Introduction: Liver cirrhosis is associated with an imbalance between vasodilation and vasoconstriction in the sinusoids. Therefore the investigation of the nitric oxide - cyclic guanoin monophosphate (NO-CGMP) pathway, a key regulator of vascular smooth muscle tone, is essential.

Aims & Methods: The rat model of thioacetamide (TAA) was used to induce liver fibrosis/cirrhosis and alterations of the NO-CGMP pathway and subsequent liver damage were assessed. 25 male Wistar rats were studied (11 untreated controls and 14 TAA treated animals 0.03 g TAA/100 ml drinking water for 16 weeks). TAA dosage was adjusted weekly based on body weight changes. Hepatic gene expression of endothelial and inducible NO synthase (eNOS and iNOS), phosphodiesterase type 5 (PDE5) soluble guanylate cyclase (sGCa1 and b1), gCa3 and sGCh1 was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-aminotransferases (ALT, AST), alkaline phosphatase (AP), albumin and bilirubin). The degree of fibrosis was estimated by histological criteria (i.e. Desmet scores). PDE5-expression was determined by immunohistochemistry. Kruskal-Wallis test was used for statistical analysis of group differences.

Results: 43% (6/14) of TAA-treated rats developed liver fibrosis (Desmet score of 1–3) while 57% (8/14) developed liver cirrhosis (Desmet score of 4). No major differences in ALAT, ASAT, and AP serum concentrations were observed in either group. However, bilirubin was significantly elevated in TAA-treated rats, while albumin concentrations were significantly reduced. Gene expression analysis revealed significantly increased expression of cGMP (1.5 fold), PDE5 (2.5 fold) and sGCh1 (2.1 fold) in fibrotic livers compared to controls. CGMP concentrations in fibrotic animals were slightly decreased (-34%). Significantly elevated expression of eNOS (2.26 fold), PDE5 (1.1 fold), sGCa1 (1.70 fold) and sGCh1 (3.6 fold) was observed in cirrhotic livers compared to controls, while CGMP concentrations were significantly decreased (-40%). Inos expression was only detected in fibrotic and cirrhotic livers, but absent in controls. Immunohistochemistry revealed markedly increased PDE5-expression in cirrhotic livers, which was predominantly localized in hepatic stellate cells.

Conclusion: The analysis of the animal model of TAA-induced liver fibrosis/ cirrhosis revealed alterations of the NO-CGMP pathway, characterized by reduced concentrations of cGMP, a key mediator of vasodilation, due to increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to portal hypertension. Thus, administration of PDE5-inhibitors, possibly combined with aCGMP-activated agents, should be further studied in clinical trials as a promising therapeutic approach to target portal hypertension.

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) related liver fibrosis. Group 3 innate lymphocytes (ILC3s), which have similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s and Th17 cells were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s were used in the culture from naive C57BL/6 mice in vitro, were transferred into Rag1−/− mice with carbon tetrachloride (CCL4) related liver fibrosis. In addition, ILC3s in Rag1−/− mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-α, INF-γ decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokine secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCL4 administration, even at week 6. Transferring Th17 cells into Rag1−/− mice increased liver fibrosis. By contrast, the ILC3s in spleens and livers decreased significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipient mice decreased liver fibrosis and reverse liver fibrosis.

Conclusion: Our study has uncovered the protective role of ILC3s in liver fibrosis, which is through secrete IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

Introduction: Internal biliary drainage has been confirmed better than external drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, whereas the relevant evidence is still unclear.

Aims & Methods: We aimed to investigate the potential relation between the expressions of bile acid receptor and TLR4/NO2 in intestinal mucosa and its influence on the intestinal mucosal barrier with obstructive jaundice. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NO2. Sixty male adult Kunming mice were randomly assigned to four groups: SH (sham operation), OJ (obstructive jaundice), ID (internal drainage), ED (external drainage) (n = 15 in each group). On the 7th day from the first operation, the OJ and SH mice were executed and specimens of blood and ileal tissue of groups were collected. ED and ID were reordered on day 8 for biliary drainage procedure. Blood was drawn from heart for liver function test. The terminal ileum specimen was collected for test of histology using haematoxylin-eosin (HE) staining. Western blot (WB) and real-time polymerase chain reaction (RT-PCR) were used to detect the expression of protein and mRNA of FXR,TGR5, TLR4 and NO2 in intestinal mucosa.

Results: We have successfully established the animal models. The histopathological examination revealed notable inflammatory infiltration and hyperplasia disruption at terminal ileum in OJ mice; significant alleviation of above injuries by ID while little improvement by ED. FXR-TLR4: After biliary obstruction, the expression of protein and mRNA of FXR were significantly increased, while the expression of protein and mRNA of TLR4 were significantly decreased compared with SH group’s (P<0.05). After ED, compared with OJ group’s expression of protein of FXR was decreased while TLR4 were increased. The mRNA of both FXR and TLR4 were increased. After ID, the expression of protein and mRNA of FXR were significantly decreased compared with OJ group’s but were still lower than that in SH group and were both better than ED group’s. And the expression of protein and mRNA of TLR4 were significantly increased compared with OJ group’s (P<0.001), but were still lower than that in SH group and were both better than ED group’s. The trend of TLR4 expression was almost the same between vehicle group and no gavage group. After gavage with FXR agonist, the differences of TLR4 expression of four groups disappeared (P>0.05). TGR5-NO2: IDC and WB suggested that after OJ surgery, the protein expression of both TGR5 and NO2 decreased obviously compared to that of SH mice; then the level of TGR5 and NO2 protein fell remarkably after ID surgery close to SH level while in ED group there was only a slightly reduction form OJ level and still with a high expression of TGR5 and NO2 protein. Detection of RT-PCR found that TGR5 mRNA and NO2 mRNA level in OJ group increased several times as that of the SH group; after ID surgery, the expression of TGR5 mRNA significantly reduced, NO2 mRNA level also fell down consistently, but the effect was not observed in ED mice.

Conclusion: The expression of intestinal FXR and TLR4, TGR5 and NO2 could be one of the critical mechanism why internal drainage is better than external drainage in restore intestinal barrier function of obstructive jaundice mice.

Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestatic injury and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncocgenic microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, mice were sacrificed and small intestines in the lumen were carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing – metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF-α and IL-1β mRNA levels increased in the small intestine of BDL-mir-21 KO mice compared with WT. TLR-4 and TGF-β mRNA expression was increased in both sham- and BDL-mir-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Strikingly, mir-21 KO reverted mRNA of tight junction proteins to control levels. BDL-mir-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, mir-21 KO not only show a decreased small intestine permeability through a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased intestinal tight junction markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. **Introduction:** Sorafenib is the only approved systemic therapy for advanced hepatocellular carcinoma (HCC). However, the application of Sorafenib in therapy has faced increasing challenges due to drug resistance. Drug resistance is known to be associated with cancer stem cells (CSC). The transcription factor ZBP-89 was reported to be involved in cell growth and apoptosis in tumor and acts as a potential tumor suppressor in HCC. It has been shown that high levels of ZBP-89 expression were statistically associated with better survival of HCC patients. Unfortunately, the mechanism of ZBP-89 in modulating sensitivity of Sorafenib in CSC remains unknown.

**Aims & Methods:** In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of Huh7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTT assay. We then examined the expression pattern of Notch1 and liver CSC markers in Huh7 and Hep3B CSC after the treatment with Sorafenib. MTT assay was also used to measure the effect of ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. The levels of ZBP-89 and CD44 were measured using q-PCR in human tissue samples. The regulatory effects of ZBP-89 on CSC phenotype were explored in-vitro including drug resistance. The immunoblotting sphere formation assay, soft agar formation assay and colony formation assay. Gene expression and protein interaction in stemness signaling pathways were analyzed.

**Results:** We found that sphere-forming HCC cells had significantly higher resistance to Sorafenib, compared with their parental cells. The expression of Notch1 and EpCAM was increased along with the low dose of Sorafenib, suggesting that the activation of Notch1 pathway was associated with the drug resistance in liver CSC. Studies further indicated that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib in sphere-forming HCC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissue samples. In vitro study indicated that tumor sphere formation was impaired by the transfection of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed investigation against control cells showed that overexpression of ZBP-89 resulted in reduced expression of CSC markers EpCAM, CD133, Sox2 and c-myc at both mRNA and protein levels. In addition, the overexpression of ZBP-89 or silencing of Notch1 reduced the number of colonies formed by sphere-forming HCC cells, demonstrating opposite effects of these two proteins. Mechanistic studies revealed that ZBP-89 was able to repress the expression of Notch1 and reported that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib in HCC.

**Conclusion:** Sphere-forming HCC cells, which contained high levels of Notch1 and EpCAM, were resistant to Sorafenib. The overexpression of ZBP-89 was found to result in the loss of CSC phenotype and improve the sensitivity of Sorafenib in CSC through its interaction with activated Notch1. In conclusion, we believe that targeting ZBP-89 is likely to be a new therapeutic strategy to overcome resistance to Sorafenib in HCC.

**P0008 PROTECTIVE EFFECT OF AKKERMANSIA MUCINIPHILA AGAINST IMMUNE-MEDIATED LIVER INJURY IN A MOUSE MODEL**

**W. Wu**, D. Shi**, D. Fang**, X. He**, L. Li**

1State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China; Hangzhou/Pre
2Department of Gastronenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China; Hangzhou/Pre

**Contact E-mail Address:** wwr725@zju.edu.cn

**Introduction:** Accumulating evidence indicates that gut microbiota participates in the pathogenesis and progression of liver diseases. The severity of immune-mediated liver injury is associated with different microbiotic communities. Akkermansia muciniphila can regulate immunological and metabolic functions. However, little is known about its effects on gut microbiota structure and function.

**Aims & Methods:** This study investigated the effect of *A. muciniphila* on immune-mediated hepatitis and potential underlying mechanisms. Twenty-two C57BL/6 mice were assigned to three groups (N = 7–8 per group) and continuously administered *A. muciniphila* MUC-011 or vehicle intraperitoneally for 2 weeks. Groups were sacrificed 1 day or 7 days after treatment. Mouse livers were isolated, and the liver tissue was homogenized. Liver injury and immune responses were determined by biochemical and histological analyses. Differences were considered significant when *P* < 0.05.

**Results:** We found that oral administration of *A. muciniphila* (Akk) decreased serum ALT and AST and alleviated liver histopathological damage induced by Con A. Serum levels of pro-inflammatory cytokines (IL-2, IFN-γ, IL-12p70, MCP-1, MIP-1α) were significantly lower in the Akk group. Histological analysis revealed that Akk significantly decreased hepatic cell apoptosis; Bel-2 expression increased, but Bax and DR5 decreased. Further investigation showed that Akk enhanced Ocludin and Tight junction protein, two proteins related to strengthened intestinal barriers. Fecal 16s rDNA sequence analysis indicated that Akk increased microbial diversity. The community structure of the Akk group clustered distinctly from that of the Control and Normal groups. Relative abundance of Firmicutes increased, and Bacteroidetes abundance decreased. Correlation analysis showed that injury-related factors (IL-12p70, IFN-γ, DR5) were negatively associated with specific genera (*Ruminococcaceae_UCG-009, Lachnospiraceae_UCG-001*, Akkermansia), which were enriched in mice pretreated with Akk.

**Conclusion:** Our results suggested that *A. muciniphila* (Muc) (ATCC BAA-835) had beneficial effects on immune-mediated liver injury by alleviating inflammation and hepatocellular death. These effects may be driven by the protective profile of the intestinal community induced by the bacteria. The results provide a new perspective on the immune function of gut microbiota in host diseases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Despite evidence that the microbiota is involved in the pathogenesis of obesity, the microbiota of patients with nonalcoholic fatty liver disease (NAFLD) has not been well characterized. NAFLD is considered a hepatic manifestation of metabolic syndrome and is particularly associated with insulin resistance, obesity, and gut-derived endotoxin.
Aims & Methods: The aim of our study is to assess if there are any differences in the microbiota of patients with biopsy-proven NAFLD and healthy controls (HC). In addition, peripheral blood endotoxin (ET) and gut-permeability was analyzed in NAFLD (mild fibrosis vs severe fibrosis) and HC patients. A total of 201 patients were enrolled in this study: 68 HC and 134 biopsy-proven NAFLD (77 mild fibrosis and 56 severe fibrosis). One stool sample was collected from each participant. All NAFLD patients included in this study underwent percutaneous liver biopsy. Healthy controls were volunteers. The composition of gut bacterial communities was determined by 16S rDNA sequencing. In addition, peripheral blood ET was determined using endotoxin activity assay (EAA). Gut-permeability was assessed by Lactulose mannitol ratio (LMR). Trial registration: This trial has been registered in the University Hospital Medical Information Network (UMIN) Clinical Trials Registry as UMIN00002709.
Results: Among those taxa with greater than 1% representation in any of the disease groups, it was significantly decrease in Bacteroidetes at phylum level in NAFLD compared with HC. At genus level, Faecalibacterium prausnitzii (F.P) was significantly decreased in NAFLD compared with HC. F.P is significantly decreased in NAFLD with severe fibrosis compared with those with mild fibrosis patients. In addition, endotoxin levels were increased in NAFLD with severe fibrosis than those with mild fibrosis. Furthermore, occupation ratio of F.P was negatively correlated with blood ET levels (R²=0.32) in NAFLD. Additionally, it showed a significant correlation among three items of F.B, EAA and LMR (F.B vs EAA: P < 0.0001, LMR vs EAA: P < 0.0001, LMR vs F.B; P < 0.0025).
Conclusion: Our study indicated that the change of the gut microbiota and pathologic connection were suggested in acknowledgment of the decrease on the biomarker of NAFLD in LEESe analysis. More biomarkers at genus level (Lachnospira, S24-7, etc.) were identified in pairwise comparison of one mouse model with the Control.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0012 PREVALENCE OF METABOLIC SYNDROME AND LIVER STEATOSIS IN A PROSPECTIVE MULTICENTER STUDY OF PATIENTS REFERRED FOR HYPERFERRITINEMIA

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). Liver steatosis is often suspected in patients with HF.
Aims & Methods: To study the prevalence of hepatic steatosis defined by MRI in these patients. A prospective study of 312 consecutive with HF (>200 μg/L women; 300 μg/L men) and/or TSI > 45%, confirmed in two determinations, was conducted from December 2010 to April 2013. The MS was defined by the presence of three of the following factors: waist circumference ≥94 cm men/≥80 cm women; Triglycerides ≥150 mg/dL or treatment for this dyslipidemia; HDL < 40 mg/dL women/ < 50 mg/dL men or treatment for this dyslipidemia; glucose ≥100 mg/dL or Type 2 diabetes; hypertension: blood pressure ≥130 mmHg/≥85 mmHg or treatment for arterial hypertension (1). LIC was determined by MRI 1.5 Tesla system (SIR method) (2). We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis.
Results: 312 patients (272 men/40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729, 6 (SD 449.6); mean TSI 40, 8 (SD 15.8); 276 patients have all the required criteria to determine the MS presence: 115/240 men (48%) and 20/36 women (55%). Magnitude of patients with MS (49%); 141 without MS (NMS) (51%). In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis. 251 patients with MS criteria and MR for steatosis; NMS group (128): no steatosis 103; steatosis 25; MS group (123): no steatosis 72, steatosis 51 (total: no steatosis 175, steatosis 70). When we study if the presence of liver steatosis was more frequent in the MS group, the results obtained were statistically significant, p=0.000.
Conclusion: Nearly 50% of the patients referred for hyperferritinemia to the hospitals of our city, had MS; the patients with MS had more frequently liver steatosis than the patients without MS.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In a previous study from our group (1), in a secondary hospital, we did not find differences in the liver iron concentration (LIC) of the different groups, and we can not predict liver iron overload for hyperferritinemia (HF)
patients with HFE mutations and (transferrin saturation index (TSI) values above 0.12). But we did not have C282Y/C282Y patients in this series.

**Aims & Methods:** To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque Country. Prospective study of 312 consecutive patients with HF. Olynyk et al. (2) described three different groups according to HFE mutations and TSI: Group A: no predisposing mutations (PM) for HH and TSI > 45; Group B: PM for HH: C282Y/C282Y; C282Y/H63D, H63D/H63D, and TSI > 45; Group C: no PM for HH and normal TSI; Group D: PM and normal TSI. In the Basque Country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

**Results:** In all the patients HFE study was available: C282Y/C282Y 14 (4.49%); C282Y/H63D/H63D 47 (15.06%); H63D/H63D 99 (31.73%); wt/wt 98 (31.41%); C282Y/S65/S65 1 (0.32%); H63D/S65/S65 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MR. Mean age: 55 ± 13.3, 272 men and 40 women. Group A: 54; Group B: 32 Group C: 160; Group D: 86. The mean LIC index: in Group A: 70.71 ± 27.89, group B: 70.53 ± 56.67, group C: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences (p = 0.0000).

**Conclusion:** The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

**P0015 INTERLEUKIN-25 PROTECTS AGAINST HIGH-FAT DIET-INDUCED HEPATIC STEATOsis IN MICE BY INHIBING IL-25 AND M2 KUPFFER CELL PRODUCTION**

A. Wang, 1, X. Zheng, 2, B. Li, 1, H. Xiao, 1, J. Hong, 1, X. Zhu 1

1Gastroenterology And Hepatology, The First Affiliated Hospital of Nanchang University, Nanchang/China
2Pharmacy, The First Affiliated Hospital of Nanchang University, Nanchang/China

**Introduction:** Alternatively activated anti-inflammatory macrophage (also termed M2 Kupffer cell) is important for prevention of the development of steatosis and liver injury in non-alcoholic fatty liver disease (NAFLD). Our previous studies demonstrated that interleukin (IL)-25 is downregulated in NAFLD mice and exogenous IL-25 protected against NAFLD by inducing M2 Kupffer cells.

**Aims & Methods:** We aimed to explore the intracellular signaling pathways of IL-25 to regulate macrophage polarization and direct effects of IL-25 on Kupffer cells.

**Results:** Exogenous IL-25 induced expression of type 2 cytokine and alternative activation of Kupffer cell in vivo. It could also promote hepatic macrophages to differentiate into M2 Kupffer cells in vitro. Interestingly, IL-25 recovered the expression of IL-25 mRNA in the liver of NAFLD mice. Furthermore, IL-25 could induce the expression of IL-25 in cultured hepatocytes by activation of STAT6, rather than MZF1, API or NF-κB. STAT6 was sufficient and necessary for IL-25 expression. Deletion and site-directed mutagenesis of the IL-25 promoter revealed that IL-25 transcriptional activation depended primarily on a putative STAT-Binding sequence between nucleotides –682–674 upstream of the start site. STAT6 binding to this sequence increased in response to IL-25 treatment in vitro and in vivo. Finally, IL-25 induced M2a Kupffer cells could ameliorate HFD-induced hepatic steatosis by reducing M1 macrophages and restoring M2 Kupffer cell compositions. Moreover, IL-25 inhibited LPS-induced hepatic steatosis by reducing M1 Kupffer cell activation.

