9 and lower albumin levels, and the higher frequencies of liver metastases at diagnosis in only 18% of cases compared to 45% of other presentations of PDAC and provide models of neoplastic progression from a benign intraductal tumor through increasing grades of dysplasia to PDAC, and mutations in KRAS and/ or NRAS median key signaling during early development of the tumors (ref 2).

Better prediction of histological grades using non-invasive tools is urgently needed for IPMN patients to make appropriate management decisions.

Aims & Methods: In the current study, we sought to define if quantification of major driver mutations such as KRAS and NRAS in the plasma cfDNA could serve as biomarkers for diagnosis of localized PDAs and risk stratification of IPMNs. We first established protocols for absolute quantification of very low concentrations of the target mutant alleles using a Bio-Rad QX200 droplet digital PCR platform (ddPCR). Using this novel protocol, feasibility of the assay was tested. At present, 92 PDA and 145 IPMN patients with either benign or malignant neoplasms have been recruited (UMIN000012810).

Results: Although ddPCR-based assays have rather high precision and sensitivity (0.01%), limited plasma cfDNA yields in patients with resectable PDAs (Stage 0-1). However, patients in significant intrinsic errors due to “subtle presence” and missing targets at very low abundance during compartmentalization could be effectively overcome by pre-amplification, and the sensitivity of mutant KRAS detection was greatly improved (80.3%) relative to a standard protocol (37.5%). Initial efforts have been made to quantify the cfDNA using conventional PCR, but the low sensitivity of this approach has limited its feasibility as a routine clinical test. New technologies for quantifying cfDNA are now sensitive enough for reliable application in the clinic (ref 1). Pancreatic ductal adenocarcinoma (PDAC) is among the most lethal human malignancies. Intraductal papillary mucinous neoplasias (IPMNs) are precursors of PDAC and provide models of neoplastic progression from a benign intraductal tumor through increasing grades of dysplasia to PDAC, and mutations in KRAS and/or NRAS are found in about 50% of IPMNs. These results suggest that diagnosis at the preclinical stage is necessary to change disease prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.
The median follow-up period was 7.4 months (range 1.5–14.9 months); disease control rate, severity grade and dose-intensity) were analyzed. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate, severity grade and dose-intensity) were analyzed. The median OS, PFS and objective response rate were 12.0 months (95% confidence interval [CI] 9.515–14.485), 7.8 months (95% CI 5.021–10.579) and 48.5%, respectively. The incidence of neurotoxicity was 54.5% and 12 (18.2%) patients experienced grade ≥ 3 neurotoxicity. 30 (45.5%) patients showed grade ≥ 3 neutropenia and 10 (15.2%) patients had febrile neutropenia. Grade ≥ 3 gastrointestinal AE was observed in 11 (16.7%) patients and 26 (42.4%) patients experienced dermatologic AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

Conclusion: These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in East-Asian population group. Similar to previous studies, this combination therapy showed remarkable neurotoxicity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

P0789 EVALUATION OF THE EFFICACY OF ENDOSCOPIC SPHINCTEROTOMY IN THE TREATMENT OF SYMPTOMATIC PANCREATIC DUCTAL ADENOCARCINOMA UNDERGOING GENETICALLY-BASED CHEMORADIOThERAPY.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer death worldwide and the most challenging cancer to be treated. The most common presentation of PDAC is abdominal pain (AP), due to pancreatic blockage, which can be managed by endoscopic sphincterotomy (ES) to manage them.

Methods: This was a retrospective multi-centered observational study in 4 tertiary referral university centers. All patients with symptomatic pancreatic ductal adenocarcinoma undergoing genetic-chemotherapy were analyzed. Endoscopic sphincterotomy (ES) was performed to improve the symptoms and reduce the need for surgery.

Results: A total of 21 patients met the inclusion criteria. The mean age was 69 years (range 38–88). The mean number of cysts was 3.5 (1–10). None of the patients had adenocarcinoma. The mean number of cysts was 3.5 (1–10). The median number of cysts was 3.5 (1–10), the larger measuring 12.7 mm [5–25] mm. They were located for 59% in the head, 17% in the body or tail, and they were diffuse in 24%. None patient had worrisome features (WF). Among the patients whom failed (4/21), one had a second ES with final success, whereas 4 have been operated (2 for initial pain, 2 for WF). Among the patients whom failed (4/21), one had a second ES with final success, whereas 4 have been operated (2 for initial pain, 2 for WF).

Conclusion: ES for symptomatic IPMN without WF is effective in 81% of the patients. Further studies taking into account statin dose, duration and subgroups of patients are needed in order to clarify the association.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this study, we aimed to overcome the subsampling issue and to establish a framework for quantification of rare tumor cell-derived mutant alleles for non-invasive diagnosis of gastrointestinal cancer. To establish more reliable ddPCR protocol for quantification of low-frequency alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight pre-amplified KRAS variants was examined using a Bio-Rad QX200 droplet digital PCR platform. Plasma samples from patients with colorectal (n = 10) and pancreatic cancer (n = 9) were evaluated, and cfDNA from healthy volunteers (n = 30) was utilized to calculate reference intervals.

Results: Limited cfDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of mutant alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight pre-amplified KRAS exon 2 as the first-step PCR. Eight pre-amplification cycles followed by a second-run ddPCR were sufficient to approach approximately 5000–10,000 target alleles/ng cfDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background was presented by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant KRAS was determined to be ~0.09% based on samples from healthy individuals.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic KRAS, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rapid on site evaluation for endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of the pancreas provides immediate information regarding cellular adequacy, avoiding repeated procedures.

Aims & Methods: The aim of this study was to evaluate the impact of ROSE in EUS-FNA of solid pancreatic lesions. Retrospective study of consecutive EUS-FNA of solid pancreatic lesions, in a tertiary center, between 2012 and 2016. A total of 259 EUS-FNA were performed in 197 patients with median age of 68 years (46% male) with mean age of 63.4 (+/-12.8) years. The anatomical distribution of the lesions was: 56.4% in the head, 17% in the body, 10% in the uncinate process and 5.8% in the tail. The mean number of passes were 3.3 (+/-1.4) and the needle size was 25G in 60.8% and 22G in 23.8%. ROSE was performed in 34.7% of the punctures (23.6% along with the initial EUS-FNA), with a mean number of passes 3.4 (+/-1.9). The diagnostic yield of initial EUS-FNA without ROSE was 44.8% ± 8.3% whereas ROSE was performed (p < 0.001). When not conclusive, there was no significant differences in the diagnostic yield of the repeated EUS-FNA with (and without ROSE). Beyond ROSE in the first puncture, higher levels of Ca 19.9 (199 vs 10 ng/mL, p = 0.001), size of the lesion (36.1 vs 29.8 mm, p < 0.001), invasion of adjacent structures (64.6% vs 47%), metastasis to lymph nodes and malignancy (73.2% vs 25.4%, p < 0.001) were more associated with EUS-FNA diagnostic accuracy. In multivariate analysis, ROSE (p = 0.001) and the size of the lesion (p = 0.023) were independent predictors of adequate diagnostic samples. In this study, ROSE was an essential tool in EUS-FNA (dual adenoscarcino- noma 54.7%), benign in 25.8% and indeterminate in 9.3%.

Conclusion: In agreement with the reported evidence, ROSE along EUS-FNA improved the diagnostic yield in solid pancreatic lesions and should be considered whenever possible in the first puncture, until an overall adequate diagnostic yield (>80%) is achieved.

and antiﬁbrrotic properties. Increasing evidences point out MSC action via subcellular extracellular vesicles (EVs). MSC EVs recapitulate the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in a porcine model, the healing potential of MSC EVs delivered through a thermoresponsive gel (Pluronic F127) allowing the administration in a sol state through a catheter and gelation in situ at body temperature to retain EVs at fistula site.

Aims & Methods: Seventeen esophageal fistulas were surgically created by placing two plastic stents during 30 days into the neck of 9 pigs and randomized into control group (n = 6) and treated groups (gel alone n = 6 and gel-EVs n = 5). In the gel-EVs group, Pluronic F127 gel contained allogeneic EVs collected from the swine donor with open conditioned media. A BALB/c nude mouse was analyzed to compare morphological features, while the major/minor axis of the images were compared by the experienced pathologist. Cellular-to-nuclei ratio for normal, low-grade dysplasia (LGD), high-grade dysplasia (HGD), and cancer) were examined under MPM. MPM and H&E imaging could demonstrate cell autofluorescence and second-harmonic generation in situ to enable EV retention in the fistula tract. Besides, the gel further provided a proangiogenic and an anti-inﬂammatory effect. The combined action of MSC EVs and the gel enhanced the healing associated with an anti-fibrotic effect in the esophageal fistula model. This investigation paves the way towards a future subcellular localized fistula therapy merging safety and efﬁcacy.

Introduction: Real-time multiphoton morphological imaging for diagnosing gastric atypical hyperplasia and adenocarcinoma

P0795

K. He1, L. Zhao1, M. Wang1, X. Wang1, L. Liu2, Z. Fan2

The First Affiliated Hospital with Nanjing Medical University, Nanjing/China

Contact E-mail Address: fanzhining@njmu.edu.cn

Introduction: Compared with histopathology, real-time histology or virtual biopsy is important for clinical diagnosis, especially for endoscopic examination. Based on two photon fluorescence (TPF), multiphoton microscopy (MPM) imaging could demonstrate cell autofluorescence and second-harmonic generation (SHG) signal from collagen, which implied real-time information on tissue architecture and cellular morphology. More importantly, no contrast agent is needed for this live diagnosis. The aim of this study is to evaluate the feasibility of MPM to histologically diagnose gastric diseases, compared with other chromoendoscopy and H&E histology.

Aims & Methods: A pilot study was performed between March 2016 and August 2016. 30 gastric tissue slides (normal, low-grade dysplasia (LGD), high-grade dysplasia (HGD), and cancer) were examined under MPM. MPM and H&E images were compared by the experienced pathologist. Cellular-to-nuclei ratio was analyzed to compare morphological features, while the major/minor axis ratio was calculated to reveal cellular asymmetry.

Results: Near-infrared light (800nm) was optimized and applied for multiphoton autofluorescence imaging in gastric tissue. Under MPM, gastric dysplasia tissue demonstrated enlarged, while cancer tissue were characterized by irregular size and shape, enlarged nuclei, and increased nuclear-to-cyttoplasmic ratio. All these were confirmed by H&E images. (Figure 1) The mean cellular/nuclei ratio for normal mucosa was 20.55 ± 5.94, LGD 34.60 ± 3.90, HGD 46.85 ± 3.72, and cancer 56.80 ± 3.37 (P < 0.05). The mean major/minor axis ratio for normal mucosa was 1.31 ± 0.09, LGD 2.02 ± 0.16, HGD 1.70 ± 0.12, and cancer 1.43 ± 0.18 (P < 0.05).

Conclusion: MPM-based optical biopsy was feasible and efﬁcient to clinically diagnose gastric cancer. With miniaturization and integration of endoscopy, MPM can be applied to provide real-time histological diagnosis without invasive biopsy for gastric cancer in the future.

Introduction: Limited data are available with regard to the prevalence of upper gastrointestinal endoscopic ﬁndings in asymptomatic healthy individuals as an endoscopy is an invasive and costly procedure.

Aims & Methods: Individuals were recruited from general population in Latvia as part of the GISTAR pilot study. The study group has been referred for an upper endoscopy and was tested for serum pepsinogens and pepsinogen I/II ratio < 3

P0798 REBAMIPIDE SOLUTION AS A NOVEL SUBMUCOSAL INJECTION PROMOTES HEALING SPEED AND QUALITY OF ESD-INDUCED ULCER BY SUPPRESSING FIBROSION

Development Of Minimally Invasive Surgery, Keio University, Tokyo/Japan

Department Of Pathology, Keio University, Tokyo/Japan

Contact E-mail Address: aifujimoto@a8.keio.jp

Introduction: Peroral administration of rebamipide in additional to proton pump inhibitor (PPI) was reported to be effective to promote ulcer healing after endoscopic submucosal dissection (ESD). In this pilot study, we assessed the efficacy and safety of a novel rebamipide solution as a submucosal injection agent for ESD using in vivo porcine models.

Aims & Methods: The protocol was approved by the ethics review board of our animal experimental laboratory in advance (13055-0). ESDs of about 30 mm in diameter were performed at four sites in the stomachs of three pigs. An endoscopist blinded to the test agents performed the ESDs with a 2% rebamipide solution at two sites (rebamipide group) and with base solution alone at the other two sites (control group). The safety and the treatment results of rebamipide group were assessed. The gastric ulcer stages were evaluated by endoscopy once weekly up to week 4 after the ESD to determine a healing score based on ulcer staging using the classification of Sakita and Miwa. A1 stage was defined as score 1. A2, H1, H2, S1, S2 were defined as healing score 3, 2, 4, 5, 6, respectively. The average scores of each week were compared in the rebamipide group and the control group with the Wilcoxon signed-rank test. The pig was sacrificed at 1 week after the ESD and the other two were sacrificed at 4 weeks, for pathological evaluation of ESD-induced ulceration and ulcer scarring by HE. The number of neutrophils and width of the fibrosis were counted in the five fields. The width of the fibrosis was defined as the maximum diameter of the submucosa to the muscular layer at a site of ESD-induced ulceration or ulcer scar.

Results: There were no adverse events related with the use of the rebamipide solution. The average healing score was significantly higher in the rebamipide group than in the control group at 4 weeks after ESD. The histopathological assessment of the ulcers at 4 weeks, mucosal healing was remarkably better in the rebamipide group than in the control group, with a thicker and more homogeneous mucosal layer. Fibrosis was significantly less extensive in the rebamipide group than in the control group at 4 weeks (p = 0.02). In the evaluation of inflammation, the average number of neutrophils was lower in the rebamipide group than in the control group at both 1 week and 4 weeks, but not to a significant extent.

Conclusion: The rebamipide solution appeared to be safe and effective as an injection material for promoting the healing of ESD-induced ulcers. It also seemed to smoothen the folds of the ulcer circumference after ESD by suppressing fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0799 EFFECT OF ILAPRAZOLE ON THE HEALING OF ENDOSCOPIC SUBMUCOSAL DISSECTION-INDUCED GASTRIC ULCER: INTERIM ANALYSIS OF RANDOMIZED, MULTICENTER STUDY

Internal Medicine, Hallym University College of Medicine, Chuncheon/Korea, Republic of

Gastroenterology, Hallym University Donggum Sacred Hospital, Gyunggi-Do/Korea, Republic of

Contact E-mail Address: sgum91@hallym.or.kr

Introduction: The optimal treatment regimen or duration of endoscopic submucosal dissection (ESD)-induced gastric ulcer has not been established. The aim of this study was to assess the efficacy of novel PPI, ilaprazole for the treatment of ESD-induced gastric ulcer.

Aims & Methods: This was a prospective, open-label, randomized multicenter trial. Between June 2015 and April 2017, a total of 305 patients who underwent ESD for gastric neoplasm were randomly allocated with ilaprazole 20 mg or rabeprazole 20 mg daily for 8 weeks. The primary outcome was ulcer healing rate at 4 and 8 weeks.

Results: In the intention-to-treat analysis, the ulcer healing rate of each treatment group was not significantly different at 4 or 8 weeks (ilaprazole vs. pantoprazole; 96.7% vs. 96.4%, p = 0.80 at 4 weeks, 99.7% vs. 99.0%, p = 0.19 at 8 weeks). There was no independent predictive factors for a high ulcer healing rate in the multivariate analysis.

Conclusion: According to this interim analysis of trial, ilaprazole and rabeprazole showed no significant difference in the healing of artificial gastric ulcer. Most of the ulcers achieved complete healing within 4-8 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

Agents. ESD postoperative bleeding rate in the patients with LDA was significantly higher than those in the patients with other anti-thrombotic agents and the patients with non anti-thrombotic agents. Furthermore, we compared the delayed bleeding rate in the patients continuing antithrombotic therapy with that in the patients with cessation of antithrombotic therapy or with heparin bridge therapy. The patients who were taking antithrombotic agents were treated with continuation of aspirin or clopidogrel. The cessation period of antithrombotic therapy before ESD followed the guidelines for therapeutic endoscopy in antithrombotic agents-users from Japan Gastrointestinal Endoscopy Society. We defined delayed bleeding as a postoperative bleeding after ESD lasting for more than 8 hours.

Results: The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7%: 29/512) (p = 0.0087). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.7 ± 4.6 days and 7.0 ± 6.8 days, respectively, without significant difference (p = 0.48). Of 153 patients taking antithrombotic agents (continued and withdrawn from them were antiplatelet drugs) during ESD (continuation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference (p = 0.63). The delayed bleeding rate of continuation group was 0.24% (p = 0.24). Deep vein thrombosis was observed in one patient in the cessation group.

Conclusion: Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients continuing antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy. Therefore, it is inappropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

esophageal squamous cell carcinoma at the endoscopic center of Xinjiang Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal patches were fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

**Results:** In bloc ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophageal mucosa was successfully transplanted to “ulcer surface” using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median time of 8.6 days with a graft survival rate at 93.06%. Postprocedural stent accompanied by dysphagia occurred in seven patients on post-procedure day 247 (range, 18–34 days). The median sessions of EBD and intraluminal steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as overall bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 25 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

**Conclusion:** Transplantation of autologous esophageal mucosa appears to be a safe means of relieving the severity of esophageal stenoses following circumferential ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**ENDOSCOPIC CLOSURE OF POST-SURGICAL FISTULAS OR PERFORATIONS WITH OVER-THE-SCOPE-CLIP**

P. Santos1, D. Reis2, C. Noronha Ferreira3, J. Lopes4, L. Carrilho Ribeiro5, J. Velosa5

**Introduction:** Gastrointestinal perforations and post-surgical fistulas are feared complications with high morbidity and mortality. The over-the-scope-clip (OTSC) has been successfully used for its resolution.

**Aims & Methods:** We aimed to evaluate the therapeutic efficacy of OTSC in the management of upper digestive tract post-surgical fistulas or perforations. This was a retrospective review of consecutive patients at a single center from January 2011 to January 2017 who underwent upper endoscopy with attempt OTSC placement for the closure of post-surgical fistulas or perforations. Statistical analysis: IBM SPSS 23.0.

**Results:** A total of 18 patients (72% women), with a mean age of 48.9 ± 18.1 years were treated with an OTSC for the closure of post-surgical fistulas or perforations. Mean fistulas size was 5.8 ± 3.5 mm. Median follow-up time was 20.5 (5–84) months.

**Discussion:** OTSCs can be safely and effectively used in patients presenting with post-surgical fistulas or perforations and, when feasible, may be more advantageous and less costly than surgery. Further research is required to characterize the determinants of long-term success and risk factors for failure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**A PROSPECTIVE STUDY USING A NEW DEVICE FOR ENDOSCOPIC RESSECTION OF EARLY NEOPLASIA IN BARRETT’S ESOPHAGUS**

**Introduction:** Early neoplastic lesions in Barrett’s Esophagus (BE) can be effectively and safely removed by endoscopic resection (ER) using multi-band mucosectomy (MBM). Recently a new MBM device became available, designed for improved visualization, easier passage of accessories, and better suction power compared to other marketed MBM devices.

**Aims & Methods:** This study aims to document performance of the new MBM device as resectable neoplasic lesions in BE. This is a company sponsored, international, multicenter, single-arm, prospective registry study enrolling 300 subjects with early neoplasia in BE. Primary endpoint is successful ER defined as complete resection of the delineated target area in one procedure. Secondary outcomes: adverse events, procedure time.

**Results:** To date 259 subjects have been enrolled at 14 centers (Europe 10, US 3, Canada 1). Mean age was 67 ± 9 years, with 87% males. In these 259 subjects, a total of 301 lesions were removed using the new MBM device, with a mean of 2.5 ± 1.92 resections per procedure. Indication for ER was high-grade dysplasia (HGD) in 65%, early adenocarcinoma in 20%, visible lesion with low-grade dysplasia in 10%, and a visible lesion suspicious for neoplasia without pre-treatment histology in 5%. The primary endpoint of successful ER of a target lesion.
was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 (1%) patients (CI 0.21 – 3.89%). Two perforations were closed with clips, all three patients received intra-venous antibiotics and were admitted to hospital for 2, 3 and 9 days. Bleeding requiring intraprocedural hemostasis occurred during 15% of procedures. Significant post-procedural bleeding requiring intervention occurred in 6 cases (2%). Dysphagia requiring endoscopic dilatation occurred in 7 patients (3%), after ER with a mean number of 4.0 ± 2.9 resected pieces. Mean total procedure time for ER using the new MBM device was 33 ± 17.1 minutes.

**Conclusion:** The new MBM device used in this study proved to be effective for resection of early neoplastic lesions in BE: successful ER was achieved in 96% of procedures. Perforations were seen in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0807  
**COST–EFFECTIVE ANALYSIS COMPARING STANDARD BIOPSY VS. DIGITAL BIOPSY BY CONFOCAL ENDOMICROSCOPY**

Gastroenterology, Instituto Ecuatoriano de Enfermedades Digestivas, Guayaquil, Ecuador

**Contact E-mail Address:** carlosouakim@yahoo.co.ec

**Introduction:** Endoscopy has greatly influenced gastrointestinal endoscopy. However, most lesions can be suspected but not certainly diagnosed only on the basis of endoscopic findings and therefore, endoscopy is needed. On the other hand the reliability of detecting lesions histologically depends on the site, number, and size of biopsy (Bx) specimens with a 20–30% probability of sampling mistakes. Probe based Confocal Laser Endomicroscopy (p-CLE) allows endoscopic in-vivo mucosal cellular evaluation of the gastrointestinal (GI) tract with a high (90%) diagnostic accuracy. It allows to target Bx. Moreover, the NPV is > 98%. There is no information in the literature regarding the economic impact of performing digital biopsies (DBx) by p-CLE.

**Aims & Methods:** The aim of this study is to perform a cost–effectiveness analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx following the literature recommendations (LR) vs. the diagnosis with DBx using p-CLE. This was a retrospective study with prospective collection data of patients included from Jan 2014 to Nov 2016. The pathologies included for p-CLE evaluation are summarized in Table 1. The diagnosis costs using standard Bx was calculated following the literature recommendations (Table 2). The standard Bx costs included the histological process and physician honoraria per Bx ($50,000), and one biopsy forceps for per patient ($50,000). The DBx cost by p-CLE included the probe, the processor and the physician honoraria ($USD 500,000). Baseline characteristics, p-CLE indications, the diagnostic accuracy of p-CLE and costs were described.

**Results:** 78 patients were included, 51.2% were female. The mean age was 50.18 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%), and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 patients. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%), and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 patients. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%), and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 patients.

**GASTRIC PER-ORAL ENDOSCOPIC PYLOROMYOTOMY (G-POEM) IN THE TREATMENT OF REFRactory GASTROPARESIS: EXPERIENCE OF THE FIRST 9 CASES IN A MEXICO**

O. V. Hernandez Mondragon, R. Palos Cuellar, G. Blanco Velasco, A. Alfonso-Volques, M. L. Hernandez Reyes, Endoscopy, IMSS, Mexico city/Mexico

**Contact E-mail Address:** mondragonmd@yahoo.co.uk

**Introduction:** Gastroparesis is a syndrome characterized by a delayed gastric emptying, absence of a mechanical obstruction. Reduction in QOL scores have been observed. Etiologies include: idiopathic, diabetic, post-surgical. Diagnosis is based on the combination of symptoms and a delayed gastric emptying scintigraphy(GES) of > 10% after 240min. Multiple treatments have been used with temporary results and morbidity, so new treatment options has been explored. G-POEM is a new endoscopic treatment which is based in the POEM treatment for achalasia patients and consist in a creation of a submucosal tunnel in order to perform an endoscopic pyloromyotomy. Initial results have been promising.

**Aims & Methods:** The aim of this study was to evaluate the safety and efficacy of G-POEM in a group of Mexican patients with refractory gastroparesis. This prospective study was carried out in a tertiary care center in Mexico city, between December 2016 and April 2017. We included patients with refractory gastroparesis defined as presence of symptoms such as: nausea, vomiting, early satiety with inability to finish a normal meal, bloating and upper gastrointestinal pain. These patients were premedicated with a sedative and did not respond and have a positive gastroparesis cardinal symptom index (GCSI) score combined with a > 10% of retention at 240min in the GES study. Exclusion criteria were malignancy, peptic ulcer disease, normal GES and coagulation disorders. Procedure steps were shown in a POEM procedure, beginning 5cms below the pylorus with an longitudinal incision, then submucosal tunnel creation, myotomy of the pyloric arch up to the serosa and 2cms before this point and finally closure with clips. Follow-up included GCSI, endoscopy and GES at 3 months after procedure. Characteristics of procedure, and patients were documented. Student paired t-test was used for comparisons between groups and p < 0.05 was considered as statistically significant.

**Results:** There were 9 patients included in this initial study, the mean age was 42.4 ± 8.5yrs, 6 patients were female and 3 male. The most common etiology was postsurgical 4/9 (44.4%), followed by diabetic 3/9(33.3%) and idiopathic 2/9 (22.2%). The mean G-POEM time was 61.4 ± 7.8 min, and complications were self-limited and presented in only 4 patients, the GCSI score decreased 68% between the pre-procedure levels as well as the GER which decreased 67% compared with levels at 3 months after G-POEM (34.3 ± 5.8 vs 13.1 ± 3.2 p = 0.003/ 20.74 ± 5.3 vs 6.83 ± 1.78 p = 0.001 respectively). 7/9 (77.7%) normalized the GES<10% at (240min). Endoscopy at 3 months after procedure didn’t show any complication (Table 1).

**Conclusion:** G-POEM is a safe and effective procedure in Mexican patients with refractory gastroparesis with a normalization of the GES in up to 77% of these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remained unclear whether endoscopic management of FBs under general anaesthesia could improve endoscopic outcomes when compared with topical pharyngeal anaesthesia.

Aims & Methods: The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anaesthesia methods of endoscopic intervention in population with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

Results: Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31–63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency odynophagia (415 cases, 32.1%), foreign body sensation (340 cases, 26.3%) and sore throat (267 cases, 20.1%). The duration of FB impaction ranged from 4 hours to more than 2 years with a median time of 1.06 (3.6–3) days. Bony FBs, jujube pit, food bolus and dental prosthesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n = 1025, 86.9%), especially in the upper oesophagus (972 cases, 79.5%), followed by stomach (n = 95, 8.1%), duodenum (n = 36, 3.0%) and pharynx (n = 24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (356 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased (p < 0.001). Furthermore, complication rate significantly increased with time (p < 0.001). Age (OR = 1.15, 95%CI: 1.20–1.91, p < 0.001), type and location of FBs (OR = 4.51, 95%CI: 2.95–6.90, p = 0.001; OR = 2.26, 95%CI: 1.48–3.46, p < 0.001), anaesthesia methods (OR = 1.35, 95%CI: 1.05–1.75, p = 0.02) and duration of FB impaction (OR = 1.74, 95%CI: 1.50–2.00, p < 0.001) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anaesthesia could not improve positive FB detection (p = 0.18) or success rate of endoscopic management of FBs (p = 0.135), as well as decrease the complication rate when compared with topical pharyngeal anaesthesia (p = 0.523). VS 47.5%, p = 0.033).

Conclusion: FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with topical pharyngeal anaesthesia. Overall, Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

P0810 CLINICAL OUTCOMES AFTER ENDOSCOPIC RESECTION FOR ESOPHAGEAL SQUAMOUS CELL CARCINOMA COMPARING THE CASES WITH MM AND SM1 INVASION

S. Yoshimizu1, T. Yoshio2, K. Namikawa2, A. Ishiyama2, T. Tsuchida1, J. Fujisaki2
1Gastroenterology, Kameda Medical Center, Chiba/Japan
2Gastroenterology, Cancer Institute Hospital, Tokyo/Japan

Contact E-mail Address: toshiyuki.yoshio@jfcr.or.jp

Introduction: Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SM1 invasion as MM/SM1 invasive cancer is reported to have 8–20% of metastatic risks and is defined as relative indication for ER in guideline of Japan Esophageal Society. For them, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients’ condition.

Aims & Methods: To know the difference of metastatic risk and long time outcome retrospectively studied 121 cases of ESCC with pathological MM/SM1 invasion (MM/SM1:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

Results: Enrolled cases included 112 males and 9 females and their median age was 66 (39–96). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by re-EMR and 1 case by APC, resulted in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 21 cases (21.6%). Additional therapy was performed in 15 cases (15.5%) (ope/CRT/RT/9/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SM1, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 12 cases (50.0%). Additional therapy was performed in 9 cases (37.5%) (ope/CRT/RT/chemistery: 3/4/1/1). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different each other. The frequency of LVI was significantly higher in SM1 than in MM (p = 0.05) and the frequency of DI was higher in SM1, although not significant (p = 0.161). The metastatic recurrence was observed significantly frequent in SM1 than MM (16.7% vs 2.1%; p < 0.01). The 5-year overall survival (OS)/disease specific survival (DSS)/relapse free survival (RFS) were 81.7%/100%/94.1% for MM and 62.9%/87.9%/91.7% for SM1. OS and RFS were not different each other, however, CSS was superior in MM than in SM1 (p < 0.01).