**Conclusion:** Our results elucidate the molecular mechanisms of IL-25 during amelioration of hepatic steatosis and provide the scientific basis of direct IL-25 treatment or macrophage transfusion therapy for NAFLD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** NASH is considered an important risk factor for liver fibrosis. Although literature data indicates that statins may be beneficial when given for fibrosis accompanying NASH using the scales of FibroMax, 120 patients with NASH and metabolic syndrome were followed-up for a period of 3 years. We excluded patients taking a series of drugs, with genetic metabolic disorders or impaired intestinal absorption (celiac disease) or alcoholics. Steatosis, fibrosis...
and NASH were quantified by using the FibroMax scales at baseline and after three years of statin treatment. Patients were randomized in two groups: the active group of 60 patients receiving low-dose hydrophilic statin (rosuvastatin 10 mg/day) and the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–8%, F3–2%; F4–0% of patients. NashTest also proved a positive evolution under statin treatment, compared with placebo. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–8%, F3–2%; F4–0% of patients. NashTest also proved a positive evolution under statin treatment, compared with placebo. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–29%, S1–41%, S2–30%, F0–31%, F1–28%, F2–13% and F3–8% of patients in active group, compared with the witness group. complex and pathological changes in the liver, determined by the test
Starnage (r = 0.76; p < 0.0001). The dependence obtained is confirmed by
the equation of simple linear regression.
Conclusion: In patients with AO, there is a direct relationship between the
presence of pathological changes in the liver and the initial manifestations of ather-
oseclerosis. The results obtained make it possible to evaluate the individual risk of
atherosclerosis in this category of patients. Clinical significance of the results is
the need for a more thorough examination of patients with AO and suspicion of
liver pathology to assess the development of not only the disease of the liver itself,
but also cardiovascular complications.

Introduction: Insulin resistance is the main pathogenic determinant of both
NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver
(1). Overexpression of hepassocin (HPS) increased hepatic lipid accumulation and
NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-
duced hepatic steatosis and decreased NAS in mice.

Aims & Methods: The aim of this study was to explore the relationship between
hepassocin and diabetic patients with or without NAFLD. The study included 80
patients that were divided into 4 groups: Group I: included 20 patients who
were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who
were diagnosed as non alcoholic fatty liver disease, Group III: included 20 patients
who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV
(control group): included 20 healthy person who were matched in age and sex with patients group.

Results: There was stastically significant decrease in mean value of serum hepass-
ocin of group 1 and IV on comparing with group II and group III. For group III
there was statistically significant increase in mean value of serum hepassocin on
comparing with other groups. There was a significant serum hepassocin up reg-
ulation in patients with type 2 diabetes and non alcoholic fatty liver diseased patients
(Group 3) mostly than diabetic patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may
facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes
mellitus.

Introduction: Visceral adipose tissue (VAT) and gut are thought to be the two
main sources of damage factors promoting non-alcoholic fatty liver disease
(NAFLD). As one part of VAT, mesenteric adipose tissue (MAT) may be
unique in VAT for it can affect liver directly via portal vein. However, the
relationship of MAT status with different stages of NAFLD is not clear, as
well as the role of inflamed MAT in NAFLD.

Aims & Methods: Mice fed with high fat diet or normal diet were sacrificed in
time gradients (4w, 8w, 12w). Then, MAT in high fat diet feeding mice was
removed or not at 8th week and mice were sacrificed at 12th week.

Results: Mice have developed hepatic steatosis at 8th week and progressed to
steatohepatitis by 12th week. Among four parts (mesenteric, epididymal, perire-
nal and retroperitoneal) of VAT, merely MAT became inflamed (mRNA
expression of TNF-a increased, P < 0.01 and IL-10 decreased, P < 0.05) by
8th week, which happened to coincide with the presence of hepatic steatosis.
Removal of inflamed MAT significantly worsened liver pathology, as well as
resulted in hepatic inflammation (mRNA expression of MCP-1 increased,
P < 0.01 and IL-10 decreased, P < 0.01) and lipid accumulation (mRNA expres-
sion of ACC1 increased, P < 0.01 and PPAR-e decreased, P < 0.01). Meanwhile, intestinal permeability was higher in the MAT removal group than that in the
Sham group, which was supported by higher lipopolysaccharide (P < 0.05) in
serum and lower mRNA expression of ZO-1 (P < 0.01) and occludin (P < 0.05)
in small intestine.

Conclusion: These results suggest MAT inflammation arises at the early stage of
NAFLD. Removal of inflamed MAT promotes the development of NAFLD and
injures the intestinal barrier. Thus, we propose that MAT inflammation seems to
be a compensatory response, on the fact that inflamed MAT protects the liver
from the gut-derived damage factors via confining them within MAT, rather than
aggravates NAFLD.

Introduction: Non alcoholic fatty liver disease (NAFLD) is a broad term describ-
ing simple steatosis, non alcoholic steatohepatitis (NASH), NASH cirrhosis and
NASH-induced hepatocellular carcinoma (1). Incidence increased in patients
type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differntiate
simple steatosis from steatohepatitis (Area Under Curve 0.936, senstivity 90%,
Specificity 90%, positive predictive value 81%, negative predictive value 94%).

Results: Correlation between results of stiffness by elastography and NAS by
biopsy revealed that: There was a significant positive association between average
stiffness by elastography and definitive NASH (NAS 5 and 6) in patients with
(type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differntiate
simple steatosis from steatohepatitis (Area Under Curve 0.936, senstivity 90%,
Specificity 90%, positive predictive value 81%, negative predictive value 94%).

Conclusion: Shear wave ultrasonic elastography is a promising non invasive
technique to differentiante simple steatosis from steatohepatitis in patients with
(type 2 DM.

Introduction: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal permeability.
Aims & Methods: A clear role of translocation for luminal intestinal bacteria is yet to be defined but we hypothesize that the recently described gut vascular barrier (GVB) is impaired in experimental portal hypertension leading to protein loss and increased accessibility of the vascular compartment for translocating bacteria.
For this purpose two different models of experimental portal hypertension, namely partial portal vein ligation (PPVL) and bile duct ligation (BDL) were used in mice subjected to standardized gnotobiotic conditions (sdMDM2).
A novel in vivo confocal endomicroscopy technique was established in order to detect early intestinal vascular leakage. FITC-dextran (70 kDa) was injected intravenously and confocal probe was placed in the intestinal lumen (terminal ileum) to visualize villus-capillaries. Leakage was measured over time (10 minutes) as a ratio between the mean fluorescent intensity inside the vessel (lumina proper) and inside the vessel. Immunofluorescence (IF) stains of the intestinal diaphragms marker plasmalemma vesicle-associated protein-1 (PV-1) were performed for GVB analysis.
Results: Confocal endomicroscopy data revealed an earlier and significantly increased leakage of 70kDa through the intestinal vasculature in both BDL and PPVL mice. FITC-70kDa-dextran did only leak in BDL and PPVL but not in control (sham operated) mice. Interestingly GVB stains showed increased expression of PV1 in intestinal vessels (CD34+) of BDL but not PPVL mice.
Conclusion: Portal hypertension per se has an impact on the GVB increasing FITC-70kDa-dextran leakage from intestinal capillaries to the lamina propria in both BDL and PPVL. However, the IF showed only in BDL an increased PV1 expression indicative of a wider opening of the intestinal diaphragms than in PPVL. Therefore, different mechanisms appear to be involved in alterations of the gut-vascular barrier in pre-hepatic portal hypertension and biliary cirrhosis.
Disclosure of Interest: All authors have declared no conflicts of interest.

with that of the control group, demonstrating that P3K/AKT signal pathway was partially responsible for development of pathological angiogenesis. However, the treatment with celecoxib strongly decreased the protein expression of VEGF, CD31, P3K and AKT in the spleen of cirrhotic rats.

**Conclusion:** The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by celecoxib could ameliorate portal hypertension and splenomegaly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with Escherichia coli (E. coli), Klebsiella pneumoniae being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiotics.

**Aims & Methods:** With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SPB were explored. These insights might lead to an initiation of antibiotics on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with E. coli with different MOI (MOI 0, 1, 5 and 10) for 2–4 hours post confluence. Experiments with heat inactivated E. coli were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Occludin and E-cadherin. Two different models of experimental LC – namely partial portal vein ligation (PPVL) and sham-operated mice – were used to test the effect of microbial metabolic products. Effects of microbial metabolic products were performed as controls. Enterochromaffin cells (ECC) were treated with microbial metabolic products and changes in mRNA and protein levels of Occludin and E-cadherin were assessed. With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SPB were explored. These insights might lead to an initiation of antibiotics on time and reduced mortality in SBP.

**Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with E. coli with different MOI (MOI 0, 1, 5 and 10) for 2–4 hours post confluence. Experiments with heat inactivated E. coli were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Occludin and E-cadherin. Two different models of experimental LC – namely partial portal vein ligation (PPVL) and sham-operated mice – were used to test the effect of microbial metabolic products. Effects of microbial metabolic products were performed as controls. Enterochromaffin cells (ECC) were treated with microbial metabolic products and changes in mRNA and protein levels of Occludin and E-cadherin were assessed.

**Conclusion:** By using an *in vitro* model, we demonstrate destabilizing effects of E. coli on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent a mechanism by which bacteria can affect the epithelial immune responses and therefore to promote bacterial translocation in SBP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2. University of Guadalajara, Guadalajara/México

**Contact E-mail Address:** edgar.mendivil@live.com

**Introduction:** Liver fibrosis is the excessive accumulation of extracellular matrix (ECM) following a chronic liver injury. It is characterised by an increase in gene expression of proinflammatory molecules such as TGF-b1, IL-1b, IL-6 and TNF-a, as well as an excess synthesis of ECM components such as COL-1. Capsaicin (CAP) is a pungent compound found in chilli peppers which has shown anticancerogenic, antiinflammatory and antifibrotic properties. Moreover, sulforaphane (SFN) is an isothiocyanate which is in cruciferous such as broccoli and it has exhibit an antioxidiant effect in several in vitro and in vivo models.

**Aims & Methods:** The objective of this project was to evaluate the antifibrogenic and antiinflammatory effects of a daily supplementation with CAP and SFN in a rat model of liver fibrosis due to carbon tetrachloride (CCL4) intoxication. 35 male Wistar rats were included (n=7/group); animals were administrated intraperitoneally 5 times per week during 8 weeks with a mix of CCL4/molar (1.5/week 1, 1.1/week 2 and 1.3 week 3–8). Healthy and CCL4-fibrotic controls received only supplementation vehicle (Tween 2% in PBS). Treated groups receive SFN 5ug/kg, or CAP 2mg/kg, or both supplements daily by oral gavage since the beginning of CCL4-intoxication regimen until sacrification. Masson staining and PCR was performed in liver samples. Hepatic enzymes were analysed in serum.

**Results:** Groups treated with CAP and SFN showed a decrease of >30points in percentage of liver fibrosis according to Masson staining (p<0.05), hepatic function improve since AST and ALT serum levels diminish (p<0.01) also a lower gene expression of TGF-b1, COL-1, TNF-a, IL-1b and IL-6 was detected in treated animals when compared with fibrotic controls (p<0.01).

**Conclusion:** Thus, CAP and SFN seem to exert a hepatoprotective effect in this model of chronic-induced liver damage. These findings suggest that dietary sources of CAP and SFN might be included in dietetic guidelines for the prevention of liver fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0033** **DIAGNOSIS OF GASTRIC VARIcES BY ENDOscopIC ULTRASONOGRAPHY USING COLOR DOPPLER**

T. Sato

Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenterology, Sapporo, Japan

**Contact E-mail Address:** taka.sato@ja-hokkaidoukouseiren.or.jp

**Introduction:** Gastric variceal bleeding is common complication, and it is associated with higher morbidity and mortality rates than hemorrhage from esophageal varices. Oesophagogastroduodenoscopy is usually the initial investigation in the portal hypertension for the purpose of the distinction between gastric varices and gastric folds. The aim of this study was to investigate endoscopic color Doppler ultrasonography (ECDUS) findings of gastric varices.

**Aims & Methods:** Two hundred-fifteen patients with gastric varices were evaluated with ECDUS. To begin with, identification of gastric varices was performed with B-mode scanning and then, color flow mapping was done. On B-mode scanning, submucosal gastric varices, and para-gastric collateral veins were obtained as hypoechoic vessels within gastric wall or in the tissue and spaces exterior to the adventitia of gastric wall. ECDUS provides a color display of blood flow and evaluates the flow pattern using fast Fourier transform (FFT) analysis. FFT analysis can indicate the flow pattern and calculate the velocity of blood flow. We monitored the color flow images of gastric varices, and para-gastric or peri-gastric collateral veins. Endoscopic findings of gastric varices were evaluated according to the grading system outlined in The General Rules for...

Results: The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2 ± 6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7 ± 6.2 cm/s (n = 52), while the mean velocity of enlarged tortuous (F2) type gastric varices was 16.7 ± 5.0 cm/s (n = 163). The velocities of F3 type gastric varices were significantly higher than those of F2 type (P < 0.0001). Next, we evaluated the wall thickness to submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6 ± 0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2 ± 0.2 mm (n = 42), while the mean thickness of RC or erosion negative varices was 1.7 ± 0.3 mm (n = 173). The thickness of RC or erosion positive varices was significantly thinner than that of the negative cases (P < 0.0001). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow up (bleeding cases, n = 10), and mean thickness of these bleeding cases were 1.2 ± 0.2 mm.

Conclusion: ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.
HEPTEM 57 (50–59), p = 0.05). This finding, together with a decreased concentration of endothelial-MP carrying TM (TM-MP/L: 232 (190–287) vs 377 (218–493), p = 0.002) and endothelial-Pc receptor (EPCR/CD65E-MP/L: 16 (14–25) vs 37 (24–70), p < 0.001), demonstrated a local greater endothelial damage in cirrhotics.

Conclusion: In cirrhotics, venous hypercoagulability and portal site specific endothelial damage, associated with hampered antithrombotic properties, may be important local risk factors in the pathogenesis of PVT along with the documented venous stasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In clinical trials rifaximin-α (RFX) has been shown to reduce recurrence of episodes of overt hepatic encephalopathy (HE) and HE-related hospitalisations. UK real-world data confirmed reductions in hospital admissions and length of stay with RFX use; however, data on use of emergency department (ED; A&E in UK) resources are still scarce. This study assessed the impact of RFX on utilisation of ED resources.

Aims & Methods: Patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were included in this retrospective observational study. Patient records were reviewed; details of demographic and clinical characteristics, and all-cause ED attendances and admissions were collected in the 6 and 12 months pre- and post-RFX initiation. The analysis included only patients who were alive at the end of the study periods.

Results: Of the 145 patients included, 114 (79%) were alive at 6 months and 102 (70%) at 12 months post-RFX initiation. At RFX start, mean age was 61 years, 63% were male; 67% had alcohol-related liver disease; for patients with available MELD score (70%), the mean was 16; 78% were on lactulose. Use of ED resources in the 6 and 12 months pre- and post-RFX initiation is shown in Table 1. Six patients developed adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE is well-tolerated and associated with significant reductions in ED attendances, with or without admission, both within 6 and 12 months of RFX initiation.

Introduction: Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis, with necessity of hospital admission in many cases. The economic burden of HE is substantial. After ascites, HE is the second most common reason for hospitalization of cirrhotic patients. HE is also the most common, possibly preventable, cause for readmission.

Aims & Methods: We aimed to assess the factors associated with the increased likelihood of hospital readmission for HE after the onset episode.

We completed a retrospective Retrospective analysis of admissions for HE of patients with liver cirrhosis, between October 2010 and October 2015. Only the onset episode was included. Patients were followed for 1 year or until readmission for HE. All patients were discharged under lactulose therapy. Descriptive statistics, uni and multivariate analysis, logistic regression, and ROC curves analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: In this study 119 patients were included: 78% men with a mean age of 59 ± 13 years: 88% had hepatocellular carcinoma, and 45% had Child-Pugh C. The most frequent cirrhosis etiologies were alcoholic disease (60%) and HCV infection (12%). The precipitating factors, for the onset episode, more frequently detected were diuretic overdose (36%) and infection (31%). All patients were treated with standard therapy, with an adequate lactulose dose. The readmission rate after the first episode of HE was 72% (75% men). The estimated average time to relapse was 18 weeks. The most frequent causes of readmission were also diuretics overdose (31%) and infection (30%). The patients who were readmitted had a higher MELD score than patients without recurrence (13.9 vs. 11.6 points; p = 0.015). This association was verified in the multivariate analysis (OR = 1.1, p = 0.044).

Conclusion: In this cohort, there was a high rate of readmission for HE after the inaugural episode, which carries a great impact on individual health and high socio-economic costs. A higher MELD score was independently associated with a high probability of readmission for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia and hypalbuminemia were markers for portal hypertension and hepatic synthetic dysfunction, respectively, have been shown to reduce the like- lihood of sustained virological response and to increase the rates of serious adverse events.

Aims & Methods: The aim of this study was to evaluate the impact of thrombocyto- penia and hypalbuminemia on treatment outcome and disease complica- tions. We included in this study 855 HCV-infected cirrhotic patients treated withombitasvir/paritaprevir/r-dasabuvir/r-ribavirin for 12 weeks in 10 university hospi- tals in Romania. The following groups were studied: 151 patients (17.7%) with albumin <3.5 g/dl, 239 (28%) with thrombocytopenia (a cutoff of 10000/mmc was used) and 71 patients (8.3%) with both hypalbuminemia and thrombocy- topenia before initiating antiviral treatment. Safety (as AE >5% and SAE), efficacy, change in HCV RNA undetectable and week 12 post-therapy and complica- tion rate were evaluated using Pearson’s correlation, multivariate analysis and Chi-Square test.

Results: Main patient characteristics were: 100% genotype 1 b, a median age of 63 yo, 466 women (54.57%), high rate of previous interferon-based-treatment (36.1%). End-of-treatment and sustained virological response rate were both >99% and there was no correlation with the presence of thrombocytopenia or hypalbuminemia. The rate of adverse events in the whole cohort was 17.5% at 2 weeks reaching 18% at the end of treatment with only 0.8% severe adverse events with no statistical association with the presence of thrombocytopenia and hypalbuminemia. The multivariate analysis showed significant association of thrombocytopenia (<10000/mmc) with higher (>1) degree of oesophageal varices (p = 0.011), one of upper digestive hemorrhage during treatment (p = 0.002). Low albumin (<3.5 g/dl) also correlated with higher (>1) degree of oesophageal varices (p = 0.001) and onset of upper digestive hemorrhage during treatment (p = 0.002).

Conclusion: The efficacy and safety of theombitasvir/paritaprevir/r-dasabuvir/r-ribavirin (as recommended by national regulations) was not different in cirrhotic patients with hypalbuminemia and thrombocytopenia, but complica- tions rate was higher so close follow-up and proflatic measures should be recommended, especially if previously exposed to interferon containing regimens.