Conclusion: ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SM1 invasion, although we treat MM/SM1 in the same way. Additional therapy should be considered more positively in cases of SM1 than in cases of MM, considering metastatic risk and patients’ conditions.

2Dept. Of Surgery, Klinikum Suedstadt Rostock, Rostock/Germany
Friedrich Loeffler Institute, Neustadt/Germany

Contact E-mail Address: joern.bernhard@klinik suedrostock.de

Introduction: ESD in generally is still under evaluation. The one-piece resection of lesions larger then 2 cm has many advantages against piece meal resection. One problem in ESD is to lift and prepare the specimen simultaneously. We used the ANUBIS-system for intragastric ESD.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubisscope (Karl Storz, Germany). After insertion of the scope insufflations of CO2 were done using a grasper and a hook-knife. Also the grasper could use for coagulation. The stomach was done using CO2. After the opening of the valves at the tip of the Anubisscope (Karl Storz, Germany). After insertion of the scope insufflations of CO2. After the opening of the valves at the tip of the ANUBIS-system for intragastric ESD.

Conclusion: The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER

T. Morinushi
Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatus@yahoo.co.jp
Introduction: Narrow band imaging with magnifying endoscopy (NBI-ME) is used for gastric cancer; however, whether NBI-ME is useful as a screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

Aims & Methods: We aimed to determine the usefulness of NBI-ME as a screening tool for gastric cancer. We retrospectively studied 3515 patients who had undergone screening upper gastrointestinal endoscopy between April 2013 and March 2014. We excluded patients with advanced gastric cancer and those who had undergone gastrectomy. Thus, we studied 1080 patients who received NBI-ME and 2435 patients who had undergone conventional endoscopy. We classified the degree of atrophy of the background gastric mucosa using the Kimura-Takemoto classification. Severe atrophy was noted in 1620 patients (Group S), and mild atrophy in 1895 patients (Group M). We evaluated the biopsy rate, the detection rate of gastric neoplasms, and the accuracy of biopsy using NBI-ME compared to conventional endoscopy.

Results: The biopsy rate of NBI-ME and conventional endoscopy in Group M was 5.4 and 7.7%, respectively, while in Group S it was 14.9 and 14.8%, respectively. The biopsy rate did not differ significantly between those who received NBI-ME and those who had undergone conventional endoscopy. The detection rate of gastric neoplasms using NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S (p < 0.01). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S was noted to be 36.4 and 14.1%, respectively. Thus, the diagnostic accuracy of biopsy using NBI-ME is significantly superior to conventional endoscopy in Group S (p < 0.01).

Conclusion: NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

P0814 BEST PRACTICE IN PLACEMENT OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY WITH JEJUNAL EXTENSION TUBE FOR CONTINUOUS INFUSION OF LEVDOPA CARBIDOPA INTESTINAL GEL IN THE TREATMENT OF ADVANCED PARKINSON'S DISEASE: THE ROLE OF GASTROENTEROLOGIST

A.G. Gravina, I. Apicella, V. M. Ormando, M.R. Amato, M. I. Russo, M. Romano, P. Esposito

Medical And Surgical Department Of Clinical And Experimental Internistic “F Mognaschi”, Hepatorgastroenterology And Digestive Endoscopy Unit, University of Studies Prot. Vanvitelli, Napoli/Italy

Contact E-mail Address: antonietta.gravina@yahoo.it

Introduction: Levodopa is the gold standard in pharmacological treatment of the advanced Parkinson’s disease (APD) and its oral administration in advanced disease is associated with development of symptoms and motor and non-motor complications. Due to its short plasma half-life, Levodopa requires repeated dosing (1, 2). Improved gastric emptying is common in APD and reduces the absorption of Levodopa, requiring progressively higher doses and more frequent administrations. Continuous duodenal administration of modulated Levodopa/ Carbipedia gel by jejunal extension tube placement through Percutaneous Endoscopic Gastrostomy (PEG-J), is a new therapeutic protocol in advanced APD (3).

Aims & Methods: Aim of this work is to verify efficacy and safety of intestinal gel (LCIG) delivered continuously through an Intrajejunal percutaneous tube (PEG-J). 24 adult (14 M, 10 F, median age 71 years) with APD and preserved sensitivity to L-Dopa were enrolled. 7 days before PEG-J placement, to evaluate the possible presence of mucosal or anatomical gastric anomalies, each patient underwent endoscopic esophagogastroduodenoscopy (EGD). Treatment with LCIG consists in a water-based suspension containing micronized levodopa (20 mg/mL) and carbidopa (5 mg/mL) in methylcellulose, administered by continuous jejunal infusion for 12h/day using a portable pump by PEG-J. Clinical evaluations were performed at baseline(T0), before LCIG initiation, and after 3 (T3) and 6 (T6) months of therapy. To evaluate efficacy and safety outcomes it has been used Unified Parkinson’s Disease Rating Scale (UPDRS) parts II, III and IV. For the analysis of the differences between the clinical variables and to exclude bias due to the small number of the sample in the question, the non-parametric Kruskal-Wallis H test was used for the comparison of three samples. A statistically significant value of p was less than 0.05. The analyzes were carried out using SPSS version 13 (SPSS Inc., Chicago, IL, USA).

Results: 1) Success rate for PEG-J placement was 100%; 2) Eight/24 patients (33%) dropped-out LCIG at T3; 3) Sixteen/16 patients (100%) showed statistically significant (p 0.05) higher performances in daily common activities and statistically significant (p 0.05) lower incidence and severity of motor fluctuation in T3 compared to T0 and T6; 4) During observational period, 6 patients experienced adverse events.

Conclusion: 1) This study demonstrates that continuous intrajejunal LCIG’s infusion treatment is highly effective in decreasing motor fluctuations in advanced PD patients compared to oral administration of levodopa-carbidopa; 2) This therapeutic approach should be proposed in well selected APD patients with preserved sensitivity to L-dopa.

P0815 PREDICTIVE RISK MODEL FOR POST-ENDOSCOPIC SUBMUCOSAL DISESECTION ULCER BLEEDING OF STOMACH

Y.H. Cho1, S.K. Shin1, E.H. Kim1, Y.C. Lee1, S.K. Lee1, J. Park2

1Department Of Gastroenterology, Severance Hospital, Yonsei University College of Medicine, Seoul/Korea, Republic of
2Department Of Gastroenterology, Yonsei University College of Medicine Dept. Of Internal Medicine, Seoul/Korea, Republic of

Contact E-mail Address: last_message@yuhs.ac

Introduction: Post-endoscopic submucosal dissection (ESD) bleeding is the most common complication of ESD. In previous studies, the post-ESD bleeding occurred from 1.8% to 15.6% of total procedures [1–4]. Recently, many patients who underwent ESD, have been prescribed antiplatelets or anticoagulants, because of various underlying diseases such as cerebrovascular accidents or...
cardiovascular diseases [5]. Thus, the verified risk prediction model of post-ESD bleeding may help to determine preventive therapeutic options and restarting date of antiplatelet agents.

Aims & Methods: The aim of this study is to develop the predictive risk model of post-ESD bleeding. A total of 3574 patients, who were taken ESD from January 2007 to February 2014 in a Korean tertiary hospital, were included in this retrospective study. To avoid overfitting of the prediction model, we divided the patients randomly into two groups, either a derivation group or a validation group. Preoperative and procedural-related variables were selected via univariate and multivariate analysis. A risk score was calculated to assess the bleeding prediction model of a patient in the derivation group and was discriminated in the validation group.

Results: Post-ESD bleeding occurred in 248 patients (6.94%). In the derivation group, the model also showed good discrimination (C-index 0.662). In the validation group, the model showed good discrimination (C-index 0.655). Based on the model, the risk of post-ESD bleeding was divided into three grades, low risk (score ≤ 4), medium risk (score > 4 and ≤ 13), and high risk (score > 13). The incidence of post-ESD bleeding in the low, medium, and high risk group were 5.7%, 7.1%, and 10.3%, respectively. In the validation group, the incidence of post-ESD bleeding in the low, medium, and high risk group were 6.1%, 7.4%, and 11.0%, respectively.

Conclusion: Our study investigated a prediction scoring system of estimating the bleeding risk, including the patient, endoscopist factors. A risk score can be calculated before the procedure and the endoscopists can predict bleeding potency before the gastric ESD. Based on the scoring system, endoscopists may alter therapeutic plans such as prolongation of admission dates or mediation schedules.

4. Park YM, Cho E, Kang HY, Kim JM. The effectiveness and safety of LED-BLI-ME were demonstrated the high diagnostic performance of LED-BLI-ME for early gastric cancer. Secondary end point was to compared the diagnostic accuracy of LED-BLI-ME for EGC. First end point was to compare the diagnostic accuracy and between LED-BLI-ME and BLI-ME. Our study was approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. In addition, this study has been registered in the University Hospital Medical Information Network Clinical Trials Registry (UMIN-CTR: http://www.umin.ac.jp/ctr/) as trial UMIN 000025275.

Results: The clinicopathological features in the patients were as follows; mean age was 71.9 ± 8.74, gender (male/female) was 31/14, location (UM/L) was 9:15:21, macroscopic type (elevated: flat: depressed) was 18:1:26, median tumor size was 19.6 ± 19.6 mm, and final pathological diagnosis (well differentiated adenocarcinoma: moderately differentiated adenocarcinoma: poorly adenocarcinoma) was 37:1:7, respectively. Diagnostic accuracy of demarcation line of EGC using LED-BLI-ME and BLI-ME were 91.1% (41/45) and 91.1% (41/45), respectively. The rate of high confidence for diagnosis of a demarcation line of EGC using LED-BLI-ME and BLI-ME were 84.4% (38/45) and 91.1% (41/45), respectively. There was no significant difference of diagnostic accuracy between two modalities. The consistency rate in the demarcation line, microvascular pattern, and microsurfaces pattern of EGC between LED-BLI-ME and BLI-ME were 91.1% (41/45), 91.1% (41/45), and 97.8% (44/45), respectively. Conclusion: LED-BLI-ME were demonstrated the high diagnostic performance for diagnosis of EGC demarcation, similar to BLI-ME.

P0818 RISK FACTORS OF COMPLICATION RELATED TO ENDOSCOPIC MANAGEMENT OF FOREIGN BODIES IN THE ESOPHAGUS: A PROSPECTIVE STUDY IN 595 CASES FROM MULTIPLE CENTERS IN CHINA

L. Wang, L. Wang
The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Contact E-mail Address: wanglj76@hotmail.com

Introduction: Foreign bodies (FBs) ingestion is a common medical emergency accounting for 4% of all emergency endoscopies, secondary only to the GI bleeding.1) 70%–75% of FBs are located in the esophagus2). The need of endoscopic management reached up to 63%–76%,3,4,5 with 3%–20% of incidence of complications.6-9 According to the latest guidelines from ESGE, emergent endoscopy is recommended for the impaction of sharp-pointed objects within 24 hours20. However, there were still different opinions on the endoscopic methods with different FBs.

Aim & Methods: The study was performed from October 2015 to August 2016 among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.

Results: 1) The most common types of foreign bodies were fish bones (34.0%), chicken bones (22.1%), fruit nuclei (17.7%), and food bolus (14.6%). The majority of them were sharp objects (≤ 2.5 cm, 74.0%), subsequently followed by middle objects (2.5–6.0 cm, 24.5%) and long objects (> 6 cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (24.5%) and distal segment (8.9%) of esophagus. 2) 96.3% of all cases had obvious clinical symptoms. Clinical symptoms occurred more often in the proximal segment of the esophagus (98.1%) than any other segments of the upper gastrointestinal tract (92.6%) (P < 0.001). 3) The successful retrieval rate through endoscopy was 94.5%. It was even higher with general anesthesia (99.3%) than without it (92.7% (P < 0.01). 4) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects (P < 0.001). The rate was increased by 2.2- and 6.1-folds after impacted for over 24 hours as compared with less than 24 hours. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97–5.74). In particular, the incidence of perforation was 5.6%, which was strongly related with long retention time and sharp objects (P < 0.03), but not with locations or lengths of the objects (P > 0.05).

Conclusion: General anesthesia could largely improve the retrieval rate through endoscopy. Foreign bodies, especially sharp ones, should be removed as soon as possible within 24 hours, to further decrease severe complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

4. Palta R, Sahota A, Bemar A et al. Foreign body ingestion: characteristics and treatment of advanced precursor lesions and cancer. The annual incidence of dysplasia was 2.35% in the updated Sydney system and the recommended five gastric biopsies were performed. The histological assessment and biopsy sampling protocol has been standardized in the updated Sydney system and the recommended five gastric biopsies were widely applied in the staging system for gastric cancer risk stratification9. Some believes that the GA risk screening requires consideration of the cost - suffering of patients as well as rational utilization of medical resources, so adopt five biopsy pieces (lesser curvature of the antrum and corpus, angulus biopsy) with quite accurate consistency with five biopsy pieces protocol using OLGA and OLGIM staging (94.0% and 92.9%), together with a rather low omission diagnostic rate of OLGA and OLGIM III + IV (5.8% and 7.2%).

Conclusion: The incisura angularis with more moderate and severe GA and IM should be recommended as conventional biopsy site during endoscopy. The three types of atypia (antrum and corpus combined) was obviously associated with quite high consistency, more convenience and less cost comparing with five biopsy pieces protocol using OLGA and OLGIM staging system, and thus could be recommended in the further gastric risk screening applying OLGA and OLGIM staging.

P0819 BIOPSY STRATEGIES FOR ENDOSCOPIC SCREENING OF PRE-MALIGNANT GASTRIC LESIONS

Z. Neng
Department Of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China

Contact E-mail Address: zm1990morphone@163.com

Introduction: GA and IM are detectable precancerous lesions of most gastric carcinomas. Early endoscopy examination may potentially result in early detection and treatment of advanced precursor lesions and cancer. The annual incidence of GA and IM in Europe, for GA was 0.1% and for IM was 0.25% in the Netherlands. The histological assessment and biopsy sampling protocol has been standardized in the updated Sydney system and the recommended five gastric biopsies were widely applied in the staging system for gastric cancer risk stratification9. Some believes that the GA risk screening requires consideration of the cost - suffering of patients as well as rational utilization of medical resources, so adopt five biopsy pieces (lesser curvature of the antrum and corpus, angulus biopsy) with quite accurate consistency with five biopsy pieces protocol using OLGA and OLGIM staging (94.0% and 92.9%), together with a rather low omission diagnostic rate of OLGA and OLGIM III + IV (5.8% and 7.2%).

Conclusion: The incisura angularis with more moderate and severe GA and IM should be recommended as conventional biopsy site during endoscopy. The three types of atypia (antrum and corpus combined) was obviously associated with quite high consistency, more convenience and less cost comparing with five biopsy pieces protocol using OLGA and OLGIM staging system, and thus could be recommended in the further gastric risk screening applying OLGA and OLGIM staging.

2Department Of Surgery, Keio University School of Medicine, Tokyo/Japan

Contact E-mail Address: ogotou-gi@keio.jp

Introduction: In gastrointestinal stromal tumors (GISTs) without a risk of metastasis to other organs, local resection is acceptable. In small GISTs, however, it is controversial whether surgical resection is necessary because of a risk of recurrence/metastasis in these tumors are considered to be quite low. Laparoscopic endoscopic cooperative surgery (LECS) is a promising surgical technique as one of minimally-invasive, function-preserving surgeries. By using this technique, we are aggressively resecting gastric SMTs including relatively small ones.

Aims & Methods: To investigate necessity of surgical resection for small GISTs, we retrospectively assessed a malignant potential of these tumors which were resected nonexposed endoscopic wall-inversion surgery (NEWS) (nonexposure LECS technique) as well as feasibility and safety of this technique. Between August 2013 and October 2016, NEWS was conducted in 33 consecutive SMTs which met all of following conditions: possible GIST which was preoperatively diagnosed by histology or imaging modalities, less than 3 cm in size and involving mainly the submucosal layer only. NEWS procedure, a lesion was resected in a following manner: endoscopic mucosal markings, laparoscopic serosal markings just behind the mucosal markings, endoscopic submucosal injection, laparoscopic sero-muscular incision and suturing with the lesion invected together with the stomach, endoscopic submucosal tunnel creation, and peroral retrieval. Short-term outcomes of NEWS and a potential risk of recurrence/metastasis in each tumor according the Fletcher's classification were assessed.

Results: Mean age and size of the lesion were 59.9±21.5 years-old and 2.3±1.4 cm, respectively. The procedure was successfully completed in all cases in a mean procedure duration of 206±43 min. The patients were discharged without severe adverse events 7.5±1.5 days after the procedure. The first endoscopy after the procedure was performed 5.8 months after discharge in 22 cases, which showed no residual food in the remnant stomach in all cases. Neither apparent impairment of food intake nor disease-related death occurred and a body weight loss was 0.9±2.3 kg during the mean observational period of 16 months. GIST was histologically diagnosed in 20 cases. A risk of recurrence/metastasis in these GISTs was classified into high (2), intermediate (1), low (12) and very-low (5), respectively. In a comparison of two groups (high/intermediate and low/very-low), a mean tumor size and existence ofdle formation were 31.7±21.6mm and 67% and 12% (p=0.036), and 67% and 12% (p=0.028), respectively.

Conclusion: Some small GISTs which could be retrieved transorally had a high malignant potential. NEWS was feasible, safe and therefore recommended for these tumors including ulcerated GISTs as a minimally-invasive surgical option to avoid an additional surgical scar for the retrieval of the specimen and a risk of intragastric tumor cell seeding into the peritoneum during the procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

performed off PPIs). At 24–36 months, esophagitis was present in 9 out of 41 examined patients (p < 0.04 vs. 3 months). In 6 out of 10 patients with esophagitis present at 3 months, who underwent control endoscopy at 24–36 months, esophagitis resolved completely even though only 2 patients had been treated by a PPI.

Conclusion: After POEM, the majority of patients with esophagitis had erosions on site of submucosal tunnel and early esophagitis often occurred in patients without an abnormal acid exposure. These findings suggest an ongoing healing process after POEM might interfere in findings of presumed post-POEM reflux esophagitis. Thus, the rate of real post-POEM reflux esophagitis may be lower than previously thought.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0824 ENDOSCOPIC SUBMUCOSAL TUNNEL DISSECTION FOR LESSER GASTRIC CURVATURESUPERFICIAL NEOPLASMS

D. Shi, R. Li, W. Chen, X. Wang, C. Ma, D. Zhang Gastroenterology, the First Affiliated Hospital of Soochow University, Suzhou China

Contact E-mail Address: lrhcsz@163.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used for resection of gastrointestinal neoplastic lesions, but there are still technical challenges in treating large ones especially located in lesser gastric curvature. In the tunnel technique, incisions at the lower and upper edge lesions are joined by a submucosal tunnel and then lateral incisions are made. The mucosa is thereby easily separated from the muscular layer. We report our experience of endoscopic submucosal tunnel dissection (ESTD) in lesser gastric curvature.

Aims & Methods: To estimate the safety and efficiency of endoscopic submucosal tunnel dissection (ESTD) for lesser curvature superficial neoplasms. 47 patients underwent ESTD and 21 received endoscopic submucosal dissection (ESD). Operation time, security, En bloc resection rate and complications were compared between the two groups. The major difference between the ESTD and ESD is that, instead of pre-cutting circumferential incision, a submucosal tunnel was created by submucosal dissection from the oral incision to the anal incision. Bilateral resection was then performed to remove the lesion completely.

Results: The differences between the two groups in the age of the patients and the diameter of the lesions had no statistically significant (P > 0.05). En bloc resection rate was 100% in the study group and 90.5% in the control group (19/21), and the difference was statistically significant (P < 0.05). The average operation time of the ESTD group was 59 minutes (50–70 minutes), whereas the control group was 67 minutes (48–110 minutes), the difference was statistically significant (P < 0.05). The intraoperative bleeding rate of the study group was 57.7% (15/26), the control group was 100%. The difference was statistically significant (P < 0.05). The incidence of perforation was 0% in the study group and 9.5% in the control group (2/21), and the difference was statistically significant (P < 0.05). There was 1 case of delayed bleeding after operation in the two groups, there were no postoperative perforation, and the difference was not statistically significant (P > 0.05). The incidence of bleeding and metastasis of the two groups after operation was not statistically significant.

Conclusion: ESTD for lesser curvature superficial neoplasms can obviously shorten the operation time and have a higher security, compared with the traditional ESD operation.

historical diagnosis to guide management decisions. Western data on ESD for SMT is absent. Aims was to analyse the data from our referral centre.

Aims & Methods: A prospectively collected ESD database was analysed to identify patients with SMT of the UGI. All lesions underwent EUS assessment with the aim to exclude MP involvement prior to resection, and in the case of neoplastic and non-neoplastic lesions, resection was performed endoscopically.

Results: 290 ESDs for SMT were performed. The median age was 59 years (range 18-93). 17 cases (6%) were referred from other hospitals. The majority of these cases (76%) were resected endoscopically. Common reasons for non-endoscopic resection were absent radiological features (50%) and obvious MP in the endoscopic images (28%). To FAE (0%) necessitating a higher number of endoscopies. Median age among the two groups were comparable at 75 and 69 years respectively. Male predominance in both the groups (70% and 67%). Adenocarcinoma was the most common malignancy (56%), followed by squamous cell carcinoma (35%) among the study subjects. We observed a higher frequency of oesophageal cancer (28%) to FAE (0%) necessitating a higher number of endoscopies. Patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscopically and histologically. MP involvement cannot be reliably excluded prior to EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

Conclusion: ESD for selected UGI SMT is an effective treatment. Long-term endoscopic follow-up confirmed the absence of recurrence endoscopically and histologically. MP involvement cannot be reliably excluded prior to EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

Introduction: The incidence of oesophageal cancer has increased significantly over the past two decades. The majority of these cancers are incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expandable metallic stents (SEMS) have a well-recognised role in the palliative management of patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscopically and histologically. MP involvement cannot be reliably excluded prior to EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

Aims & Methods: The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation in oesophageal cancer via different approaches (EC or FAE) at the Royal Infirmary of Edinburgh (RIE). A retrospective observational study was conducted between May 2014 to April 2016; a total of 62 SEMS. The approach to stent insertion was subject to operator choice and availability of fluoroscopic assistance, and as such can be akin to randomized study. We compared early and late complications associated with two techniques. Early complications included pain, vomiting, bleeding, perforation and tachycardia. Late complications included tumour overgrowth, oesophagitis, oesophageal stricture and stent migration. We also compared morbidity, the need for repeat procedures and the number of additional stents required following each approach.

Results: Forty-seven stents were inserted by EC and fifteen by FAE. The median age among the two groups were comparable at 75 and 69 years respectively. There was male predominance in both the groups (70% and 67%). Adenocarcinoma was the most common malignancy (56%), followed by squamous cell carcinoma (35%) among the study subjects. We observed a higher frequency of oesophageal cancer (28%) to FAE (0%); however no malposition was observed in the EC group. Early complications were comparable in both groups, however chest pain (21%) was more frequently observed no malposition was observed in the EC group. Early complications: infections in 12 patients (16.4%), perforations in 2 (2.7%); late complications: stenosis in 7 (9.6%): dilation in 6, 1 patient (3%) had MP injury which precluded complete resection. Three of five lesions of the completely ESD procedures were in the proximal body of the stomach, however only two lesions of the completely resected lesions were in the proximal body (P=0.004). Otherwise, there were no significant differences between the patients and lesions characteristics. The histology of the SMT lesions were 9 NET, 6 leiomyoma, 5 Granular cell tumours, 4 inflammatory fibroid polypl, 2 Gliast, 2 dystrophic Lipomas, 1 myofibroblastic tumour and one Warthin’s like tumour. Nineteen patients had completed surveillance endoscopy (SE) without an endoscopic and histological recurrence (Median follow up 18 months). Six patients are pending SE. The four patients with deep MP involvement were referred for surgery.

Conclusion: Our results are comparable to findings of other authors (1, 2), in that neither approach is superior. Both FAE and EC techniques have similar early and late complications and comparable median survival. EC offers the advantage of stent placement with direct visualization, however a learning curve must be acknowledged. FAE insertion is a time-consuming procedure and exposes both patients and endoscopy staff to radiation. In conclusion, the approach used should be based on individual characteristics including operator experience, tumour characteristics and previous endoscopic interventions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0828 CAUSTIC INJURIES OF THE SUPERIOR GASTROINTESTINAL TRACT: 15 YEARS OF EXPERIENCE

M. Rocha, T. Moreira, M. Salgado, L. Maia, S. Barrias, I. Pedrito
Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: martalemorsocha@gmail.com

Introduction: Ingestion of caustic substances is relatively frequent and can cause significant morbidity and mortality in the upper gastrointestinal tract, carrying important morbidity and even mortality.

Aims & Methods: We aimed to characterize the population assisted for caustic ingestion, the therapeutic approach, complications and risk factors for severe oesophageal lesions.

Retrospective cohort of adults presenting due to caustic ingestion between 2000 and 2015. Demographic and clinical data were collected. The endoscopic Zargar classification was applied. We analysed risk factors for severe oesophageal lesions, defined as Zargar 2b-3. Statistical tests Mann-Whitney, Spearman (significance level 5%).

Results: Overall 72 patients were included, with a mean age 53 ± 17 years, 65.3% female. Ingestion was voluntary in 49.3% of the cases, 33.3% had previous suicide attempts. Alkaline substance in 90.4%. Most common symptoms at admission: 60.3% odyphagia, 11.3% epigastric pain, 32.9% vomiting. Orpharyngeal lesions in 41.1%. In 79.5% endoscopy was performed in the first 12 hours. Oesophageal lesions were present in 46.6% of patients (Zargar classification: 1-2.7%, Ha-23.3%, Hb-5.5%, IIIa-6.8%, IIIb-8.2%). Gastric lesions in 58.9% and duodenal lesions in 13.7%, 53.4% were hospitalized, 51.3% in intensive/intermediate care units. The mean length of hospital stay was 14.9 days. Medical treatment prescribed: 76.7% proton pump inhibitors, 15.1% corticoids, 15.1% prophylactic antibiotics. Parenteral feeding was initiated in 28.8% of patients. Eight patients required invasive ventilation and two were tracheotomised. Early complications: infections in 12 patients (16.4%), perforations in 2 (2.7%); late complications: stenosis in 7 (9.6%): dilation in 6, surgery in 3. One patient died from gastric perforation after voluntary ingestion of acid. Severe oesophageal lesions were associated with increased inflammatory parameters, tachycardia and/or hypotension at admission and motivated longer hospital stays, requirement of intensive care and further complications (p<0.002). The ingestion of acidic substances (100% of voluntary intake) was associated with severe oesophageal damage in 3/7 (42.9%) patients, severe gastric lesion in 5/7 (71.4%), acidemia in 5/7 (71.4%), complications in 5/7 (71.4%) and 100% hospitalization.

Introduction: A value of the combination of magnifying endoscopy of and image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diagnosis for the early gastric neoplasm. That method is useful, but in order to master it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm CF-H260I with 563 nm). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combination of light provides more information about the vasculature and architecture on the mucosal surface than that obtained with typical white-light imaging. When we use acetic acid indigocarmine mixture (AIM) with LCI, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects are 120 lesions of 115 patients with gastric neoplasm. We are indicated the endoscopic submucosal dissection (ESD), and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy (with endotherapy, as defined in BSG/ACPGBI guidelines 2). Non-complex polyp multidisciplinary team meeting was created within the North East of England. The aims of our study were to evaluate and compare the sensitivity, specificity, and clinical outcome of gastric ESD in patients aged 85 years or older. However, few studies have reported the short-term and long-term outcomes of gastric ESD in elderly patients.

Aims & Methods: The aims of our study were to evaluate and compare the efficacy, safety, and clinical outcome of gastric ESD in patients aged 85 years or older and in younger patients. The subjects were 705 patients who collectively presented with 876 gastric tumors (288 adenomas and 588 early gastric carcinomas). All patients underwent ESD at our hospital between June 2007 and December 2012. Of 705 patients were divided into two groups: elderly (aged $<85$ years, consisting of 59 patients with a collective 71 lesions) and non-elderly (Group B: aged $\geq85$ years, consisting of 646 patients with a collective 805 lesions). We evaluated the clinical and pathological findings, resection rates, complications, and long-term outcomes, including the survival rate. The local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection. The 3- and 5-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort.

Results: The patients’ mean ages were 87 (Group A) and 71 years (Group B), and the male-to-female ratios were 30/29 (Group A) and 646/805 (Group B). No significant differences were found in the mean tumor size for Group A (15 mm) and Group B (20 mm). Regarding histopathological findings, the prevalence rates of tubular adenoma were 23.8% (21/71; Group A) and 33.8% (267/805; Group B); intramucosal carcinomas, 52.1% (37/71; Group A) and 53.8% (433/805; Group B); shallow submucosal invasive carcinomas ($<500 \mu$m), 7.0% (5/71; Group A) and 6.5% (52/805; Group B); and deep submucosal invasive carcinomas ($>500 \mu$m), 11.3% (8/71; Group A) and 6.6% (53/805; Group B). Once again, the groups showed no significant differences. The en bloc resection rates were 98.6% (70/71; Group A) and 97.1% (782/805; Group B); histological complete resection rates were 94.4% (67/71; Group A) and 92.9% (748/805; Group B), and the curative resection rates were 78.8% (56/71; Group A) and 86.3% (695/805; Group B). Among the non-curative cases, 13 (86.6%) of the 15 lesions in Group A and 46.3% of the 32 lesions in Group B were resected en-bloc, respectively. There were no significant differences observed in the survival rates. 6 (10.0%) of 59 patients in Group A and 54 (9.3%) of 646 patients in Group B died, and disease-specific mortality rates in Groups A and B were 0% (0/59) and 0.8% (5/646), respectively.