Disclosure of Interest: All authors have declared no conflicts of interest.

BACTERIAL INFECTION IN PATIENTS WITH DECOMPENSATED CIRRHOSIS - A PREDICTOR OF LONG-TERM MORTALITY INDEPENDENT OF DISEASE SEVERITY

Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafa1da_m_p sousa@hotmail.com

Introduction: Bacterial infections are common in cirrhotic patients and the pro-inflammatory response superimposed on the hemodynamic dysfunction of portal hypertension predisposes to the development of complications. Some authors suggest that the occurrence of infection should be considered a separate clinical stage, since it alters the natural history of cirrhosis.

Aims & Methods: Retrospective assessment of patients with cirrhosis hospitalized for first episode of decompensation between 2011–2015. The aim was to evaluate the prognostic significance of bacterial infections regardless of the severity of the underlying liver disease.

Methods: Four patients (85% male, mean age 59 years, mean MELD 15, 72% alcoholic cirrhosis) were included with a total of 197 hospitalizations. Hospitals admissions were more frequent due to variceal haemorrhage (42%) and encepha- lopathy (37%). The incidence of bacterial infection was 23%: 41% respiratory, 31% spontaneous bacterial peritonitis and 24% urinary. Of these, 51% were nosocomial and in 20% an infectious agent was isolated. The survival rates at 30 days, 3 months, 6 months and 1 year were 65%, 55%, 34% and 27% in patients with infection and 97%, 90%, 85% and 78% in those without infection (p < 0.001). In the multivariate analysis, survival was independently associated with MELD (hazard ratio (HR) 1.073, p = 0.012), age (HR 1, 032, p = 0.012) and infection (HR 3, 821, p < 0.001). Bacterial infection remained an independent predictor of mortality, even when excluding patients with in-hospital mortality and during hospital stays (HR 3,093, p < 0.001) and in-hospital stay (HR 1,465, p < 0.001).

Conclusion: Patients with cirrhosis exposed to a bacterial infection are at increased risk of death. This risk remains in the long term when we exclude patients with in-hospital mortality and at 30 days and regardless of the severity of the underlying disease (MELD).

A proportionally greater elevation in liver transplant candidacy in patients with NAFLD and portal vein thrombosis

M. Basaranoglu
Gastroenterology, Bismilam Vakif University, Istanbul/Turkey

Contact E-mail Address: metin_basaranoglu@yahoo.com

Introduction: NASH progresses to cirrhosis and its complications including hepatocellular carcinoma. It is possible that risk factors for NAFLD-associated cirrhosis may differ in Eastern countries from those in the West. Thus, we aimed to document the characteristics of patients with NAFLD-associated cirrhosis from Turkey, an European country sharing 97% of its borders with Asia. Relative to other Eastern Europeans, the Turkish population exhibits a higher rate of obesity that may impact that to in the West.

Aims & Methods: To characterize non-alcoholic fatty liver disease (NAFLD) presentation with esophageal varices. METHODS: We have kept the records of patients at our hepatology unit and affiliated liver center. Data were collected for esophageal varices at the advanced endoscopy unit. A cohort of patients with esophageal varices from 2003 to 2014 was reviewed. Eligible patients were ≥18 years of age and have had esophageal varices diagnosed by upper gastrointestinal endoscopy examination. They had regular clinical follow-up and endoscopic examinations at our clinic. Efficacy data were based on the last evaluation. Transplanted cases were excluded. The main inclusion criterion was the presence of esophageal varices with or without gastric varices. Only 258 patients with esophageal varices had high-risk varices had reliable data and were included in this study. Each patient was evaluated for fundal varices, PVT, cirrhosis, HCC, and mortality. After the first evaluation, patients were divided into 4 groups: Those with hepatitis B, hepatitis C, NAFLD and others related to autoimmune hepatitis, Wilson Disease, primary biliary cirrhosis, etc.

Results: Primary end-point of the study was to use this cohort of patients with esophageal varices to evaluate the relationship between this disease and several etiologies, including NAFLD, hepatitis B, hepatitis C, or other liver-related diseases. We started to draw this comparison in terms of PVT, HCC, survival and mortality. Of the 258 patients with esophageal varices, NAFLD in 39.0% (101 patients), hepatitis B virus in 29.1% (75 patients) and HCV in 11.2% (29 patients). The mean age of NAFLD was 56.4 ± 16.0 years and 62% of these patients were men. Moreover, 47.5% had PVT, 5.0% had HCC, and 45.5% had fundic varicose veins. The mortality rate was 47.5% during follow-up, but increased to 80% in the presence of HCC. PVT was observed in 47.5% of patients with NAFLD, 29.3% of patients with hepatitis B, 17.2% of patients with hepatitis C, 23.3% of patients with other liver-related diseases (P < 0.0001). Of the 111 patients (43%) that died during the study period, 72 patients (64.9%) had no PVT (P = 0.057). HCC was: 5.0% in patients with NAFLD, 26.7% in patients with hepatitis B, 34.5% in patients with hepatitis C, and 5.7% in other diseases (P < 0.0001). Of the 38 patients with HCC, 13% had PVT. Moreover, HCC increased the mortality rate in almost all the groups. Of the patients, 50.0% with NAFLD, 33.3% with hepatitis B, 26.3% with hepatitis C, and 58.3% with other diseases were alive at the end of the 5-year period with a significant difference according to the Kaplan-Meier log Rank test (P < 0.004). Risk for mortality, measured by risk ratio (RR), did not change per gender (RR: male/ female = 43.3%/42.5%, P > 0.05) or with the occurrence of cirrhosis (RR: 44.8%/28.6%, P > 0.05). However, it changed with the emergence of fundic varices (RR: 49.0%/24.3%, P = 0.024 in favor of fundic varices development) and HCC (RR: 78.9%/38.6%, P = 0.0001 in favor of HCC development).

Conclusion: Data revealed a proportionally greater rise in liver transplant candidacy due to NAFLD-associated cirrhosis with portal vein thrombosis. The mortality rate of patients with NAFLD-associated cirrhosis did not differ from that in patients with virally caused cirrhosis. We confirmed that NAFLD was the third leading cause of HCC on the transplantation waiting list. Older patients in patients with virally caused cirrhosis. We confirmed that NAFLD was the third leading cause of HCC on the transplantation waiting list. Older patients in patients with NAFLD-associated cirrhosis from Turkey had a higher risk of HCC than patients with viral hepatitis. From the variables identified in the multivariate analysis, a predictive model of MDR bacterial infection was created. Assuming a sensitivity of 66% and a specificity of 72%, we considered the cut-off of ~0.0415 as clinically relevant, regarding likelihood of developing a MDR bacterial infection (AUCROC 0.723; 95% CI 0.667-0.780). The occurrence of a MDR infection was associated with a longer duration of hospitalization (p = 0.0017). In the multivariate analysis there was no independent association between MDR infection and in-hospital mortality and one month after discharge. The prevalence of MDR infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0045 EFFECT OF TREATMENT OF CHRONIC HEPATITIS C WITH SOFOSBUVIR AND DACLATASVIR IN PATIENTS OLDER THAN 60 YEARS K. Elnoemany1, M. Badr2
1Gastroenterology, National Liver Institute (NLI), Menofya University, Shebin Elkom/Egypt
2Internal Medicine, Menofya University, Shebin Elkom/Egypt

Contact E-mail Address: dr_kareemmn@yahoo.com

Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing of the impact of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients. Aims & Methods: The aim is to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after three months of end of treatment.

Results: Old chronic hepatitis C patients who were treated achieved primary virological response (SVR) (after 3 months of end of treatment) in about 96% of treated patients. Before treatment, patients with chronic hepatitis C had worse scores especially in work, sleep, rest and recreation and pastimes categories. After treatment, patients who received sofosbuvir/daclatasvir with or without ribavirin had significant improve in work, sleep, rest and recreation and pastimes categories with p-value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and after 3 months of end of treatment.

Conclusion: Treatment of chronic hepatitis C in old-aged patients had a significant improvement in HRQOL.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Accurate determination of the degree of hepatic-fibrosis is mandatory not only for the diagnosis and prognosis of disease, but also for deciding on the antiviral treatment. Indeed, many studies have been dedicated to the search of non-invasive fibrosis markers capable of providing an accurate information about hepatic fibrosis stage in patients with chronic hepatitis C (CHC). Direct and indirect markers of hepatic fibrosis are useful for prediction of liver cirrhosis but have limited accuracy for the diagnosis of significant fibrosis. Therefore, the development of more advanced scores combining both direct and indirect markers may improve their diagnostic accuracy.

**Aims & Methods:** This work is concerned with determining the levels of some of fibrosis markers, which are directly involved in deposition and removal of extra-cellular matrix (ECM), together with other indirect fibrosis markers so as to construct a predictive score capable of identifying the presence of significant fibrosis with a high degree of accuracy. Then, we aimed to estimate its performance against that of the other simple noninvasive tests in chronic hepatitis C patients.

**Material and Methods:** A total of 148 Egyptian HCV patients were subjected to routine laboratory workup in addition to estimation of serum AFP, hyaluronic acid (HA), platelet-derived growth factor (PDGF), tissue inhibitor of metallo-proteinase-1 (TIMP-1) and collagen IV. According to fibroscan, patients were classified into those with non-significant fibrosis (F < 2) and significant fibrosis (F ≥ 2).

**Results:** Based on univariate analysis, ten variables were significantly higher in patients with significant fibrosis. Patients with F2-F4 had 2.08-fold, 2.14-fold, 1.80-fold and 1.90-fold increase in the concentrations of collagen IV, HA, PDGF and TIMP-1, respectively. Multivariate regression demonstrated that only age, AFP, PDGF, collagen IV and TIMP-1 retained significance. Therefore, a five-marker named score Egypt (EGY) Fibro-mark (FM) was developed. A significant correlation was found between its candidate markers and liver fibrosis progression. AFP was found to have highest correlation (r = 0.47, P < 0.0001) followed by collagen IV (r = 0.46, P < 0.0001), Age (r = 0.43, P < 0.0001), TIMP-1 (r = 0.40, P < 0.0001) and PDGF (r = 0.40, P < 0.0001). ROC curve was used to estimate and compare the diagnostic accuracy of these candidate variables. As a consequence, these markers were in a decreasing rank: AFP ≥ collagen IV ≥ AGE ≥ TIMP-1 and PDGF (AUC 0.79), collagen IV (AUC 0.78), Age (AUC 0.76), TIMP-1 and PDGF (AUC 0.75). Additionally, Bivariate Spearman’s rank correlation coefficient between EGY-FM and its candidate markers was determined for estimating the impact of each marker on the predictive criteria. The diagnostic value of Egy FM was then assessed by ROC curve showing an AUC of 0.89 for diagnosing significant fibrosis at an optimal cut-off point of 4.05 with 77% sensitivity, 84% specificity, 1.80% accuracy (95% CI)

**Table 1:** The correlation of each score to hepatic fibrosis progression

**Conclusion:** Egy Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than FRT, King’s score, APRI. Fibro-score and FibroQ in this group of Egyptian patients.

**Introduction:** In patients with chronic hepatitis C, host genetics influence liver fibrosis, particularly modulates in genes controlling the inflammatory and immune response pathways. In this context, interleukin 28B (IL-28B) rs12979860 single-nucleotide polymorphisms (SNP) is considered the most important. Controversial data suggests that IL-28B SNP relate to the severity of hepatic histology. Some studies showed that rs12979860 C allele may be associated with greater hepatic inflammation, higher alanine aminotransferase levels and increased risk of worse clinical outcomes, other studies have not found this association. Furthermore, other studies found that the T allele affects the severity of liver fibrosis and had a mean staging score higher than other genotypes. Else, none of the previous studies concerned the association between the IL-28B SNP and signs of fibrosis severity.

**Aims & Methods:** We aimed to evaluate the cirrhotic development in C/T genotypes using FibroScan, extracellular matrix (ECM) proteins and the model for end-stage liver disease (MELD) in order to resolve conundrum regarding the association between interleukin 28B (IL-28B) rs12979860 and disease severity in chronic hepatitis C (CHC). So we assessed the allelic and genotypic frequencies of IL-28B rs12979860 in 272 HCV-infected Egyptian individuals; investigate serum levels of ECM proteins, including hyaluronic acid (HA), laminin, collagen type IV and the N-terminal pro-peptide of collagen type III (PHINP) as well as its association with liver fibrosis, as assessed by FibroScan, in different IL-28B rs12979860 genotypes; From another view, if C allele has a protective role, we expected that the C/C genotype increases cirrhosis, whereas, if the T allele is associated with liver fibrosis progression we expect that the T/T genotype increases cirrhosis behavior using FibroScan, ECM proteins and the MELD score between C/T IL-28B genotypes and evaluate the diagnostic performance of Fibroscan and these ECM proteins in IL-28B rs12979860 genotypes.

**Results:** IL-28B rs12979860 CT genotype is the commonest genotype among patients constituting ≈73% of the studied sample. The CC and TT genotypes constituted ≈18% and ≈9% respectively. Liver cirrhosis percentage increased with the increasing number of T alleles as it was 10%, 52% and 96% in CC, CT and TT genotypes, respectively. FibroScan values (kPa) gave a strong positive correlation (r = 0.6; P < 0.0001) with IL-28B polymorphism. Similar to FibroScan, HA, laminin (r = 0.3), collagen IV (r = 0.4) and PHINP (r = 0.4) serum levels showed significant (P < 0.0001) positive associations with IL-28B polymorphism. There was stepwise increase in the values of fibroscan and ECM proteins from CC to TT genotypes, so that elevated ECM proteins serum levels were associated with the presence of IL-28B T allele. (Table). In comparison with CC genotype, IL-28B rs12979860 T allele had a significant 2.4-fold increase (in case of CT) and 4.7-fold increase (in case of TT) in Fibroscan score values (kPa). The same was true for ECM proteins serum levels. Interestingly, the characteristics of the cirrhotic patients with TT genotype were completely different from the cirrhotic patients with CT genotype as assessed with FibroScan, ECM proteins and MELD score. Among cirrhotic patients, liver stiffness was 31.13 ± 2.78 kPa in TT genotype vs 20.96 ± 0.74 kPa in CT genotype. MELD was 9.6 ± 0.73 in TT genotype vs 3.9 ± 0.41 in CT genotype and ECM proteins were significantly (P < 0.0001) higher in patients with TT than CT genotype. AUC values for FibroScan, HA, laminin, collagen IV and PHINP serum levels to differentiate CC from other IL-28B genotypes were 0.91, 0.85, 0.82 and 0.82, respectively. These values rise to 1.0, 0.97, 0.93, 0.98 and 0.93, respectively, when comparing CC to only TT genotype.

(DAAs) needs to be investigated in real world treatment settings in Egypt to transaminases represent a category of patients with mild and slowly progressive Chronic hepatitis C virus (CHCV) patients with persistently normal enzymes in real-world Egyptian cohort. Data of CHCV genotype 4 patients

Contact E-mail Address: med.b.dean@azhar.edu.eg

Introduction: Recently, new direct antiviral agents (DAAs) with different mechanisms of action have been developed to provide much more efficacious and better-tolerated therapeutic strategies for treatment patients with hepatitis C virus (HCV) infection. Several clinical trials have investigated a 12-week therapy with fixed dose of all-oral three-drug combination of daclatasvir (DCV), a potent pan-genotypic nonstructural protein 5A (NS5A) inhibitor, in 60 mg once daily; asunaprevir (ASV), an NS3 protease inhibitor, in 200 mg twice daily; and beclabuvir (BCV), a non-nucleoside NS5B thumb-1 polymerase inhibitor, in 75 mg twice daily (BCV-TRIO) for treatment of patients with HCV genotype 1 infection.

Conclusion: We aimed to report the efficacy of 5 different DAAs regimens for treatment of CHCV genotype 4 patients with persistently normal liver enzymes in real-world Egyptian cohort. Data of CHCV genotype 4 patients with normal liver enzymes who started treatment with different DAAs between September and September 2016 in a single specialized viral hepatitis treatment center in Egypt were retrieved. Treatment regimens included: Pegylated RBV combination was the most effective among the studied regimens. SOF/DCV/RBV, (SOF/RBV) and (SOF/SIM) respectively.

Table 1: Distribution of different fibrosis markers in IL-28B CC, CT and TT genotypes

Table 2: Distribution of different fibrosis markers in IL-28B CC, CT and TT genotypes

P0049 THE SAFETY AND EFFICACY OF THE COMBINATION OF DACLATASVIR, ASUNAPEVIR, AND BECLABUVIR IN THE TREATMENT OF CHRONIC HEPATITIS C VIRUS GENOTYPE 1 INFECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Chronic hepatitis C virus (CHCV) patients with persistently normal transaminases represent a category of patients with mild and slowly progressive disease. Proper management of these patients with direct acting antivirals (DAAs) needs to be investigated in real world treatment settings in Egypt to further validate the accumulating data of the achieved high sustained virologic response (SVR) rates with the use of these drugs in clinical trials.

Aims & Methods: We aimed to report the efficacy of 5 different DAAs regimens for treatment of CHCV genotype 4 patients with persistently normal liver enzymes in real-world Egyptian cohort. Data of CHCV genotype 4 patients with normal liver enzymes who started treatment with different DAAs between September and September 2016 in a single specialized viral hepatitis treatment center in Egypt were retrieved. Treatment regimens included: Pegylated interferon alpha 2b/Sofosbuvir/Ribavirin (PEG/SOF/RBV), Sofosbuvir/ Daclatasvir (SOF/DCV), Sofosbuvir/Ribavirin (SOF/RBV) and Sofosbuvir/Simeprevir (SOF/SIM).

Results: Of the included 1149 patients (562 males and 587 females). 158 patients were treatment experienced (13.75%) and 146 patients (12.7%) had liver cirrhosis. Regarding the used treatment regimens; 244 (21%) patients were treated with PEG/SOF/RBV, 382 (33.5%) with SOF/DCV, 152 (13.5%) with SOF/DCV/RBV, 117 (10%) with SOF/RBV and 254 (22%) with SOF/SIM. The overall SVR rate was 97.5% while the SVR rates for different regimens were: 94.7%, 97.7%, 100%, 91.5% and 98% for (PEG/SOF/RBV), (SOF/DCV), (SOF/DCV/RBV), (SOF/RBV) and (SOF/SIM) respectively.

Conclusion: Different DAAs achieved high SVR rates in treating CHCV genotype 4 with normal liver enzymes in a real-world cohort from Egypt. SOF/DCV/RBV combination was the most effective among the studied regimens.

Introduction: Egypt has the highest prevalence of HCV worldwide. Prevalence of HCV was reported to be 13.9% among healthy populations. Adults have higher HCV prevalence (15.7%) than children (4%). Geographically, HCV is highly prevalent in the Nile delta (15.8%) than in Upper Egypt (9.02%). The household contacts of HCV seropositive patients had been shown to have a high risk of HCV infection.

Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt.

In this multicentre hospital case control based study a total of 4894 Egyptian individual cases were recruited to the hospitals from different Egyptian population in Upper & Lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates). The index HCV patients were 1106 cases whereas the families or close household contact of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications (first and second degree consanguinity, living and sharing usual family activity and having at least 15 years of exposure to the index case). The positive cases (index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA > 6 months, 2-Adults (above 18 years) of both sexes 3-Any stage of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC) based on the following criteria: positive Anti-HCV but negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnosis and PCR HCV to confirm HCV infection. Sequencing analysis of the HCV PCR was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were +ve while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among house hold contacts was 17.29% & 19.17% while the SVC was 2.4% & 11.8% in lower & Upper Egypt respectively. When the genotyping of the positive cases were performed it was found that the following pattern was noticed in the upper & lower Egypt respectively: genotype 4a (90.3% & 70.1%), 4m (4.8% & 11.8%) 4n (0.5% & 3.2%) 4e (0.2% & 2.9%) 4d (0.5% & 1.9%) 4c (0.8% & 1.2%) & 1a (2.9% & 8.3%) as shown in the following table.

<table>

Introduction: Red blood cell distribution width (RDW) is a numerical measure of the variability in size of red cell Reflects variability in the size of circulating red blood cells. RDW can be used as a prognostic marker in heart failure. In hepatic patients it was approved to be an independent predictor of liver fibrosis in patients with chronic HBV infection, and it is higher in patients with alcoholic liver disease and non alcoholic liver cirrhosis. The gold standard for assessing the histological out come of liver disease is liver biopsy. This procedure is costly and carries a small risk of complications due to sampling error, invasiveness and requires hospitalization of at least 6-18h. These limitations have stimulated the development of non- invasive techniques for assessing the presence and the degree of liver fibrosis. Several laboratory scores composed of routine laboratory markers that are readily available have been proposed for non-invasive prediction of liver fibrosis in chronic hepatitis C (CHC) patients.

Aims & Methods: The aim of this work is to use RDW as a marker for non-invasive prediction of the stage of hepatic fibrosis in patients with chronic hepatitis C genotype4. 100 patients with chronic hepatitis C were subjected to routine clinical and laboratory investigations in addition to molecular diagnosis and PCR HCV to confirm HCV infection. Sequencing analysis of the HCV PCR was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were +ve while 2.9% were spontaneously cleared the virus (SVC). P0052 CANCER INCIDENCE IN VARIOUS ORGANS OTHER THAN THE LIVER FOLLOWING DIRECT-ACTING ANTIVIRAL (DAA) THERAPY FOR HEPATITIS C

1Dept Of Gastroenterology, Kyoto Medical Center, Kyoto/Japan
2Dept Of Gastroenterology, Kyoto Medical Center, Japan, Kyoto/Japan

Contact E-mail Address: b-endoh@umin.ac.jp

Introduction: The incidence of liver cancer and its recurrence have been reported frequently at an early stage in patients who underwent interferon (IFN)-free direct-acting antiviral (DAA) therapy [1]. The underlying mechanisms of
cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

**Aims & Methods** We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as defined by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

**Results** There was a significant difference in the age and sex of the patients treated with DAA (n = 324, median age: 70, male: 41%) and those treated with IFN (n = 445, median age: 58, male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 23 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancer cases occurred mainly in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract/pancreas, lungs, and other organs. The median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0 and 5.0% for the DAA group, and 0.2 and 0.9% for the IFN group, respectively. The difference between the groups was significant (p = 0.02) based on Cox regression analysis using IPTW.

</tbody>
</table>

**Conclusion:** Because cancer detection in organs other than the liver can be challenging in management of hepatitis, some cases with cancer found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the present study, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

**P0054** *IS THERE AN INCREASE IN THE INCIDENCE OF HEPATOCELLULAR CARCINOMA IN CIRRHOTIC PATIENTS WITH HEPATITIS C TREATED WITH THE DIRECT-ACTING ANTIVIRALS?*

J. C. Branco, R. Carvalho, S. Alberto, A. Martins

Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Lisboa/Portugal

**Contact E-mail Address:** ebranco,joana@gmail.com

**Introduction:** The impact of the virological cure on the evolution of cirrhotic patients treated with direct-acting antiviral agents (DAA) has been recently evaluated. Recently, some papers reported an elevated incidence of recurrence of hepatocellular carcinoma (HCC) and others a possible rise on the de novo incidence of HCC in the first year after treatment with DAA, but not others.

**Aims & Methods:** This is a prospective study of cirrhotic patients treated with DAA between February/2015 and January/2017, under HCC screening with ultrasoundography according to international guidelines. The main endpoint of the study was to determine the incidence of “de novo” and recurrent HCC. The secondary endpoint was to search for possible predictive factors associated with the occurrence of HCC. Statistical analysis performed on SPSSv.24. Results: 106 cirrhotics (73% mean; 54.5 ± 8.8 years), MELD 7.3 ± 2.6, 60% with portal hypertension (n = 64) and 22% with decompensated cirrhosis (n = 23, 22 Child-Pugh B). Two patients with previous HCC, stage Barcelona Clinic Liver Classification (BCLC) A, invasive after loco-regional treatment. The sustained virological response at week 12 was 89.9% (71/79); 4 deaths, 1 relapse, 1 therapeutic failure and 2 losses to follow-up (FU). In 11 ± 7 months of FU, we registered 4 cases of HCC, 4 “de novo” and 1 recurrence, which corresponded to an incidence of 3.8% of “de novo” HCC (13% in decompensated cirrhosis). The BCLC staging was: stage A, 2 stage B, 2 stage C and the one with the recurrence was stage D. A Child-Pugh B class (p = 0.004), low platelets level (p = 0.001) and hospitalization for decompensation (p = 0.045) were associated with the occurrence of HCC; the genotype did not have association. The mean time to HCC development was 7.5 months (2–14).
The regulation of miR-506 gene expression and its role in exchanger 2 (AE2) and type III inositol 1, 4, 5-trisphosphate receptor were transfected in human cholangiocytes (H69 cells) and the role of pro-sizes of miR-506 promoter were cloned in a luciferase expression vector, which were expressed in PBC cholangiocytes and directly targets both Cl–/HCO3– transporter and PDC-E2. MicroRNA (miR) dysregulation and PDC-E2 overexpression is a common feature. MicroRNA (miR) dysregulation and PDC-E2 overexpression is a common feature. miR-506 induces dedifferentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; (ii) miR-506 overexpression increases oxidative and endoplasmic reticulum (ER) stress; (iii) caused DNA damage; and (vi) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and ATP reduction) and PDC-E2 overexpression. Co-culture of miR-506 over expressing cholangiocytes with PBC immune cells induced immunocyte activation and proliferation of PBC immune cells.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease associated with autoimmune phenomena targeting intrahepatic bile duct cells. PBC is a disease through PBC etiopathogenesis remains still obscure, development of anti-mitochondrial auto-antibodies against pyruvate dehydrogenase complex-E2 (PDC-E2) is a common feature. MicroRNA (miR) dysregulation occurs in liver and immune cells of PBC patients, but their functional relevance is largely unknown. We previously reported that miR-506 is overexpressed in PBC cholangiocytes and directly targets both Cl–/HCO3– exchanger 2 (AE2) and type III inositol 1, 4, 5-trisphosphate receptor (InsP3R3), leading to cholangitis.

Aims & Methods: The regulation of miR-506 gene expression and its role in cholangiocyte pathophysiology and immune activation was studied. Different sizes of miR-506 promoter were cloned in a luciferase expression vector, which were transfected in human cholangiocytes (H69 cells) and the role of pro-inflammatory cytokines, bile acids, estrogens and glucocorticoids was evaluated on the promoter activities. MiR-506 or a negative control miRNA sequence were also cloned in an expression vector under the regulation of the CMV promoter; these constructs were stably transfected in H69 human cholangiocytes, and cholangiocyte pathophysiology and immune activation were evaluated. Experimental overexpression of miR-506 in cholangiocytes dysregulated the cell proteomic profile (by mass spectrometry) affecting proteins involved in different biological processes including mitochondrial metabolism. In cholangiocytes, miR-506: (i) induced differentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; (ii) induced oxidative and endoplasmatic reticulum (ER) stress; (iii) caused DNA damage; and (iv) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and ATP reduction) and PDC-E2 overexpression. Co-culture of miR-506 overexpressing cholangiocytes with PBC immune cells induced immune activation and proliferation of PBC immune cells.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: The study population consisted of 106 men and 94 women with a mean age of 64.6±14.4 kg/m². The median age of F0, F1, F2, F3 and F4 were 1.33, 1.57, 1.73, 1.95, 1.98, respectively. The median IQR/median was 0.21. Furthermore, we formed the group into one F0-F1. The obtained results of shear wave elastography were presented in the form of quantilicative variables. Median stiffness with interquartile range (25%-75%) in groups: F0 - F1-5, 4 (4, 8-7, 2) kPa, F2-8, 5 (3, 8-9, 8) kPa, F3-13, 5 (10, 1-14, 5) kPa and F4-22, 0 (18, 2-25, 5) kPa. The parameters of liver elastometry in the various groups on the METAVIR scale differed statistically significantly between p < 0.05. When carrying out a correlation analysis between the stiffness indices of the liver parenchyma and the morphological stage of fibrosis, a strong correlation was revealed: the Spearman coefficient was r = 0.16 (p = 0.01). Cutoff value for the general group was: F0-75; F1-13, 25; F4-14, 9 kPa. In 10 patients, results for SWE differed from morphological conclusion. Analyzing reasons we observed that in 8 (80%) patients there was NAFLD and in 6 cases more than 66% was. To study fatty dystrophy impact on elastographic values we examined patients with the given disease (16 patients) from the secondary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1-5, 4 (4, 5-5, 6) kPa, F2-8, 5 (3, 8-9, 5) kPa, F3-13, 5 (10, 1-14, 5) kPa and F4-22, 0 (18, 2-25, 5) kPa. According to ROC analysis, threshold values for lesions F2-7, 3 mm²/s; F3-9, 8; F4-14, 9 kPa. However, stage correlation for hepatic fatty disease with elastography results was none: r =0.11 p=0.246214.

Conclusion: Quantitative indicators of SWE in patients with diffuse liver disease in correlation with steatosis is more than in patients without the given disease (16 patients) from the secondary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1-5, 4 (4, 5-5, 6) kPa, F2-8, 5 (3, 8-9, 5) kPa, F3-13, 5 (10, 1-14, 5) kPa and F4-22, 0 (18, 2-25, 5) kPa. According to ROC analysis, threshold values for lesions F2-7, 3 mm²/s; F3-9, 8; F4-14, 9 kPa. However, stage correlation for hepatic fatty disease with elastography results was none: r =0.11 p=0.246214.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0059 NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) AND THE EFFECTS OF SHEAR WAVE ELASTOGRAPHY FOR HEPATIC FIBROSIS STAGING

Introduction: To study the effect of NAFLD on the results of shear wave elastography (SWE) in patients with chronic diffuse liver disease.

Aims & Methods: We have performed outcome analysis in 100 patients with chronic liver disease from 2015 to 2016. There were 41 male patients (41%), and 59 female patients (59%), age (Me (LQ-UQ)) 49 (39-56), minimal age 18 years, maximal age was 77 years. All patients were found to have chronic diffuse hepatic diseases and were hospitalized for morphological and functional investigation. All patients had shear wave elastography (SWE) with quantitative measure tissue stiffness, Metavir stage scoring for received results.

Results: Based on the obtained morphological results, we have formed the following subgroups of patients: F0 - F1-31 people, F2-9; F3-15 and F4-45 patients. Given that patients with a degree of fibrosis on the scale METAVIR F0 and F1 do not require active conservative therapy, we combined the data of the group into one F0-F1. The obtained results of shear wave elastography are presented in the form of quantilicative variables. Median stiffness with interquartile range (25%-75%) in groups: F0 - F1-5, 4 (4, 8-7, 2) kPa, F2-8, 5 (3, 8-9, 8) kPa, F3-13, 5 (10, 1-14, 5) kPa and F4-22, 0 (18, 2-25, 5) kPa. The parameters of liver elastometry in the various groups on the METAVIR scale differed statistically significantly between p < 0.05. When carrying out a correlation analysis between the stiffness indices of the liver parenchyma and the morphological stage of fibrosis, a strong correlation was revealed: the Spearman coefficient was r = 0.16 (p = 0.01). Cutoff value for the general group was: F0-75; F1-13, 25; F4-14, 9 kPa. In 10 patients, results for SWE differed from morphological conclusion. Analyzing reasons we observed that in 8 (80%) patients there was NAFLD and in 6 cases more than 66% was. To study fatty dystrophy impact on elastographic values we examined patients with the given disease (16 patients) from the secondary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1-5, 4 (4, 5-5, 6) kPa, F2-8, 5 (3, 8-9, 5) kPa, F3-13, 5 (10, 1-14, 5) kPa and F4-22, 0 (18, 2-25, 5) kPa. According to ROC analysis, threshold values for lesions F2-7, 3 mm²/s; F3-9, 8; F4-14, 9 kPa. However, stage correlation for hepatic fatty disease with elastography results was none: r =0.11 p=0.246214.

Conclusion: Quantitative indicators of SWE in patients with diffuse liver disease in correlation with steatosis is more than in patients without the given disease (16 patients) from the secondary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1-5, 4 (4, 5-5, 6) kPa, F2-8, 5 (3, 8-9, 5) kPa, F3-13, 5 (10, 1-14, 5) kPa and F4-22, 0 (18, 2-25, 5) kPa. According to ROC analysis, threshold values for lesions F2-7, 3 mm²/s; F3-9, 8; F4-14, 9 kPa. However, stage correlation for hepatic fatty disease with elastography results was none: r =0.11 p=0.246214.

P0061 EXOSOMIC miR-224 REGULATED TUMOR INVASION AND MIGRATION THROUGH IL-6/STAT3 PATHWAY IN HEPATOCELLULAR CARCINOMA

F. An, D. Chen, Q. Zhan, M. Xia, X. Wu
Gastroenterology, West China University of Medical Science, Sichuan, China

Contact E-mail Address: wdl0825@163.com

Introduction: It was found regulated progression of liver cancer in our previous studies, IL-6/STAT3 pathway play key role, but the precise underlying mechanism remains to be explored. It was found exosomes are the vesicles released by the tumor cells into tumor microenvironment, they are a powerful diagnostic tool due to relative stability and composition covering the whole range of cancer-related biomarkers including proteins, metabolites, DNA, DNA modifications, coding and non coding RNA. Thus, study the roles of exosomic miRNA could be useful for therapy and prognosis prediction of hepatocellular carcinoma (HCC).

Aims & Methods: The expression of miR-224, IL-6, STAT3 and SMAD4 in tumor as well as adjacent tumor tissues of HCC were detected by RT-PCR. Tumor migration and invasion were induced by miR-224. The Exosome from the supernatant of HCC cells can be found translocated into HCC cells conversely, when the HCC cells were induced by miR-224. The Exosome from the supernatant of HCC cells was isolated and the translocation roles of exosome was studied in vivo, the up regulation of miR-224, IL-6/STAT3 and down regulation of SMAD4 were also found in the transplantation tumors which were induced by miR-224. The Exosome from the supernatant of HCC cells can be found translocated into HCC cells conversely, when the HCC cells were induced by IL-6, the overexpression of exosomic miR-224 and STAT3 and decrease of exosomic SMAD4 were detected. It was speculated miR-224 can regulated HCC progression through IL-6/STAT3/SMAD4 pathway by exosomic way.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prevalence of hepatocellular carcinoma (HCC) in Africa is higher compared to the rest of the world due to the high incidence of chronic infection with hepatitis C virus (HCV). In Egypt, HCV infection is the leading cause of HCC, which is usually diagnosed at late stages. Due to the absence of reliable and accurate biomarkers for early detection of liver cancer, circulating microRNAs have recently emerged as great candidates for early diagnosis of HCC. These small non-coding RNA molecules are responsible for controlling gene expression and RNA stability. Therefore, the aim of this study is to investigate the potential of liver-specific circulating microRNAs as an accurate non-invasive diagnostic tool for the early detection of HCV-induced HCC.

Aims & Methods: Seven main microRNAs (miR-125a, miR-139, miR-34a, miR-221, miR-16, miR-145 and miR-199a) were selected due to their expression patterns in HCC as well as their contribution to the development of hepatocarcinogenesis. A total of 165 patients were enrolled in this study, from which serum samples were collected and categorized into four main patient groups: 42 Egyptian patients with hepatitis C (CHC) without cirrhosis, 45 CHC with hepatocellular carcinoma (HCC), 38 HCC with HCV patients, and 40 healthy controls. The expression profile of the seven microRNAs was evaluated using TaqMan real-time reverse transcription-polymerase chain reaction. Additionally, the conventional markers for HCC (α-fetoprotein (AFP) and des-γ-carboxyprothrombin (DCP)) were measured using commercial kits.

Results: Serum levels of miR-125a, miR-139, miR-145 and miR-199a were significantly decreased (p < 0.01) in HCC than in the CHC and LC groups (Table 1). On the other hand, miR-16 and miR-34a were significantly increased (p < 0.01) in HCC patients compared to the normal group. However, no significant difference was shown in the expression of miR-16, miR-34a, and miR-221 between the CHC, LC, and HCC groups. As a single biomarker, miR-34a showed the highest sensitivity and specificity among all microRNAs investigated, followed by miR-221, miR-125a, miR-139, miR-145, and miR-199a.

**p < 0.01 significant increase than control; *p < 0.01 significant decrease than CHC; #p < 0.01 significant decrease than control; &p < 0.01 significant decrease than CHC and LC; †p < 0.01 significant decrease than CHC

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-221 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a in the HCC patient group indicates that these microRNAs can differentiate HCC from CHC and LC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary hepatocellular carcinoma (HCC) is one of the most common malignancies all over the world. HCC is associated with poor prognosis. However, the mechanism of HCC initiation and development remains unclear. In our previous work, high-throughput microarray assay in collected clinical HCC samples followed by bioinformatic analysis suggested that Metallothionein 1G (MT1G) might be one of the key factors in HCC.

Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSP (Methylation specific PCR) and BGS ( Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was investigated by overexpression or knockdown in HCC cell lines. The effects of MT1G re-expression were also determined by flow cytometry.

Results: MT1G was inactivated in all (6/6) HCC cell lines tested, but was readily expressed in immortalized liver cell line LO2. The expression of MT1G was
regulated in cancer tissues compared with the adjacent non-tumor tissues (E). The expression level of MT1G in the liver cancer tissues was closely correlated to the promoter hypermethylation status. The MT1G expression in silenced HCC cell lines could be restored by demethylating agent. We generated HCC cell lines overexpressed MT1G. Ectopic re-expression of MT1G by stable transfection in SMCC-7721 and HepG2 cells induced colony formation (P<0.001), suppressed cell motility and invasiveness (P<0.05), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP13 and Vimentin. The in vivo growth of HCC cells in nude mice was also markedly inhibited after stable expression of MT1G (P<0.001). MT1G over-expression in HCC cells induced the cell apoptosis (P<0.01).