Conclusion: Gastric ESD in patients aged 85 years or older can be effectively and safely performed. According to the long-term outcomes, gastric ESD performed as a local resection (total biopsy) in elderly patients may be acceptable, even in the non-curative cases.

PO831 RESULTS FROM THE FIRST UK VIRTUAL COMPLEX POLYP MDM

A. Chattree, M. Rutter
Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: amitchattree@nhs.net

Introduction: Data from the UK Bowel Cancer Screening Programme (BCSP) has established that the assessment and management of large non pedunculated colorectal polyps (LNPCPs) varies markedly, leading to variable and often sub-optimal outcomes, especially for the most complex lesions. A multicentre complex polyp multidisciplinary team meeting was created within the North East of England BCSP with the aim of ensuring more robust decision making and management of complex LNPCPs.

Aims & Methods: A virtual multicentre MDM was conducted via audioteleconferencing within the North East of England between 2014-6 to discuss complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in BSG/ACPGBI guidelines). The MDM considered 210 cases, of which 30 patients were referred for complex LNPCPs were not discussed. Patient data was distributed securely via NHSmail. Outcomes were assessed prospectively using key performance indicators (KPIs) from the BSG/ACPGBI guidelines.

Results: 61 complex LNPCP cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and were referred to a finding MDM meeting. The 12-month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection...
rate of complex LNPCPs with features suggestive of increased malignancy risk was 20% (51.31% ± 19.14% p = 0.029) vs. 18% (34.09% ± 15.46% p = 0.482).

**Conclusion:** Endoscopists with higher ADR tend to detect significantly more SSA and adenomas with 1–2 cm in size, but have lower proportions of pedunculated adenomas than those with a low ADR. In our study cohort no significant differences in flat shape or diminutive size was measurable.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0852 DIFFERENCES IN DISTRIBUTION OF SIZE, SHAPE AND SERRATED HISTOLOGY OF COLORECTAL ADENOMAS BETWEEN ENDOSCOPISTS WITH LOW (<20%) AND HIGH (>20%) ADENOMA DETECTION RATE**

**Aims & Methods:** Our study aim is to investigate the differences of size, shape and serrated histology of adenomas between low- and high-ADR group in our screening cohort. We analyzed 2534 screening colonoscopies performed by 266 endoscopists between 2007 and March 2017 within the austrian certificate of screening colonoscopy. T-Test was used to assess differences.

**Results:** 39.1% of endoscopists were categorized in the ADR low- and 60.9% in the high-ADR group. Overall, mean ADR was 23.06% (SD 0.55) with a minimum of 0.39% and a maximum of 48.72%. In the low-ADR group mean ADR was 14.56% (SD 0.42) and 28.51% (SD 0.50) in the high-ADR group. Relating to size, there was a significant difference (p = 0.029) in detection of adenomas of 1–2 cm with a mean of 8.44% (SD 6.02) in low- vs. 10.22% (SD 6.64) of all adenomas in high-ADR group but no differences between adenomas <0.5 cm, 0.5–1 cm and those bigger than 2 cm. Regarding shape, proportion of pedunculated adenomas in low-group-ADR differ significantly higher (p = 0.002), with a mean of 19.36% (SD 14.60) vs. 17.40% (SD 9.55) but there were no differences between flat and sessile adenomas. With a mean proportion of 4.43% (SD 5.61) vs. 6.64% (SD 5.97), the proportion of sessile serrated adenomas (SSA) differ significantly between low-ADR vs. high-ADR group (p < 0.01). There was no significant difference regarding traditional serrated adenomas (p = 0.800).

**Aims & Methods:** We aimed to identify the potential risk factors that are associated with a higher technical difficulty during ESD in a Western European setting where there are no available Asian experts. We prospectively recorded consecutive ESD cases performed by members of the ESD Working Group of the Spanish Society of Digestive Endoscopy. Demographic and clinical characteristics of the patients, location and morphology of the lesions, and technical factors were collected. We defined difficult ESD as those aborted procedures, time-consuming (duration >180 min.) or when changing the technique to piecemeal resection was needed to remove the tumor. Analyses were carried out using IBM SPSS software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous variables are reported as the mean ± standard deviation (SD). A Kolmogorov-Smirnov test was used to evaluate normal distribution. Categorical variables are reported as either frequencies or percentages. Statistical differences between the groups were analyzed using a chi-squared method for categorical data. The meaningful variables with a p value < 0.1 in the univariate analysis were included in the logistic regression model. Multivariate analysis was performed using binary logistic regression methods. Odds ratios (ORs) and 95% confidence intervals (CI) were calculated to assess the strength of the influence of each individual variable.

**Results:** We included 265 lesions in 265 patients [mean age ± SD: 69 ± 10; 150 males (56.6%)]. They were recruited in 15 Spanish University Hospitals between January 2016 and March 2017. Location of the lesions were: esophagus (n = 7; 2.6%), cardia (n = 5; 1.8%); stomach (n = 48; 18.1%); duodenal bulb (n = 1; 0.3%); colon (n = 144; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size was 38.6 ± 18.5 mm. Median duration of the procedure was 105 min. (8–375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258; 97.3%) both situations, duration >3 h and a piecemeal resection, were noted in 21 (8.1%) patients. Duration >3 h in 25 cases (9.7%) and unsuccessful en bloc
resection in 20.7% were observed in isolation, respectively. Table 1 shows the univariate and multivariate analysis of factors regarding technically difficult ESD.

Table 1: Univariate and multivariate analysis of possible factors related to technically difficult ESD.

</table>

Conclusion: The factors independently associated with technically difficult ESD (aborted procedures, time-consuming or finished with a piecemeal resection) were: lesion size >30 mm, poor manoeuvrability, recurrent lesions and intraprocedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curve.

P0834 EPOCH-MAKING TECHNIQUE OF FULL-THICKNESS RESECTION FOR THE COLORECTAL TUMOR BY USING LAPAROSCOPY ENDOSCOPIQUE COOPERATIVE SURGERY (LECS) (Y. Tamegai1, Y. Fukunaga2, A. Chino3, S. Saito1, J. Fujijsaki1, M. Ueno3)

1Dept. Of Endoscopy, Cancer Institute Hospital, Tokyo/Japan
2Dept. Of Surgery, Cancer Institute Hospital, Tokyo/Japan

Contact E-mail Address: yoshitomo.tamegai@jcf.or.jp

Introduction: We established the Laparoscopy Endoscopy Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal endoscopic submucosal dissection (ESD) procedure. The local full-thickness resection of the combined procedure of laparoscopy assisted colectomy (LAC) and ESD procedure. Also, it is the method that is epoch-making for minimal invasive treatment that keeps an intestinal function.

Aims & Methods: The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1376 colorectal tumors in 1341 patients (female: 777/564; mean age, 66.1years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: female = 7/4; mean age, 63.5years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastases does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be as follows: 1) Intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia involved appendix or diverticulum. We examined the clinicopathological outcomes of the above-mentioned 11 cases.

Results: Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The results which we judged as the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticulum, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. An operative time was an average of 195.8 minutes (127 to 332) and the postoperative bleeding was an average of 8.9 g (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.7(6 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10–60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesive ileus, we followed favorable course.

Conclusion: We developed a LECS procedure to overcome the limit of ESD, and completed full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0838 RANDOMIZED CONTROLLED TRIAL OF ABDOMINAL VIBRATION STIMULATION AND WALKING EXERCISE FOR BOWEL CLEANSING PRIOR TO COLONOSCOPY

Gastroenterology, Ajou university School of Medicine, Suwon/Korea, Republic of

Contact E-mail Address: cnohn23@gmail.com

Introduction: Adequate bowel preparation is important to perform colonoscopy for accurate mucosal examination, lesion detection and treatment. Walking exercise is known to be effective for colon cleansing. However, it is difficult for patients with uncomfortable walking to improve the status of bowel cleansing.

Aims & Methods: We aimed to identify themes important to patients undergoing GI investigations, to enable questionnaire development. Patients who had undergone upper or lower GI investigations (gastroscopy, colonoscopy and CT pneumocolon) were invited to attend for a semi-structured interview. The interviews provided an in-depth understanding of patient experience of GI procedures. 6 over-arching and inter-linking themes emerged across all procedures: anxiety, expectations, choice/control, communication/information, comfort and embarrassment/dignity. Relation of themes was seen e.g. if the procedure appointment was sooner than expected, patients were anxious about the potential outcome. Choice was important in terms of appointment, endoscopist and choice of pre-medication, however it was highly individualised. Communication prepared patients and managed expectations, with one patient describing poor endoscopist communication affecting the whole experience. Patients described embarrassment related to changing and waiting areas; sensitive nature of the test; exposure and physical reaction. Discomfort during the procedure was attributed to instrument and air insertion.

Conclusion: Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for bowel cleansing. This work will be used to develop PREMs for bowel cleansing.

prparation. In this randomized, prospective, investigator-blind study and single center setting, 141 inpatients for elective colonoscopy were randomized to two groups. PEG solution was used for bowel cleaning in all patients. The one is walking over 3000 steps and the other is having abdominal vibrator more than 30 minutes before colonoscopy. After examination we recorded procedure results, sedation information, patient’s satisfaction and adequacy of bowel preparation by using the Boston Bowel Preparations Scale (BBPS).

Results: There were no significant differences between vibrator group (n = 75) and walking group (n = 66) in bowel preparation quality (Total BBPS 7.40 vs 7.23, p = 0.519), withdrawal time (30.40 vs 30.05 mins, p = 0.829), number of polyps (4.09 vs 3.17, p = 0.085), patient satisfaction (4.39 vs 4.12, p = 0.249) and number of diarrhea after taking PEG (11.49 vs 11.42, p = 0.903). Vibration group was superior than walking group in time of first defecation after taking PEG (112.89 vs 123.42 mins, p = 0.005) and evacuation intubation time (6.23 vs 8.52 mins, p = 0.011).

Conclusion: Bowel preparation accompanied with abdominal vibration stimulation showed almost similar results to a walking group which was conventional methods for adequate bowel preparation. The patients with the conditions which cause uncomfortable gait such as old age, CVA, Parkinsons, or joint disease, bowel preparation with abdominal vibrator is expected to help in proper bowel cleansing for therapeutic colonoscopy.

Introduction: Rheological properties of the submucosal cushioning solutions are crucial to avoid complications secondary to endoscopic resections. Electrical resistance (R) of a substance is a measure of the difficulty to pass an electric current through that solution. The higher the R, the resection will be quicker, easier and safer, with less temperature increase. Our group has developed a new solution to perform submucosal injection (TriBio).

Aims & Methods: To analyze the electrical (R) and rheological (temperature, viscosity, height and lasting of the cushioning) properties of different submucosal solutions in an ex vivo model of porcine stomach. Tested solutions were: Saline (S), Glyceol® (GC), Hyaluronic acid (HA), Distilled water (DW), Platelet-rich plasma (PRP), Glucosated serum 10% (GS), Gelaspan (GP), TriBio (TB) and PRP + TB. Measurements were done at time 0 and 30 minutes.

Results: The solutions that showed the best basal R were: PL, HA, GS, TB and PRP + PRP. At 60 minutes, the best R were: PRP, TB, PRP + TB, HA and GS. The best durability at 60 minutes was for TB, PRP, TB + PRP and PRP that maintained the height at around 80% of its original in comparison to the other substances with were at around 60%. During the resection the solutions that underwent a lower temperature increase were: TB + PRP, PL, and TB.

Contact E-mail Address: sara.sjoblom@vgregion.se

Introduction: Patients with chronic diseases, such as inflammatory bowel disease, experience a lower degree of being involved in health care than others. Compared with other countries Swedish patients report lower possibility to be involved in their care and receive less information about care (1).

Aims & Methods: To investigate the perception of written and oral information given before and after a colonoscopy, the perceived knowledge of planned follow-up and preference to be more involved in decisions/participate in their care in different patient groups. Outpatients (> 18 y) undergoing colonoscopy (all indications) were consecutively included (n = 862). Before the procedure patients completed questionnaires regarding sociodemographic data and the written information about bowel preparation and examination. After the procedure patients reported their perceptions about the information provided regarding the colonoscopy and the follow-up.

Results: Data from 862 patients were analyzed (447 females) (mean age 52, 18–90 y) A large number of patients (n = 740, 87%) rated the written information sent home before the colonoscopy as distinct, while a subset (n = 110, 13%) rated it as indistinct/very indistinct. When questions of importance were asked to the medical staff during the colonoscopy most patients were content with the answers from the physician or nurse. A small proportion of patients (n = 57, 7%) stated that they received too little information or that they did not understand the information about the colonoscopy results; these patients were mainly younger (< 50 y) (p < 0.001). The majority of the patients (n = 602, 74%) reported thorough knowledge about the follow-up, while 26% (n = 207) lacked this knowledge. More than 1/3 (n = 275) of the patients wished to be more involved in decisions regarding their care and treatment. Desire for a higher degree of involvement were more pronounced in patients (< 40 y (p < 0.05) and in patients with IBD (p < 0.05) compared to patients with other indications for colonoscopy. Patients referred from outpatient clinics in the hospital desires a higher degree of involvement than patients referred from primary care (p < 0.01).

Conclusion: The majority of the patients undergoing colonoscopy reported that they received satisfactory information about the procedure and preparation. However, there is room for improvement regarding follow-up information and patients’ involvement in their care and treatment. Specifically, improvements seem warranted for younger patients and patients with chronic diseases, such as IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0841 THE INCIDENCE OF SYNCHRONOUS ADVANCED NEOPLASIA OF RECTAL LATERALLY SPREADING TUMORS WITH A SKIRT**

**Department Of Gastroenterology, Saka Central Hospital Advanced Care Center, Saka, Naganos, Japan**

**Contact E-mail Address:** shou0122@hotmail.com

**Introduction:** A "skirt" is a slightly elevated flat lesion with wide pits occasionally observed at the margin of laterally spreading tumors (LSTs), and rectal LSTs had significantly more skirt lesion in comparison to colonic LSTs. Although the clinicopathological, endoscopic, and molecular characteristics of LSTs with a skirt have been reported [1], there are no reports concerning the incidence of synchronous neoplastic lesions of rectal LSTs with a skirt.

**Aims & Methods:** The aim of this retrospective study was to clarify the incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt. A total of 13,116 cases underwent colonoscopy in our hospital between January 2012 and June 2016. Of these, 101 consecutive rectal LSTs were examined to assess the incidence of synchronous AN detection rate and the number of AN according to the location of AN lesion; divided into the right colon, left colon and rectum. A skirt was defined on the basis of the following endoscopic findings: spreading across the margins of the LST, consisting of a slightly elevated flat lesion, and containing wide pits. AN was defined as the presence of any of the following features: adenomas larger than 10 mm, adenomas with villous histology or high-grade dysplasia including intra-mucosal carcinoma and invasive cancer.

**Disclosure of Interest:**

All authors have declared no conflicts of interest.

**Results:**

</tbody>
</table>

**Conclusion:**

The rectal LSTs with a skirt had significantly lower synchronous advanced neoplasia than rectal LSTs without a skirt, especially in the right colon and left colon. Our results may suggest that rectal LSTs with a skirt have different characteristics compared with rectal LSTs without a skirt in terms of the incidence of synchronous neoplastic lesion.

**Contact E-mail Address:** ibon@igtp.cat

**Introduction:** Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hialuranic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

**Aims & Methods:** To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomized to receive one of the following shields onto the lesions: PRP + TriBio, PRP and TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers were macroscopically and histopathologically evaluated.

**Results:** Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; p < 0.05). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio.

**Conclusion:**

The use of a combination of two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon.

**Introduction:** Colonicoscopic procedures have become massive in the last years since colorectal cancer (CRC) is becoming a prevalent disorder. The next frontier of this technique will be to provide an active substance in a precise site of the colon (targeted therapy). This has many advantages (targeted therapy, dose adjustment, limiting side effects, assessment of mucosal healing, etc.); however, this selective and direct administration of drugs is not possible nowadays, but it is a true challenge. Following these evidences we have developed drug eluting platform to locally treat CRC lesions.

**Aims & Methods:** To evaluate the efficacy of intratumoral injection of our drug-eluting platform with different combinations of these antitumoral drugs (alpha-cept 2 mg/mL, cetuximab 16 mg/mL, panitumumab 6 mg/mL, irinotecan 3.5 mg/mL and bevacizumab 5 mg/mL) in a rat model of azoxymethane-induced colorectal cancer. Rats underwent endoscopic follow-up at 1 and 2 weeks after endoscopic therapy. Afterwards, animals were sacrificed and tumors were excised and macroscopically and histopathologically evaluated.
Results: Intratumoral injection was feasible in all animals with no adverse events. Blood flow and size of tumors ranged from 6 to 8 mm. Approximately 50% of anti-VEGF injection compared with Anti-EGF obtained the best results (significantly reduction in size and cell necrosis). However, only alfibenprat showed total acute tumoral necrosis.

Conclusion: Intratumoral injection of anti-VEGF in a drug-eluting platform is able to produce tumoral necrosis in an experimental model of CRC. This technique could open a new way to manage CRC.

Introduction: Three-dimensional (3D) imaging technique has been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colonic lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colorectal neoplasms compared with conventional 2D endoscopy. We evaluated 12 non-polypoid colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasm was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35 ± 0.58 for 2D endoscopy and 3.75 ± 0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy (p < 0.01). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p < 0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.50 ± 0.53 for 2D endoscopy and 3.87 ± 0.35 for the 3D system, p = 0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient’s needs. Colonoscopy is by many patients considered as a painful and strenuous procedure. To investigate congruence and differences between patients’ and caregivers’ report of pain during colonoscopy. Patients (18 years) undergoing an outpatient colonoscopy (all indications) have consecutively been included (n = 862). Before the procedure the patients completed questionnaires regarding sociodemographic information and anxiety. After the colonoscopy the patients registered their pain experience on a six-grade scale, ranging from “no pain” to “extremely severe pain”. Caregivers (physicians and endoscopy nurses) estimated patient’s pain using the same scale.

Results: Data from 785 patients has been collected, mean age 52 (18–90) years; 40% female. Only 22% of the patient’s reports moderate pain and a subgroup of 14% were not adequately relieved. These subgroup reported severe, very severe or extremely severe pain. 90% of the patients were given analgesics and sedation during the investigation. For patients who reported, “severe, very severe or extremely severe pain” (n = 111), pain was underestimated by physicians and nurses in 58% of all assessments. This was most commonly seen among the youngest patients, 18–29 years (n = 99), where pain was underestimated in 25.5% among the group. There was also a difference according to gender; physicians underestimated pain in 60% of men who reported “moderate pain” (n = 66) while the nurses underestimated pain in 27% among the same group of men. Women’s pain was overestimated by caregivers in 26% (n = 188) of all cases with mild pain. Patients undergoing colonoscopy for the first time (n = 331), and reporting “moderate pain”, were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety (p < 0.001). Presence of anxiety and a high level of anxiety among the group was associated with a shorter time delay and the patient’s pain report. The agreement between pain reports from patients and caregivers were poor to fair, with slight differences between nurses (Kappa = 0.37; p < 0.000) and physicians (Kappa = 0.29; p < 0.000). In total, congruent pain reports between patients and caregivers were seen in 36% of all assessments.

Conclusion: Agreement between caregivers’ and patients’ pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD. Characterization of colonic lesions in IBD patients remains challenging even by using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]). Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic dysplasia, and to validated by international experts (Frankfurt Advanced Chromoendoscopic IBD Lesions FACILE GROUP). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel sign, signs of inflammation (table). A library of 60 colonic lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariate analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: Of the 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/Ps and 12 (20%) pseudopolyps. Across the experienced academic raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 92%, 91%, 40%, 72%, 72%, 72% and 72%. Individual rater accuracy ranged from 66% to 77%. Sensitivity, specificity, PPV, NPV, accuracy, for predictions made with high confidence were 72%, 90%, 97%, 46%, 76%, which were significantly more accurate compared with a low confidence of diagnosis (76% vs 65%; p < 0.001). Univariate analysis showed that the non polypoid lesions, irregular and vessel architecture and signs of inflammation within the lesion were predictive of dysplasia. Subsequent multivariate analysis confirmed that of these endoscopic findings non polypoid lesion OR 11.6 (95% CI 6.71–20.2), surface pattern
The role of probe confocal laser endomicroscopy with image enhanced endoscopy in characterisation and endoscopic resection of dysplastic lesions in inflammatory bowel disease patients

Introduction: Detection, characterization and therapeutic management of flat dysplastic lesions during surveillance colonoscopy in inflammatory bowel disease (IBD) can be a challenge. The recent SCENIC consensus has introduced a new terminology and concept “endoscopically resectable” when the distinct margins of a detected lesion could be identified. New endoscopic techniques and skills are required to recognize the margins reliably and assess the surrounding mucosa to plan endoscopic removal successfully and organ sparing. We report our experience of the use of probe confocal endomicroscopy (pCLE) combined with selective electronic virtual (VCE) and dye chromonendoscopy (DCE) for management of challenging dysplastic lesions during surveillance in IBD.

Aims & Methods: IBD patients underwent surveillance colonoscopy using high-definition (HD)-iSCAN (Pentax EC-3940F; Japan) VCE and DCE in combination with pCLE (Cellvizio, Paris, France). pCLE was applied following IV injection of fluorescein 5% 10ml to assess the histological features of the lesion, the margins and the mucosa surrounding the visible colonic lesion. Biopsies eventually proved dysplasia or SSA of the colonic lesions. The study was approved by the Calgary Conjoint Health Services Research Ethics Board of the University of Calgary. All patients gave informed consent.

Results: Seven patients with IBD and disease duration of ≥8 years and in clinical remission (Eaden, 2001 #2) (mean age 55 years; 6 male, UC = 4 CD = 3) were prospectively included. They underwent surveillance colonoscopy using HD-iSCAN (Pentax EC-3940F; Japan). When a colonic lesion was detected, selective iSCAN - VCE was performed with or without DCE (five out of seven had DCE)

(continued)
with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Is) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered ‘pseudopolyps’ had a 8 mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

**Conclusion:** This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

2Gastroenterology, Dudley Group Hospitals, Birmingham City University, Birmingham/United Kingdom

Contact E-mail Address: toshikokawai@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr: Akita Sumitomo Hakelite, Japan) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Aims & Methods: The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥75 years in comparison with those in younger patients. We evaluated 291 lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at Kure Medical College and Chagako Cancer Center. The patients were divided into two groups, an elderly group (group A: age, ≥75 years; 95 patients, 97 lesions) and a non-elderly group (group B: age, <75 years; 176 patients, 194 lesions). We evaluated the en bloc resection rate, complete resection rate, curative resection rate, resected tumor size, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

Results: The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.1% (70/194); Tis, 92.3% (38/97) and 44.8% (87/194); T1a, 10.3% (10/97) and 10.3% (20/194); and T1b, 13.4% (13/97) and 8.8% (17/194) in groups A and B, respectively, showing no significant difference. The mean resected tumor size was 33.9 ± 16.6 mm in group A and 34.7 ± 15.2 mm in group B, and the median procedural time was 75.6 min (range, 10-420 min) in group A and 75 min (range, 10-533 min) in group B, showing no significant difference. The en bloc resection rates were 96.9% (94/97) and 99.0% (192/194); the complete resection rates, 94.8% (92/97) and 94.8% (184/194); and the curative resection rates, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and delayed bleeding occurred in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period: group A, 523 ± 469 days; group B, 628 ± 582 days), the 3-year overall and disease-specific survival rates were respectively 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of colorectal cancer metastasis (2.6%, 5/194) in other diseases in group B, while one patient (1.1%, 1/95) died of other diseases in group A.

Conclusion: ESD performed with SB Knife Jr is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms in elderly patients.

P0850 QUALITY IN COLONOSCOPY: HAVE YOU REALLY GOT TO THE CAECUM?
S. Budihal
Department Of Endoscopy, Nottingham University Hospitals, Nottingham/United Kingdom

Contact E-mail Address: shvibudihal@yahoo.co.uk

Introduction: Poor quality and incomplete colonoscopy is associated with missed diagnosis and failure to prevent interval cancers.1 Caecal intubation rate is the most frequently used Quality Indicator of colonoscopy. British Society of Gastroenterology guidelines recommend obtaining “clear images of caecal landmarks or terminal ileum” while the European and American guidelines suggest “a suitable photo documentation preferably a panoramic view of the ileocecal valve and caecum”. In this retrospective study we aimed to assess colonoscopists’ practice in photo documentation of colonoscopy completion.

Aims & Methods: Colonoscopy reports for colonoscopies performed at an endoscopy unit over a University Hospital over a period of three months from 01/01/2014 to 03/01/2014 were retrieved from the Trust’s Endoscopy database. Photo documentation from the reports were then analysed for caecal landmarks and terminal ileum images.

Results: A total of 292 colonoscopies were performed by 21 endoscopists (5 Colorectal Surgeons (24%), 3 Nurse Endoscopists (14%), 3 Specialist Registrar Gastroenterologist (14%) and 10 Consultant Gastroenterologist (48%). Caecal intubation was achieved in 248 cases (85%). In 8(53%) cases the anastomosis was reached. The ileo-caecal valve was photographed in 172(70%) cases, the appendix in 102(41%) cases, the caecum in 83(33%) cases and a panoramic view was achieved only in 43(17%) patients. Terminal Ileum was intubated in 53 cases (21%) and images were recorded in 25 cases (40%). In the case of anastomosis, 7 images (88%) of the anastomosis were obtained. In some of the reports images were labelled and in a number of reports no photos were recorded at all.

Conclusion: This study shows that photo documentation is poor and needs to be improved in order to adhere to national and international guidelines. Evidence of caecal intubation is imperative as it can protect against medicolegal implications.2 Obtaining clear images of caecal landmarks will ensure definite caecal intubation and efforts towards recording them will prompt the endoscopist to attain adequate mucosal view. In order to achieve excellence we suggest colonoscopists obtain images of all caecal landmarks including the ileum (when intubated), label photographs and where possible record video clips of caecal intubation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sessile Serrated polyps (SSA/PS) are pre-malignant lesions that may lead to colorectal cancer in accelerated manner. These lesions are easily missed by endoscopists as these are difficult to detect in IBD patients. We aimed to assess the prevalence, detection rate and endoscopic findings of SSA/PS in long standing IBD patients prospectively undergoing surveillance colonoscopy using dye (DCE) or virtual electronic chromoendoscopy (VCE) or high definition white light (HD-WLE) colonoscopy in IBD.

Aims & Methods: A total of 270 randomized patients (55% men; age range 20–77 years, median age 49 years) with long-standing IBD (median duration of the disease 14 years) undergoing surveillance colonoscopy were assessed by HD-WLE (n=90), VCE (n=90) or DCE (n=90). Surveillance colonoscopy with High Definition (HD) alone, or with iSCAN VCE or DCE was performed. Endoscopic features were recorded in each group with regard to location, morphology (polypoid/non polypoid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification.3 The histology was reported by modified Vienna classification.4

Results: Thirty -three SSA/PS were detected in 20 (11UC; 9 CD; 11 female, age range 34–72 y, median age 61 years) patients out of the 270 patients with IBD enrolled (12.2%). The endoscopic features of SSA/PS lesions were: non-polypoid appearance (51.5%), predominant localization in the proximal colon (vs distal) (87%), ≤5 mm in size (48.4%), Kudo pit pattern modified type I (79%). Kudo pit pattern modified type I had a sensitivity of 79% and specificity of 82% for diagnosing SSA/PS at surveillance colonoscopy in IBD patients. There was no difference in detection rates of SSA/P using HD-WLE, DCE or VCE.

Conclusion: SSA/PS are not an infrequent finding at surveillance colonoscopy in IBD. There are prevalent in the right colon location and these generally have Kudo pit pattern of I0. SSA/PS can be recognized endoscopically by Kudo pit
Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic histology obtained values of sensitivity, specificity, positive and negative observations, the use of the FICE classification for prediction of adenoma-hyperplastic and 1 serrated adenoma. From the global assessment of all polyps contributed to these results.

The use of FICE technology by inexperienced endoscopists in the conclusion:

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic accuracy. However, the efficient results in histological prediction are a reflection of the clinical practice by trained endoscopists, and their application remains to be confirmed outside this context.

Aims & Methods: To evaluate the in vivo histological prediction acuity of colorectal polyps (<10 mm; hyperplastic polyps vs adenomas) in WLE (White light endoscopy) and using FICE technology, comparing both modalities. Prospective evaluation, using WLE and FICE, of colorectal polyps <10 mm in patients submitted to colonoscopy between 12/2016 and 02/2017 by four inexperienced endoscopists in FICE, except for a previous 20-minutes interactive session. Polyps were evaluated using the FICE classification (tubular or oval crypts (adenoma), round crypts or featureless appearance (hyperplastic polyps), indicating their confidence level (low <90% vs high >90%)).