Conclusion: Our results demonstrate that MT1G promoter methylation directly mediates the transcription down-regulation and commonly occurs in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, inva-
sion, and induction of cell apoptosis.

Contact E-mail Address: giulia_metzger@web.de
Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze the role exerted by CUX1 during deacetylase inhibitors mediated cell death in liver cancer cells. CUX1, endoplasmic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CUX1 and furthermore treated with deacetylase inhibitors and autophagy activators.

Results: CUX1 knock down caused a suppression of ER stress and autophagy markers BIP, CHOP, ATF4, ATF6, Beclin1, MAP1LC3B, UVRAG and TFE2 at early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BIP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CUX1 over-expression after 6 hours of treatment, whereas they show to lose this ability after 24 hours. CUX1 knock-down reduced significantly its protein level after treatment with deacetylase inhibitors. CUX1 knock down counteracts the accumulation of BIP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BIP independently from CUX1.

Conclusion: ER stress and autophagy markers are under the control of CUX1. The cell death induced by deacetylase inhibitors is strictly connected with CUX1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CUX1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0066 CUX1 CONFRS RESISTANCE TO APOPTOTIC CELL DEATH IN LIVER CANCER CELLS
E. Hofmann1, P. Di Fazio1, D. Bartisch1, T. M. Gress2, T. T. Wissniowski2
1Department Of Visceral Thoracic And Vascular Surgery, Philippus University Marburg, Marburg/Germany
2Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektionologie, Philippus Universität Marburg, Marburg/Germany

Contact E-mail Address: ellihofmann@yahoo.de
Introduction: CUX1 (CUTL1) is a transcription factor able to promote the cell death induced by deacetylase inhibitors, autophagy activators and apoptosis mediators. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CUX1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CUX1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL targets, hereafter TRAIL) and furthermore treated with siRNA for CUX1. The cell death was analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed. Western blotting was performed for caspase 8 and Flip detection

Results: Treatment with superkiller TRAIL, at 50 and 100ng/ml, caused cell death in HepG2 and Hep3B cells after 48h proven by an accumulation of 40% of sub-G1 events. CUX1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100ng/ml). CUX1 knock down did not change the expression of TP53, KRT18, CDKN1A and CDKN1B. Interestingly, silencing CUX1 increased the activity of caspase 3/7 after treatment with soluble TRAIL. The effect was neutralized by pan-caspase inhibitor zVAD. Apoptosis array evidenced an increased protein level of un-cleaved caspase 3 after CUX1 knock down. Caspase 8 uncleaved form was down-regulated at protein level after CUX1 knock down and treatment with TRAIL. Its cleaved forms were up-regulated. FlipL decreased in favor of FlipS also.

Conclusion: CUX1 mediates the resistance of liver cancer cells to TRAIL signaling. Knock down of CUX1 restores the potential of TRAIL to trigger cell death.

Disclosure of Interest: All authors have declared no conflicts of interest.
The results were in agreement with those reported by Awadallah et al.[6] who found a statistically highly significant elevation in the serum SCCA among patients with HCC before and after therapeutic intervention. Our results showed that SCCA level ranged from 2.5–10 with a mean of 5.53 in HCC patients without interventions, 3.3–7.6 with a mean of 5.3 in patients with HCC before therapeutic interventions, 1.2–5.6 with a mean of 3.3 in cirrhotic group, 0.6–1.05 with a mean of 0.824 in chronic HCV group while healthy controls had much lower values ranging from 0.3–0.95 with a mean of 0.646.

When combined sensitivity of both markers were calculated in our study at the best-cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93% (Table 4).

### Conclusion

In the present study patients with HCC either with or without therapeutic intervention have significantly higher level of AFP in comparison to chronic HCV, cirrhotic and control groups this is in agreement with Awadallah et al.[6] who reported a statistically highly significant elevation in the serum AFP in HCC group when compared with control group. Moreover, the mean serum level of AFP in group A (HCC before intervention) was 263 ng/ml that decreased to 209.4 ng/ml in group B after therapeutic intervention and this agreed with Feng et al.[7] and Molinari et al.[8] Also, at AFP level of 200 ng/ml, the sensitivity was 90%, while the specificity was 60%. Our results showed that SCCA level ranged from 2.5–10 with a mean of 5.53 in HCC patients without interventions, 3.3–7.6 with a mean of 5.3 in patients with HCC before therapeutic interventions, 1.2–5.6 with a mean of 3.3 in cirrhotic group, 0.6–1.05 with a mean of 0.824 in chronic HCV group while healthy control group had much lower values ranging from 0.3–0.95 with a mean of 0.646. Thus, a highly significant increase in serum SCCA level in patients with HCC before and after therapeutic intervention when compared to cirrhotic, chronic HCV and control groups (P < 0.001). These results were in accordance with Hussein et al.[9] and El Ezawy et al.[10] SCCA was also higher among patients with HCC before intervention compared to patients with HCC after intervention as found by Bin et al.[11]

Applying the ROC curves analysis showed the best cut-off value to differentiate HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielding 80% sensitivity and 90% specificity. These results were in agreement with Trevisani et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion <5 cm in size or 3 lesions <3 cms) so no statistical correlation was done between serum AFP level and tumor size. Our results showed a significant positive correlation between serum SCCA and AFP among patients with HCC before and after therapeutic intervention. Our data are in agreement with that of Hussein et al.[9] and El Ezawy et al.[10] who detected that SCCA were positively significantly correlated with AFP level. When combined sensitivity of both markers was calculated in our study at the best-cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93%. Matching results were found by Gianluigi et al.[4]

### Disclosure of Interest

All authors have declared no conflicts of interest.

The overall formula that could best predict HCC was then constructed:

$$\text{HMC-CU score} = 0.164 \times \text{Gender} + 0.141 \times \text{Hb} + 0.118 \times \text{INR}$$

The formula was validated using the bootstrap algorithm with 1000 samples. The HMC-CU score had an area under the ROC curve (AUC) of 0.76 (95% CI: 0.74–0.78) with sensitivity of 68% and specificity 66%. AUC was 0.76 and the 95% confidence interval was 0.74–0.78.

**Conclusion:** The HMC-CU score constructed from routine parameters is accurate in diagnosing the presence of HCC compared with HCV-related CLD. The advantage of our score is its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes only routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non-HCC patients all are Egyptians with a background of HCV type 4 related CLD. A validatory study is undertaken and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS-FNA) is one of the alternative methods for tissue sampling of liver solid mass. However, the diagnostic efficacy using cytology has limited. Comparative studies of needle types were not performed and their diagnostic yield was unknown.

Aims & Methods: In this study, we evaluated the feasibility and diagnostic accuracy of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G ProCore needle (PCN) was performed to evaluate the patient with solid liver mass. The primary outcome was the diagnostic accuracy of EUS-FNB for malignancy, and adequacy of the specimen for histology. The secondary outcomes were (1) the proportion of patients in whom immunohistochemical (HIC) stain was possible, and (2) compared diagnostic yield of FNB according to the needle size (40–50 mm, 51–60 mm and > 60 mm).

Results: Forty-one patients (13 women; mean age, 67.9±10.3 years [range, 46– 86]) underwent evaluation with EUS and identified hepatic lesions ranging in size from 0.7 cm to 15 cm. EUS-FNB with 20G (n = 10), 22G (n = 24) or 25G PCN (n = 7) was performed (right lobe: n = 10, left lobe: n = 31). The median number of needle passes was 2.4±0.8 (range, 1–5). Technical success rates for tissue acquisition were 97.6%, but both specimen adequacy for histology and available HIC stain was 92.6%. Three (74%) patients were non-diagnostic and subsequently proved to be malignant; 1 by smear cytology and 1 after surgical resection. The diagnostic yield, sensitivity and specificity of EUS-FNB for the diagnosis of malignancy were 92.6%, 92.6% and 100%, respectively. The diagnostic yield in 25G PCN and 22G PCN was significantly higher than 20G PCN (p = 0.045). There was one bleeding complication, but controlled with endo- scopic hemostasis with endoclip.

Conclusion: EUS-FNB with core biopsy needle may be a safe and useful modality in the management of patients with hepatic solid mass. Moreover, 25G and 22G FNB may be adequate for liver biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly-diagnosed HCC patients with ascites (mean age = 56.0 y, male = 74.8%, hepatitis B virus = 73.2%) were analyzed. We compared Child-Pugh score, Model for End-stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival.

Results: During a median 9.0 months of follow-up (range; 0.1-154.0), mortality was observed in 212 (48.5%) patients. MELD-Na showed highest time-dependent area under receiver-operating characteristics curves (AUROC)s at 1 year (0.672) that was significantly higher than ALBI grade (0.605), MELD score (0.580), and Child-Pugh score (0.580). The median survival was significantly lower for those with MELD-Na < 12 than MELD-Na ≥ 12 (median: 13.6 vs. 3.7 months, p < 0.001). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by radiofrequency ablation (15.7%) and resection (13.4%). Overall survival was significantly different among those who received treatment than those who did not (median survival: 13.3 vs. 2.4 months, p < 0.001). When patients were further stratified by mUCC stage and MELD-Na score, treatment was not associated with better outcome for mUCC stage IV patients with MELD-Na ≥ 12 (median survival: 22.2 vs. 1.8 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups.

Conclusion: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, indicating that apnea on the use of percutaneous needle is not absolute. Treatment efficiency for HCC treatment. For these patients, MELD-Na showed better performance than MELD, Child-Pugh per se.

P0075 ADHERENCE TO BARCELONA CLINIC LIVER CANCER GUIDELINES IN FIELD-PRACTICE: RESULTS OF PROGETTO EPOTACARCINOMA CAMPANIA

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients’ survival.

Aims & Methods: We analyzed the region-wide Italian database of Progetto Epotacarcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 regional centers.

Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapy recommended by BCLC algorithm, while 29.4% underwent different treatment. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP > 200 ng/mL, more early stage and monofocal HCC, lower frequency of nodules > 5 cm, portal vein thrombosis and metastases were observed. The multivariate analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes C-B, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5 months, while in patients managed differently was 31.9 months (p < 0.001).

Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required.

P0076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common cause are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, etc. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression.

Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People’s Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group

Contact Email Address: medicalcyan@qq.com

Disclosure of Interest: All authors have declared no conflicts of interest.
were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHOQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SPS). The questionnaire scores of the two groups were analyzed.

Results: A total of 95 valid questionnaires were collected and divided into cirrhosis group (n = 40) and control group (n = 45). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081, showing no difference from cirrhosis group. WHOQOL included four domains: physiological domain, psychological domain, social relationship domain, and environment domain. The scores of liver cirrhosis group: physiological field (22.23 ± 3.312), psychological field (19.59 ± 3.925), social relationship field (9.64 ± 2.497), environment domain (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological field, 19.87 ± 3.152 in psychological field, 10.58 ± 2.061 in social relation field and 28.36 ± 5.091 in environmental field), they had no significant difference between the two groups (P > 0.05). The depressions in the cirrhosis group: self-rating anxiety scale (SAS) 7.534 was significantly higher (P = 0.034) than that of control group (42.61 ± 11.564). Meanwhile, there was no significant difference between the Self-rating Anxiety Scale scores of the cirrhosis group (38.46 ± 11.917) and control group (37.00 ± 12.521) (P > 0.05) (Table 1).

### P0077  THE IMPORTANCE OF INDIVIDUAL CORRECTION OF EATING BEHAVIOR IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Y. Nikiforova
Department For The Study Of Diseases Of The Liver And Gastrointestinal Tract (from 05.2016 Year - Department Study Of Digestive Diseases And Their Comorbidity With Non-communicable Diseases), St.-L.T. Mula Therapy Institute of NAMS of Ukraine, Kharkov/Ukraine

Contact E-mail Address: dr.jana@mail.ru

Introduction: At the present stage, the treatment of patients with non-alcoholic fatty liver disease has insufficient effectiveness due to the simultaneous availability of a number of recommendations and the lack of an individual approach. Not enough attention is paid to the study of nutritional behavior and the role of nutraceutics, as additional risk factors for the development of non-alcoholic fatty liver disease, methods for studying the characteristics of eating behavior should be applied more widely, which will allow timely appropriate correction. A more extensive study of nutrigenetics will make it possible to designate a personified diet, taking into account the detected polymorphisms, which will make it possible to achieve a significant improvement in metabolic parameters in this category of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Pavlov First Saint Petersburg State Medical University, Saint-Petersburg/Russian Federation

Contact E-mail Address: liya73@mail.ru

Introduction: Non-alcoholic fatty liver disease (NAFLD) is liver disease with histological signs of accumulation of cholesterol excessive amount in hepatocyte in the absence of alcohol consumption by the patient (due to causes other than). The search for accessible, non-invasive and effective methods of screening for this pathology, allowing to detect NAFLD at early, potentially reversible stages of development is relevant. The purpose of the work was frequency estimation of the prevalence of steatosis according to elastometry with controlled attenuation parameter (CAP®) among young people and associated with them specific body composition.

Aims & Methods: 59 volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in research. There were 22 (37.3%) men and 33 (62.7%) women among them without verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the risk factors, the prevalence of steatosis in the said group of patients was performed with the apparatus FibroScan 502 Touch. The final figures of elasticity of the liver were estimated in KPa (METAIVR). The controlled attenuation parameter (CAP®) in dm3 was used for the severity of steatosis. Moreover, there was the bioelectrical impedance analysis of body (BIA), evaluated: body mass index (BMI), body fat.

Results: The signs of violations of the structure of the liver were diagnosed in 15 people out of 59 (25.4%). The signs of steatosis were found in 12 (20.3%) students. The signs of liver rigidity were found in 7 (11.9%) people (E > 5, 8KPa). At the same time the combination of liver fibrosis and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal in 23 (40, 3%) people; within fat body composition the normal values in 19 (33, 4%). Results of binary regression analysis showed that the chance of development of hepatic steatosis in case of excess adipose tissue increase 28 times (p = 0.045), influence of BMI, gender, age was statistically insignificant.

Conclusion: Based on the results obtained, it can be concluded that there is high enough level of distribution of liver steatosis among young people. Transient elastography (TE) with controlled attenuation parameter (CAP®) is a fast, reliable, repeatable non-invasive method for the assessment of NAFLD. The development of hepatic steatosis among practically young healthy persons validly associated with the increase the amount of adipose tissue in the body. Confirmed the importance of evaluation of body composition and lack of information of using only BMI when evaluating the chances of development of NAFLD.

P0080 SALVAGE TECHNIQUE USING A MICRO GUIDEWIRE FOR DIFFICULT BILIARY CHOLANGIOPANCREATOGRAPHY

Ichinomiya Nishi Hospital Dept. of Gastroenterology, Ichinomiya/Japan

Contact E-mail Address: a-mori@anzu.or.jp

Introduction: Biliary cannulation is indispensable for therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in patients having biliary disease. Selective biliary cannulation is often difficult due to anatomical constraints. Numerous techniques have been attempted to overcome such problems. Although a wire-guided selective cannulation technique into the bile duct is a useful approach, conventional guidewires (0.025 or 0.035 inch) are relatively rigid and prone to get entrapped in the long curved narrow distal segment (NDS) or malignant stricture and sometimes get cocked off the NDS in such cases. It may be better to use finer and more flexible guidewire. Hence, we developed a novel guidewire technique using a micro guidewire technique for performing a precut papillotomy, endoscopic ultrasound-guided techniques or performing a precut papillotomy, endoscopic ultrasound-guided biliary drainage and one was interrupted because of developed serious condition.

Conclusion: GTWt as a salvage technique for unsuccessful selective biliary cannulation cases improves the success rate of ERCP, and could be attempted before performing a precut papillotomy, endoscopic ultrasound-guided techniques or other cumbersome procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0081 ERCP IN VERY ELDERLY PATIENTS AGE 85 OR OLDER

M.T. Ayoubi1, Khajekin1, F. Castellino1, N. Leone1, M. Berruti2, G. Sансол1, L. Framarr1, A. Repici2

Contact E-mail Address: ayoubi@libero.it

Introduction: To evaluate the safety and effectiveness of this procedure (ERCP) in patients age 85 years and older.

Methods: From first January 2010 until end December of 2016 in our digestive unit 3153 patients underwent ERCP, including 315 (11.3%) patients over 85 years. Characteristics of these patients: The mean age was 89 (range 85–99), 117 males and 254 females. 43 (12.2%) were in treatment with antithrombotic drugs. The initial diagnosis in 218 patients (61.2%) was choledocholithiasis, malignant CBD stones in 92 patients (29.5%), postoperative leak in 11 patients (3, 13%) and unknown CBD stones in 31 patients (8,83%). All patients underwent the following clinical evaluation before and after ERCP. 34 patients underwent antibiotic therapy. The endoscopic success of ERCP in cases of choledocholithiasis was 98,2% and for malignant CBD stones was 82, 6%.

Results: Among 40 ERCP-naive patients, 40 were ERCP-difficult-cases, 97% (232/240 patients). After ERCP with GTWt, four patients developed mild acute pancreatitis, which resolved in a few days. No serious procedural accidents were reported. The 40 ERCP-difficult cases included 22 patients with a long curved NDS, six patients with juxtapapillary duodenal diverticulum, six patients with malignant stricture, and four patients with difficult front view of papilla. Among eight patients who failed with GTWt, seven were successful performing precut papillotomy or endoscopic ultrasound-guided biliary drainage and one was interrupted because of developed serious condition.

Conclusion: GTWt as a salvage technique for unsuccessful selective biliary cannulation cases improves the success rate of ERCP, and could be attempted before performing a precut papillotomy, endoscopic ultrasound-guided techniques or other cumbersome procedures.

P0082 ALCOHOL CONSUMPTION CAN REDUCE THE RISK OF GALLSTONE DISEASE: A SYSTEMATIC REVIEW WITH Dose-Response META-ANALYSIS OF CASE-CONTROL AND COHORT STUDIES

B.H. Cha1, M. Jang2

1Sheikh Khalifa Specialty Hospital, Ras Al Khaimah/United Arab Emirates
2Medical Research Collaborating Center, Seoul National University Hospital, Seoul, Korea, Republic of

Contact E-mail Address: doctorhyo@gmail.com

Introduction: Gallbladder stone (GBS) is a common gastrointestinal disease can progress to severe cholecystitis and is a strong risk factor for gallbladder cancer (GBC). Recently, clinical epidemiologic studies revealed that the alcohol consumption has a protective effect for development of gallstone diseases. However, the relationship between alcohol consumption and gallstone disease development risk is still not completely determined.