Statistical analysis: SSIPS v2.3

Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic and 1 serrated adenoma. From the global assessment of all polyps and observations, the use of the FICE classification for prediction of adenoma-hyperplastic histology values of sensitivity, specificity, positive and negative predictive value identical to WLE (100%, 62.5%, 100% and 60%, respectively).

Overall, diagnostic acuity in histological prediction was identical in both modalities (76%). The individual acuity of the endoscopists ranged from 66% to 100%. However, scores were not associated with a higher probability of correct classification, both in WLE (77% vs. 75%) and FICE (75% vs. 80%), p > 0.05.

Conclusion: The use of FICE technology by inexperienced endoscopists in the histological prediction of colorectal polyps has no advantage over WLE, having both suboptimal acuities. The lack of recourse to magnification may have contributed to these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Contact E-mail Address: mekamine@hotmail.com

Introduction: Adequate bowel preparation is one of the most important quality factors of colonoscopy. Several formulations of bowel preparation have been evolved in order to have a clean colon and be well tolerated by patients. Currently, PEG 4L solution is the preferred method of bowel preparation to colonoscopy. This preparation has the disadvantage of being poorly tolerated by patients. Furthermore, recent studies have shown that a low-volume PEG solution mixed with Bisacodyl (4L + 15mg) for bowel cleansing is as effective and better tolerated as a large volume PEG (4L).

Aims & Methods: This study aims to evaluate the efficacy and tolerance of the new regimen of Bisacodyl compared to the classical regimen (4L of PEG).

Materials and methods: A prospective comparative randomised study comparing the tolerance, acceptability and efficacy of a protocol A based on 4L of PEG and a protocol B corresponding to 2L of PEG +15mg of Bisacodyl. Using the Boston Bowel Preparation Scale (BBPS) by endoscopists, who did not know bowel preparation type, to evaluate the quality of preparation.

Results: Sixty-six patients were included (35 in group A and 31 in group B), with a sex ratio = 1. The average age of patients was 52.5 ± 15 years (17–86 years) with a median of 51.5 years. Sixty-two patients in the first group found the preparation difficult or moderately difficult vs 3 in group B (p = NS) with mild to severe side effects 54% of group A and 29% of group B (p = 0.03) and A mean side effect per patient was 2.26 vs. 1.89 (p = NS). Nausea and vomiting were respectively (34% and 24%) vs (12% and 5%) (p = NS). However, 5 patients in group A had sleep disorders vs only one case in group B. Four patients who received 4L of PEG had expressed their refusal to resume the same preparation if necessary while 2 patients in group B had refused. A score greater than or equal to 7 was recorded in 6/18 patients with a median of 4/3 (1 case in group B). The overall score obtained was 6.49 ± 7.32, respectively. This score (BBPS) tended to be better in protocol B than in protocol A in the right segment (2.55 vs 2.17), transverse colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). This same trend was recorded in the left colon, in the number of patients with hypoplastic adenoma compared to an adequate score of (9/9), with 4 patients in group B and no patient in group A. Seven patients refused to repeat the test even if indicated. This refusal was secondary to the preparation in 4 cases (2 cases of each group). Abdominal pain and post-endoscopic distension were respectively (62.8% and 65.7% vs 52% and 22.5%) (p = 0.016 and p < 0.001).

Conclusion: Preliminary results from our study suggest that the low-volume 2 L PEG with bisacodyl does improve patient tolerability with a tendency to be better for good bowel preparation as compared to the traditional 4 L PEG. We continue our study to have a more significant number of patients view these data.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0858 COLONOSCOPY ON THE LEFT, RIGHT? I. Mocanu, A. Laranjo, S. Piets, N. Veloso, L. Gonçalves, R. Godinho, I. Medeiros

Gastroenterology, Hospital Espírito Santo de Évora, Évora/Portugal

Contact E-mail Address: irma.mocanu.24@gmail.com

Introduction: While it is well established that colonoscopy is a more sensitive technique to train, with high variability of time spent to reach the cecum, depending on endoscopist experience, patient characteristics and type of colonoscopy used. Recently, the ROLCOL study demonstrated an advantage in time and patient comfort during progression in right lateral position (RLP) when compared with traditional left lateral position (LLP).

Aims & Methods: To compare time to reach cecum, patient and endoscopist comfort (using a visual analogue scale (VAS) in colonoscopies with progression on RLP and LLP. Prospective study, between January and April 2017, of colonoscopies under conscious sedation, randomly assigned to RLP and LLP. Olympus 190 series and Fuji EC-530 W13 colonoscopes were used. Inclusion criteria: routine colonoscopies, patients ≥18 years of age, abdominal surgeries other than colonic, examinations done by residents in second and fifth year of training and specialists. Exclusion criteria: incomplete colonoscopies or prior history of colon surgery.

Results: One hundred and eighty-eight colonoscopies (94 on each side) were included. There was no statistical difference in mean age (RLP:5.8 ± 15 years; LLP: 5.8 ± 15 years vs p = 0.81). In the VAS score of comfort: 4.2 ± 3.8 vs. 4.0 ± 3.6; p = 0.64, respectively. However, colonoscopist comfort was higher in LLP (4.6 ± 3.7 vs. 3.8; p = 0.005). This did not change after exclusion of less experienced endoscopists colonoscopies (581 vs. 579 seconds, VAS 3.7 vs. 3.95; p = 0.005). Globally, there was no difference in “time to cecum” between the two positions (612 ± 633 seconds; p > 0.05), nor the patients comfort (VAS 3.92 ± 3.94; p > 0.05). This did not change after exclusion of less experienced endoscopists colonoscopies (581 vs. 579 seconds, VAS 3.7 vs. 3.95; p = 0.005). Surgical and overweight patients did not benefit from any of the positions (time to cecum: 650 ± 702 vs 570 ± 657; p = 0.50, comfort: 4.2 ± 4.1 vs. 3.8 ± 3.96; p = 0.05, respectively). However, endoscopists comfort was higher in LLP (4.6 ± 3.7 vs. 3.8; p < 0.005). Both groups required position change during progression or loop palpation by the nurse in equal percentage (54% vs. 50% vs. 49.5% vs. 50%; p > 0.05). Additionally, there was no difference in time to cecum, patients or endoscopists comfort between the colonoscopies performed with Fuji or Olympus colonoscopes.

Conclusion: In our experience, progression in right lateral position did not show additional advantage over standard LLP in time to reach the cecum or patients comfort. We did not find any difference in time to progression or comfort between Olympus and Fuji colonoscopes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0859 NON-GRANULAR LATERALLY SPREADING COLONIC LESIONS ≥20MM (LSL) ARE SMALLER AND MORE COMMON MULTIPLE THAN GRANULAR LSL: IMPLICATIONS OF A ‘COLONIC MUCOSAL PHENOTYPE’ FOR PRACTITIONERS OF ENDOSCOPIC RESECTION

D. J. Tate1, H. Awadie2, L. Desomer1, M. Sidhu1, K. Goodrick1, N. G. Burgess1, D. M. Farnworth1

1Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney/ Australia/NSW
2Westmead Clinical School, University of Sydney, Sydney/Australia/NSW

Contact E-mail Address: djjate@gmail.com

Introduction: The surface morphology of laterally spreading colonic lesions ≥20mm (LSL) can be described as granular (G) or non-granular (NG). NG lesions are more difficult to detect, harder to resect endoscopically and harbour a higher risk of submucosal invasive cancer (SMIC) than G lesions.

Aims & Methods: We aimed to characterise the population of LSL in patients undergoing EMR at Sydney Eastern Regional Medical Centre, Australia between 2008 and 2011. LSL were identified within a prospective observational cohort of patients undergoing endoscopic mucosal resection at a single academic tertiary centre. LSL were interrogated using high-definition white light (HDWL) at the time of EMR and the morphology of LSL were described along with patient, lesion and procedural factors. All LSL detected during the study period were eligible. LSL with mixed or indeterminate morphology were excluded. Serrated LSL were excluded. Lesions not attempted for EMR were excluded. Patients with multiple LSL were categorised according to the largest (dominant).
Results: 1382 LSL in 1243 patients were analysed. 1155/1243 (92.9%) patients had a solitary LSL. The majority of patients with multiple LSL had two (77.3%) or three (15.9%) lesions. 889/1382 (64.3%) of LSL were G. LSL were more likely to be solitary (87.0%) than NG LSL (77.5%, p < .001). G LSL were more commonly large (>40 mm in size) (49.5%) than NG LSL (26.0%, p < .001) and were more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, p = .034). In 88 patients with multiple LSL the dominant LSL was G (49/88 [55.7%]). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, p = .029.

Table 1: The morphology of the dominant (largest) laterally spreading lesion (LSL) predicts the presence and number of synchronous LSL. Morphology of the dominant lesion did not predict the others would be of the same morphology (p = .697). The dominant LSL was large in 43.2% of cases. Size of the dominant LSL predicted size of the other LSL (p < .001). 58.6% of dominant LSL were located in the right colon. In 65.9% patients all LSL were in the same colonic segment; this was not predicted either by the location of the dominant LSL (p = .860) or its morphology (p = .228).

<table>
<thead>
<tr>
<th>Dominant LSL Morphology</th>
<th>Solitary (n = 1155)</th>
<th>Multiple (n = 227)</th>
<th>P</th>
</tr>
</thead>
<tbody>
<tr>
<td>Granular (n = 889)</td>
<td>773 (87.0)</td>
<td>116 (13.0)</td>
<td>&lt;.001</td>
</tr>
<tr>
<td>Non-granular (n = 493)</td>
<td>382 (77.5)</td>
<td>111 (22.5)</td>
<td>.001</td>
</tr>
</tbody>
</table>

Dominant LSL Morphology: Number of synchronous LSL

Granular (n = 49) 41 (83.7) 3 (6.1) 1 (2.0) 0.29
Non-granular (n = 29) 27 (69.2) 10 (25.6) 0 2 (5.1) 0.001

Conclusion: 7% of patients will have more than one LSL. In these patients the dominant lesion morphology predicts the presence and number of additional LSL (the Colonic Mucosal Phenotype). More than 20% of NG LSL are associated with an additional LSL. A large colonic lesion is predominantly large and solitary. Practitioners of endoscopic resection should be aware that NG LSL may be multiple and ensure full examination of the colonic mucosal surface, particularly since they are higher risk for SMIC than G LSL.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0860 WIDE-FIELD PIECMEAL COLD SNARE POLYPECTOMY OF LARGE SESSEILL SERRATED POLYPS WITHOUT A SUBMUCOSAL INJECTION IS SAFE

D. J. Tate, H. Awadie, F. Bahin, L. Desomer, R. Lee, S. Heitman, K. Goodrick, M. Bourke
Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney/ Australia/NSW

Contact E-mail Address: djtate@gmail.com

Introduction: Large series suggest endoscopic mucosal resection is safe and effective for the removal of large sessile serrated polyps (>10mm (large SSP) but it exposes the patient to the risks of electrocautery, principally delayed bleeding.

Aims & Methods: We aimed to examine the feasibility and safety of piecemeal cold snare polypectomy (pCSP) for the resection of large SSP. Over 12 months sequential large SSP without endoscopic evidence of dysplasia referred to a tertiary endoscopy centre were considered for pCSP. The technique for pCSP was standardised. The lesion and its margins were assessed using high definition endoscopic imaging. Snare resection commenced at one margin including a 2-3 mm rim of normal tissue. A thin-wire snare was used in all cases. Firm downward pressure and suction of luminal gas aided tissue capture. Subsequent the assistant closed the snare until resistance was felt, and then completely once the endoscopist was satisfied with the amount of captured tissue. If transection did not occur within five seconds gentle traction was exerted on the snare catheter against the tip of the colonoscope. If transection still did not occur, the snare placement was revised. The mucosal defect was then expanded with a flushing pump containing 0.9% saline. Further resections were then performed aligning the snare with the cut edge of the expanding mucosal defect. Once the resection was completed the mucosal defect was inspected for residual serrated tissue. If residual was detected further generous snare resection was performed. Oozing of blood from the resection site was common and was not actively treated. Submucosal injection was not performed. High-definition imaging of the defect margin was used to ensure the absence of residual serrated tissue. Adverse events were assessed at 2 weeks and surveillance was planned between 6 and 12 months.

Results: 41 SSP were completely removed by pCSP in 34 patients. 7 patients had two lesions removed. The median size of SSP was 15 mm (IQR 14.5–20), range 10–35 mm. The median duration of procedures was 4.5 minutes (IQR 1.4–6.3). There was no evidence of perforation or significant intra-procedural bleeding.

The results of the 34 patients is shown in Table 1. There were no significant adverse events at 2 week follow up including delayed bleeding and post polypectomy syndrome. 8/41 lesions underwent first follow-up at median 6 months with no evidence of recurrence.

Table 1: Baseline characteristics and outcomes of the 34 patients and 41 SSP that underwent piecemeal cold snare polypectomy (pCSP). IQR – interquartile range, SC1 – first surveillance colonoscopy.

Conclusion: There is potential for pCSP to become the standard of care for non-dysplastic large SSP. This may reduce the burden on patients and healthcare systems of removing SSP, particularly by avoidance of delayed bleeding.

P0861 THE PROSPECTIVE OBSERVATION STUDY FOR OVER 10MM COLORECTAL LESIONS ENDOSCOPICALLY RESECTED USING BIPOLAR SNARE

Gastroenterology And Endoscopy, National Cancer Center Hospital East, Kashiwa/Japan

Contact E-mail Address: hirosk@east.ncc.go.jp

Introduction: Polypectomy of adenomas reduces death due to colorectal cancer; therefore colonoscopy is the gold standard to detect and treat adenomatous lesions. Most adenomatous lesions are less than 20 mm in size. Therefore, these are not indication for endoscopic submucosal dissection (ESD). Recently, there are some reports about cold snare polypectomy (CSP). CSP is effective and easy to use to remove lesions of less than 5–10 mm in size. On the other hand, in over 10 mm lesions, many endoscopists would remove it by endoscopic mucosal resection (EMR) with monopolar snare. It is expected that the bipolar snare would decrease the incidence of perforation because of electric current flow peculiar to bipolar snare that does not flow through the wall of colon. So, by using bipolar snare, hot snare polypectomy (HSP) that can be easily resected in a short time may be safely performed for over 10 mm colorectal lesions. However, there is no report about them.

Aims & Methods: We aimed to clarify removal method, procedure time and complications for over 10 mm colorectal lesions endoscopically resected using bipolar snare. Consecutive patients with over 10 mm colorectal lesions endoscopically resected using bipolar snare in National Cancer Center Hospital East between September 2016 and March 2017 were enrolled in this study, prospectively. The removal method rate of these lesions, each procedure time, complete rate of these lesions, each procedure time, complication rate, bleeding rate and perforation rate, and pathological finding were assessed.

Results: A total 92 lesions in 67 patients were analyzed. 47 patients (70%) were male, and the median age was 67 years (range: 44–88). The median lesion size was 15 mm (range: 10–30). The macroscopic type was 33 (36%) polyloid lesions and 59 (64%) flat lesions. The location was 55 (60%) lesions in right colon, 31 (34%)
EMR – endoscopic mucosal resection, IPB – intra-procedural bleeding, IPP – intra-procedural perforation, CSPEB – clinically significant post-endoscopic bleeding (bleeding after EMR requiring admission to hospital or re-intervention), 2w – two weeks, SC1/2 - surveillance colonoscopy 1/2. * target sign or actual hole corresponding to DMI type III/IV - Sydney Classification (1)

**Conclusion:** SMSA is a simple readily applicable clinical score that identifies a subgroup of patients who are at increased risk of EMR related complications including CSPEB and recurrence. This information is useful for planning EMR lists with respect to time and resource allocation. Moreover SMSA could have a major impact on training, both in identifying appropriate training cases and providing an objective benchmark against which to assess the progress of trainees in EMR.

**Disclose of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** Of over 10mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

**Table 1:**

| Introduction: | The SMSA polyp scoring system is an objective method of stratifying the difficulty of polypectomy based on expert consensus opinion. The score is simple, intuitive and has previously not been evaluated in a large multicentre setting.

**Aims & Methods:** We aimed to determine the ability of the SMSA polyp score to predict robust endpoints after endoscopic mucosal resection (EMR) of colorectal laterally spreading lesions (LSL). The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMR over eight years. This score describes the complexity of polypectomy with respect to four major domains (table 1) and is subsequently divided into four levels. Standardised injection and resect EMR procedures were performed with detailed patient, procedural and outcome data recorded prospectively over the study period including all features of the SMSA. In patients who had multiple lesions resected, the largest lesion was selected for analysis. The primary endpoints were time to the SM, adverse event rate and adenoma recurrence.

**Results:** 2305 lesions in 2305 patients (47.4% M, 45.2% right colon) underwent SMSA score with completion rate, adverse event rate and adenoma recurrence. In patients who had multiple lesions resected the largest lesion was retained for analysis. The primary endpoints were correlation of all features of the SMSA. In patients who had multiple lesions resected the largest lesion was selected for analysis. The primary endpoints were correlation of all features of the SMSA. Deep mural injury and perforation after endoscopic mucosal resection (EMR) of colorectal laterally spreading lesions (LSL). The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMR over eight years. similarly 7.3 in 9 were better than NBI. Kappa value among participants was 4.8; moderate agreement (p = 0.0016). All polyps were removed endoscopically after evaluation. All lesions were histologically diagnosed as SSA/P without dysplasia. Conclusion: Acetic acid was useful and promising to facilitate the endoscopic recognition of the precise margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill.

Introduction: Preoperative localization or tattooing is essential for minimally invasive surgery. Although preoperative endoscopic tattooing using India ink or indocyanine green is widely used, clinical evidence and safety profile supporting the use of these agents is lacking.

Aims & Methods: We assessed the efficacy and safety of preoperative endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopic tattooing were given autologous blood, and the tattoo was evaluated in this study.

Results: From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospectively reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattoo in the peritoneal cavity and related adverse events.

Conclusion: Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colorectal lesions.

 Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lateral spreading tumors (LSTs) are defined as lesions > 10 mm with a low vertical axis and lateral extension. They are separated in 2 groups with 2 subclasses for each of them: granular LST (LST-G) with, or without large nodule; and non-granular LST (LST-NG), separated into flat lesions (Ha) and depressed lesions (Ha+Hc). Every subclass has been associated with a proper surgical type of colonic polyps vary across ethnic groups. As more than half of small polyps (84.04%) were small (< 5 mm) whereas 8.19% were large (> = 10 mm); hyperplastic polyp, tubular adenoma (TA), and tubulovillous (TVA) adenoma were identified in 43.19%, 53.83%, and 2.34%, respectively, respectively. Premalignant (TA + TVA) polyps were found in 56.08%, 50.19%, and 64.23% of the polyps of Asian, Caucasian, and Middle Eastern patients, respectively. Premalignant lesions were found in 52.91% of small polyps.

Conclusion: The findings suggested that number, size, distribution, and pathological type of colonic polyps vary across ethnic groups. As more than half of small polyps were a tubular adenoma, we propose that polyps of all sizes should be removed when feasible.

Introduction: Evidence on an international variation of pathological types and anatomical distribution of colonic polyps is beneficial for early detection and management but limited.

Aims & Methods: To characterize differences in colonoscopy findings by ethnicity, a random sample of patients aged at least 50 years without colonic symptoms or history of colorectal diseases who underwent colonoscopy were reviewed. Of 26,508 subjects, 2651 were randomly selected. 1300 subjects who met the inclusion criteria, abnormal findings were identified in 878 cases (67.54%), of which 452 cases had 940 polyps and 7 cancer lesions were found in 6 cases. Of 452 patients with polyps, half had only one polyp (53.76%) and were Asian (54.63%), followed by Caucasian (26.99%), Middle Eastern (15.71%), and other ethnic origins (2.65%) (Figure). Ethnicity-specific polyp prevalence were 36.26%, 38.05%, 27.24%, and 34.15%, respectively. Polyps of Caucasian subjects tended to be smaller (4.52 mm) and locate on the left side of the colon (65.3%) than that of other ethnicities (44.4%-60.53%). The majority of the polyps (84.04%) were small (< 5 mm) whereas 8.19% were large (> = 10 mm); hyperplastic polyp, tubular adenoma (TA), and tubulovillous (TVA) adenoma were identified in 43.19%, 53.83%, and 2.34%, respectively, respectively. Premalignant (TA + TVA) polyps were found in 56.08%, 50.19%, and 64.23% of the polyps of Asian, Caucasian, and Middle Eastern patients, respectively. Premalignant lesions were found in 52.91% of small polyps.

Conclusion: The findings suggested that number, size, distribution, and pathological type of colonic polyps vary across ethnic groups. As more than half of small polyps were a tubular adenoma, we propose that polyps of all sizes should be removed when feasible.

Conclusion: Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

Introduction: Endoscopic submucosal dissection represents the standard of care for large superficial colo-rectal neoplasms in Japan. In Europe, few studies reported performing ESDs, essentially in the rectal location. Colonic ESD is technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is also more complex to perform than rectal ESD.

**Results:** ESDs performed during the same period.

</tbody>
</table>

**Conclusion:** Colonic ESD could be performed with similar results than rectal ESD in French expert teams with prior strong experience in animal ESDs and rectal ESDs. It allows en bloc resection of large superficial colonic neoplasms with a very low risk of recurrence. CTs comparing colonic ESD to piece-meal EMR are needed to determine the appropriate place of each technique in Europe.

Introduction: It is well known that acromegalic have been at an increased risk of colorectal neoplasm. However, there has been few reports of them in Japanese patients with acromegaly. In this study, we attempted to elucidate the risk of colorectal neoplasm in Japanese patients with acromegaly comparing with healthy controlled patients.

**Aims & Methods:** Between April 2008 and September 2016, a total of 745 patients were underwent Harday operation in our institute. Among them, a total of 178 patients were undergone colonoscopy in our hospital during perioperative period and were enrolled in the case group. In contrast, a total of 356 patients were selected randomly from those who were performed colonoscopy in our medical check-up in the same period by means of being matched to cases of the age and gender. The incidence, size, location and histology of colorectal neoplasm were investigated.

**Results:** As background, 84 patients (47.2%) were men and 94 patients were women, and the median age was 47.5 years old (18 to 75) in the case group. The median height/weight was 165.5 cm/65.1 kg in the case group and was significantly larger than the control group (163.4 cm/60.1 kg) (p = 0.038, p < 0.001 respectively). The median Body Mass Index (BMI) were 23.4 in the control group and 22.5 in the case group. There was a significant difference between two groups (p < 0.001). The frequency of colorectal neoplasm was 66.8% (119/178 patients) in the case group and was significantly higher than control group of 24.2% (86/356 patients) (p = 0.001). The average number of neoplasm was 2.44 ± 4.74 mm in the case group and 1.77 ± 3.89 mm in the control group. There was a significant difference between two groups (p = 0.001).

**Conclusion:** Colonic ESD could be perfomed with similar results than rectal ESD in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD. Colonic ESD is technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is also more complex to perform than rectal ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Colonoscopy in ulcerative colitis (UC) is performed as first diagnosis and during screening for dysplasia and disease flares. It is an invasive procedure with a burden of discomfort and possible complications. To overcome discomfort and complications due to colonoscopy an Italian high-tech start-up (Endotex, Pucciol, Italy) developed a soft, self-propelled, disposable robotic colonoscope (R), approved with CE mark.

**Aims & Methods:** We wanted to compare diagnostic performance and tolerability of R with those of standard white light colonoscope (S) in patients with ulcerative colitis (UC). Consecutive patients referred for colonoscopy to our endoscopy department with clinically mild to moderate ulcerative colitis that signed the informed consent for both procedures were studied first with R and then with S (Olympus CF-145), by two different operators, blinded to previous observations. R had the following technical specifications: 17 mm outer diameter, rest position length probe 30 cm; maximum length of probe 54 cm; working length 210 cm; NTSC CMOS analog camera. Conscious sedation with midazolam was administered as...
needed. We recorded endoscopic diagnostic accuracy according to Baron criteria, to rank the certainty of the diagnosis, and the patient’s pain/discomfort and operator’s difficulty.

Results: We studied 12 patients (7M:5F), mean age 41 years and disease duration 5.33 yrs. 53 colonic segments out of the 54 evaluated had the same assessment of disease activity (absent = 0 points, mild = 1 pt, moderate = 2 pts and severe = 3 pts). The concordance for activity score with the latest version of R (SD 0.33 pts (SD 0.60) with S, without significant difference. The caecum was reached in 11/12 cases in S by an average of 29.42 min (SD 28.94), and in 10/12 cases by R, in an average of 46.67 min (SD 24.98 min), with a mean difference of 17.25 min, not statistically significant. Incomplete colon explorations with R clustered in Milan, probably because of smaller experience. An average of 1.45 (SD 0.79) mg of midazolam were used during S while 0.41 (SD 0.38) mg during R. Mean pain/discomfort on a 0–10 scale was 2.08 (SD 1.78) for R and 4.17 (SD 1.74) for S, with a statistically significant different (p = 0.056) favouring R. Mean perceived operator’s difficulty on a 0–10 scale was 4.44 (SD 1.78) for R, and 4.08 (SD 1.44) for S, with a mean difference of 0.42 pts favouring S not statistically significant.

Conclusion: R appears to be a promising method for disease staging in patients with ulcerative colitis, because of comparable accuracy and reduction in pain and discomfort. A tool channel to obtain biopsies and perform therapeutic endoscopy, together with images of higher definition (CMOS digital Camera HD ready) and virtual chromo-endoscopy, useful for follow-up and screening for dysplasia in patients with long duration of disease are now available in the latest version of R. The “column” connected to the latest version of the robot was the size of a portable suitcase, and suitable for remote operation. Further studies with newer versions of the robot are needed to assess the role of this technology from an economic point of view and in special settings like failed, screening colonoscopies, dysplastic lesions in UC, bed-side colonoscopy, colonoscopy in rural areas.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The LST classification and Paris classification systems are internationally used to describe polyp morphology. Differences between Japanese and Western endoscopists in the use of classification systems, have been observed. We aimed to evaluate the inter-observer agreement of LST classification amongst Western & Japanese experts.

Aims & Methods: A total of 40 endoscopic video clips depicting LSTs (10% minimum) were selected by 6 expert endoscopists: 3 from Japan and 3 from the West. Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-G non-specific), Paris classification, invasiveness, treatment suggestion and mean size of lesion. We calculated the interobserver agreement with weighted kappa and Chi square.

Results: Japanese endoscopists diagnosed more lesions as LST-G than Western (62.7 vs. 45.4%), Western diagnosed more LST-NG than Japanese (54.6 vs. 37.3%; p = 0.0007). The interobserver agreement of the LST classification amongst the six experts was good with a weighted Kappa of 0.61 (IC 95% 0.45–0.78) for Japanese, and moderate at 0.45 (IC95% 0.27–0.64) for Western. Difference in concordance between the two cohorts was not statistically significant (p = 0.22). When only two categories were considered (LST-G vs NG), agreement was very good for Japanese (weighted Kappa of 0.81; 95% CI 0.65–0.97) and good for Western endoscopists (0.65; 95% CI 0.46–0.85). Again, difference in concordance was not statistically significant (p = 0.22). Piecemeal Endoscopic Resection was suggested in 34.7% cases by Western, but never by Japanese endoscopists, whereas Endoscopic Submucosal Dissection was recommended in 50.4% and 16.1% cases by Japanese and Western experts respectively (p < 0.0001).

Conclusion: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
calculated the SMSA score of difficulty and assessed the ability of SMSA to identify 5 outcomes: 3-month recurrence, 1-year recurrence, global recurrence, endoscopy (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using chi-squared tests and complemented with logistic regression models.

**Results:** The SMSA scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 399 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak (κ = 0.33). 255 patients (19.9%) had recurrence 3 months after EMR, 84 (11.6%) had recurrence at 1 year, 78 (3.5%) suffered delayed bleeding and 35 (1.8%) perforation. The level 4 polyps had significantly higher rates of recurrence at 3 months and 1 year (p < 0.001 in both cases) and delayed bleeding too (p = 0.006), but not for perforation.

**Conclusion:** The SMSA grading tool is a predictor of outcomes or recurrences and bleeding following resection of LNPLC. However, in our multi-center sample, it does not appear to overcome the necessity of a subjective indicator of difficulty, made by the endoscopist during the EMR. It seems that this score can be used to facilitate planning, training or competency assessment, but efforts should be focused on validating the scoring system in a real situation, adjusting the score of variables or including new ones.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Abstract:** P0871. Outcome by SMSA grade. Odds ratios and 95% CI ROC Curves by SMSA using the score in the continuous form.

**P0872** NARROW BAND IMAGING GUIDED BIOPSY IMPROVES THE YELLOWSkin® TECHNOLOGY FOR THE DIAGNOSIS OF GASTROINTESTINAL TUMORULCUS (GITB)

Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: sarojsinha@hotmail.com

**Introduction:** Accurate diagnosis of gastrointestinal tumorulus (GITB) is challenging due to pauci-bacillary nature of disease and poor sensitivity of histopathology. Role of tissue acquisition using narrow band imaging magnification (NBI-M) to improve yield of histopathology over high-definition white light endoscopy (HD-WLE) has not been assessed.

**Aims & Methods:** Utility of narrow band imaging with magnification versus high-definition white light imaging guided endoscopic biopsy for diagnosis of gastrointestinal tumorulus. In this prospective study from July 2015 to November 2016, adult cases of clinically suspected GITB were recruited. All patients underwent bimanual test, contrast enhanced computed tomography of abdomen, esophagogastroduodenoscopy and/or colonoscopy using both HD-WLE and NBI-M and guided biopsies using both were taken. Histopathological examination was done by two independent pathologists. A final diagnosis of GITB was made if acid-fast bacilli were seen in tissue or grown in culture, histopathology showed caseous necrosis with granulomatous inflammation or clinical/radiological and endoscopic features were suggestive of tumorulus and endoscopic response to antitubercular therapy.

**Results:** A total of 35 cases of clinically suspected GITB were recruited. A final diagnosis of tumorulus was made in 32 cases (duodenal n = 4, ileocolic n = 28). Concomitant evidence of active or healed pulmonary tumorulus was seen in 21% of cases. The mean age, haemoglobin and erythrocyte sedimentation rate of patients with tumorulus were 36.4±14.6 years, 10.2±2.4 g/dl, 37.8±15.3 mm/hour respectively. The mean duration of symptoms was 19.9 months. The most common symptoms were pain abdomen (78%), weight loss (62.5%), and loss of appetite (40.6%), fever (37.5%), vomiting (34%) and diarrhea (22%). Mantoux test was positive in 40.6% cases. The most common endoscopic findings were ulcerations (75%), nodularity (46.8%), distorted ileocecal valve (28%) and strictures (21.8%) (Table 1). The most common radiological findings were mural wall thickening (65.6%), mesenteric lymphadenopathy (56%) and strictures (40%) (Table 1). NBI-M guided biopsy confirmed the diagnosis of GITB in 46.88%, while HD WLE guided biopsy confirmed diagnosis of GITB in 28.12% (P = 0.04). The two sets of biopsies together confirmed diagnosis of GITB in 53.1%. The area under curve for NBI-M plus HDWLE, NBI-M alone and HDWLE alone were 0.770.63–0.87 0.73 (0.60–0.85) and 0.64 (0.50–0.77) respectively. Patients were started on anti-tubercular therapy for nine months. Four patients underwent surgery for intestinal obstruction while on anti-tubercular therapy. Twenty eight completed full therapy and improved.

**Conclusion:** NBI-M guided biopsy improved the yield of histology for diagnosis of GITB.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colorectal cancer is a leading cause for cancer related mortality. Adenomatous polyp, the precursor lesion, can usually be endoscopically resected to prevent cancer. Currently, there are no criteria for surgical vs. endoscopic resection and decision is individually made by the treating physician.

**Aims & Methods:** We aimed to evaluate factors associated with short-term efficacy and safety of endoscopic resection of large (>20 mm) and giant (>40 mm) adenomas. Consecutive cases that underwent endoscopic resection of adenomas larger than 20 mm were included. Endoscopic, clinical and histological details of polyps and of the endoscopic procedure were recorded as well as the need for repeat resection.

**Results:** Total of 351 resections were included. Average diameter was 30.3±10.66 mm. Surgery was indicated in 21 (5.98%) cases. In a multivariate analysis for efficacy, two variables were independent risk factors for surgery: adenoma size (OR 95%CI 1.08 (1.04–1.12) andecal location (OR 95%CI 5.97 (1.60–22.33)). Post-polypectomy complications were documented in 85 cases (24.2%: bleeding - 69 (19.7%, 54/69 managed during procedure), perforations - 8 (2.3%) and significant discomfort up to early termination of procedure - 15 (4.3%). Only 21 (6.0%) developed serious complications requiring further hospitalization. In multivariate analysis for safety, independent risk factors for post-polypectomy complications were: adenoma size (OR 95%CI 1.04 (1.01–1.06), polyph morphology (esophage OR 95%CI 2.55 (1.45–4.51), flat OR 95%CI 2.40 (1.04–5.52) and submucosal adenoma injection (OR 95%CI 1.87 (1.11–3.20)). Every increment of 1 mm in adenoma diameter above 20 mm, increased the need for surgery by 8% and the risk for complications by 4%.

**Conclusion:** Resection of large or giant adenomas is generally a safe procedure when performed by an experienced endoscopist. Although adenoma size is the most significantly related to efficacy and safety, each case of giant adenoma should be evaluated in a referral center for feasibility of endoscopic resection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Abstract:** P0873. Outcome by SMSA grade. Odds ratios and 95% CI ROC Curves by SMSA using the score in the continuous form.
Prophylactic mucosal defect closure was effective in reducing delayed bleeding (2.17 \pm 0.69 vs. 2.03 \pm 0.65; p = 0.047) and a trend for better overall cleansing (6.70 \pm 1.87 vs. 6.32 \pm 1.90; p = 0.067). On morning shifts, there was a significant association between SD prep and better overall cleansing (p = 0.030) and also right colon cleansing (p = 0.034). After adjusting for morning shifts, we found an association between SD preparation and better bowel cleansing (risk difference 0.406; 95% CI —0.023—0.834; p = 0.063). There was no difference between groups on bowel urgency (SD 2.6% vs. PD 1.7%; p = 0.718). SD preparation was associated with worse sleep quality (SD 25% vs. DA 7%; p = 0.004).

Conclusion: The implementation of a split-dose bowel preparation protocol in our hospital was associated with better bowel cleansing, especially on the right colon. Split-dose preparation was not associated with higher bowel urgency, although there was a worse sleep quality.

Contact E-mail Address: thorstenn.brechmann@rub.de

Introduction: Spinal cord injury (SCI) is a devastating event that occurs with a discharge incidence of 199 per million, which results in an estimated prevalence of up to 2525 per one million [1]. Cancer is a major cause of death in patients with spinal cord injury (SCI) [2]. Preventive strategies claim increasing attention, but must deal with special problems. Most SCI patients suffer from neurogenic bowel alterations. The loss of bowel control is the consequence of bowel inertia, constipation or evacuation difficulties. Therefore, bowel preparation requires modified and intensified regimens and more intensive care to prevent pressure ulcers and optimum skin management [3, 4, 5]. Colonoscopy itself might be associated with reduced efficacy in SCI patients, since a poorer quality of bowel cleansing or failure to reach the caecum could diminish adenoma detection rates (ADR) [6, 7], while complication rates could increase due to severe morbidity.

Aims & Methods: The primary objective was to determine the adenoma detection rate (ADR) in general, right and left hemicolectomy. Secondary objectives were polyp, advanced adenoma and carcinoma detection rates, size of adenomas and polyps in either localization, intensity and effect of bowel preparation, rate of complete colonoscopies, need for re-endoscopy, duration of colonoscopic procedures, deepest point of insertion and complications rates. We reviewed retrospectively consecutive SCI patients who underwent colonoscopy from 2003 to 2014 and assigned an age-, gender- and year of performance-matched control group.

Results: In 236 SCI, compared to 414 control patients, bowel preparation lasted longer (3.57 ± 1.5 vs. 1.15 ± 0.6 days, p = 0.001), achieved insufficient cleansing rates more often (23.7 vs. 3.6%) and caused more adverse events. Colonoscopy achieved a comparable quality. In 20.1% of SCI patients and colonoscopy needs more efforts to succeed, but requires modified and intensified regimens and more intensive care to prevent pressure ulcers and optimum skin management [3, 4, 5]. Colonoscopy itself might be associated with reduced efficacy in SCI patients, since a poorer quality of bowel cleansing or failure to reach the caecum could diminish adenoma detection rates (ADR) [6, 7], while complication rates could increase due to severe morbidity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are limited data concerning risk factors and consequences of colorectal endoscopic submucosal dissection (ESD) conversion to mucosal resec-
tion (EMR) in western centers.

Aims & Methods: Hospital-based frequency-matched case-control retrospective study. All patients were identified from a database of 223 consecutive dissections between 2013 and 2017. The cases were those with ESD conversion to EMR for a >20 mm colonic lateral spreading tumor (LST). The controls were randomly selected according to frequency 1:2 matching for tumor size (±50 mm) and location

P0879  CONTRIBUTION OF COLONOSCOPY IN ELDERLY PATIENTS OLDER THAN 70 YEARS

Introduction: The elderly patients are considered as a particular population. Colonoscopy has an important place at this population because of the limited number of normal paracemic examinations and the high incidence of tumor disease, specially the colo rectal cancer.

Aims & Methods: The aim of this study was to determine the indications and results of colonoscopy in people older than 70 years We performed a retrospec-
tive descriptive study over a 3 years from beginning of the endo-

Results: A total of 1059 colonoscopies were performed; 10.3% were indicated for people older than 70 years. The mean age was 74.15 years with a median age of 75 years and a maximum age of 91 years. The prevalence of males was 51.0, 10.5% of cases (n = 10) were diabetic, 12.6% (n = 12) hypertensive, 12.6% (n = 12) with ischemic heart disease, 8.4% (n = 8) had either or 9% (n = 9) had a digestive neoplasia. Colonoscopy was indicated for hematochezia 40% (n = 38), transit disorders in 33.6% (n = 32), abdominal pain in 14.7% (n = 14), IBV in 3.1% (n = 3), radiographic abnormalities in 13.6% (n = 13), iron defici-
cency anemia in 4.2%, and for patients with a family history of colorectal cancer in 1% of cases. Colonoscopy was abnormal in 83% (n = 93), with polyps in 48.3% (n = 45), suspected lesions of malignancy in 16.1% (n = 15), Diarrhea in 33.6% (n = 32), and steatosis in 12.6% (n = 11) (p = 0.02). The rate of malignant lesions diag-

P0880  ENDOSCOPIC CLOSURE OF ACUTE IATROGENIC PERFORATIONS OF THE GASTROINTESTINAL TRACT AND PREDICTORS OF NEED FOR EARLY SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Acute iatrogenic perforations are one of the recognized complica-
tions of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the
burden of surgery, combined with the availability of various endoscopic closure devices.

**Aims & Methods:** To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting surgery as a first line treatment, and failure of endoscopic treatment.

**Medical literature (Cochrane library, EMBASE, MEDLINE)** from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute iatrogenic perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

**Results:** 764 studies were identified. 28 studies, in human, met our inclusion criteria and were analysed. A total of 474 endoscopic closures were performed in these studies. The overall technical success rate was 93.1% (n = 451/474, 95% CI: 90.4–95.4%), clinical success was 89.7% (n = 451/474, 95% CI: 85.5–93.9%), and complication rate was 1.3% (n = 7/474, 95% CI: 0.3–2.3%). Technical success for endoclamp closure was 96.6% (95% CI: 94.2%–98.2%), and clinical success was 93% (95% CI: 87.1%–97.2%), and complications rate was 0% (95% CI: 0%–9.6%) for OTSC. For OTSC (Over the scope clip device), technical success was 83.8% (95% CI: 63.9%–96.6%), clinical success was 77.9% (95% CI: 56.8%–93.3%), and complication rate was 4.1% (95% CI: 0%–14%). The technical success rate for Self-expanding metal stent (SEMS) is 100% (95% CI: 71.5%–100%), clinical success is 91% (95% CI: 74.1%–108%), and complication rate of 9.1% (95% CI: 78%–112%). Only one study for endosuturing met our criteria, with technical and clinical success rate of 100%, and without any complication. Factors predicting failure of endoscopic treatment and need for surgical intervention included large perforation size, leukocytosis, fever, severe abdominal pain, large amount of peritoneal free air, necrotic or soft inflammatory margins, unfavourable anatomical site, stool containing blood, and failure of endoscopic closure.

**Conclusion:** Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations. Several factors have been suggested as predictors of need for surgery as a first line treatment. The study is limited by the low methodological quality of most studies included, indicating the need for further research.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0882 “O-RING SIGN” AS A NOVEL COLONOSCOPIC FINDING WITH NARROW-BAND IMAGING FOR DETECTING DERESSED-TYPE COLORECTAL LESIONS

T. Fuji

Dept. Of Gastroenterology, TF Clinic Dept. of Gastroenterology, Tokyo/Japan

Contact E-mail Address: tfclinic@tkhikai.plala.or.jp

**Introduction:** In recent years, colorectal cancer (CRC) has become a focus of attention as likely representing “missed” or “rapidly-growing” lesions in colonoscopy screening for colorectal cancer (CRC). Currently, lesions thought responsible for CRC include sessile serrated adenomas/polyps or flat and depressed-type lesions occurring on the right side of the colon, and there is an increasing need for endoscopic modalities to prevent overlooking these lesions. Colonoscopic screening using narrow-band imaging (NBI) during colonoscopy is the most effective method for detection of depressed and flat lesions (1). With NBI, the detected area is recognized as “whitish” and the surrounding ring-like mucosa as “brownish”, which constitutes the “O-ring sign”.

**Aims & Methods:** We aimed to evaluate the incidence and characteristics of the “O-ring sign” in depressed-type colorectal lesions. A total of 227 endoscopically resected and histologically confirmed depressed lesions (1a + 1c, 156, 1c, 71) were included for analysis. The colonoscopic images of these lesions were retrospectively examined for “O-ring sign” positivity and intensity (grade 0, negative; grade 1, mildly to moderately positive; and grade 2, highly positive). Of these, 16 were excluded as un evaluable and a total of 211 evaluable lesions were analyzed.

**Results:** Of the 211 lesions (1a + 1c, 141; 1c, 70) analyzed, 84 (1a + 1c, 12; 1c, 24), 105 (1a + 1c, 69; 1c, 36), and 22 (1a + 1c, 12; 1c, 10) were found to be in grades 0, 1, and 2, respectively, with 60.2% of these shown to be “O-ring sign”- positive (127/211), with IIa + Ic and Ic accounting for 57.4% (81/141) and 65.7% (46/70), respectively, of these lesions. While an examination by tumor size and location revealed no clear tendency in “O-ring sign” positivity, an examination by grade revealed a higher “O-ring sign” positivity rate among those with high-grade dysplasia (84.6%, 11/13) than those with low-grade dysplasia (59.2%, 11/19).

**Conclusion:** NBI colonoscopy screening for the “O-ring sign” as an index appears to improve the detection of depressed-type colorectal lesions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0883 THE LEARNING CURVE FOR COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) BETWEEN EXPERT AND TRAINEE ENDOSCOPISTS

N. Akimoto1, K. Mitsui1, T. Teramoto1, S. Fujimori2, I. Iwakami3

1Gastroenterology, Nippon Medical School, Graduate School of Medicine, Tokyo/ Japan

2Gastroenterology, Machida Ichio Hospital, Tokyo/Japan

Contact E-mail Address: naohiko.akimoto07@gmail.com

**Introduction:** Endoscopic submucosal dissection (ESD) has been acceptable as a minimally invasive therapy and providing en-bloc resection for early malignant and pre-malignant lesions of gastrointestinal cancer. Colorectal ESD has some difficulties such as a risk of perforation and its severity compare to gastric ESD. Hence, Colorectal ESD is more challenging than gastric ESD in endoscopic technique. In Japan, where has high incidence of gastric cancer, endoscopists

---

could have many experiences of gastric ESD that may be beneficial for the introduction of colorectal ESD. However, little is known about the learning curves of the young endoscopists who perform the colorectal ESD first.

Aims & Methods: We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ESD. The study cohort comprised 300 consecutive colorectal ERCP performed by three endoscopists in Nippon Medical School Hospital and Machida Ichio Hospital from 2010 to August 2016. The ESD devices were Flush knife BT (Fujifilm), Dual knife (Olympus), Hook knife (Olympus) or a combination by operators demand. The endoscopist A and B, who had over 10000 examinations of colonoscopy and experiences of gastric ESD (as expert group), and endoscopist C had about 1000 colonoscopies and performed colorectal ESD first (as trainee group). The completion rate of operation, which is defined as en-block resection rate without changing operator, operation time, complication rate (time/m2/min) and complications were analyzed in each endoscopist. Furthermore, we divided these procedures in three periods equally as early, middle and late.

Results: The median age was 70 (range 26-91) years old, and genders were 158 males and 103 females. Tumor locations were proximal colon, distal colon and rectum in 143(54.8%), 59(22.6%), and 59(22.6%), respectively. The histological types were well and moderately differentiated tubular adenocarcinoma, adenocarcinoma with mucinous carcinoma, invasive ductal, and other diseases and that is why ERCP is increasingly performed for patients with liver cirrhosis. Endoscopic sphincterotomy (EST) has become a standard step in the management of large common bile duct stones. EST followed by large balloon dilation (LBD) facilitated extraction of the large bile duct stones. Despite the increasing use of both techniques, a head-to-head comparison between EST followed by LBD and EST followed by ML is lacking in the literature.

Conclusion: Trainee endoscopist may have a good learning curve in completion rate and increasing experience reflects in a remarkable success in colorectal ESD. We concluded that the training of colorectal ERCP first was acceptable by the trainee endoscopist who had no experience of gastric ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO884 LARGE BALLOON DILATATION VERSUS MECHANICAL LITHOTRIPSY AFTER ENDOSCOPIC SPHINCTEROTOMY IN MANAGEMENT OF LARGE COMMONBILE DUCT STONES AMONG CIRRHOTIC PATIENTS

Contact E-mail Address: emara_20007@yahoo.com

Introduction: Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to surgical and anesthetic risks. EST followed by LBD is the most accepted method with liver cirrhosis to tolerate ERCP to treat their biliary tract or pancreatic diseases. Patients with liver cirrhosis are three times more susceptible to cholecystitis, cholangitis, and esophageal varices than the non-cirrhotic population plus the biliary and pancreatic cancer incidence is three times higher in cirrhotic patients. Endoscopic sphincterotomy (EST) has become a standard step in the management of large CBD stones. EST followed by large balloon dilation (LBD) facilitated extraction of the large CBD stones. Despite the increasing use of both techniques, a head-to-head comparison between EST followed by LBD and EST followed by ML is lacking in the literature and to our knowledge none were done on cirrhotic patients. Aims: This study was aimed at comparing the therapeutic benefits and complications between mechanical lithotripsy and large balloon dilation after sphincterotomy in patients with liver cirrhosis. Ninety eight cirrhotic patients with calculi obstructive jaundice were included and randomly divided into 2 groups. Group A was treated by large balloon dilation (LBD), Group B; 49 patients treated by mechanical lithotripsy. All patients underwent sphincterotomy initially. Inclusion criteria for this study included: Age of 18-60 years, any sex, liver cirrhosis patients Child A or B with clinical and laboratory proved obstructive jaundice, presence of large bile duct stones and deep selective cannulation of the bile duct. Exclusion criteria included: Known allergy to the used contrast material, Child C cirrhosis, the Need for needle knife precutting in order to achieve bile duct cannulation, Selective bile duct cannulation achieved after mechanical lithotripsy, pancreatic neoplasms, Portal Hypertension I, Coagulopathy. All patients were subjected to thorough history taking, complete clinical examination. Pancreatic enzymes concentrations were measured 4 hours before and 24 hours after the procedure, complete blood count and liver function tests were performed both before and after the procedure. Before and during ERCPC, stone size and number were verified. Diagnosis of common bile duct stones was confirmed either by pre-ERCPC investigations including abdominal ultrasonography (US), CT, MRCP or at the time of ERCPC Large CBD stone: Is defined before ERCP by a bile duct stone>12 mm or more (transverse diameter of the largest stone) by US, CT or MRCP and during cholangiography showed large filling defect more than 12 mm that could not be extracted using a standard balloon catheter.

Results: There were no dropouts and all subjects remained in the study till the end of the follow-up period. Little is known about the learning curves of the young endoscopists who perform the colorectal ESD first. Aims: We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ESD. The study cohort comprised 300 consecutive colorectal ERCP performed by three endoscopists in Nippon Medical School Hospital and Machida Ichio Hospital from 2010 to August 2016. The ESD devices were Flush knife BT (Fujifilm), Dual knife (Olympus), Hook knife (Olympus) or a combination by operators demand. The endoscopist A and B, who had over 10000 examinations of colonoscopy and experiences of gastric ESD (as expert group), and endoscopist C had about 1000 colonoscopies and performed colorectal ESD first (as trainee group). PO885 SAFETY AND EFFICACY OF ENDOSCOPIST-DIRECTED BALANCED PROPOFOL SEDATION (BPS) DURING ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP)

A. Lapidus1, I. M. Grañek2, A. Suisse3, A. Klein4, K. A. Yassin5, I. Khamaysi5
1The Ruth And Bruce Rappaport Faculty Of Medicine, Technion - Israel Institute of Technology, Haifa/Israel
2Institute Of Gastroenterology And Hepatology, Ha’Emek Medical Center, Afula/Israel
3Department Of Gastroenterology, Rambam Health Care Campus, Haifa/Israel

Contact E-mail Address: alon.lap@gmail.com

Introduction: Endoscopist-directed balanced Propofol sedation (BPS), defined as a fixed dose of an opioid and benzodiazepine combined with incremental doses of Propofol, has been shown to be a safe and effective moderate sedation regimen for gastroscopy and colonoscopy. However, there are very limited data on the safety and efficacy of endoscopist-directed BPS in ERCP.

Aims & Methods: We aimed to evaluate the safety and efficacy of endoscopist-directed BPS, as well as to compare patient outcomes with anesthesiologist-directed BPS, for both in-patients and out-patients undergoing ERCP. We performed a retrospective cohort study using prospectively collected endoscopy registry data of all ERCP procedures performed in the endoscopy center where both endoscopy-directed BPS during ERCP is routine practice amongst the ERCPists, all of whom have up-to-date advanced cardiac life support (ACLS) certification. ERCP nurses also maintain up-to-date certification in ACLS and cardiopulmonary resuscitation equipment and medications are available within the advanced endoscopy suite. During ERCP, the endoscopist and the endoscopy nurse as a team were responsible for monitoring patient vital signs (e.g., pulse, blood pressure, oxygen saturation levels). Each endoscopist was responsible for directing the provision and dosing of the BPS. Patient-level demographics and pre/post procedure vital signs were collected along with BPS drug dosages, American Society of Anesthesiologists score (ASA) and measured "hard endpoint" patient outcomes, including: need for bag-mask ventilation or endotracheal intubation, cumulative adverse events during ERCP due to sedation needs, patient admission/out-patients only) or need for change in level of hospital care (in-patients only), and mortality within 24 hours of ERCP.

Results: Over the course of 17 months (October 2015 - March 2017), 501 patients underwent ERCP and received endoscopist-directed BPS (Cohort 1: 380 (76%) inpatient, mean age 64.1 years, 46% males, 24% ASA I, 65% ASA II, 11% ASA III). During this same time period, 24 patients received anesthesiologist-administered BPS (Cohort 2: 19 (79%) inpatient, mean age 65.6 years, 67% males, 11% ASA I, 32% ASA II, 25% ASA III). In Cohort 1, the indications for ERCP were: 231 (46%) suspected cholecdocholithiasis, 68 (13%) stent replacement, 62 (12%) evaluation of known/suspected malignancy, 48 (10%) jaundice, 40 (8%) post-hepatobiliary intervention complications, 8 (2%) abdomino-inal pain, and 44 (9%) other unspecified. BPS dosages (mean ± SD: range) were: Fentanyl: 0.06 ± 0.02 mg: 0.05 – 0.10 mg: Midazolam 1.7 ± 0.7 mg: 1.0 – 2.5 mg: and Propofol 178 ± 103 mg: 10 – 640 mg. Propofol dose inversely correlated with patient age (r = −0.42, p < 0.001), ASA score (r = −0.19, p < 0.001) and Mallampati score (r = −0.24, p = 0.001). No clinically meaningful differences were found in patient vital signs pre and post ERCP. Moreover, no patient required bag-mask ventilation, endotracheal intubation nor hospital admission/ change in level of in-hospital care following ERCP. One patient in Cohort 2 who
received anesthesiologist-directed BPS, required bag-mask ventilation and the ERCP was aborted due to sedation effects. There was no mortality from any cause within 24 hours of ERCP. All patients were discharged from the advanced endoscopy suite without adverse events.

Conclusion: Endoscopist-directed BPS appears feasible, safe and efficacious for ASA I-Iii patients undergoing inpatient or outpatient ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO886 A NOVEL METHOD OF PREVENTING DUODENOBILIARY REFLUX BY MEANS OF SUSPENDED OVERLENGTH BILIARY STENTS IN PATIENTS WITH BILIARY STRICTURE

Y. Huang, X. Yan, H. Chang, Y. Zhang, W. Yao, K. Li
Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 13911765322@163.com

Introduction: Endoscopic insertion of plastic or metal stents is a well-established treatment for malignant or part of benign biliary obstruction. The major limitation of this technique is stent occlusion. Duodenobiliary reflux has been considered as a key contributor to stent occlusion. No appropriate method can so far prevent duodenobiliary reflux. Different strategies to prolong the patency of plastic stents included changing stent size, stent design, but stent sludge due to duodenal biliary reflux remains an unsolved problem. We have been using a novel suspended overlength biliary stents (reformed with nasobiliary tube) as substitution for ordinary biliary plastic stent to prevent the reflux from January 31, 2014 to December 31, 2016.

Aims & Methods: The aim of the study is to evaluate the efficacy and patency of the suspended overlength biliary stents. The suspended overlength biliary stents (SOBS) were placed in introhepatic bile duct in 61 patients with extrahepatic bile duct stricture who were followed up at least three months from January 1, 2016 to December 31, 2016. Nasobiliary tube of 7.5Fr or 8.5Fr with multiple side holes were cut 30 cm with operation knife from the top on sterile operating table. The purpose of the set of 30 cm length is to ensure the tail reaches the duodenal horizontal part. The SOBS were placed in the introhepatic bile duct by using conveyer under the fluoroscopic guidance at the end of ERCP. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the existence of duodenal biliary reflux. 74 patients who were performed at least two or more ERCP with extrahepatic bile duct surgery treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Results: (1) The mean age of SOBS and OBS were 68.8±15.6yrs and 60.4±14.7yrs (P=0.002), respectively. (2) 35 (57.4%) and 34 (45.9%) patients were malignant biliary obstruction in SOBS and OBS group, respectively (P=0.227). Malignant obstruction included bile duct cancer and biliary duct invasion of pancreatic cancer. Benign obstruction included autoimmune pancreatitis, chronic pancreatitis, post operation stenosis, inflammatory stenosis due to cholelithiasis. (3) The mean first and second patency was 4.5 months and 5.6 months in OBS groups. All the patients in OBS group experienced at least three months to 15 months). No evidence of duodenal biliary reflux were detected in SOBS patients with malignant biliary obstruction. (4) The occlusion rates of SOBS and OBS group after 3, 4, 5, 6 months of first ERCP were 13.1% and 36.5%, 27.1% and 55.4%, 42.4% and 67.6%, 55.9% and 77.0%, respectively (P=0.003, 0.001, 0.005, 0.015). Multiple factors with logistic regression analysis showed that gender, age, location of biliary stricture were not related with the patency except the character of stricture. (5) SOBS were occluded in only 11 patients (11/61, 18%) with the patency (biopsy, air/water and balloon channel). Samples were centrally cultured. No evidence of duodenal biliary reflux was detected. Survival and culture interpretation were consistent with Dutch guidelines. Contamination was defined as AM20: any microorganism with ≥20 colony forming units (CFU)/20mL, and MGO: presence of microorganisms with gastrointestinal or oral origin, independent of CFU count.

Conclusion: Similar to our previous findings, in 47% of all Dutch ERCP/EUS centres at least one patient-ready DLE was AM20 or MGO contaminated. Of all DLEs, 13% was contaminated with digestive tract bacteria, indicating inadequate reprocessing. These results suggest that any additional awareness of contamination of duodenal biliary reflux and reduce the occlusion rate effectively due to duodenobiliary reflux in both malignant and benign biliary stricture.

Introduction: Recent studies describe multiple outbreaks of multi-drug resistant organisms caused by contaminated duodenoscopes, used for endoscopic retrograde cholangiopancreatography (ERCP) procedures. Contamination of duodenoscopes is distributed to the complete treatment, which includes a peroperative clean-up (e.g. soaping with a detergent and a jet of water) of the duodenoscope with an antireflux valve. Endoscopy (ESGE) clinical guideline.

Introduction: Although a newly digital cholangio/pancreato-scopy (SpyGlass DS) for therapeutic evaluation of pancreatobiliary neoplasms.
tumor extent using SpyDS plus mapping biopsy was 92%. One patient developed mild cholangitis after the procedure. As for IPMN, pancreatocystosis using a SpyDS could visualize intraductal papillary tumors in all patients, and SpyDS guided biopsy/cytology was successfully performed. Diagnostic accuracy of malignancy was 100% without any adverse event after the procedure. **Conclusion:** Preoperative evaluation using a SpyDS plus histological evaluation for pancreaticobiliary neoplasm was found to be useful and safety. Further study is needed to establish evidence about the usefulness of this technique. **Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0889 ACUTE PANCREATITIS AND HYPERAMYLASEMY DEVELOPMENT AFTER ENDOSCOPIC RETROGRADE CHOLANGIPANCREATOGRAPY – CHALLENGES AND PREVENTION**

**Contact E-mail Address:** dr.p.petrov@gmail.com

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

**Aims & Methods:** To analyze the frequency of probable causes of asymptomatic hyperamylasaemy and acute pancreatitis after ERCP and their prevention. Two significant increase in the indications for implementing ERCP, gastroenterologist began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Advanced endoscopy trainees (AETs) achieve ERCP competency at variable rates and specific case volumes do not ensure competence. However, training and credentialing guidelines continue to utilize an absolute procedure volume to determine competence. There are limited data on whether current training composition and volumes ensure ERCP competence in the US.