Methods: We performed a comprehensive search of MEDLINE, EMBASE and Cochrane library from January 1st, 1996, to December 31st, 2016 for studies assessed the relationship between alcohol consumption and gallstone disease development risk. The eligibility criteria was included: 1) studies involving the patients with gallbladder stone with or without cholecystitis; 2) cohort or case-control studies investigated the association between alcohol consumption and gallstone disease development. Newcastle-Ottawa Scale was used to assess the methodologic quality of each studies. Data was obtained from each selected studies regarding: 1) baseline characteristics of the study (cohort, case-control); 2) number of participants; 3) participants’ clinical features; 4) country; 5) publication year; 6) Risk or odds ratios with 95% confidence intervals of alcohol consumption and risk of gallstone. The random effect model was used to estimate the pooled relative risks (RR) with 95% confidence intervals (CIs).

Results: Twenty-five cohort and case-control studies were included, and total 12, 581 cases with gallstone diseases among those 172, 509 controls. Alcohol consumption indicated a decreased risk of GSD development (Pooled RR = 0.84 [0.79–0.90], P < 0.001). Subgroup analyses according to the alcohol doses (g/day) confirmed a gradual risk-reduction effect on GSD compared to non-drinkers (Light: RR = 0.97 [0.94, 1.00], p = 0.864; Moderate: RR = 0.82 [0.79, 0.86], p = 0.777; Heavy: RR = 0.70 [0.62, 0.80], p < 0.01).

Disclosure of Interest: All authors have declared no conflicts of interest.

A188

United European Gastroenterology Journal 5 (S5)
Conclusion: In this systematic review with meta-analysis, alcohol consumption has a dose-dependent negative co-relationship with the risk of gallstone disease development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0083 ERCP WITH SHORT-TYPE SINGLE BALLOON ENTEROSCOPE IN PATIENTS WITH SURGICALLY ALTERED PATIENTS
M. Kida1, H. Yamautchi1, Y. Kawaguchi1, E. Miyata1, R. Hasegawa1, T. Kaneo1, K. Okuwa1, T. Iwa1, H. Kikuchi1, H. Imaizumi2, W. Koizumi2
1Endoscopy & Gastroenterology, Kitasato University, Sagamihara/Japan
2Gastroenterology, Kitasato University School of Medicine, Sagamihara/Japan

Contact E-mail Address: m-kida@kitasato-u.ac.jp

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is challenging in patients who have undergone surgical reconstruction of the intestine. In 2001, double-balloon enteroscope (DBE) was reported by Yamamoto et al to be an effective procedure for the diagnosis and treatment of small intestine diseases. Since 2005, single-balloon assisted ERCP was first successfully by Haruta et al used to treat a large anastomotic stricture in a patient who undergone biliary reconstruction by R-Y choledochojunostomy after liver transplantation. After that, several studies with long enteroscope have reported that balloon enteroscope-assisted ERCP (B-ERA-CP) is a safe and effective procedure with about 69–100% of reaching the blind end. However long type enteroscope allows us to use limited number of ERCP devices because of its length 200 cm. Then Olympus Co. introduce the prototype of short single balloon enteroscope (SBE) with a bigger channel 3.2 mm in diameter was developed. We will present its usefulness and limitation.

Aims & Methods: In order to investigate the usefulness and limitation of short-type SBE, we have performed totally 183 cases/302 procedures of ERCP with short-type SBE (30 patients with B-II (24 cases, 30 procedures), R-Y gastrectomy (RY; 94, 138), Hepatico-Jejunostomy without gastrectomy (HJ; 29, 58), and Child/Whipple (CW; 36, 76) from 2009 to 2016. We have investigated its rate of reaching blind end, time of procedure, success rate of therapeutic procedure, complications and its limitations.

Results: Using short type SBE, the rate of reaching blind end is B-II: 97% (29/30), R-Y: 91% (126/138), HJ: 72% (39/58), CW-95% (71,76), and 88% (totally). Success rate of therapeutic procedure in reached blind end cases, is B-II: 100% (27/27), R-Y: 96% (104/108), HJ: 94% (34,36), CW-100% (67,67), and 97% (232/238) totally. The average time of procedure is B-II: 38.6 min, R-Y: 47.2, HJ: 38.5, and CW:44.3, respectively. The reason of unreached cases in HJ without gastrectomy. 238) totally. The average time of procedure is B-II: 38.6 min, R-Y: 47.2, HJ: 38.5, and CW:44.3, respectively. The reason of unreached cases in HJ without gastrectomy.

Conclusion: ERCP with short-type SBE in patients with surgically anatomy is feasible with high success rate, except for cases with HJ without gastrectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0084 CHOLECYSTECTOMY FOLLOWING ENDOCOSCOPIC RETROGRADE CHOLANGIOGRAPHY AND DUCT CLEARANCE FOR CHOLEDOCHOLITHIASIS: A SINGLE CENTRE EXPERIENCE FROM UNITED KINGDOM
F. Rana1, D. Majumdar2, P. Sambaia1, D. Craig1, J. Greenaway1, V. Mitra1
1Dept. Of Gastroenterology, James Cook University Hospital, Middlesbrough/United Kingdom
2Dept. Of Gastroenterology, James Cook University Hospital, Middlesbrough/United Kingdom

Contact E-mail Address: fahdrana@outlook.com

Introduction: Patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and duct clearance for common bile duct stones (CBDS) should be followed up with an early cholecystectomy to prevent recurrent biliary complications (1, 2) and acute gallstone pancreatitis. Recently the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) recommended that definitive eradication of gallstones by cholecystectomy prevents the risk of a recurrent attack of acute pancreatitis (AP). For patients with an episode of mild acute pancreatitis, early definitive surgery should be undertaken, either during the index admission of or within two weeks (3, 4).

Aims & Methods: 1) To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS between 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. All patients were followed up for a minimum period of 2 years following their ERCP.

Results: Of 273 patients underwent ERCP for CBDS. Out of these 21.2% (n = 58) had previously had CCX and were excluded. Out of the remaining 215 with gall bladder (GB) in situ, 87.4% (188/215) underwent successful duct clearance at index or subsequent ERCP. Of these, 47.3% (89/188) underwent CCX (218/188) patients were currently awaiting CCX and 51.6% (97/188) did not undergo CCX. The outcomes in remaining 13.4% (n = 27) patients in whom duct clearance was not achieved are discussed later. In the CCX group, the median time between ERCP/duct clearance and CCX was 123 days (range 0–89 days). In this group, 113 patients had gall stone pancreatitis (GSP) on presentation and the median time between ERCP and CCX in the GSP group was 136 days (range 35–287 days); 12 of these had mild pancreatitis with a median time to CCX of 140 days (range 60–287 days). 4 patients re-presented with CBDS while awaiting CCX after duct clearance; 1 had pancreatitis on readmission. 51.6% (97/188) patients who did not undergo CCX after duct clearance are referred to as non-cholecystectomy (non-CCX) group. This was mainly secondary to high ASA grade. We compared patient demographics and presentation with the CCX group and the results were as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>CCX group (n = 89)</th>
<th>Non-CCX group (n = 97)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Median Age</td>
<td>61 years</td>
<td>79 years</td>
</tr>
<tr>
<td>Median ASA grade</td>
<td>1</td>
<td>2.8</td>
</tr>
<tr>
<td>Female patients</td>
<td>67%</td>
<td>56%</td>
</tr>
<tr>
<td>Male patients</td>
<td>33%</td>
<td>44%</td>
</tr>
<tr>
<td>Pancreatitis on presentation</td>
<td>17%</td>
<td>11.4%</td>
</tr>
<tr>
<td>Readmission with CBDS</td>
<td>4.5%</td>
<td>5.4%</td>
</tr>
</tbody>
</table>

In 27 patients duct clearance was not achieved; 26% (7/27) underwent surgical management (CBD exploration on table cholangiogram and CCX). The remaining 74% (20/27) patients were deemed unsuitable for invasive intervention and were either for symptomatic stent change only or conservative management.

Conclusion: The time period between duct clearance and CCX was longer than anticipated, especially in patients with mild acute pancreatitis as none of them underwent CCX during index admission or within 2 weeks of ERCP/duct clearance. Some patients re-presented with CBDS while awaiting CCX. We looked into potential causes of delay in CCX – delayed referral to surgery, long waiting time for elective CCX and patient choice. We propose to develop a local pathway for patients with CBDS and gallstones and induce a robust system for referring patients for CCX following duct clearance. This would help to minimize readmission and potential complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0085 THE DEVELOPMENT OF MULTI-LAYER DRUG ELUTING MEMBRANE USING ULTRASONIC SPRAY COATING TECHNIQUE
J. Park1, D.H. Lee2
1Internal Medicine, Inha University School of medicine, Incheon/Korea, Republic of
2Inha University School of medicine, Incheon/Korea, Republic of

Contact E-mail Address: psinha@naver.com

Introduction: The placement of self-expandable metallic stent has become the treatment of choice to restore luminal patency in the palliative treatment of unresectable malignant biliary stricture. Currently, drug-eluting stents (DESs) are developed to prevent tumor invasion into the stent and to prolong stent patency. However, the capacity of drug per unit area varies with the position in membrane, and the control of drug release is impossible in current available DESs.
Aims & Methods: The aim of current study is to develop the multi-layer drug eluting membrane using ultrasonic spray coating method, which have uniform capacity of drug and be able to control the drug-release capacity. Methods: The drug eluting membrane was made using ultrasonic spray coating machine (MediCoat-2JX). The membrane consists of two kinds of coating material. One is silicone (MED-6640), that was used to basic structure of membrane and the other coating agent is polyurethane (tecphilic, tecotane, Tecoflex and pellettane). The gemcitabine was used as antitumor drug, and coated to membrane by mixed form with polyurethane (gemcitabine, 250μg/ml; polyurethane, 500μg/ml). The thickness of membrane and the capacity of drug in membrane were measured at the proximal and distal end, and mid portion. The drug release capacity and duration was measured by using drug releasing test in vitro for 3 days. Results: The mean thickness of membrane was 50um. The mean capacity of drug per unit area was 100μg/cm², and the amount was constant in all tested area (Standard deviation, 5μg/cm²). In drug release test, the capacity of releasing drug was different depended on the kinds of polyurethane. The total amount of released drug in 24hrs was 919 μg, 858 μg, 868 μg in tecphilic coating, tecotane coating, tecoflex coating, and pellettane coating. The total of released drug amount depended on polyurethane was described in table 1.

<table>
<thead>
<tr>
<th>Drug release amount</th>
<th>Gencitabine (ug)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coating Polymer</td>
<td>24hrs</td>
</tr>
<tr>
<td>Tecophilic</td>
<td>919</td>
</tr>
<tr>
<td>Tecothane</td>
<td>819</td>
</tr>
<tr>
<td>Tecoflex</td>
<td>681</td>
</tr>
<tr>
<td>Pellettane</td>
<td>580</td>
</tr>
</tbody>
</table>

Conclusion: The ultrasonic spray coating technique could be applied to make multi-layer drug eluting membrane with regular thickness. The membranes contained the uniform capacity of drug in all tested area. The releasing drug capacity is able to control by applying different kind of polyurethane.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Local treatment of primary bile duct cancer is a challenge and endoscopic stent insertion is widely used to maintain the bile duct patency. Drug eluting stent is currently developed to add the ability of antitumor effect.

Aims & Methods: We aimed to evaluate the anti-tumor effect of the paclitaxel, gemcitabine, and mitomycin C-eluting polyurethane membrane in a tumor model. Total of 24 mice were used in current study and divided into four groups, each group had six mice. Membranes containing different antitumor drugs (paclitaxel, gemcitabine, mitomycin C, 100μg/disc) were inserted beneath the tumor mass in mouse models. Tumor size and body weight of the tumor model were monitored for 22 days after insertion of the membrane. The results were compared with the tumor model which was inserted only silicone membrane (control).

Results: Tumor volumes on day 22 of membrane treatment were decreased in all drugs, that were significantly different compared to those of control (paclitaxel, 291.77mm³, P value = 0.4116; gemcitabine, 63.38mm³, P value = 0.0001; mitomycin C, 119.02 mm³, P value = 0.0029; control 136.26mm³). The antitumor effect of gemcitabine was tended to be superior compared to other drugs. However, it was not statistically different. No significant difference in body weight change was observed among groups.

P0087 ADVANCES IN CYTOLOGY FOR THE EARLY DIAGNOSIS OF PANCREATICO-BILIARY MALIGNANCY

C. Meredith1, P. Irandoust2, P. Baird3
1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/ Australia/NSW
2Cytology, Lavery Pathology, Ryde/Australia/NSW

Contact E-mail Address: dcmeredith@gmail.com

Introduction: Liquid-based sample preparations for cytology have improved the cellular yield in pancreatobiliary (PB) malignancy.2-4 The SurePath (SP) method-ology produces a pellet of concentrated cellular material which enables addi-}

ational slides for immunohistochemical (IHC) staining for tumour markers Ki67, p53 and CDX2. The presence of the mitosis-related marker, Ki67, in high con-centration with a specific pattern adds a level of confidence in diagnosing malignancy using cytological preparations. The aim of this study was to assess Ki67 staining in biliary epithelium obtained from patients with bile duct obstruction.

Aims & Methods: Brushings were obtained from the common bile duct during endoscopic retrograde cholangiopancreatography (ERCP) in patients presenting with biliary obstruction. After collecting the sample, the brush was placed imme-diately into a SurePath vial and shaken vigorously for 20 to 30 times to disrupt the cells. In the cytocentrifugation laboratory, the vial (with brush included) was agitated on a platform vortex for 10 minutes to shake the cells off the brush into the solution. The high cellular content enabled the preparation of multiple slides for IHC and these slides were reviewed independently by two senior cytopathologists.

Results: Thirty-four (34) consecutive patients with bile duct obstruction were included in the study. The cohort had a mean age of 70.2; 41% were female. Adenocarcinoma was identified in 19 (56%) and atypical/reactive cells in 9 (26%). Ki67 positive nuclei were present in 90–100% of the cells in malignancy cell clusters, while sheets of normal cells had positive nuclei in less than 20% of cells. Atypical cells sheets had an intermediate percentage range.

Conclusion: SP is superior to conventional slide-based cytology preparations in the diagnosis of malignant bile duct strictures. Advantages include ease of collect-}

ion, no requirement for a cytology technician, a sizable pellet of intact cells for the cytopathologist to examine and the ability to undertake IHC staining. Ki67 is a marker of cell division and cells stained with Ki67 are increased significantly in adenocarcinoma as confirmed by this study. The presence of a large number of cells stained with Ki67 as well as the pattern of intracellular staining adds a level of confidence for the cytopathologist to diagnose malignancy, particularly when there is no clinical or scan evidence of a tumour mass. Early diagnosis is the key for curative surgery and specific cell tumour markers &/or their pattern may impact significantly on the outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0088 IMPACT OF PALLIATIVE BILIARY DRAINAGE BETWEEN METAL STENT AND PLASTIC STENT ON SURVIVAL RATE IN UNRESECTABLE DISTAL MALIGNANT BILIARY STRICTURE IN SOUTH OF THAILAND

P. Chattaranapakitakul, B. OvatIlarnpon, N. Nethitsunton
Faculty Of Medicine, Prince Of Songkla University, NCI Institute of Gastroenterology and Hepatology, Hatyai/Thailand

Contact E-mail Address: tanawat_kuey@hotmail.com

Introduction: Palliative biliary drainage was used to improving obstructive jaun-
}

dice, nutritional status, quality of life along with survival rate in unresectable distal malignant biliary stricture patients. The ERCP with biliary drainage with or without systemic chemotherapy are mainstay of treatment in these patients. The benefits of biliary stent drainage which are different in cost on survival rate, nutritional status and efficacy of biliary drainage in DMBS patients are still questionable in limit health budget country.

Aims & Methods: We aimed to assess the impact of endoscopic palliative biliary drainage stents on survival rate, nutritional status and efficacy of biliary drainage of patients in distal biliary malignant stricture patients. All of the computerized medical records of distal biliary malignant stricture patients, who were undergoing endoscopic biliary drainage from January 01, 2012 to December 30, 2015 in Songklanagarind Hospital were retrospectively review. ERCP with biliary drainage stents was undertaken at the discretion of attending physicians. The overall survival rate, nutritional status (body weight), efficacy of biliary drainage (level of total bilirubin) after biliary drainage between the metal stent group, plastic stent group and plastic stent followed with metal stent group were compared.

Results: Sixty eight patients (45 males, mean age 63.7±14.8 years) were enrolled, 35 patients were classified into the plastic stent group, 18 patients were classified into the metal stent group, which are different in cost on survival rate, and 15 patients were classified into the plastic stent followed to metal stent group. Demographic data, primary malignancy, tumor staging and ECOG score, initial total bilirubin and stricture length were similar between 3 groups. The median survival time was 5.4 months for 95% CI (3.2–8.5) and overall survival rate was lowest in the metal stent group (median 3.2 months 95% CI 1.8–6.9). Mean weight reduction and the declining of total biliary after biliary drainage were not significantly different between biliary
Aims & Methods: Between January 2006 and March 2016, a total of 185 advanced or recurrent BTC patients receiving a first line systemic chemotherapy for at least two cycles were retrospectively studied. Serum CA 19-9 was measured at baseline (CA19-9_Pre) and after two cycles of chemotherapy, and patients were categorized into three groups based on CA19-9 response: CA19-9 decrease group (≥30% decrease), stable group (<30% decrease and ≥20% increase) and increase group (≥20% increase). The Cox proportional hazards model was used to analyze the prognostic factors for OS and PFS, using the landmark method.

Results: The primary tumors were located as follows: 68 (37%) in intrahepatic cholangiocarcinoma, 47 (26%) in ampulla cancer, 13 (7%) in neuroendocrine tumor, and 12 (7%) in recurrent biliary tract cancer. The median CA 19-9 levels at baseline and after two cycles were 264 IU/mL and 194 IU/mL, respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median OS obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median PFS and OS were 5.2 months (95% confidence interval [CI], 2.9–13.2) and 13.71 months (95% CI, 11.38–22.06). There was a statistically significant trend for CA 19-9 and RECIST responses (p = 0.03). Compared with CA19-9 decrease group, hazard ratios for stable and increase groups were 1.22 (95% CI, 0.79–1.87) and 2.54 (95% CI, 1.68–3.85) for OS (p for trend 0.15). Multivariable analyses showed that CA19-9 response was prognostic both for OS and PFS in addition to CA19-9_Pre and performance status.

Conclusion: CA 19-9 response after two cycles as well as baseline served as a prognostic factor for OS and PFS in patients with advanced and recurrent BTC on systemic chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0089 PROGNOSTIC VALUE OF EARLY CA19-9 RESPONSE DURING CHEMOTHERAPY IN PATIENTS WITH ADVANCED OR RECURRENT BILIARY TRACT CANCER
N. Takahara1, Y. Nakai2, K. Saito3, T. Nakamura4, T. Sato2, T. Takeda2, R. Uchino1, S. Mizuno1, H. Kogure1, S. Matsubara1, M. Tada1, H. Isayama2, N. Takahara1

Aim: The aim of this study was to investigate the feasibility and clinical impact of early CA19-9 measurement in patients with advanced or recurrent BTC receiving systemic chemotherapy. A total of 165 patients receiving two cycles of chemotherapy were analyzed.

Method: Serum CA 19-9 levels were measured at baseline and after two cycles of chemotherapy. CA 19-9 response was categorized into three groups: increase (≥20% increase), stable (0%–20% increase), and decrease (<20% decrease). Kaplan-Meier survival analysis and multivariate Cox regression analysis were performed to identify the prognostic factors for overall survival (OS) and progression-free survival (PFS).

Results: A total of 165 patients were included in the analysis. The median OS and PFS were 15.6 months and 6.8 months, respectively. The 1-year OS and PFS rates were 63% and 50%, respectively. The median CA 19-9 levels at baseline and after two cycles were 81 IU/mL and 42 IU/mL, respectively. The CA 19-9 decrease group had a significantly better OS (median 19.8 months vs. 12.6 months, p = 0.007) and PFS (median 7.8 months vs. 4.9 months, p = 0.02) compared to the other groups. Multivariate analysis showed that CA 19-9 response was an independent predictor of OS and PFS.

Conclusion: Early CA 19-9 measurement during chemotherapy could be a potential prognostic factor for OS and PFS in patients with advanced or recurrent BTC.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
and data on the biliary drainage procedure were collected from medical records. Definitions of failure of drainage or other severe drainage related complications are shown in table 1.

Results: In total, 187 patients were included. Initial drainage was performed in a non-referral center in 125 patients (66.8%). The initial drainage procedure was endoscopic in 158 patients (84.5%) and percutaneous in 29 patients (15.5%). A stent was placed in 91 patients (61.5%) at the initial drainage procedure. The highest bilirubin level in the 2 weeks prior to drainage was 248 (IQR 138–377) µmol/L. Only 14 (8.1%) patients had cholangitis prior to the initial drainage procedure. Failure of drainage or other severe complications related to the initial drainage procedure were noted in 117 (62.6%) patients. Failure of drainage or reintervention was most common and was noted in 85 patients (50.8%). Bile duct injury occurred in 3 (1.6%) patients, acute pancreatitis in 5 (2.7%) patients and cholangitis in 11 (5.9%) patients. Two (1.1%) patients had cardiopulmonary complications and 1 (0.5%) patient had a duodenal perforation. The median period until the initial and second drainage procedure was 13 (5–31) days and the bilirubin level dropped below 50 µmol/L in 27 patients (14.4%). After initial drainage, 20 patients (10.7%) died within 30-days and 66 patients (35.3%) within 90 days. The median OS after initial drainage was 6.6 (95% CI: 2.0–15.2) months.

Conclusion: Patients with unresectable PC on imaging have a very high failure and complication rate after initial biliary drainage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0093 UNILATERAL VERSUS BILATERAL STENT-IN-STENT PLACEMENT OF METAL STENTS FOR MALIGNANT HILAR BILIARY OBSTRUCTION

H. Toyonaga, Y. Taniguchi, T. Inokuma
Gastroenterology, Kobe City Medical Center General Hospital, Kobe/Japan
Contact E-mail Address: toyonaga.pc@gmail.com

Introduction: Endoscopic biliary stenting is widely accepted as effective palliation therapy for unresectable malignant hilar biliary obstruction (MHBO). Although draining more than 50% of liver volume is associated with better outcomes, it is technically difficult. We retrospectively reviewed 23 consecutive patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group). In the Uni group, we placed one SEMS. In the Bi group, we placed crossed wired metal stents with the SEMS technique. Technical success rates, complication rates and stent patency were compared between groups.

Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups (p = 0.669).

Conclusion: Endoscopic bilateral SEMS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0094 CLINICAL ASSESSMENT OF THE SAFETY AND EFFICACY OF A NOVEL BIODEGRADABLE STENT IN PATIENTS WITH BILIARY OBSTRUCTION: A PILOT STUDY

H. Olthman1, N.Y. Yaacob2, E.J. Koslak3, R. Jarmin1, Z. Mohamed2

Introduction: The commonest indication for biliary stent is for the treatment of obstructive jaundice and for the management of bile leak. The currently available stents are made of either plastic or metal alloy. The stents can be inserted endoscopically to provide internal drainage of the bile into the duodenum. Among the disadvantages of plastic stents are recurrences of jaundice due to biofilms formation, which require a repeat ERCP procedure to remove the stent before 3 months. We have embarked to study the safety and feasibility of a biodegradable biliary stent (BiBS), which can treat biliary obstruction without the need to undergo a repeat endoscopic procedure to remove the stent.

Aims & Methods: This is a pilot study enrolling 30 subjects with symptomatic jaundice and pruritus caused by either benign or malignant biliary obstructions that were amenable to treatment by ERCP guided stenting. Primary objective was technical success and safety. Procedural and technical successes were assessed during the stenting procedure. Adverse events or complications were monitored throughout the studies. The secondary endpoints were clinical success, which was measured by a reduction of at least 20% of the initial serum bilirubin level at Day 7 post stenting. A simple self-assessment scale from 0 to 10 was used to assess quality of life before and after the stenting.

Results: 30 patients had the Biodegradable Biliary Stent (BBS) implanted. 18 patients (60%) were males, the mean age was 56.9 years, 26 patients (86.7%) had benign biliary duct disease and 4 (13.3%) patients had malignant condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

9 patients had the fast and medium degradation stents respectively and 12 had the slow degradation stents implanted. All stents were 3-mm in diameter and the length ranges from 60 to 120 mm depending on the level of obstruction. It took an average of 29.6 minutes to complete each procedure, and the mean stent deployment duration was 6.0 minutes. It ranges from 13.5 minutes in the initial phase and improved to 1.5 minutes in the later phase. Biliary sphincterotomy was not made in single biodegradable stents, but however, all patients with biliary stone had sphincterotomy to facilitate retrieval of the stones. Serum bilirubin level (SBL) showed reduction of 52% from the mean SBL of 54.9 mol/L prior to stenting to 26.2 mol/L at Day 7. Quality of life score improved from 2.0 up to 8.5 after stenting. The BBS ranks high in terms of loadability, tractability over guide-wire, and pushability with push catheter. There was minimal force required to implant it and it has good visibility by fluoroscopy. The BBS is as flexible as the conventional plastic stents and can be accurately deployed under fluoroscopy. Technical success or completion of the ERCP and stent deployment was achieved in all 30 patients.

Conclusion: This pilot study has shown encouraging results. It benefit the patient to avoid the burden of a second ERCP procedure for plastic stent removal. However, these results should be interpreted with caution as this is a pilot study to assess the safety and efficacy of the biodegradable stent on limited number of volunteers with symptomatic jaundice. We plan to conduct a phase 2 study involving a larger number of cohorts with a more specific indication of benign and malignant biliary stricture.

Disclosure of Interest: H. Othman: The Biodegradable Biliary Stents used for this study is sponsored by ang International GmbH, Winsen, Germany. The authors have no financial relationship with the company which could inappropriate influence or bias the content of this presentation. All other authors have declared no conflicts of interest.

Introduction: Stellate cells contribute significantly to the development of several diseases. In particular, liver stellate cells are responsible for liver fibrogenesis and further for cirrhosis that culminates into cancer development eventually. In pancreas, it is known that stellate cells sustain the tumor cells via autophagy mechanism.

Aims & Methods: This study aimed to clarify the involvement of Toll-like receptor 5 (TLR5) in the activation of human stellate cells. LX-2 liver stellate cells and HPSC (human pancreatic stellate cells) were treated for 48 hours with 2.5 ng/ml TGF-beta 1. The analysis of activation markers was performed by RT-qPCR, western blotting and immunofluorescence. Real-time cell monitoring with Incucyte was performed. TLR5 PCR Array was performed. TLR5 knock down was obtained with commercially validated siRNAs.

Results: Treatment with 2.5 mg/ml TGF-beta 1 caused the activation of both LX2 and HPSC cells. Over-expression of alpha-smooth muscle actin (a-SMA) and collagen 1 (COL1A1) transcripts was observed. The protein level of a-SMA and COL1A1 significantly increased also. Interestingly, SNAI1, SLUG, TLR3 and TLR4 transcripts were induced by treatment with TGF-beta 1 in both cell lines. SNAIL 1 was over-expressed at protein level also. Knock down of TLR5 neutralized the activity of TGF-beta 1 by keeping the expression of the above markers at basal level or even not expressed.

Conclusion: TLR5 for the first time, has been identified as key player of the activation of stellate cells. Its contribution represents a new aspect in terms of interaction between immune system and stellate cells and could represent a potential new target for the diseases of the gastrointestinal tract involving the activity of stellate cells. TLR5 and its natural agonist flagellin could be a key link between impairment of microbiota and organo-fibrosis in the gastrointestinal tract.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The cystic fibrosis transmembrane conductance regulator (CFTR) has a major role in pancreatic ductal secretion and it’s genetic defects damage the pancreas. It is known that intracellular Ca2+ homeostasis is disturbed in bronchial epithelial cells in cystic fibrosis (CF), but the connection of CFTR and the intracellular Ca2+ signaling has never been suggested in pancreatic damage in CF.

Aims & Methods: Our aim was to characterize the Ca2+ homeostasis of CFTR-deficient PDC. Wild type (WT) and CFTR knockout (KO) mouse pancreatic ductal and acinar cells and iPSC (induced pluripotent stem cell) derived human organoids from 2 CF patients and controls, human CF pancreas cell line (CFPAC-1; ΔF508 mutant) were used for intracellular Ca2+ measurements. Mitochondrial membrane potential (ΔΨm) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

Results: The plateau phase of the agonist-induced Ca2+ signal was elevated in CFTR-deficient PDC, which was caused by decreased function of the plasma membrane Ca2+ pump (PMCA). The functional inhibition of TLR5 had no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24h treatment of the CF organoids with VX-809 have restored the PMCA function to the control level. Similarly native CFPAC-1 cells and PDEC treated with siRNA to inhibit the expression of CFTR showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained [Ca2+]i levels decreased ΔΨm and induced cytochrome c release in CFTR KO PDEC without significant alterations in mitochondrial morphology.

Conclusion: Dysfunction of PMCA leads to disturbed Ca2+ homeostasis in CFTR-deficient PDC and the consequent cellular Ca2+ overload impairs mitochondrial function contributing to the pancreatic damage in CF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0097 EXPDF IMPACTS PANCREATIC DIFFERENTIATION OF HUMAN PLURIPOTENT STEM CELL DERIVED PANCREATIC ORGANOID

Contact E-mail Address: alexander.kleger@uni-ulm.de

Introduction: Given their capability to differentiate to every cell type of the human body, human induced pluripotent stem cells (hiPSCs) provide a unique platform for preclinical and developmental studies and regenerative medicine. The use of a pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE) and pancreatic endoderm (PE). We have recently reported the generation of a novel three-dimensional pancreatic organ culture system that generates functional acinar-/ductal-like structures from pluripotent stem cells (Hohwieler et al, GUT. 2016).

Aims & Methods: In the current study we implemented this culture system to understand the role of exocrine differentiation and proliferation factor (Expdf), a signalling molecule proposed to be involved pancreatic differentiation in zebrafish. CrisprCas9 technologies were used to ablate Expdf in human embryonic stem cells, while a piggy bac engineering approach allowed us timed expression to understand the role of exocrine differentiation and proliferation factor (Expdf).

Results: First, a limited role of Expdf was observed until the PE stage, while PP formation was strongly diminished. Moreover, a dramatically altered organoid morphology was observed in both knockout lines leading to mostly cystic structures. Phenotyping for ductal and acinar lineage allowed to investigate these
changes in more detail and genome wide expression profiling helped us to under-
stand the role of Expdf in more detail.

Conclusion: Thus, we report a novel signalling molecule playing a critical role 
during human pancreas development based on a pluripotent stem cell differen-
tiation platform.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0098 MELATONIN METABOLITE: N1-ACETYL-N2-FORMYL-5-METHOXYKNYURAMINE STIMULATES PANCREATIC ENZYME SECRETION VIA CCK RELEASE. STUDY ON THE RATS

J.M. Jaworek
Dept. Of Medical Physiology, Jagiellonian University CM, Krakow/Poland

Contact E-mail Address: jolanta.jaworek@uj.edu.pl

Introduction: N-acetyl-N\textsuperscript{2}-formyl-5-methoxykynuramine (AFMK), melatonin 
metabolite was demonstrated recently as a putative pancreatic calcium 
regulator against acute inflammation. AFMK significantly attenuated acute pancreatitis; 
evertheless, its effect on pancreatic exocrine function has not been investigated yet.

Aims & Methods: 1. To investigate the effects of intraduodenal (i.d.) application of 
AFMK on pancreatic enzyme secretion under basal conditions and following the 
stimulation of this secretion with diversion of pancreatic-biliary juice (DPBJ) 
and to examine the role of CCK in this process. 2. To assess the effect of AFMK on 
CCK receptor in pancreatic acinar cell line AR42J. Material and methods: For in vivo study Wistar rats weighing 300 g were employed. Under pentobarbi-
tane anesthesia the animals were surgically equipped with silicone catheters, 
inserted into pancreatic-biliary duct, and into duodenum. AFMK (5.10 mg/kg i.d.) 
was given to the rats under basal conditions or following stimulation of pancreatic 
secretion with DPBJ. Lorglumide, the CCK1 receptor antagonist (1 mg/kg i.d.) 
was administered 15 minutes prior to the application of AFMK. Samples of pancreato-biliary juice were collected to measure the amylase outputs. The blood samples were taken for determination of CCK by ELISA kit. For in vivo study AR42J cells were incubated in presence of AFMK alone or in combination with CCK. The protein signal of CCK receptor 
was determined by Western blot.

Results: AFMK given i.d. produced the dose-dependent increases of pancreatic 
amylase secretions both; unstimulated, as well as that induced by DPBJ. The rises 
were determined by Western blot.

Conclusion: our results confirmed the functional activity of the TRPM2 channel 
in pancreatic acinar cells. In our further investigations we aim to clarify the 
pathogenic role of TRPM2 in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic ductal fluid and HCO\textsubscript{3}\textsuperscript{-} secretion are crucially impor-
tant in the physiology and pathophysiology of the exocrine pancreas. However, 
the investigation of human pancreatic secretory processes is great challenge due to the 
limited access to human pancreatic ductal cells. The recently developed three-
dimensional pancreatic organoid cultures (OC) may help to overcome this lim-
itation. However, the ion secretory processes in pancreatic OC is not known.

Aims & Methods: Our aim was to characterize the ion transport processes in 
mouse pancreatic OCs. Mouse pancreatic ductal fragments were isolated by 
enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a 
week in OC media. Changes of the intracellular pH was measured to characterize 
the ion transporter activities of the epithelial cells in OC.

Results: Basolateral administration of 20 mM NH\textsubscript{4}Cl in standard HEPES or 
CO\textsubscript{2}/HCO\textsubscript{3}\textsuperscript{-} buffered solution resulted in rapid intracellular alkalization, 
which was followed by a recovery phase. Removal of NH\textsubscript{4}Cl induced rapid 
acidification followed by regeneration to the resting pH levels. The regeneration 
phase was inhibited by the removal of extracellular Na\textsuperscript{+}. The administration of 
10 mM CFTPM\textsubscript{172}, a selective inhibitor of cystic fibrosis transmembrane con-
ductor regulator decreased the regeneration from alkali load. Basolateral 
administration of 20 mM amiloride and 20 mM H\textsubscript{2}DIDS decreased the intracel-
icular pH suggesting the activity of Na\textsuperscript{+}/H\textsuperscript{+} exchanger and Na\textsuperscript{+}/HCO\textsubscript{3}\textsuperscript{-} cotrans-
porter on the basolateral membrane.

Conclusion: The ion transport activities in mouse OC are similar to those observed 
in freshly isolated primary tissue. This suggest that OC will be suitable 
to study human ductal epithelial ion transport.

Introduction: Acute pancreatitis (AP) is the most common inflammatory disorder 
in the gastrointestinal tract with an overall mortality of 20–30% in severe cases. 
The treatment of AP is not resolved yet, urging the identification of novel drug 
targets. Toxic cellular Ca\textsuperscript{2+} overload was highlighted as a key event in pancreatic 
acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition 
of Orai1 in pancreatic acinar cells markedly decreased the Ca\textsuperscript{2+} toxicity and 
the severity of AP. However, We have no information regarding the role of Orai1 
in pancreatic ductal physiology or pathophysiology.

Aims & Methods: Wild type FVB/N mice were used for the isolation of pancreatic 
ductal fragments. The intracellular pH and Ca\textsuperscript{2+} level of the pancreatic 
ductal cells (PDC) were measured by microfluorimetry. The effect of selective Orai1 
inhibitors provided by CalciMedica was evaluated.

Results: The tested compounds dose-dependently inhibited Ca\textsuperscript{2+} influx through 
the carbachol induced Ca\textsuperscript{2+} signal in PDC. Inhibition was complete at a con-
centration of 10 mM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reti-
culum Ca\textsuperscript{2+} stores were depleted with cyclopiazonic acid and the inhibition of 
store-operated Ca\textsuperscript{2+} entry (SOCE) was investigated after the re-addition of 
extracellular Ca\textsuperscript{2+}. Under those conditions CM-B and CM-C significantly, but not 
dramatically, decreased SOCE in PDC (55.96% and 55.03% respectively). The 
removal of extracellular Na\textsuperscript{+} to abolish activity of the Na\textsuperscript{+}/Ca\textsuperscript{2+} exchanger 
had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed that 
the inhibition of Orai1 has no effect on the basal secretion of HCO\textsubscript{3}\textsuperscript{-} by PDC, which is the main physiological function of these cells.

Conclusion: We showed that Orai1 has a significant role in the Ca\textsuperscript{2+} signaling of 
PDC. In the next step we will evaluate the pathophysiological relevance of the 
channel.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0102 ACUTE PANCREATITIS OF UNKNOWN ORIGIN AND IDIOPATHIC JUVENILE PANCREATITIS IN SWEDEN

A194 United European Gastroenterology Journal 5(5S)
Aims & Methods: We searched factors to predict hospital mortality in early stage of severe acute pancreatitis. We analyzed medical records of patients who were diagnosed with severe acute pancreatitis and pancreatic cancer, which had been registered within unknown etiology (PEUE) at the Center for Digestive Diseases at Karolinska University Hospital from January 2008 to December 2016.