**Aims & Methods:** (i) To define ERCP learning curves using a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERCP training in AETPs. ASGE-recognized AETPs were invited to participate and AETs were graded on every ERCP after completion of 25 hands-on ERCP exams. Grading was performed using our previously developed and validated tool [The EUS and ERCP Skills Assessment Tool (TEESAT)] which assesses technical and cognitive competence in a continuous fashion. Grading for each skill was done using a 4-point scoring system: 1=no assistance, 2-minimal verbal cues, 3-multiple verbal cues or hands-on assistance and 4-unable to complete. A comprehensive data collection and reporting system was built using REDCap, a web-based data collection software, and SAS to create learning curves using cumulative sum (CUSUM) analysis for overall and individual technical and cognitive components of ERCP. Individual results and comparison to peers were sent to AETs and trainers quarterly. Acceptable and unacceptable failure rates were set a priori. AETs with <20 evaluations were excluded and success was defined as a skill score of 1 or 2. Individual and combined graphs to assess change in cannulation success rates were constructed and the Cochran-Armitage trend test was used to assess improvement in success rates.
**P0891 SIMILAR POST-ERCP PANCREATITIS RATES IN ENDOSCOPIST- VS ASSISTANT-CONTROLLED WIRE-GUIDED BILE DUCT CANNULATION: A SINGLE CENTRE OBSERVATIONAL STUDY**

M. Hu, A. Bhagwat, M. Hayat
Dept Of Gastroenterology, Northumbria Healthcare NHS Foundation Trust, North Shields/United Kingdom

Contact E-mail Address: maxworth.hu@gmail.com

**Introduction:** A recent randomised study by Buxbaum et al demonstrated a significantly lower rate of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PERCPP) in endoscopist- versus assistant-controlled bile duct cannulation. We set out to audit the rates of PERCPP at our centre based on this finding.

**Aims & Methods:** All ERCPs performed by two endoscopists between April 2015 and March 2016 were audited retrospectively. The two endoscopists practiced endoscopist-(E1) and assistant-controlled (A1) wire-guided cannulation exclusively. Both E1 & A1 had access to the same indications, sphincterotomes, equipment, and teams. Data was obtained and anonymised from electronic patient records and endoscopy reporting software. PERCPP was defined as abdominal pain with hyperamylasaemia at least three times the upper limit of normal (ULN) 24–48 hours after ERCP with or without corresponding imaging findings within 7 days; or abdominal pain with a further rise in pre-existing hyperamylasaemia to at least three times ULN 24–48 hours after ERCP with or without corresponding imaging findings within 7 days. Additional data was collected for CT evidence of post-ERCP complications, hyperamylasaemia without pancreatitis, bleeding, and post-ERCP cholangitis. Patient and procedural characteristics predisposing to pancreatitis were also recorded.

**Results:** Of the 62 programs invited, 20 AETPs participated and 20 AETs were included in the final analysis. At the end of training, median number of ERCPs performed/AET was 350 (15–500). Overall, 2649 ERCP exams were graded; the majority were ASGE biliary grade 1 (77%) and only 14% for pancreatic indication. Among biliary ERCP cases, AETs attempted native papilla cannulation and sphincterotomy in 1199 (53%) and 901 (40%) cases, respectively. The mean time allowed for cannulation was: overall - 4.0 min (SD 4.3), native papilla - 5.7 min (SD 4.8), and AET failed cannulation cases - 6.2 min (SD 5). There was no change in the time allowed for native papilla cannulation during the 1-year period (p = 0.28). AETs were involved in a small proportion of cases requiring advanced cannulation techniques such as double-wire technique, placement of pancreatic duct stent and precut sphincterotomy (6%). Learning curves for individual endpoints, overall technical and cognitive aspects noted substantial variability. Majority of AETs achieved overall technical (60%) and cognitive (100%) competence at the end of training. While there was a statistically significant improvement in overall and native papilla cannulation rates (both p < 0.001), only 18% of AETs achieved competence for native papilla cannulation (Table 1).

**Conclusion:** The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing a centralized national database to report individualized ERCP learning curves using a novel web-based comprehensive data collection and reporting system. Using strict definitions, a minority of AETs achieved competency in native papilla cannulation which may, in part, be due to limited cannulation time provided to AETs. Selective native papilla deep cannulation needs to be considered native papilla cannulation which may, in part, be due to limited cannulation curves using a novel web-based comprehensive data collection and reporting system. Publishing a centralized national database to report individualized ERCP learning curves and competence among AETs in ERCP validating the shift away from copist’s case load. Further randomised trials, or a crossover study; provided the no characteristics predisposing to PERCPP overtly skewed towards either endoscopist or assistant-controlled technique.

**Introduction:** Most endoscopic retrograde cholangiopancreatography (ERC) -related procedures are performed under “conscious sedation”, a drug-induced depression of consciousness during which patients are comfortable and able to maintain purposeful responses to verbal or tactile stimulation, and cardiorespiratory function generally remains intact 1. Meanwhile, we sometimes observe adverse events related to conscious sedation after ERC such as aspiration pneumonia 2. So far, it is unknown whether immediate recovery from conscious sedation with an antagonist is necessary or not.

**Aims & Methods:** We aimed to reveal the efficacy of flumazenil, an antagonist to benzodiazepines, on the prevention of adverse events, especially, aspiration pneumonia related to conscious sedation which is most frequent after ERC. One hundred ninety patients who underwent ERC between January to December...
2014 in a general hospital in Japan were included. The patients were divided to two groups: the group with flumazenil (F group) and the group without flumazenil (non-F group) just after ERCP and they were compared and analyzed. Examination items were 1) patient characteristics, 2) procedure characteristics, and 3) occurrence rates of post-ERCP aspiration pneumonia. Pearson's Chi-square test and Fisher's exact test were used for statistical analysis of categorical data.

Results: 1) One hundred fifteen patients (60.5%) were administered flumazenil just after ERCP (F group) and 75 patients (39.5%) were not (non-F group). The median age, 76 (47–94) in the F group and 78 (46–94) in the non-F group; male/ female ratio, 57/58 in the F group and 34/41 in the non-F group. The distributions of the basic disease (CBD stone/malignant biliary disease/malignant pancreatic disease/others) were 64/8/17/26 in the F group and 30/11/16/18 in the non-F group. The distributions of used benzodiazepines (midazolam/diazepam/none) and the patient number who got aspiration pneumonia were 102/13/0 and 1 in the F group and 59/13/2 and 1 in the non-F group, respectively (Fisher's test: p-value = 0.074). There were no significant differences of patient characteristics between both groups, especially the mean procedure times were 36.7 minutes in the F group and 30.3 minutes in the non-F group, respectively. The details of procedures for the major papilla (endoscopic sphincterotomy/endoscopic papillary balloon dilation/others/none) were 40/13/5/56 in the F group and 25/5/3/41 in the non-F group. The distributions of endoscopic biliary drainage or stenting/none were 94/21 in the F group and 59/16 in the non-F group (Fisher's test: p-value = 0.085). There were no significant differences of procedure characteristics between both groups. 2) Two patients (1.05%) developed aspiration pneumonia just after ERCP. One (94 years old, male) was in the F group and the other (81 years old, female) was in the non-F group (Pearson's Chi-squared test p-value = 1). Both of them were over 80-year-old. The patients who were given oxygen during ERCP were 86/54 in the F group and 58/30 in the non-F group, one patient developed pneumonia (Pearson’s Chi-squared test p-value = 1).

Conclusion: Flumazenil did not have any preventive effect on the occurrence of aspiration pneumonia related to conscious sedation after ERCP.

Introduction: Pancreatitis is the leading complication of endoscopic retrograde cholangiopancreatography (ERCP). Some studies have shown that the provision of intravenous hydration may reduce the incidence of this serious adverse event, the post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP). In our department we implemented an aggressive hydration protocol (AHP) for patients undergoing ERCP in order to prevent PEP.

Aims & Methods: The aim of this study was to evaluate the impact of this protocol on the incidence and severity of PEP. Patients and methods Retrospective analysis of all patients submitted to ERCP in one center during 16 months, including patients hospitalized in the gastroenterology department who were managed according to the AHP and patients hospitalized in other departments who underwent standard hydration (SH). Patients who underwent AHP received intravenous sodium lactate solution (RL) at 200 mL/hour starting 1 hour before, during the procedure and the anesthetic recovery; in those who remained asymptomatic after the ERCP, the RL was maintained at 100 mL/hour for 8 hours and after it was changed to a balanced salt solution with glucose (PG) at 80 mL/hour; in those patients who had abdominal pain or amylase >3 times normal limit after ERCP, the RL was maintained at 200 mL/hour during 8 hours and after it was changed to PG at 120 mL/hour. We evaluated the incidence and severity of PEP, the established predictive factors and procedure-related risk factors for PEP (except the difficulty of cannulation) and the occurrence of complications. Data were analyzed with SPSS statistical software.

Results: We analyzed 192 patients, 290 ERCP (AHP n = 168, SH n = 122). The incidence of PEP was 12% (11/90), significantly lower in the SH group (4/11 versus 7/11; p = 0.766). In the SH subset, only 1 PEP was moderate and the remaining 3 were mild. In the AHP group, 3 PEP were moderate and 4 were mild. There were no complications related to AHP. We didn’t find any patient or procedure-related variable significantly associated with the development of PEP.

Conclusion: Our AHP didn’t reduce the incidence of PEP or its severity. Indeed, the AHP group presented more PEPs than the SH group, although the difference between both PEP incidences was not significant. Despite our study didn't show any advantage related to the use of an AHP, intravenous aggressive hydration may have a role in PEP prophylaxis. Further studies are needed to establish its true value.

P0895 PROSPECTIVE STUDY OF EARLY PRECUT VS. UTMOST PRECUT WITH PANCREATIC STENT IN INITIAL PANCREATIC DUCT CANNULATION

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han
Internal Medicine, Konin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: euntpark@hanmail.net

Introduction: In biliary access, repeated biliary cannulation attempts are a risk factor for post ERCP pancreatitis (PEP). Early precut is an effective technique for successful biliary cannulation and can significantly reduce the incidence of PEP. The aim of this study was prospectively to evaluate clinical efficacy the performance of utmost early precut with pancreatic stent in the patients in whom pancreatic duct cannulation was performed initially.

Aims & Methods: When guidewire was placed in the pancreatic duct initially by chance, the patients were randomized into early precut (Group A) or utmost early precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy with or without early precut sphincterotomy. In Group B, from the first, pancreatic stent was inserted and then precut with an incision over a pancreatic stent was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

Results: From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 24 (95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the Group A and 14.8 minutes in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B (P < 0.001).

Conclusion: In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidewire facilitated biliary cannulation and the success rate of cannulation but also promise low incidence of post-ERCP pancreatitis. In experienced hands, utmost early precut technique can dramatically reduce the trauma of ampulla and risk of PEP compared with conventionally persistent cannulation attempts.

P0896 POST-ERCp BLEEDING IN THE ERA OF MULTIPLE ANTIPATELETT agents

H. Oh1, J. I. El Hajj2, J. Easler2, E. Fogel2, J. Watkins2, L. Mchenry2, G. Lehman2, J.S. Choi1, H. Kang1, S. Sherman2
1College Of Medicine, Chang-An University, Seoul/Korea, Republic of
2Gastroenterology And Hepatology, Indiana University, Indianapolis/United States of America

Introduction: Antithrombotic therapy with antipatelel agents (APA) has been increasingly utilized during the last few decades. This study aimed to determine the risk of post-ERCP bleeding among those patients who are taking APAs, especially in the era of multiple agents.

Aims & Methods: From July 2012 to May 2016, the patients who underwent 1st ERCP and used APA were identified from the ERCP database of 3 institutions in US and Korea. The outcome variables were the frequency, type, and severity of ERCP-related bleeding according to the use of APA.

Results: The frequencies of post-ERCP bleeding among the four different groups were 16 of 2083 (0.8%) in No drug group, 12 of 256 (4.7%) in Aspirin group, 3 of 48 (6.3%) in Single APA group, and 4 of 48 (8.3%) in Multiple APA group (p < 0.001). Most cases of post-ERCP bleeding were mild (29/35, 88%). In the univariate analysis, post-ERCP bleeding was associated with age, pull-type sphincterotomy, and APA, and inversely associated with balloon dilation of the biliary access, millivantage analysis, pull-type sphincterotomy odds ratio [OR] 7.829, 95% confidence interval [CI] 1.411–43.453, p = 0.019) and country (Korea; OR 0.124, 95% CI 0.042–0.361, p < 0.001) were associated with post-ERCP bleeding.

Conclusion: The frequency of post-ERCP bleeding was statically higher in patients on any APAs within 6 days prior to ERCP. However, in the multivariate analysis, APA use was not associated with post-ERCP bleeding. Until a large study has substantially powered differences in bleeding rates, caution is recommended when considering invasive procedures during ERCP in patients on APAs.

2Department Of Pathology, Soon ChunHyang University School of Medicine, Bucheon/Korea, Republic of

Contact E-mail Address: yunanh@schmc.ac.kr

Introduction: In a recent, a digital version of single-operator cholangioscope (SpyGlass DS) and direct POC (DPOC) using a multibending ultrasound endoscope were introduced as improved forms of each POC, especially in image quality and technical difficulty, respectively.

Aims & Methods: In this study, we prospectively compared the procedure success rates of SpyGlass DS and DPOC for diagnosis and treatment of BD lesions. A total of 15 patients with BD lesions (diameter of CBD >8 mm) requiring evaluation or treatment using POC were enrolled prospectively. All patients received POCs using SpyGlass DS and multibending ultrasound endoscope for DPOC.

According to the presence of obstructive lesion, all patients were classified as obstructive type or non-obstructive type, respectively. Procedural success defined as an ability to advance the cholangioscope to the desired target and get adequate cholangioscopic visualization for the targeted lesion.

Results: The overall technical success rates of SpyGlass DS and DPOC were 100% and 93.3%, respectively (P = 0.5). In DPOC, 1 patient was failed to insert the endoscope into the CBD. In SpyGlass DS, 2 patients were failed to visualize the targeted lesion. The procedural success rates of SpyGlass DS and DPOC according to the type of lesion were not different in 9 obstructive type (100% vs. 88.9%, P = 0.5) and 6 non-obstructive type (66.7% vs. 100%, P = 0.227). The successful diagnostic and therapeutic procedures with DPOC and SpyGlass DS were observed in 8 of 8 patients (100%) and 7 of 9 patients (77.8%) (P = 0.265), respectively.

Conclusion: Both advanced image quality of SpyGlass DS and improved technical difficulty of DPOC by a multibending ultrasound endoscope showed comparable and high procedure success rates in patients with dilated BD. Future prospective studies focused on overall cost savings and long-term clinical outcomes are seems to be required for deciding adequate indications of each POC systems.

Disclosure of Interest: All authors have declared no conflicts of interest.

Prospective study on methods and success of biliary cannulation of 458 virgin papillae: quality assurance of ERCP at our department

A. Orban-Szalay1, K. Lorinczy1, C. Rabai1, M. Horvath1, F. Zsigmond1, T. Gyokeres1
Gastroenterology, Medical Centre, Hungarian Defence Forces, Budapest, Hungary

Contact E-mail Address: tiborgyokeres@freemail.hu

Introduction: The cannulation of a virgin papilla is the most difficult and high-risk step in ERCP and it requires significant experience to maximize the success and to minimize poor outcomes. Cannulation rate is one of the accepted quality indicators of ERCP. It is mandatory to regularly assess quality indicators of endoscopic procedures to maintain and improve endoscopic service.

Aims & Methods: We prospectively collected data about cannulation details of all patients with virgin papillae and post-ERCP complications from April 2016 to April 2017.

Results: During this 12-months period we have performed 1102 ERCPs, in 458 of them we had virgin papilla. All ERCPs had therapeutic intentions and all of the patients were followed up. In 13 patients papillae were not accessible due to duodenal stenosis (10/13) or postoperative situations (3/10). In two of them the indication was ceased (because the biliary obstruction resolved spontaneously), 11 patients got percutaneous transhepatic drainage (PTD). The primary cannulation success rate of accessible papillae was 88.5% (394/445) while the overall cannulation success was 96.6% (430/445). 56.1% of primary successful cannulations were achieved by conventional method, in 14.2% we used pancreatic guidewire assisted technique, in 20.1% we used early precut sphincterotomy, and in the remaining 9.6% we used combined techniques. In 51 primary unsuccessful cases we repeated ERCP attempt in 4 days on average and successfully cannulated 70.5% (36/51) of them at the second or third attempts. 27 of them were achieved by conventional method, 7 of them after extending the precut, one case was achieved by pancreatic guidewire technique, and we used proflactific pancreatic stent in one patient, as well. Out of the 15 patients with finally unsuccessful cannulation, we performed precut without deep cannulation in 10 cases. 7 of them resolved after precut, 2 of the 10 patients got PTD and one patient related to another indication. In 4 patients out of the 15 unsuccessful cannulations the obstruction resolved without any further intervention and one patient got PTD. We had in sum 3.4% (15/445) post-ERCP pancreatitis, 7 of them were mild, and 8 moderate, we had no severe one. We observed endoscopic signs of biliary atresia in 34 cases that required endoscopic treatment (infiltration/coagulation/stoning), 7 of them (1.6%) required blood transfusion. Three patients suffered perforation during ERCP. One of them got biliary stent and was discharged uneventfully on the 8th day. We had 2 sphincterotomy related percutions, 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Conclusion: Quality assessment of ERCP performance is essential. Our overall cannulation rate was acceptable. We used pancreatic guidewire technique just after the 10th attempts of pancreatic sphincterotomy. In the second phase of process to avoid long lasting traumatisation of the papilla. Our complication rate of post-ERCP pancreatitis was good while the post-sphincterotomy phase of process to avoid long lasting traumatisation of the papilla. Our common and severe complication of ERCP. The incidence rates of and risk factors for PEP in a prospective large cohort study. This is a prospective cohort study of all patients who underwent ERCP-related procedures at 5 high-volume centers between February 2015 and May 2016. Patients who presented with acute pancreatitis, post biliary reconstruction, and failure to reach the papilla were excluded. The incidence rates of PEP and its severity were examined. Multivariate analysis was used to identify the risk factors for the different groups of patients who presented with two of the following: patients were diagnosed with PEP: 1) elevated levels of serum amylase, 2) abdominal pain lasting more than 24 hours, and 3) abnormal findings of acute pancreatitis on computed tomography. An increase in serum amylase level of at least 3 times greater than the normal upper limit at approximately 18 hours after the procedure (the next morning) was regarded as significant. The severity of PEP was graded according to the severity assessment of the Japanese Ministry of Health, Labour, and Welfare. Results: A total of 1912 patients were finally analysed. PEP occurred in 142 patients (7.3%); it was mild in 117 patients (6.0%) and severe in 25 patients (1.3%). Univariate analysis showed that female gender, naive papilla, surgically altered gastrointestinal anatomy, no coexistence of acute cholangitis, diagnostic ERCP, early precut, procedure time after reaching the papilla, number of cannulation attempts, precut sphincterotomy, intraductal ultrasonography, pancreatic duct injection, insertion of guidewire into the pancreatic duct, and placement of prophylactic pancreatic stent were significant risk factors. In the multivariate analysis, female gender (OR 2.273; 95%CI 1.570–3.291), naive papilla (OR 3.024; 95%CI 1.805–5.066), surgically altered gastrointestinal anatomy (OR 2.607; 95%CI 1.378–4.931), procedure time after reaching the papilla (OR 1.009; 95%CI 1.901–1.017), pancreatic duct injection (OR 2.297; 95%CI 1.493–3.524), and intraductal ultrasonography (OR 1.620; 95%CI 1.015–2.585) were independent risk factors.

Conclusion: The incidence of PEP was similar to those reported in previous studies. These risk factors are important as predictors of PEP. A shorter procedure time and avoidance of unnecessary pancreatic duct injection are important for prevention of PEP.

Aims & Methods: The aim of this study was to evaluate the transduodenal tractcholecystectomy technique in the treatment of gallbladder disease without choledochotomy. In the patient with cholesterol gallstones and high surgical risks were enrolled between January 2015 and March 2017. Endoscopic ultrasound (EUS)-guided cholecystoduodenostomy by deploying a double-flanged fully covered metal stent with hot stent delivery was performed and endoscopic sphincterotomy (EST) was also performed during this procedure for those patients with accompanying common bile duct stones. One or two weeks later an forward-viewing endoscope was advanced into the gallbladder via the stent, and cholecystolithotomy or polypectomy was performed. After the stents were removed, a pigtail-type naso-cholecystic drainage catheter was inserted into the gallbladder over the guide wire and removed 2 days later. Four weeks later gallbladder was assessed by abdominal ultrasound.

Results: EUS-guided cholecystoduodenostomy with double flanged metal stent deployment was successfully performed in all of 26 patients (Male:Female, 11:15; mean age, 61 ± 16.19yrs). After the procedure, fistulas had formed in each of the patients and the stones of 7 patients expelled themselves completely. Endoscopic sphincterotomy (EST) and polypectomy (2) were performed through the stents, and then the stents were removed. Common bile duct stones were also successfully removed in 6 patients. EST showed all the fistula closed completely after 3 days. The ultrasound examination of the gall-bladder 4 weeks later showed no stones remaining and also showed satisfactory functioning of the gallbladder. The mean follow-up period was 11 months (range: 1-27 months). Cholesterol gallstones recurrence were not detected in any patient during follow-up.

Conclusion: EUS-guided placement of a novel metal stent with hot stent delivery is a safe and simple approach for performing an endoscopic cholecysto-duodenostomy, which can subsequently allow procedures to be performed for treating biliary disease, including cholecystolithotomy.

Introduction: The second generation of quantitative endoscopic ultrasound (EUS) elastography allows the quantitative analysis of tissue stiffness and can be a useful auxiliary tool in the differential diagnosis of pancreatic solid tumors (1)(2).

Aims & Methods: The aim of this study was to evaluate the accuracy of the quantitative EUS elastography in the differential diagnosis of pancreatic solid masses, discriminating malignant from benign masses, using strain ratio (SR) analysis. A prospective study was performed for 15 months and included 29 consecutive patients who underwent EUS for the evaluation of solid pancreatic masses. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean of 3 measures was considered as the SR final result for each lesion, EUS-fine-needle aspiration of the lesions was performed after SR assessment and the final diagnosis was based on the cytology or histology results. Accuracy of the elastography was obtained by the analysis of ROC curves.

Results: Included 29 patients in a total of 30 lesions with conclusive histological/ cytoLogic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors comparing with the benign tumors (55.56 vs 22.93, p = 0.001). The sensitivity and specificity of SR for discrimination of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusions: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnostic and follow-up of these patients.

Introduction: Determining the cause of suspected biliary strictures is always challenging in clinical practice. Although EUS-guided tissue sampling (EUS-TS) revealed a better diagnostic yield in suspected malignant biliary obstructive lesions comparing to ERCP-guided tissue sampling (ERCPTS), there was few studies for which techniques are better dependent on primary tumor. Aim: The aim of our study is to compare the diagnostic yields between EUS-TS and ERCPTS in patients with suspected malignant biliary obstructive lesion according to primary tumor sites. By reviewing medical records, we enrolled patients who underwent same-session examination of EUS and ERCP for the evaluation of suspected pancreaticobiliary obstructive lesion. For cytopathologic diagnosis, endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) or biopsy (EUS-FNB) and ERCPTS using brush cytology and/or forceps biopsy were performed. The diagnostic performances were compared between two techniques according to primary tumor sites.

Results: From January 2011 to September 2016, we enrolled 125 patients and 32 patients were excluded due to the following reasons: loss of follow up in 8, ERCPTS from pancreatic duct in 23, and ERCPTS from peripapillary biopsy in 4. Among the enrolled patients (93 patients; 62 males, mean age 65.8 years, 86 (92.5%) had malignant tumor such as cholangiocarcinoma in 39, pancreatic cancer in 37, and other malignant tumors in 10 patients. And 7 (7.5%) patients had benign lesions. EUS-TS revealed higher rate of overall diagnostic accuracy comparing to ERCPTS (82.8% vs. 60.2%, p=0.001). Depending on primary lesions, the diagnostic accuracy for pancreatic lesions was statistically higher in EUS-TS than ERCPTS (84.4% vs. 51.1%, p=0.003). Conclusion: EUS-TS is superior to ERCPTS for the evaluation of suspected malignant pancreaticobiliary obstructive lesions. Especially, if the biliary obstruction was caused by pancreatic lesions, EUS-TS would need to be a priority for cytopathologic diagnosis.

P0907 PREVALENCE OF POSTERIOR MEDIASTINAL LYMPHADENOPATHIES IN PATIENTS UNDERGOING ENDOSCOPIC ULTRASONOGRAPHY-FINE NEEDLE ASPIRATION: INDICATIONS: A PORTUGUESE SINGLE-CENTRE PROSPECTIVE STUDY
J. Veloso Du Carmo, S. C. Marques, M. Bispo, C. Chagas
Gastroenterology, Hospital Egas Moniz - Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: jouanavcarmo@gmail.com

Introduction: Significant heterogeneity in geographic distribution in the prevalence of posterior mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasonography (EUS) for evaluation of malignant neoplasms. A prospective, unicentric study was performed between July and December 2016. Medialstinal stations 9, 8, 7, 6, 5, 4L and 2L were systematically evaluated using a linear echoendoscope in all patients undergoing EUS due to benign extra-thoracic pathology, without history of oncologic disease. Demographic, clinical and EUS features were analysed, including location, number, shape, dimensions and echogenicity of the lymphadenopathies.

Results: We analysed 75 patients; M:F, 32:43; Mean age, 63.6 years. The majority (72%) of the patients presented lymphadenopathies in at least one mediastinal station, and 88% were found in stations 7 or 4L. Only 6% of these had short axis diameter >10 mm, most were oval (59%) or triangular (37%) and 40% had a hyperechogenic center. The prevalence of lymphadenopathies was higher in smoker patients (83% vs 64%, p=0.024), with a higher average number of lymphadenopathies per patient in this group (2.1 vs 1.6; p=0.017). Similar findings were documented in patients with relevant occupa- tional or environmental respiratory exposure (prevalence 83% vs 71%; average number 3 vs 1.7). By logistic regression analysis, none of the variables analysed were independently associated with the presence of mediastinal lymphadenopathies.

Conclusion: This prospective Portuguese study documented a higher prevalence of mediastinal lymphadenopathies than previously reported in northern Europe, in patients with no evidence of oncologic disease. This higher prevalence, mostly in smokers or patients with relevant occupational exposure, may negatively influence the specificity and positive predictive value for malignancy of mediastinal lymph node (N) staging by EUS, with particular relevance in esophageal and pulmonary cancer staging.

Introduction: Recent studies demonstrated the positive impact of neoadjuvant treatment for gastric adenocarcinoma T ≥ 2 and/or N+. Aims & Methods: We aimed to assess the accuracy of endoscopic ultrasound in the selection of patient with gastric adenocarcinoma for neoadjuvant therapy. A unicentric retrospective analysis of patients with the anatomopathological diag- nose of gastric adenocarcinoma between 2011 and 2016, who performed endo-scopic ultrasound for staging and underwent surgery without prior neoadjuvant treatment. The concordance (kappa) and accuracy [sensitivity (S) and specificity (E)] of the endoscopic ultrasound for T ≥ 2 and/or N + (criteria for neoadjuvant treatment) were assessed using the anatomopathological staging of the resected surgical specimen.

Results: The final sample included 144 patients (64.6% male) with a median age of 68.5 ± 12.2 years. In most cases (80.6%), the neoplasia was distal (antrum, incisura angularis and body). The neoplasia was of the intestinal type, diffuse and mixed in 65.3%, 18.8% and 16% of the cases, respectively. After examination of the resected surgical specimen, 53.5% of patients had criteria for neoadjuvant treatment (T ≥ 2 and/or N +). The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥ 2 and/or N + were 0.70 (p < 0.001), 85.2% (95% CI: 75.6–94.2%) and 87.3% (95% CI: 76.5–94.4%), respectively. The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥ 2 and/or N + were higher in proximal lesions (cardia and JEG) (k = 0.924, S-94.4% and E-100%) compared with distal lesions (k = 0.671, S-82.5% and E-84.9%) and in intestinal type lesions (k = 0.765, S-84.9% and E-92.7%) compared with diffuse type lesions (k = 0.682, S-88.4% and E-80%) or mixed (k = 0.566, S-81.8% and E-75%).

Conclusion: In one of the largest series of patients, we showed that endoscopic ultrasound was an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.

Introduction: The role of endoscopic ultrasound (EUS) and fine needle aspiration (EUS-FNA) require initial imaging characterization and frequently follow-up. Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) for CEA measurement and cystic fluid is the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA with cystic fluid analysis in follow-up of PCs is not clear.

Aims & Methods: To determine if patients with pancreatic cysts with a second repeated EUS-FNA for cystic fluid analysis for CEA and cytology had a change in cyst classification or on clinical decision. Retrospective analysis of a EUS database, with 284 patients who had EUS-FNA for pancreatic cyst evaluation from 2007–16, of which 35 had 2 EUS procedures, and of these, 22 had 2 con-secutive EUS-FNA procedures.

P0910 DETERMINATION OF INTRACYSTIC GLUCOSE CONCENTRATIONS IN THE DIFFERENTIAL DIAGNOSIS OF PANCREATIC CYSTS: A PROSPECTIVE STUDY
A. Cantamessa, M. Bruno, S. Gaia, G. Saracco, C. De Angelis
Gastroenterology Unit, Universita` of Turin, Turin/Italy
Contact E-mail Address: eusdeng@hotmail.com
Introduction: Despite advances in imaging techniques, differential diagnosis of pancreatic cysts still remains challenging. There has been an increasing interest in new pancreatic cyst biomarkers as a way to differentiate different cyst subtypes and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a promising marker. The aim of this prospective study was to verify this early finding.
Aims & Methods: We enrolled in the study all the patients who underwent Endoscopic Ultrasound (EUS) guided Fine Needle Aspiration of a pancreatic cyst at our Institution from October 2015 to February 2017. The cyst fluid was sent for cytology, mucin staining and determination of amylase, Carbohydrate Antigen 19-9 (CA 19-9), Carcinemobryonic Antigen (CEA) and glucose. When determined necessary by the endoscopist, needle-based confocal laser endomicroscopy (nCLE) of the cyst wall and/or contrast-enhanced EUS was performed. A definitive diagnosis of the nature of the cyst was reached relying on surgery, cytology or mucin staining, a typical pattern of nCLE or by consensus (on EUS endoscopy (nCLE) of the cyst wall and/or contrast-enhanced EUS was performed. A definitive diagnosis of the nature of the cyst was reached relying on surgery, cytology or mucin staining, a typical pattern of nCLE or by consensus (on EUS-FCN A) of the cyst wall and/or contrast-enhanced EUS was performed. A definitive diagnosis of the nature of the cyst was reached relying on surgery, cytology or mucin staining, a typical pattern of nCLE or by consensus (on EUS

Results: Twenty-nine patients (13 males, median age 72 years, range: 30-83) entered the study. Nineteen (66%) pancreatic cysts were unilocular (12) and complex (7). The median largest diameter of the median largest cyst was 45 mm (range: 20-70 mm). Sixteen (55%) cysts were located in the pancreatic head, 10 (35%) in the body and 3 (10%) in the tail. CE-EUS was performed in 14 (48.3%) patients, nCLE in 19 (65.5%) patients. Eighteen (60.7%) cysts were classified as mucinous (6 mucinous cystadenomas; 12 intraductal papillary mucinous neoplasm) and 11 (37.9%) as non-mucinous (6 serous cystadenomas; 5 pseudocysts). The final diagnosis was reached relying on surgery in 9 patients (31%), on clinical follow-up in 11 patients (n = 8 (27.6%) and on consensus in 8 (27.6%). Mean glucose concentrations in mucinous cyst were significantly lower than in non-mucinous cysts (7.7 mg/dl vs 95.7 mg/dl, p < 0.0001). In the diagnosis of mucinous cysts, sensitivity of CA 19-9 (cutoff more than 5000 U/ml), CEA (cutoff more than 192 mg/ml) and glucose (cutoff less than 50 mg/dl) was respectively 22.2%, 66.7% and 94.4%. Specificity was respectively 72.7%, 100% and 100%. Accuracy was respectively 41.4%, 79.3% and 96.6%. Only two subjects in this cohort were affected by diabetes, this condition did not impact on intracystic glucose concentrations.
Conclusion: Although limited by the small sample size, this study confirms the utility of intracystic glucose levels in differentiating mucinous from non-mucinous pancreatic cysts. This cheap, new marker outperformed CA 19-9 and CEA in sensitivity, specificity and accuracy.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0911 UTILITY OF LIQUID BASED CYTOMETRY IN EUS-FNA SAMPLES FOR THE PANCREATIC LESION

Introduction: Liquid-based cytology (LBC) preparation method is one of the new techniques, which is widely used in gynecological and non-gynecological cytology samples, due to its ability to decrease screening time, insufficient sample rate, and air-drying artifacts compared to a conventional smear method. Additionally, immunocytochemistry (IHC) can be performed all at once.
Aims & Methods: The aim of this study is to show the actual method of LBC and to evaluate the utility of LBC in EUS-FNA samples of the pancreatic lesions. 292 specimens obtained by EUS-FNA from patients with pancreatic disease were analyzed in this study. Clinical diagnosis was pancreatic cyst in 210 patients, acinar cell carcinoma in three cases, adenocarcinoma cell carcinoma in one case, invasive ductal carcinoma derived from IPMN in three cases, metastatic pancreatic tumor in eight cases, pancreatic neuroendocrine tumor (PNET) in 20 cases, solid-pseudopapillary neoplasm (SPN) in five cases, mass-forming pancreatitis in four cases, and autoimmune pancreatitis (AIP) in 40 cases. Just after EUS-FNA, tissue sample in the FNA needle was flushed out into petri dish with saline. The specimen was carefully examined to include sufficient material rate of cytology and histology are 99.1%(223/225) and 89.3%(201/225). Positive predictive values of cystology and histology are 81.7%(184/225) and 67.6%(152/225). 65.8%(48/73) of pathologically non-diagnosed cases could be differentiated as malignant or non-malignant by cytology. In 26 specimens, in which insufficient material was needed, IHC was available in 23 of the 26 specimens (88.5%) and ICC was available in all specimens. In the three specimens, IHC was not available owing to pathological insufficiency.
Results: LBC in pancreatic cyst samples obtained by EUS-FNA may be useful for reducing insufficient material rate and conducting ICC as well as in samples in other medical fields.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0893 ANTIBIOTIC PROPHYLAXIS AFTER PANCREATIC CYST PUNCTURE – IS LESS MORE? ONE-TIME VERSUS EXTENDED CIROFLOXACIN PROTOCOL

Introduction: Echoendoscopy with fine needle aspiration (EUS-FNA) is a useful tool for the characterization of pancreatic cystic lesions (PCL) due to its ability to detect malignant cystic lesions, cystic neoplasms and to provide samples for biochemical and cytological examination. This is a safe procedure, with low complications (0–2, 5%). Nevertheless, peri-procedural and even several days after EUS-FNA antibiotic prophylaxis has been the standard practice due to the possible risk of pancreatic infection.
Aims & Methods: We aimed to compare the complications two protocols: group 1: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA; and group 2: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA plus three days of oral Ciprofloxacin, 500 mg, bid. Retrospective study of single-operator EUS-FNA of PCL in two centers with different antibiotic prophylaxis protocols, between January 2014 and December 2016. A telephonic questionnaire regarding post-procedural complications was applied to all patients that agreed to enter the study.
Results: Two hundred and four EUS-FNA were analyzed: 51.5%(n = 105) in group 2.40%(n = 123) women, mean age 63.4 ± 12.8 years. We were able to contact 86.9%(n = 86) patients in group 1 and 94.3%(n = 99) in group 2 (p > 0.05). The mean time between EUS-FNA and questionnaire application was 14, 7 months for group 1 and 17 months for group 2 (p > 0.05). There was no statistical difference between the two protocol groups regarding the morphological features of the PCLs (size, morphology, location) or procedure (needle size, location of puncture, number of passages or percentage of cysts with complete collapse after aspiration). Five patients had intra-cystic limited bleeding after puncture (two in group 1 and three in group 2). In group 1, 6.2%(n = 6) reported complications: 1 major (mild acute pancreatitis) and 5 minor (epigastric pain, vomiting). In group 2, 9.1%(n = 9) reported 1 major (mild acute pancreatitis) and 4 minor (epigastric pain, nausea) complications. Differences were not statistically significant between the two groups (p > 0.05). The patients with intra-cystic bleeding did not have a worse outcome. Additionally, five patients (1.9%) reported any type of adverse reaction related to antibiotic use (75% in group 2). Conclusion: EUS-FNA is a safe procedure, with 1% rate for major complications in our series and none of them with evidence of infection. We did not find any additional benefit from extension of antibiotic prophylaxis beyond the one-time administration during EUS-FNA. It has been questioned whether antibiotic
Disclosure of Interest: All authors have declared no conflicts of interest.
Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of the FNA needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

**Aims & Methods:** We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive PC patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS needle pre-loaded with 2 gold markers with knurled design. After the 2 markers were deployed, the EUS fiducial needle insert was exchanged out for a second pre-loaded EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and complications. The primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

**Results:** Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n = 6), neck (n = 2), and the body (n = 2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, p = 0.002). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

**Conclusion:** EUS-guided fiducial placement with a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

**Introduction:** Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE).

**Aims & Methods:** Our aim was to develop and to validate a computational algorithm, which would be able to evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarce in" or "abundant in bubbles (<10% or >10% of bubbles covering the frame, respectively). Reproducibility (k coefficient), sensitivity (Se), specificity (Sp), Receiver Operating Characteristic (ROC) curve, and calculation times were measured for different algorithms (Grey-level of co-occurrence matrix [GLCM], fractal dimension, Hough transform, and Speeded-Up Robust Features [SURF]) using the experts’ reading as reference. Algorithms with highest reproducibility, Se and Sp were then selected for a validation step on the second set of frames.

**Results:** Both SURF and GLCM algorithms had high operating points (Se and Sp over 90%) and a perfect reproducibility (k = 1). At the validation step, the GLCM detector strategy had the best diagnostic capabilities, with Se = 95.79%, Sp = 95.19%, and a mean calculation time of 0.037s per frame. Table 1: Sensitivity (Se), specificity (Sp), negative predictive value (NPV), positive predictive value (PPV) and area under receiver operating characteristic curve (AUROC) of four algorithms for evaluation of bubble abundance in small bowel capsule endoscopy still frames (development step).

**Conclusion:** A GLCM detector strategy has high diagnostic performances to categorize "scarce in" or "abundant in bubbles" SB-CE frames. This algorithm is of interest for clinical use (i.e. quality in CE reporting) and for research (providing an objective comparison tool of different preparations, including anti-bubble agents).

**Disclosure of Interest:** X. Dray: Xavier Dray has received consultation fees from Covidien GI solutions

All other authors have declared no conflicts of interest.
Aims & Methods: Data was collected from 14 patients that swallowed capsules in a multi-center clinical trial using an x-ray imaging capsule (GUT 2016). The patients were sent home to continue their normal life routine while the capsule naturally traveled in the gastrointestinal tract until excretion. (Subjects signed informed consent and the study was performed after local IRB approval). The capsules contained electronics and software that allowed for live communication between the capsule and a recording device that is placed directly on the patient’s back. This device tracks the position of the capsule and communicates with it, receiving diffused gas pressure from the capsule sensor and fusing this information with 3D position information from the capsule. The capsule system exhibited position accuracy of ±1 cm and the ability to detect movements in real time, as well as potential of ~1 ml of payload for drug containment.

Results: The average total transit time of the capsule was 43 hours (range: 15-68 hours). The average transit time to cecum was 13.8 hours, and the average time across the colon was 12.8 hours (range 6–25). The position tracking and the RF communication between the capsule and the recorder showed >90% coverage in all cases, even in obese patients. No adverse events were reported. Figure 1 illustrates the recorder placement on the patient back. Figure 2 is a typical averaged capsule position trace in the colon.

Conclusion: A capsule with accurate position tracking, 2-way communication, and on line algorithms can determine colonic entrance and identify exact locations in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic treatments in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic treatments in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic treatments in the colon.

P0920 COLON CAPSULE ENDOSCOPY: HOW DOES INADEQUATE PROCEDURE CLEANSING CORRELATE WITH PROCEDURE ACCURACY?
S. Perek, S. Farkash1, N. Schwartz2
1Medicine A, Rambam Health Care Campus, Haifa/Israel
2Pathology, HaEmek Medical Center, Afula/Israel
Contact E-mail Address: shayperek@gmail.com

Introduction: Colon Capsule Endoscopy (CCE) procedure requires a preparation regimen, which provides a clean colon, clear capsule images and promotes capsule propulsion through the entire colon. A four-point cleansing grading scale - system (poor, fair, good and excellent) has been used to describe the quality of colon preparation. “Poor” and “fair” are considered inadequate cleansing, while “good” and “excellent” – adequate for polyp detection. Adequate cleansing has been associated with significantly higher diagnostic accuracy, when compared with inadequate cleansing (72% vs. 28% respectively).[1]

Aims & Methods: Evaluate the relation between CCE procedure cleansing and accuracy – with an emphasis on inadequate cleansing. This is an additional post study analysis[2], including 767 screening population participants, from 17 sites in the United States and Israel, who underwent CCE procedure followed by a blinded colonoscopy. Capsule preparation included 12 mg Senna, 4 liters split dose of sulfate-free polyethylene glycol (PEG), with 6 and 3 oz of oral sulfate solution - for capsule propulsion. The CCE video was reviewed by 1 of 5 highly experienced CCE gastroenterologists. These physicians assessed colon cleansing on a “poor” to “excellent” scale. Incomplete studies were included in the analysis. Polyps were considered a match, if the size measured by the capsule (~50%) range overlapped the size measured by the colonoscopy (~50%) range, and polyp location estimates by the 2 methods were in the same or adjacent segments[2].

Results: The mean age of the analyzed cohort was 57.1 (SD 5.8) with 342 males (48.6%).

Conclusion: This analysis indicates, that when utilizing 4 liter PEG and oral sulfate solutions for CCE procedure preparation, current cleansing assessment scale and methodology may need to be re-evaluated - to better correlate with polyp detection. Currently, “fair” cleansing may not indicate inadequate cleansing for polyp detection.

P0921 COLON CAPSULE ENDOSCOPY MAY REDUCE COLONOSCOPY MISS RATE – A MULTICENTER STUDY
S. Perek1, N. Schwartz2
1Medicine A, Rambam Health Care Campus, Haifa/Israel
2HaEmek Medical Center, Afula/Israel
Contact E-mail Address: shayperek@gmail.com

Introduction: Colonoscopy miss rate is an area of intense focus, as it directly correlates with colorectal cancer incidence rate. Previous studies reported a colonoscopy miss rate of 2%–22%, depending on polyp size and histology [1].

Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas [2]. Determining the nature of polyps detected by CCE but missed by the first colonoscopy, may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient’s CCE report was assessed. Based on the findings in this report, the colonoscopy performing physician decided whether or not to immediately follow up with a second colonoscopy. 70 of the CCE findings were detected by the second colonoscopy. These 70 polyps were compared with 683 polyps detected by blinded colonoscopy, using logistic regression model. Adjusted Odds Ratios (Adj.OR) and corresponding Confidence Intervals (CI) were estimated.

Results: Of the 70 polyps missed by first colonoscopy and detected by second colonoscopy, 20 (29%) were 6 mm or larger (based on colonoscopy size estimation). 19 (27%) were either adenomatous or sessile serrated lesions and 16 (23%) were described as either flat or sessile-flat by colonoscopy performing physician. Stratification of polyps based on location:

<table>
<thead>
<tr>
<th>Detected by blinded colonoscopy (n = 683)</th>
<th>Detected after CCE and unblinding (n = 70)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cecum</td>
<td></td>
</tr>
<tr>
<td>Ascending</td>
<td>64 (84%)</td>
</tr>
<tr>
<td>Transverse</td>
<td>181 (94%)</td>
</tr>
<tr>
<td>Descending-Sigma</td>
<td>98 (96%)</td>
</tr>
<tr>
<td>Rectum</td>
<td>243 (90%)</td>
</tr>
<tr>
<td></td>
<td>97 (85%)</td>
</tr>
</tbody>
</table>

Colon cleansing Sensitivity (≥6 mm); n = 272 Specificity (≥6 mm); n = 495

| Adequate cleansing                      | 153/195 = 78.5% (72.2% – 83.7%)          |
| Inadequate cleansing                   | 54/77 = 70.1% (59.1% – 79.2%)            |
| P-value                                | 0.147                                    |
| Poor cleansing                         | 3/9 = 33.3% (11.7% – 64.9%)              |
| Fair, good and excellent cleansing    | 204/263 = 77.6% (72.1% – 82.2%)          |
| P-value                                | 0.007                                    |

Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps is similar in inadequate (“poor” + “fair”) cases compared to adequate (“good” + “excellent”) cases (70.1%, 78.5% respectively; P-value = 0.147).
Multivariate logistic regression revealed that after adjusting to polyp’s size, cecal and rectal segments were associated with increased chance of CCE additive value to colonoscopy (cecum vs. ascending or transverse colon: Adj.OR = 3.2 [95%CI: 1.3–7.6] and Adj.OR = 4.5 [95%CI: 1.4–14.6] respectively; rectum vs. ascending or transverse colon: Adj.OR = 2.6 [1.1–5.8] and Adj.OR = 3.6 [95%CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonoscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonoscopy, especially lesions in the cecum and rectum.

Introduction: Only small series (<10 patients) have described endoscopic management of postoperative pancreatic fistulas (POPF). The purpose of this retrospective study was to describe the indications, technique and results of endoscopic treatment of POPF.

Aims & Methods: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified. All patients were included in this analysis. POPF was classified according to the definition of the International Study Group of Pancreatic Fistula Working Group. The indications, the techniques and results of endoscopic drainage and the patients' outcomes were registered.

Results: Among 6473 ERCP performed during the inclusion period, 31 patients had POPF treated endoscopically (14 men, 7 women, mean age 61.06 ± 14.3 years). When compared to the standard treatment of POPF, the endoscopic approach required less surgical resection, and was associated with lower infectious complications.

Conclusion: Endoscopic management of POPF can be considered as an alternative treatment, especially in high-risk patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasonography (EUS)-guided biliary drainage (EUS-BD) is increasingly used in the treatment of malignant biliary obstruction after failed ERCP. However, Multi-step process for EUS-BD is closely related to adverse events.

Aims & Methods: The present study was designed to determine feasibility and safety of stent placement using a thin delivery-system stent without dilation step during EUS-BD. Three types of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with hard tip (7Fr hard tip), 7.5Fr delivery catheter with soft tip (7Fr soft tip) and 7Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with a 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10 pigs, EUS-BD (choledochoduodenostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events within 2 weeks after EUS-BD were analyzed.

Results: Among the three types of stents, 7Fr soft tip had the least resistance in the phantom model. In the animal model, the median common bile duct diameter before puncture measured on EUS and the median procedure time was 7.36 mm (4.05–9.5) and 29.3 minutes (16–47) respectively. In all pigs, EUS-BD using the three types of stents were technically successful. Dilation was unnecessary in 25% (1/4), 0% (0/2) and 100% (4/4) for the 7Fr hard tip, 7.5Fr hard tip and 7Fr soft tip respectively. Even in the cases requiring dilation, stent placement was successful, immediately after dilation only with a thin catheter (4.5Fr). Neither cautery dilation nor balloon dilation was needed. There were no procedure-related complications occurring during and 2 week after EUS-BD. All stents remained in place without migration. At necropsy, fistulas were created between the bile duct and duodenal in all pigs and the growth of fibrous tissue was observed in the microscopic findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Conclusion: Among the three types of stents, the 7Fr soft tip was suitable for ERCP in the phantom and animal models. The thin-diameter system stent may be technically feasible and safe for EUS-BD and possibly reduce adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Aims & Methods:** We report here on the use of FCMS in post-sphincterotomy early and late bleeding. Patients referred for in- and out-patient ERCP were informed of the potential off-label treatment with FCMS of post-sphincterotomy bleeding, and of treatment approval by the local ethical committee. We treated patients presenting with delayed bleeding first with adrenaline and/or sclerosing agent injection. When this first line hemostasis failed, we placed short FCMS in the distal cholecirrhosis. Endoscopy was rescheduled after 1 month to remove the FCMS. During the early post-procedural period the patients were treated with blood transfusions if needed, and antiplatelet drugs as well as oral anticoagulants were avoided.

**Results:** 17 Patients (10M/7F), aged on an average 70 years (range 38–90) received 18 FCMS (10mm×40mm, Boston Scientific) for failed hemostasis since January 2010. Hemostasis was obtained in 16 patients, with an average loss of 1 g/dl of Hb and 9 packed red cells units transfused. In our cases we had 1 outlier, a patient that had received needle-knife sphincterotomy without early bleeding but developed delayed bleeding by hypovolemic shock. He received a second ERCP and a FCMS after 3 days. After further 3 days the patient was in the intensive care unit because of persistent bleeding and we performed a third ERCP. The FCMS was in place, but we removed it, retreated the bleeding by injective therapy and placed a second FCMS, obtaining a stable hemostasis achieved after 8 days. These cases represent a large collection of evidence showing that treating post-sphincterotomy early bleeding with FCMS is feasible, safe and effective. Late bleeding associated with needle-knife pre-cut was much harder to control and required endoscopic revision, intensive care unit support and re-stenting. Our results are consistent with and support previous research in this field.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Efficacy of Self-Expandable Metallic Stent Placement in the Management of Anastomotic Stricture after Orthotopic Liver Transplantation**

S. Jang, M. Parsi, R. Lopez, A. Bhatt, J. J. Vargo
Gastroenterology, Cleveland Clinic, Cleveland/United States of America/OH

**Introduction:** Anastomotic bile duct stricture (ABS) remains as one of the most common complications after orthotopic liver transplantation (OLT). Current standard of practice of endoscopic retrograde cholangiopancreatography (ERCP) with insertion of multiple plastic stents (PS) often requires multiple procedures before achieving satisfactory stricture resolution. In recent years, studies utilizing covered self-expandable metallic stent (cSEMS) in refractory ABS management reported varying degree of success.

**Aims & Methods:** The aim of this study was to analyze efficacy of SEMS in resolution of anastomotic stricture in patients with orthotopic liver transplantation (OLT). Technical success was determined by identifying the workforce being necessary to be a team effort involving multiple specialties. All demographic and clinical factors were compared with SEMS insertion from January 2010 to December 2016 for the management of refractory ABS. Demographic variables including age, gender, and clinical variables including body max index (BMI), number or prior ERCP with PS insertion, stent brand and dimensions and duration of SEMS insertion were collected. The rates of stricture resolution, adverse outcomes including post ERCP pancreatitis, cholangitis and stent dysfunctions (occlusion, migration) were calculated. This study was approved by the Institutional Review Board of the Cleveland Clinic.

**Results:** There were 47 OLT patients who underwent ERCP-cSEMS insertion for refractory ABS during the study period. Of 47 patients, 37 patients (78.8%) achieved stricture resolution after single SEMS treatment. Longer duration of SEMS insertion was the only variable associated with increasing probability of stricture resolution as there was 20% increase in odds of stricture resolution for every additional week SEMS was in place. Among those who achieved initial stricture resolution, 27 patients were maintained bile duct patency for the follow up period. The most common adverse outcome was internal migration of cSEMS which occurred in 11 patients (23.4%). Post-ERCP pancreatitis was observed in 3 (6.4%) patients

**Conclusion:** The efficacy rate observed in resolving refractory ABS with cSEMS placement appears to be comparable to that of multiple ERCPs with PS placement method. Furthermore, durability of ABS resolution with cSEMS use further supports its potential long-term efficacy. Hence, cSEMS should be considered as a viable alternative treatment of refractory ABS and the follow up period is associated with higher likelihood of ABS resolution. The high rate of internal migration observed with SEMS warrants further endeavor in stent design improvements.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patient developed ERCP-related pancreaticitis, successfully treated with medical was immediately detected. Successful closure of persistent sphincterotomy-stones. In all cases standard sphynterotomy was performed and perforation was always after resolution of the initial indication for ERCP. These stents have the advantage of covering the laceration and allowing free flow of bile into the duodenum instead of into the retroperitoneal space. The aim of this study was to evaluate in our cohort of patients, the benefits of FCSEMS in type II perforations.

Aims & Methods: We experienced six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 69 years; age range: 54–80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary stones, and one patient for colorectal perforation. Three FCSEMS were successfully removed after a median of 18 days, the remaining three fell out spontaneously. The median length of hospital stay was 8.5 days (range 4–20 days). There were no deaths or need for surgery.

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patients, FCSEMS was considered the only rescue therapy, but in the last years the majority of cases has been managed conservatively. The endoscopic treatment included biliary stent and/or nasobiliary drainage. In our institution, from 2010 we has been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. This study was conducted as a part of Conservative Therapy? Canena J, Surg Laparosc Endosc Percutan Tech. 2016 Feb;26(1):e9-e17

P0929 EFFICACY AND ONCOLOGIC SAFETY OF ENDOSCOPIC DUODENAL STENTING IN PATIENTS WITH ADVANCED PANCREATIC CANCER

Introduction: Duodenal obstruction is often seen in patients with advanced pancreas cancer and endoscopic duodenal stenting (DS) has become increasingly popular due to its less invasiveness compared with surgical gastrojejunostomy. With recent new advances in chemotherapy and radiation therapy, conversion surgery after neoadjuvant therapy are performed in some cases with IPC.

Aims & Methods: To evaluate the efficacy and safety of DS as palliative treatment and bridge to surgery in patients with APC. We retrospectively analyzed patients who received DS between March 2012 and March 2017. Twenty-three patients (11 men/12 women median age, 65.5; 46–82 years) with APC. GOO scoring system (GOOSS) was used as an index of clinical success.

Results: A total of 23 Patients consisting of 6 patients treated with chemotherapy and 11 patients treated with neoadjuvant chemoradiotherapy were included in this study. Obstructed parts of the duodenum were D1 in 2, D2 in 5, D3 in 12, and D1D2 in 4. technically successful DS was achieved in 22 cases (95.6%). The mean GOOSS before DS and after DS were 0.5 and 2.6 respectively (p < 0.001). The median time to restart soft solid meal after DS was 2.9 days. Biliary obstruction was seen in 13 patients and managed with endoscopic biliary stenting. Adverse events occurred in 6 patients, including 1 with cholangitis, 1 with bleeding and 3 with stent occlusion. The reintervention technical and clinical success rates were 100% (5/5) and 80% (4/5), respectively. The median survival time after DS was 159 days. In neoadjuvant chemoradiotherapy patients, 4 patients were postpone surgery for APC.

Conclusion: DS in patients with APC is effective and safe. The findings of this study suggest that DS is worth considering as the bridge to surgery in patients receiving neoadjuvant therapy.

P0930 CLINICAL FAILURE IN COLONIC STENTING FOR MALIGNANT LARGE BOWEL OBSTRUCTION: OUTCOMES AND PREDICTORS IN 172 PATIENTS

1Department Of Gastroenterology, Graduate School Of Medicine, The University of Tokyo, Tokyo/Japan
2Department Of Endoscopy And Endoscopic Surgery, Graduate School of Medicine, The University of Tokyo, Tokyo/Japan
3Dept. Of Gastroenterology, University of Tokyo, Tokyo/Japan

Contact E-mail Address: rei4848@gmail.com

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMS) for malignant large bowel obstruction has become widely accepted for an alternative to emergency surgery in the management of malignant large bowel obstruction (LBO) after the initial introduction of SEMS in 1991. Recent years, advance in procedural equipment and accumulation of experience have improved technical success rate in colon stenting for malignant LBO. However, there is still a divergence in the success rate of SEMS stent placement.

Aims & Methods: The aim of this study is to clarify the factors that reduce clinical success rate of stent placement. This study was conducted by a retrospective chart review at a single center. The endoscopy database and clinical records from the University of Tokyo Hospital, Tokyo, Japan, were reviewed retrospectively between May 2007 and February 2017. Patient’s symptoms, characteristics, clinical data were obtained from electronic medical record. The obstructions were diagnosed clinically and radiologically and were evaluated by the Colorectal Obstruction Scoring System (CROSS). Technical success was defined as deployment of a stent across the entire length of the stricture on the first attempt. Clinical success was defined as resolution of symptoms and radiological relief of the obstruction within 24 hours, as confirmed by radiographic observations.

Results: A total of 172 patients (91 males, 81 females; mean age 69.0 years) with underwent colon stenting for malignant LBO. This procedure was performed to 80 colorectal cancer (CRC) patients (48%) and to 92 patients (52%) with cancer of other etiology. Stenting was performed as a bridge to surgery (BTS) therapy in 33 patients (19.2%), whereas stenting was planned palliative procedure in 139 patients (80.8%). Sixty-seven patients (39%) had a tumor causing obstruction in the proximal colon, and 105 patients (61.0%) in the distal colon or rectum. The mean length of obstruction was 6 cm, and obstruction of 60 patients (34.9%) longer than 6 cm. The technical and clinical success rate was 98.3% and 89.5%, respectively. Clinical success rate dropped from 98.9% (91/92) to 78.8% (63/80) when attempting to stent lesions of longer than 6 cm. Clinical success rate was 85.7% (90/105) and 95.5% (64/67) (p < 0.05) when the patient had obstruction of distal colon or rectum vs in proximal colon. In multivariate analysis, placement in distal colon or rectum, obstruction by ECM, and obstruction longer than 6 cm were independent risk factors associated with lower clinical success rate (odds ratio [OR] 3.19; 95%CI 0.96–10.6; [OR] 24.5; 95%CI 3.19–189.3; [OR] 31.7; 95%CI 4.32–223.7).

Conclusion: The placement of SEMS for malignant LBO is safe and effective, but clinical success rate drops in the cases with obstructions of distal colon or rectum, longer than 6 cm, or caused by ECM. Considering the indication of colonic stenting for malignant LBO, these factors should be evaluated before procedure.

P0931 THE CLINICAL EFFICACY OF MITOMYCIN-C INJECTION THERAPY IN REFRACTORY BENIGN ESOPHAGEAL STENOSIS: A PRELIMINARY STUDY

S.G. Lim1, J. Kim1, K.M. Lee1
1Gastroenterology, Ajou University School of Medicine, Suwon/Korea, Republic of Korea
Contact E-mail Address: mdsk75@gmail.com

Introduction: Refractory Esophageal Stenosis (RES) definition differs among studies. Unresolved benign esophageal stenosis even after 5 or more sessions of endoscopic dilation therapy in most studies. Until now, there have been no treatment showing the satisfactory results. Mitomycin C (MMC) inhibits DNA synthesis reduces fibroblastic collagen formation. Tried in RES in several studies. The meta-analysis about treatment of refractory gastrointestinal stenosis with MMC in total 24 studies. The most commonly reported site esophagus (79%). Only 9 recruited adult patients (n = 38). Of these, 23 patients were RES.
Complete response of MMC for RES patients: 59.5% vs 40.5%, respectively.

**Aims & Methods:** The aim of this study was to evaluate the clinical efficacy of MMC injection therapy in patients who had refractory benign esophageal stenosis. Between October 2013 and February 2016 Enrollment criteria: Patients with refractory benign esophageal stenosis who did not respond even after five or more endoscopic dilation therapy. The patients should be more than eighteen year old. Exclusion criteria: Malignant esophageal stenosis, Pregnant or breast feeding women, Deteriorated patients who could not tolerate endoscopic procedures. The method of MMC application - Via 23 gauge injection needle (Optimum injector, Taewoong Medical, Korea) –4 mL of saline-diluted MMC was prepared, with concentration of 0.5 mg/mL - Injection of 0.5 mL MMC at eight points of the stenotic site immediately after bougienage. Follow-up – Interview After 1 week and every four weeks after MMC injection up to 52 weeks. Endoscopy Four weeks after MMC injection and when the obstructive symptoms appeared. Primary end-point – The rate of clinical success. Secondary end-points The mean score of GOOSS before and after MMC injection therapy. Complications – Definition – Clinical success: Improvement of GOOSS score more than one point after MMC injection therapy, compared before MMC injection.

**Results:** Ten patients with refractory benign esophageal stenosis were initially enrolled. Two patients were excluded due to death from hypovolemic shock due to persistent bleeding and esophagectomy as patient’s wish. Finally, Eight patients were analyzed. The rate of clinical success of MMC injection therapy in patients with refractory benign esophageal stenosis was 87.5%. Mean scores of GOOSS were significantly reduced after MMC injection therapy, from 2.5 to 0.29. In all patients, MMC injection therapy below two sessions was needed to improve the symptoms of enrolled patients. Major complications did not occur in any patients.

**Table 1: Outcomes of MMC injection therapy**

**Conclusion:** In our study, the mitomycin injection therapy was effective in patients who had refractable benign esophageal stenoses. The mitomycin injection therapy could be considered as an alternative for refractable benign esophageal stenosis. A large-scale prospective studies are required in future.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0932 Treatment with multiple reabsorbable stents of complete and partial lower GI anastomotic dehiscence and stenosis**

**Aims & Methods:** The aim of this study was to evaluate the clinical efficacy of MMC injection therapy in patients who had refractory benign esophageal stenosis. Between October 2013 and February 2016 Enrollment criteria: Patients with refractory benign esophageal stenosis who did not respond even after five or more endoscopic dilation therapy. The patients should be more than eighteen year old. Exclusion criteria: Malignant esophageal stenosis, Pregnant or breast feeding women, Deteriorated patients who could not tolerate endoscopic procedures. The method of MMC application - Via 23 gauge injection needle (Optimum injector, Taewoong Medical, Korea) –4 mL of saline-diluted MMC was prepared, with concentration of 0.5 mg/mL - Injection of 0.5 mL MMC at eight points of the stenotic site immediately after bougienage. Follow-up – Interview After 1 week and every four weeks after MMC injection up to 52 weeks. Endoscopy Four weeks after MMC injection and when the obstructive symptoms appeared. Primary end-point – The rate of clinical success. Secondary end-points The mean score of GOOSS before and after MMC injection therapy. Complications – Definition – Clinical success: Improvement of GOOSS score more than one point after MMC injection therapy, compared before MMC injection.

**Results:** Ten patients with refractory benign esophageal stenosis were initially enrolled. Two patients were excluded due to death from hypovolemic shock due to persistent bleeding and esophagectomy as patient’s wish. Finally, Eight patients were analyzed. The rate of clinical success of MMC injection therapy in patients with refractory benign esophageal stenosis was 87.5%. Mean scores of GOOSS were significantly reduced after MMC injection therapy, from 2.5 to 0.29. In all patients, MMC injection therapy below two sessions was needed to improve the symptoms of enrolled patients. Major complications did not occur in any patients.

**P0933 Evaluation of Factors Associated to a Successful Dilation in Post-ESD Strictures**

**Aims & Methods:** This is an observational and analytical retrospective study. Sixty-eight consecutive patients (mean age: 65.4 ± 11, 76.5% men) who underwent endoscopic dilation because of post-ESD symptomatic esophageal strictures between 2006 and 2016 were included. They had Barrett’s esophagus (n = 46, 67.6%), epidermoid carcinoma (n = 21, 30.9%) and other (n = 1). Patients with post-ESD esophageal dilations, esophageal motor disorders, chronic alcoholism, and NSAIDs and reduced over time. During follow-up the patients were treated with local mesalazine. Final dilation was considered successful if the patients were symptom-free and did not require further dilation procedures.

**Results:** The prevalence of post-ESD esophageal strictures is non-negligible, with a critical impact on the patients’ quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

**Conclusion:** Most patients presenting with post-ESD strictures and dysphagia improve at long-term but they need a median of 3 sessions. No specific factor was associated to a better outcome.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P0934 EFFECTIVENESS OF REPEATED DILATIONS IN THE MANAGEMENT OF ESOPHAGEAL BENIGN STRICTURES

A. Benezech, A. Debourdeau, J. Gonzalez, M. Barthet
Service De Gastroentérologie, Assistance Publique - Hôpitaux de Marseille, CHU Nord, Marseille, France

Contact E-mail Address: alban.benezech@ap-hm.fr

Introduction: Refractory or recurrent esophageal benign strictures (REBS) are frequent, and defined as the impossibility to reach or maintain a diameter of 14 mm after 5 sessions of endoscopic dilation (ED). Because of a lack of guidelines, their management remains challenging, sometimes leading to radical surgical procedure.

Aims & Methods: The aim of this study was to define the efficacy of long-term and repeated ED in the management of REBS. This was a monocentric retrospective study involving patients managed in our tertiary center between January 2002 and April 2017 (n = 43). All the endoscopic dilations were performed using Savary bougies or hydraulic balloons, depending on the operator’s choice. Demographical and clinical data were recorded for each patient. The endoscopic management was detailed with the number of procedures, the endoscopic device used, the diameter of dilation, and potential concomitant treatment (as self-expanding metal stent, steroid injection or incisional therapy). The primary endpoint was the efficacy of sustained and recurrent ED, defined as the absence of further dilation within 3 months of the last procedure or an interval between the 2 last ED greater than 3 months. A failure was considered in case of death, need for surgery, permanent enteral feeding tube or an interval between the last 2 procedures lower than 3 months. The secondary endpoints were to document the characteristics of dilation procedures and concomitant treatments, the decreasing of the number of dilations per trimester, and to elucidate potential predictive factors for success of ED.

Results: A total of 39 patients (23 men) with a mean age of 47.5 ± 20.7 years were included. The etiologies of strictures were anastomotic (46.1%), caustic (28.2%), peptic (10.3%) or other etiologies (radiation injuries, esophageal diverticulotomy, severe viral esophagitis, 15.4%). A clinical success of repeated ED was achieved in 27 patients (69.2%). Twelve patients (30.8%) experienced failure, among them seven (17.9%) required frequent dilations, two (5.1%) underwent surgery, two (5.1%) maintained an enteral feeding tube, and one patient (2.6%) died consecutively to infection pneumonia. A mean of 9.8 ± 4 ED sessions were performed per patient, with a mean treatment duration of 22.6 ± 20.1 months. Regarding concomitant treatments, 16 patients (41%) had at least one fully-covered metallic stent placement, incisional therapy was performed in 11 patients (28.2%), and 3 patients (7.7%) received corticosteroid injections. The number of dilations per trimester gradually decreased over time. No significant predictive factor of success was found, such as etiology of stricture or the use of concomitant treatment, particularly. Nevertheless, a greater number of dilations during the first trimester could promote the success of the management (3.2 ± 2.2 dilations in the success group vs 2.2 ± 0.8 in failure group, p = 0.036).

Conclusion: Repeated and maintained endoscopic dilations are effective (70%) in the management of REBS, regardless of the etiology of stricture. A prolonged management up to 2 years, and the initial rhythm of endoscopic procedures may favor the final success. A systematic schedule for ED would improve the efficacy of this management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0935 EFFICACY AND SAFETY OF NEWLY DEVELOPED ENDOSCOPIC COLONIC STENTS WITH AN INCREASED EXPANDABLE FORCE: A RETROSPECTIVE COMPARISON WITH CONVENTIONAL COLONIC STENTS

T. Nishinura1, T. Kuwai1, H. Kohno1, H. Kouno1, A. Yamaguchi1, T. Yamaguchi1, H. Imagawa1, Y. Miyasaka1, Y. Sumida1, T. Takasago1, R. Miura1, K. Tao1, S. Funaki1, S. Ishaiq2

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMSs) is a widely accepted procedure for treating malignant colonic obstruction. This procedure was covered by the National Health Insurance of Japan in January 2012, and the WallFlex colonic stent and Niti-S colonic stent can currently be used in Japan. In the previous study, we reported that the WallFlex colonic stent has more expanded force than the Niti-S colonic stent. On the other hand, the risk of stent-related perforation was lower when using the Niti-S stent due to its structure. Currently, we newly developed an SEMS (Niti-S structure, with 18-mm diameter with increased expanded force compared with the conventional type), which comprised the benefits of both WallFlex and Niti-S. In this study, we compared the efficacy and safety of the newly developed colonic stent with the conventional colonic stents.

Aims & Methods: This study aimed to compare the efficacy and safety of the newly developed colonic stent with the conventional colonic stents (the WallFlex colonic stent and the Niti-S colonic stent). Overall, 91 patients (96 lesions, male:female: 48:43, average age: 73.2 years) underwent endoscopic SEMS placement between November 2011 and March 2017 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), the Niti-S colonic stent in 51 patients (53 lesions: Group N), and the newly developed colonic stent in 5 patients (5 lesions: Group D). Stratified analysis of the clinical background, statistical success rate, procedure time, clinical success rate, and complications was performed to compare Group W, Group N, and Group D.

Results: Endoscopic SEMS placement was attempted in 96 lesions as a bridge to surgery (BTS) in 52 lesions (54.2%) and as palliative therapy (PAL) in 44 lesions (46%). In Group W, SEMS was placed in 19 lesions (50%) as BTS and in 19 lesions (50%) as PAL; in Group N, SEMS was placed in 32 lesions (60%) as BTS and in 21 lesions (40%) as PAL; and in Group D, SEMS was placed in 1 lesion (20%) as BTS and in 4 lesions (80%) as PAL. The technical success rate was 100% in all groups. The overall clinical success rate was 93.7% (90/96): 89.5% (34/38) in Group W, 96.2% (51/53) in Group N, and 100% (5/5) in Group D. Complications within 7 days included abdominal pain (3/38, 8%),...
expansion (1.38%, 3%), and liver (1.38%, 3%) in Group W and perforation due to other causes (0%) in Group N. In Group W, all cases had at least one flexible stent-related perforations (4.13%, 11%) and stent occlusion (1.38%, 3%) in Group W and stent occlusion (2.53, 4%) in Group N. All 4 patients with stent-related perforations had undergone palliative stenting with the WallFlex colonic stent, and the stent-related perforation rate in Group W was significantly higher than that in Group N (P < 0.05). In Group D, there were no complications and no stent occlusion.

Conclusion: The technical and clinical success rates were extremely high in all groups, and the complication details were also retrieved. Multiple regression models were obtained for a limited sample size and this new stent is expected to exhibit more efficacy and safety than conventional colonic stents.

Introduction: Heller-Dor operation is a radical treatment for cases of esophageal achalasia. However, postoperative recurrence of symptoms is observed in some cases. Conventionally, repeat surgery or endoscopic balloon dilatation is additionally performed on such cases. Repeat surgery is associated with issues related to adhesion, whereas endoscopic balloon dilatation is associated with issues related to effect reliability and constancy. Peroral endoscopic myotomy (POEM) is a new endoscopic treatment that was first reported by Inoue et al. in 2008. POEM can be accomplished normally without being affected by the previous Heller-Dor operation, if POEM is performed at the contralateral site of the previous myotomy. Moreover, POEM enables making a long myotomy that cannot be made in laparotomy. At our hospital, we have performed POEM on 12 cases that previously underwent the Heller-Dor operation. Herein, we report on the treatment outcomes.

Aims & Methods: We performed POEM on 210 cases between September 2011 and April 2017. Of those cases, 12 cases (5.7%) had previously undergone Heller-Dor operation. The treatment outcomes were retrospectively investigated. The recurrence of the symptoms were investigated based on the results of medical interview, endoscopy, esophagography, esophageal manometry, and 24-hour PH monitoring test.

Results: The POEM cases that previously underwent Heller-Dor operation included 8 men and 4 women with the mean age of 54.8 ± 15.4 years. As regards the cause for the recurrence of symptoms, the lower esophageal sphincter was the responsible lesion in 10 patients, the esophageal body in 1 patient, and another reason in 1 patient. POEM was performed by incising the posterior wall in all cases. Postoperative complications were not noticed in any cases. The mean length of the muscular layer incision was 14.3 ± 6.1 cm on the esophageal side and 2.8 ± 1.0 cm on the gastric side. The mean surgical duration was 183 ± 56.9 minutes. An accidental systemic perforation associated with POEM was observed. The integrated relaxation pressure was preoperatively 22.1 ± 8.6 mmHg and 13.6 ± 5.4 mmHg. The Eckardt score was 4.1 ± 2.5 preoperatively, 0.67 ± 1.1 at 3 months after the surgery, and 1.0 ± 1.2 at 12 months after the surgery (P < 0.05). The symptoms improved in all cases.

Conclusion: The treatment outcomes of the POEM performed on cases that previously underwent Heller-Dor operation were favorable. POEM differs from repeat surgery by laparotomy as it can be used to perform a long muscular layer incision without adhesion if an appropriate route is used. The major advantages of POEM are the reliability and constancy of the effectiveness compared to endoscopic balloon dilatation. POEM is a very effective treatment method for cases for which Heller-Dor operation has not been sufficiently effective.

Introduction: Surgery and endoscopic stapling have been the mainstay of treatment modalities for Zenker’s diverticulum. The need for general anesthesia (GA) is however a limiting factor in high-risk patients, as patients with ZD are often elderly with cardiorespiratory co-morbidities. In recent years, flexible endoscopic septum division (FSED) has gained popularity as a less invasive treatment modality for ZD, that can be performed under deep sedation, and has the potential to be performed safely in patients otherwise deemed unfit for full GA.

Aims & Methods: The aim of this pilot study was to assess the efficacy and safety of FSED for patients deemed unfit for GA. Patients had been referred to our tertiary centre for FSED. Data on 14 consecutive day case patients (median age 81, range 67-95, 7 females) with an ASA score of 3 that underwent FSED between August 2015 and November 2016 were collected retrospectively. All patients underwent FSED under deep sedation with propofol and remifentanil, and did not require ventilatory support. The amount of propofol used was recorded. Demographic data as well as information of the nature of symptoms and the outcome of the procedure was retrieved. The presence of dysphagia was measured with the Dukkak scale. Data on procedural and 30-day post-procedural complications, including sedation-related side effects, were collected.

Results: All patients complained of dysphagia (median Dukkak score 2, range 1-3) and regurgitation before the procedure. There were no procedure-related nor sedation related adverse events in any of the patients. There were no 30-day post-procedural adverse events. All patients but one experienced complete symptom relief after one treatment session. Median propofol used was 173 mg (range 59–
1855–63.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: To improve the quality of esophageal cancer surgery in the Netherlands, the number of retrieved lymph nodes (LNs) is evaluated in one retrospective national cohort study. The primary outcome: ‘percentage of patients with ≥15 LNs’ was analyzed by year and hospital. Factors tested with univariable and multivariable analysis for the association with ≥15 LNs were: age, Charlson score, weight loss, BMI, cT-, cN-, cM-stage, tumor location, neo-adjuvant therapy, type of procedure, intraoperative complications, hospital volume and year of resection. The postoperative outcomes: radicality, intraoperative complications, morbidity, and mortality were tested on association with ≥15 LNs.

Results: The overall percentage of patients in the Netherlands with ≥15 LNs increased from 2011 and 2016. Multivariable analysis showed an independent association with ≥15 LNs for the factors: cN2-stage (OR [95% confidence interval]: 1.37[1.05–1.79]), resection in a hospital with 26–50 or ≥50 resections/year (referent: 1–25 resections, 2.03[1.57–2.63] and 3.21[4.34–2.23]) and resection between 2012–2016 (reference: 2011, ORs: 1.55, 1.81, 2.43, 2.20, 2.64). Factors independent associated with <15 LNs are: neo-adjuvant chemo-radiation-therapy (referent: no neo-adjuvant therapy, 0.66[0.47–0.93]), intraoperative complications (0.55[0.39–0.80]) and open and minimally invasive transhiatal resection (referent: open transstomachic, 0.24[0.18–0.32]) and 0.38[0.20–0.55]). Postoperative morbidity and mortality were not associated with ≥15 LNs.

Conclusion: The evaluation of the outcomes of the quality indicator ‘a minimal number of 15 retrieved LNs’ is increased between 2011 and 2016. The variation between hospitals is decreased. The cN-stage, neo-adjuvant therapy, type of procedure, intraoperative complications, year of resection and hospital volume seem to be associated with the outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this review was to determine the optimum choice and the best conduit following colonic interposition after oesophagectomy in adults.

Results: Twenty-seven studies, involving 1849 patients (median age 60 years, 1177 males, 697 malignant disease) who underwent colonic interposition were analysed. The overall pooled morbidity rate of left vs. right colonic conduit was 5.6% [95% CI (3.59–7.60), p < 0.0001] respectively. The overall pooled mortality rate of left vs. right colonic conduit was 5.6% [95% CI (3.59–7.60), p < 0.0001] respectively. Retrosternal route placement was associated with the lowest overall pooled morbidity of 9.2% [95% CI (6.48–11.99), p < 0.0001], and lowest overall pooled mortality of 4.8% [95% CI (3.74–5.89), p < 0.0001] respectively.

Conclusion: Left colon is the conduit of choice for colonic interposition after oesophagectomy in adults and the retrosternal route should be favoured.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Our results suggest that FESD is a safe, feasible and effective treatment for dysphagia (score 1) to achieve symptom remission. This was carried out without reinstitution of chemotherapy for patients who could not undergo liver resection and continued ongoing chemotherapy. In the United European Gastroenterology Journal 5(5S)
Aims & Methods: advanced gallbladder or bile duct cancers, and is still a highly invasive surgical or more extended liver resection (HPD) is occasionally indicated in patients with There were 9 men and 5 women. The median age was 66 years old (34– 2002 and 2016. Of these 14 included 13 patients with bile duct cancer and one Consecutive one hundred one hepatobiliary resections with caudate lobectomy terms of case series of a single surgeon at three Japanese tertiary referral centers. Introduction: Hepatobiliary resection (HPD) is one of the operations associated with high rate of surgical site infection (SSI). The one of the reasons is said that SSI is associated with the preoperative biliary infection caused by preoperative examinations or drainage of biliary tract. In our clinical trial [1], SSI after pancreaticoduodenectomy could be decreased by using the peroperative selective antibiotics based on preoperative bile culture. The bacteria cultured from SSI were Enterobacteriaceae such as Enterococcus and Enterobacter species with high frequency. Recently, however, most of the patients who had planned to undergo PD received internal biliary drainage preoperatively. It means preoperative collection of the bile juice is hard for the patient with internal biliary drainage. In order to solve this problem, we compared the conventional perioperative prophylactic antibiotics (Cefmetazole: CMZ) and the broad-spectrum antibiotics covering the Enterobacteriaceae (Piperacillin/Tazobactam + Vancomycin: PIPC/TAZ + VCM), respectively. The aim of this study is to assess the impact of two types of perioperative prophylactic antibiotics on incidence of SSI. Aims & Methods: Sixty-nine patients received PD at Hokkaido University Hospital (Japan) between April 2015 and March 2016, when prospective surgical site infection surveillance was performed. Thirty-eight patients were administered CMZ as perioperative prophylactic antibiotics from April 2015 to March 2016, and 31 were PIPC/TAZ + VCM from April 2016 to March 2017. CMZ was injected intravenously every three hours from the start of the operation, and once after the operation. PIPC/TAZ was injected intravenously every three hours from the start of the operation and three times on the next day. VCM was injected intravenously in the morning of operation (20 mg/kg) and just after the operation (15 mg/kg). Comparison between CMZ group and PIPC/TAZ + VCM group was performed for SSI (surgical site infection; body mass index, age, performance status, ETS (examinations or drainage of biliary tract), ETS (operation time and blood loss) and postoperative course (the incidence of SSI, the duration of postoperative antibiotics and postoperative stay). The side effects of VCM or PIPC/TAZ, and the occurrence of multidrug resistant bacteria were investigated, as well. Results: There were no significant differences in clinical features and operative outcomes between the two groups. The patients with PIPC/TAZ + VCM received slightly shorter duration of postoperative antibiotics administration than the patients with CMZ (5.9 ± 8.5 vs. 13.0 ± 18.2 days; p = 0.048). Significantly lower incidence of SSI was observed in patients with PIPC/TAZ + VCM (9/31(29.0%)) than in those with CMZ (20/38(52.6%)) (p = 0.044). Especially, significantly lower incidence of incisional SSI was observed in patients with PIPC/TAZ + VCM (2/31(6.5%)) than in those with CMZ (14/38(36.8%)) (p = 0.004). The redneck syndrome as one of the side effects of VCM was observed in 5/31 patients (16.1%). No multiresistant bacteria were identified. Conclusion: The broad-spectrum perioperative antibiotics covering Enterobacteriaceae such as Enterococcus and Enterobacter species could decrease the incidence of SSI and duration of postoperative antibiotics administration compared to CMZ. More strict indication to select the patients who should be administered VCM, because the occurrence of side effects of VCM was relatively high.

Introduction: Pancreatic cancer is the fifth most common gastrointestinal malignancy and the most common of all biliary tract cancers. Overall, it is associated with a poor prognosis. Consensus guidelines suggest that patients with T1a cancers can be observed with cholecystectomy alone while patients with T1b or greater have cancer that should undergo lymphadenectomy in the hepatoduodenal ligament. Extent of surgery is especially important for those patients given efficient systemic therapy is lacking.

Aims & Methods: The aim of this study was to critically explore whether those surgeons who used a population-based level of care that current evidence is mainly based on small patient series. Especially we assessed the rate of T-stage specific lymph node positivity and the impact of lymphadenectomy on long-term outcomes. The National Cancer Data Base of the United States was reviewed from 2004 to 2012 to identify non-metastatic gallbladder cancer patients with T1a, T1b, or T2 stage primary tumors. Patients were grouped by whether a dedicated lymphadenectomy was performed or not while those with missing information were excluded. Groups were compared for baseline characteristics. Prognosis of lymphadenectomy was assessed by univariate and multivariable adjusted logistic regression with adjustment for important patient- and tumor characteristics. Overall survival was assessed using Cox proportional hazard regression analyses before and after full bivariate pairwise propensity score matching.

Results: Of the 3879 patients included, 287 (7.4%) had T1a, 661 (17.0%) T1b, and 2931 (75.6%) T2 gallbladder cancer. Most patients were female (n = 2751, 70.9%), median age was 72 years (range 21–90). Among patients with T1a, T1b, and T2 disease, 102 (35.5%), 278 (42.1%), and 1526, (51.1%) underwent a dedicated lymphadenectomy, respectively. Over the study period, the rate of lymph node excision increased from 43% to 58% (p for trend = 0.005). The rates of positive lymph nodes were 11.8%, 16.2%, and 42.5% for T1a, T1b, and T2-stage, respectively. 5-year overall survival rate was 31.6% for patients without and 44.6% for patients with a dedicated lymphadenectomy and 58.6%, 43.9%, and 34.5% for T1a, T1b, and T2-stage, respectively. After multivariable adjustment, the rate of lymph node positivity and the incidence of lymph node positivity increased with tumor stage compared to T1a disease (vs. T1b: OR 1.37, CI: 1.01–1.86, vs. T2: OR 1.95; CI: 1.48–2.57). Compared to their counterparts, patients who underwent lymphadenectomy for gallbladder cancer were more likely to have had an R0 resection status. When radiation therapy, were diagnosed in the T1a stage, were younger, had a lower Charlson-Deyo-comorbidity score, were operated in high volume centers and traveled a longer distance to the treatment facility. In univariate analysis, no survival benefit of lymphadenectomy was found for T1a disease (HR 1.04, 95%CI 0.70–1.54) while lymphadenectomy improved overall survival in T1b (HR 0.72, 95%CI 0.58–0.90) and T2 stage (HR 0.59, 95%CI 0.53–0.65). Given significant bias of undergoing lymphadenectomy, full bivariate, pairwise propensity-score matching was performed. A trend towards overall survival benefit was also found for T1a disease (HR 0.65, 95%CI 0.39–1.09). Overall survival benefit remained for T1b (HR 0.68, 95%CI 0.51–0.91) and T2-stage (HR 0.63, 95%CI 0.55–0.71).

Conclusion: Our results support current consensus guidelines that T1b and T2 gallbladder cancer patients should undergo LA. However, based on the high rate of nodal positivity among patients with T1a disease and the trend towards overall survival improvement among T1a patients who underwent lymphadenectomy, we suggest to rethink this dogma and advocate to perform lymphadenectomy also in surgically fit patients with T1a disease.

Introduction: Despite improvements in the perioperative care, the morbidity rate after Pancreaticoduodenectomy (PD) is still higher than 50%. In particular, infectious complications (ICs) occur in about one-third of cases. This study aimed to analyze the correlation between preoperative rectal swab (RS) and intraoperative bire cultures, and its impact on postoperative course of patients submitted to PD.

Aims & Methods: The institutional electronic database was queried for all consecutive patients admitted to our department from January 2010 to June 2016. Data were retrospectively analyzed. Based on the positivity/negativity of preoperative surveillance RS for multi-antibiotic resistant Gram-negative and Gram-positive enteric rods, the population was divided into two groups consequently compared (RS+ vs. RS-).

Results: Three hundred thirty-eight patients were considered for the analysis. Overall 50 patients (14.8%) showed a RS+, Preoperative biliary drain (PBD) was the only independent risk factor associated to RS+ (p = 0.021, OR 2.6). The group statistically differed in the overall morbidity, ICs, sepsis, pulmonary complications, reoperation and mortality (p < 0.05). At multivariate analysis, ICs and mortality remained independently associated to RS+ (p = 0.013 OR 2.9, p = 0.009 OR 3.4, respectively). Bile-culture showed a perfect correlation (species and antibiotic susceptibility) with RS culture in 157 patients (86.7%). The most common microorganisms found were E. Coli ESBL (6.6%) and Klebsiella pneumoniae carbapenemase-resistant (2.2%).

Conclusion: Preoperative RS-culture’s positivity strictly correlates to biliary colonization and posterior bacterial overgrowth. Preoperative surveillance RS in patients with higher bacterial colonization strongly predicts higher postoperative infection rate. Infection complication mortality after PD are independently associated with a positive RS culture. Our study suggests that preoperative RS can direct antibiotic prophylaxis in order to reduce the burden of ICs and deadly events after PD.

Introduction: Surgical site infections (SSIs) after gastroenterological surgery cause significant morbidity, prolong hospitalisation and increase health care costs. Thus, SSI prevention is critical. To prevent bacterial colonisation in suture material, which disables local mechanisms of wound decontamination, triclosan-coated sutures were developed. We retrospectively analysed the efficacy of triclosan-coated polydioxanone sutures in abdominal fascia and skin closure using a propensity score matching analysis.

Preoperative RS-culture’s positivity strictly correlates to biliary colonization and posterior bacterial overgrowth. Preoperative surveillance RS in patients with higher bacterial colonization strongly predicts higher postoperative infection rate. Infection complication mortality after PD are independently associated with a positive RS culture. Our study suggests that preoperative RS can direct antibiotic prophylaxis in order to reduce the burden of ICs and deadly events after PD.

Aims & Methods: The study protocol followed the principles of the Declaration of Helsinki and received ethical approval from the Ethics Committee of the Fukuoka University (approval no. 12-7-96). At our department, we used conventional abdominal closure methods during gastroenterological surgery before August 2012. Thus, we retrospectively collected surveillance data over a 1.5-year period for the control group. From September 2012, we began using triclosan-coated sutures for closure. Here, we selected data for the control group from September 2012 to September 2013. In total, we included 1768 patients (control group, n = 640; study group, n = 1128) who underwent gastroenterological surgery. Baseline differences and selection bias were adjusted using propensity score matching.