Results: During the observation period, 44 patients (17 male and 27 females) were registered with the ICD code chronic or relapsing pancreatitis, and onset of symptoms before the age of twenty. At time of first visit, the mean age was 36.7±26.9 years, range 24–57. The average period between the occurrence of first symptoms and diagnosis was 14.0 years (range 1–39 years). All patients (100%) clinically presented with recurrent acute pancreatitis. There were 28 (63.7%) patients with genetic alterations. Five out of 28 genetic positive patients (17.9%) had a definitive diagnosis of genetic etiology of pancreatitis. Seven out of 28 genetic positive patients (25%) had complications: in five patients endoscopic treatment due to pancreatic duct stenosis was performed; one patient had necrotic and bile duct stenosis and one patient, female, age 28, CFTR heterozygous mutation) a pancreatic tumor (mucinous cystadenoma with high dysplasia that was successfully surgically treated by resection). One patient died due to non-pancreatic related disease (kidney cancer). None of the patients reported alcohol overconsumption. Four out of 28 genetic positive patients (14.3%) were active smokers. Fecal elastase-1 (FE-1) was tested in 28 (63.6%) patients: 16 (57.1%) in genetic positive and 12 (75%) in genetic negative group of patients. Pancreatic exocrine insufficiency (PEI) was found in 5 out of 12 (41.7%) of genetic negative patients and in 5 out of 16 (31.2%) genetic positive patients. Average age at onset of PEI was 38 years (range 27–53). Diabetes mellitus (DM) was diagnosed in one patient in group with genetic alterations and 2 patients in group without genetic alterations.

Conclusion: We found high proportion of genetic alterations in patients with juvenile pancreatitis and PEUE. In patients in whom pancreatitis remains unexplained after excluding the most of other etiologies and presence of genetic alteration, hereditary pancreatitis seems as reasonable explanation even in presence of common bile duct stones. A number of patients with these factors require transport to a hospital with intensive care unit.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Severe acute pancreatitis has high mortality and needs intensive care. However it is difficult to stratify the severity of acute pancreatitis in early stage. Therefore revised Atlanta classification requires persistent organ failure lasting at least 48 hours.

Aims & Methods: We searched factors to predict hospital mortality in early stage of severe acute pancreatitis. This was a retrospective cohort study of all consecutive patients with severe acute pancreatitis who admitted at 44 institutions between June 1, 2009 and December 31, 2013. We evaluated ten factors that associated with mortality in previous study.

Odds ratios and 95% confidence intervals

</tbody>
</table>

Results: The mortality was 12.7% (142/1114) patients. All ten factors were associated with mortality in univariate analysis. In multivariable analysis, four factors: namely, "partial pressure of oxygen in blood <60 mmHg (room air) or mechanical ventilation", "age >70 years", "blood urea nitrogen ≥40 mg/dL (or creatinine ≥2.0 mg/dL) or oliguria (daily urine output <400 mL even after administration of furosemide)" and "lactate dehydrogenase ≥2 times upper limit of the normal range" were associated with mortality. The other factors, namely "base excess ≤-3 mEq/L", "platelet count ≤100, 000/mm3", "serum calcium <7.5 mg/dL", "creatinine ≥15 mg/dL", "number of positive measures in systemic inflammatory response syndrome criteria ≥3" and "computed tomography grade" were not associated with mortality.

Conclusion: Advanced age, respiratory failure, renal failure and high lactate dehydrogenase could predict mortality in early stage of severe acute pancreatitis. Providing these factors require transport to a hospital with intensive care unit.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0104 EARLY OR LATE CHOLECYSTECTOMY IN MILD GALLSTONE PANCREATITIS? RESULTS FROM RANDOMIZED TRIAL

Introduction: Cholecystectomy during the index admission may reduce risk of recurrent biliary events but concerns have been raised about complications if surgery is performed to early. The objectives of this study were to compare gallstone- and cholecystectomy-related complications and patient reported quality of life. The index admission is safe and feasible.

Results: Sixty-four patients between May 2009 and March 2017 were randomized into early index- or scheduled cholecystectomy (IC vs. SC). IC was performed before discharge or scheduled 6 weeks from the initial episode.

Conclusion: Cholecystectomy in mild gallstone pancreatitis is associated with increased risk for recurrent gallstone-related events. Cholecystectomy performed during the index admission is safe and feasible.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0105 COMPARISON OF PREDICTIVE SYSTEMS TO PREDICT MORTALITY IN SEVERE AND MODERATE PANCREATITIS ACCORDING TO THE REVISED ATLANTA CLASSIFICATION

Aparato Digestivo, Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain

Contact E-mail Address: ruben.pique@salud.madrid.org

Introduction: The course of acute pancreatitis (AP) ranges from life threatening to mild disease, so accurately predicting its outcome is important. The revised Atlanta classification breaks the previous mild/severe dichotomy, so the absence of predictors of severity does not preclude a mild course. Studies designed according to the new classification evaluating existing predictors are still scarce.

Aims & Methods: Our study aims at evaluating the diagnostic accuracy of easily available prognostic scores to predict mortality, persistent organ failure (severe AP) and mild AP. We analyzed a single-center retrospective cohort including all adult patients admitted between 2010 and 2015. Patients with a previous episode of AP in the six months before admission, with other primary diagnosis at discharge and those partially attended at other institutions were excluded. Severity and local complications were defined according to the 2012 Atlanta classification. Four different scores (BISAP, SIRS, APACHE II and HAPS) and the following predictors: C reactive protein (CRP) at 24 h, hemocrit and BUN at admission
and their evolution after 24 were evaluated. Accuracy was measured using different concepts in operating characteristic analyses.

Results: Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.1–72.7), 57.4% males. Most frequent comorbidities were: diabetes (10.5%), hypertension (8.6%) and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 16.8%. There were 42 (6.6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1.5–2.9), and 7.2% (5–8.8) among severe cases. BUN at admission AUC: 0.88 [0.80–0.96], USG AUC: 0.88 [0.80–0.89] and EUS AUC: 0.87 [0.80–0.93]. BUN was more sensitive than all other predictors in predicting death. APACHE II presented the highest sensitivity, 100% (81.6–100%), while the BISAP score presented the highest specificity, 93.1% (90.6–94.8%). BUN at admission AUC: 0.89 [0.86–0.97], USG AUC: 0.87 [0.84–0.92] and EUS AUC: 0.87 [0.84–0.92] also presented the best performance. The BISAP score is the best predictor in the third space. However, there is a lack of consensus regarding the details of optimal fluid administration such as the type of fluid, infusion rate and volume of administration, and the physiologic goals of fluid resuscitation4.

Conclusion: The severity of acute pancreatitis varies widely, from a mild self-limited disease to one with a severe clinical course complicated by multiple organ failure. No pharmacologic therapy has been shown to improve the prognosis of patients with severe acute pancreatitis, while the quality of supportive care including early fluid resuscitation is critically important1, 2. Fluid resuscitation maintains adequate intravascular volume by compensating for fluid shifts to the third space2. However, there is a lack of consensus regarding the details of optimal fluid administration such as the type of fluid, infusion rate and volume of administration, and the physiologic goals of fluid resuscitation4.

Aims & Methods: The aim of this study is to evaluate the association between the severity of acute pancreatitis as classified by the revised Atlanta classification1, 7 and the fluid accumulation. The primary outcome was in-hospital mortality. As a sensitivity analysis, we conducted an identical analysis using only the patients with severe acute pancreatitis. We performed subgroup analyses for patients diagnosed with severe acute pancreatitis based on the revised Atlanta classification7. One thousand seven-seventy patients were classified in the fluid <6000 ml group, and 201 patients classified in the fluid ≥6000 ml group. There were no significant differences between the two groups with regards to in-hospital mortality (fluid <6000 ml: 35.3%; fluid ≥6000 ml: 28.4%, p = 0.18). In multivariable logistic regression analysis, conversely fluid ≥6000 ml within the first 24 hours was significantly associated with reduced mortality (OR 0.58, 95%CI 0.34–0.98). We performed subgroup analyses for patients diagnosed with severe acute pancreatitis based on the revised Atlanta classification. One thousand seven-seventy patients were classified in the fluid <6000 ml group, and 201 patients classified in the fluid ≥6000 ml group. There were no significant differences between the two groups with regards to in-hospital mortality (fluid <6000 ml: 35.3%; fluid ≥6000 ml: 28.4%, p = 0.18). In multivariable logistic regression analysis, conversely fluid ≥6000 ml within the first 24 hours was associated with significantly less mortality (OR 0.56, 95% CI 0.32–0.98). The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 0.9. New scores are needed to predict a mild course, as none of the available indexes presented an AUC >0.7. The HAPS score reached the highest specificity, 87.8% (83.91%), but presented a very poor sensitivity (28.9% [24.3–33.9%]).

Disclosure of Interest: All authors have declared no conflicts of interest.

Aim & Methods: In this study, we aimed to evaluate the efficacy of serum phosphate as a prognostic factor for PEP in humans. Between January 2005 and December 2016, 176 patients who underwent serum phosphate test among patients with PEP were included in the study. Serum phosphate was measured between 12 and 24 hours after ERCP. PEP was defined as new abdominal pain with at least 3-fold increase in serum amylase or lipase levels. The severity of the pancreatitis was determined according to consensus guidelines.

Results: A total of 176 patients with mild (n = 69; 39.2%), moderate (n = 80; 45.5%), or severe (n = 27; 15.3%) PEP were included. Serum phosphate was associated with severity of PEP. Serum phosphate levels in mild, moderate and severe PEP were 3.0, 3.1, and 3.3 mg/dL, respectively (P = 0.035). In the linear regression analysis, only the serum phosphate was associated with the duration of hospitalization (P = 0.016). Hematocrit, blood urea nitrogen, and high sensitivity C-reactive protein were not significantly associated with admission duration.

Conclusion: According to our retrospective data, serum phosphate is associated with the severity of PEP, and its role as a prognostic factor for PEP can be considered.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Biological function of adenosine A2A receptors prevents post-ERCP pancreatitis (PEP). Previous animal study reported that serum phosphate correlated with severity of acute pancreatitis.

Aims & Methods: Our goal was to know the predicting ability of BISAP and Ranson in a European cohort with the updated classification of Atlanta 2012 validation. Patients diagnosed of AP in University Hospital Virgen de las Nieves from June 2010–June 2016 were included. BISAP was calculated on admission and Ranson was calculated with parameters of the first 48 hours. We assessed the presence of SAP and mortality, receiving operating curves (ROC) and area under the curve (AUC) were calculated, selecting the best cut-off value in terms of sensitivity, specificity, positive predictive value (VPP) and negative predictive value (NPV). Results: 269 patients were included. 52.8% female and 47.2% male, 17 presented SAP (6.3%), 8 deaths (3%). Etiology: 65% biliary, 10.4% alcoholic, post ERCP 3%, drugs related in 0.7%, metabolic in 1.1%, idiopathic 15.2%, mixed (alcoholic+biliary) 1.1% and others in 2.6% BISAP showed an AUC 0.9, with sensitivity of 70%, specificity of 94%, PPV 41.4%, NPV 97.9% and overall accuracy of 91.8% for the prediction of SAP. Regarding mortality prediction, it exhibited an AUC of 0.97, sensitivity of 100%, specificity 92%, PPV 27.6%, NPV 100% and accuracy 92.2% (Table 1a and 1b) RANSON showed AUC 0.85, sensitivity of 88% and specificity of 79%, PPV 41.4%, NPV 97.9% and overall accuracy of 91.8% for the prediction of SAP. Regarding mortality prediction, it exhibited an AUC of 0.97, sensitivity of 100%, specificity 92%, PPV 27.6%, NPV 100% and accuracy 92.2% (Table 1a and 1b). Biomarker and severity of the disease. Multicenter studies in European cohorts are needed to confirm our findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0110 POST-ENDOSCOPIC RETROGRADE CHolangiopancreatography Pancreatitis: Morbidity and Predictors of Severity**

E. El-Hanafy1, A. El Nakeeb2

1Facultu Of Medicin, Mansoura University, gastroenterology surgical center, Cairo/Egypt

2Facultu Of Medicin, Mansoura University, gastroenterology surgical center, Cairo/Egypt

Contact E-mail Address: dr_elah_elhanaf@yahoo.com

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly used for therapeutic management of various biliary and pancreatic diseases[1]. However, ERCP is not a procedure without morbidity[2]. Post-ERCP pancreatitis (PEP) remains the most common and serious complication after ERCP[3].

**Aims & Methods:** To detect risk factors for post-endoscopic retrograde cholangiopancreatography (ERP) pancreatitis (PEP) and investigate the predictors of its severity. This is a prospective cohort study of all patients who underwent ERCP. Pre-ERP data, intraoperative data, and post-ERP data were collected.

**Results:** The study population consisted of 996 patients. Their mean age at presentation was 58.42 (±14.72) years, and there were 454 male and 442 female patients. Overall, PEP occurred in 102 (10.2%) patients of the study population; 2 (2%) patients died. Etiology: 65% biliary, 10.4% alcoholic, post-biliary (7.8%), 15.2% mixed, 1% other. The patients were included. Blood sample including hematological parameters, biochemical test, BUN, CRP and venous gasometry including lactate were performed on admission. We assessed the presence of SAP and mortality during admission, receiving operating curves (ROC) and area under the curve (AUC) were calculated, selecting the best cut-off value in terms of sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).

**Results:** 269 patients were included. 52.8% female and 47.2% male, 17 presented SAP (6.3%), 8 (3%) patients died. Etiology: 65% biliary, 10.4% alcoholic, post-ERP 3%, drugs related in 0.7%, metabolic in 1.1%, idiopathic 15.2%, mixed (alcoholic + biliary) 1.1% and other in 2.6% The results in terms of sensitivity, specificity, PPV, NPV and AUC are summarized in Table 1a and 1b. BUN had the highest AUC in terms of SAP prediction whereas Lactate had the best in terms of mortality prediction.

**Conclusion:** Biomarkers are quick but incomplete tools for SAP prediction, which can be easily obtained at any moment throughout the disease. Our study shows good values of specificity and AUC for BUN, Cr and lactate but not for CRP concerning SAP and mortality prediction on admission, but since they are low prevalent outcomes in our sample, PPVs are low and not very reliable. Although many of these parameters have been analyzed in previous studies, we present lactate as a new biomarker with similar performance than that of Cr and BUN, suggesting a possible role for scores building or outcome monitoring.

Acute pancreatitis (AP) is a common but potentially lethal pathology due to the multiplicity and severity of its complications. Infected pancreatic necrosis and improved outcome. The early prediction of fluid sequestration may help to select patients for more or less aggressive fluid resuscitation.

All 3 patients that died had severe PEP according to Cotton. They received systemic anticoagulants (p=0.31).

All patients admitted in Intensive Care Unit (ICU) in a single centre from 2012 to 2015 for a severe AP. Baseline characteristics of the overall population were expressed as frequencies (percentages) for categorical variables, and mean ± standard deviation (SD) for continuous data. For the analysis of mortality, multivariate analysis with Cox proportional hazards regression modeling was used to identify independent predictors. Association between IPN and patients’ characteristics at baseline was evaluated using logistic regression.

Conclusion: In conclusion, this study performed in routine practice conditions showed that IPN occurs in almost half of patients hospitalized in ICU for severe AP, and is associated with increased mortality and complications rates. Overall mortality was 17.6%, and factors associated with mortality were a high BMI, CTSI and persistent OF. Those results are consistent with previous studies, but we reported a high rate of mesenteric ischemia (7/26 patients deceased) while this complication is occasionally described. IPN patients required an intervention for drainage of infected tissue removal, which was performed using minimally invasive techniques in the vast majority of cases, with no complication or severe side effect. 35% of patients were treated with drainage alone without any additional necrosectomy. Finally, PSMVT and early OF appeared to be associated with risk of developing an IPN but anticoagulation for PSMVT did not protect for cavenoma occurrence and can expose to intestinal bleeding. Our results also suggest that the optimal and early management of OF and detection of PVSMT might prevent IPN and/or its complications. Such hypothesis will need to be tested in large multicentre prospective studies.

**Results:** The median fluid sequestration in the first 48 h after hospitalization was 4.7 liter (2.8–6.8 L). It was 3.2 (1.4–5.1), 6.4 (3.6–9.5) l in those without necrosis and those with necrosis, and 7.5 (4.4–12) l in those with persistent organ failure. The univariate and multivariate analysis showed that alcohol etiology, an increasing number of SIRS criteria and Hematocrit were significantly associated with increased fluid sequestration (Table). Body mass index, APACHE II score, sodium, creatinine and blood urea nitrogen levels did not help predict fluid sequestration. Patients with and without acute fluid collections had a median sequestration of 7.2 and 4.2 L (p < 0.001), respectively. 22 patients died (73.3%); median fluid sequestration in the patients who died was 6.5 L compared to 4.2 L among the patients who survived (p = 0.05). Increased fluid sequestration was associated with prolonged hospital stay (p < 0.01), (table) Association between variables determined at admission and fluid sequestration.

Conclusion: By EPDBD therapy, the relapse rate of pancreatic stone decreased, placed into minor papilla successfully. ESWL and EPDBD, stones were removed via minor papilla, then EPS was pancreatic stone: ERP revealed type 2 incomplete divisum. After EPDBD, EPS was successful in 2 cases via major papilla, and 14 cases via minor papilla. After EPDBD therapy, the stone free rate was 75.3%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A: 22 y/o male, idiopathic chronic pancreatitis, pancreas stone: After 4th EUSL, small stones remained in the head duct which can’t be removed by basket catheter and severe pain continued, so EPDBD was done under good informed consent. After several dilation of the orifice and the head duct, stones were removed easily. This is our experience in 62 cases. In our hospital, EPS and ENPD (endoscopic nasal pancreatic drainage) are the preferred choice for pancreatic pseudocyst therapy after dilation of the stenotic duct. 114 cases were successfully treated without major complications, and their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.
This was done in consideration of the current knowledge about lesions mimicking cancer in the setting of a normal pancreatic parenchyma or existence of signs for pancreatic neoplasm.

**Aims & Methods:** Retrospective analysis of prospectively collected data in our tertiary University center. From March 2007 to October 2015, 218 (124 men, 94 women; aged 20–80 years) patients underwent EUS for suspicious solid pancreatic neoplasm because of cross sectional imaging results, idiopathic acute pancreatitis, weight loss, pancreatic hyperechogenicity, painless jaundice and elevated Ca 19-9 values. Cystic pancreatic lesions, pseudocysts and cystic pancreatic neoplasms were excluded from the analysis.

**Results:** Malignant lesions were diagnosed in 98 (45%) patients. 54 patients (24.8%) underwent surgery and 61 patients (28% of all patients) underwent clinical follow-up (16.5 ± 2.7 months, 18 needed surgery). 43 lesions not undergoing surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer (n = 6, 9.8%), neuroendocrine tumor (NET) (n = 10, 16.4%), paradoxe-nal neoplasms (n = 5, 8.9%), chronic pancreatitis (n = 13, 21.3%), necrosis (n = 3, 4.9%), autoimmune pancreatitis (AIP) (n = 3, 4.9%), microcystic serous neoplasms (n = 3, 4.9%). Stent-related pseudocyst (n = 1), ventral/dorsal split (n = 1), lipomatosis (n = 1). EUS showed sensitivity and specificity for malignancy of 91.4% and 97.7%, respectively, in the non-pancreatitis group (n = 121) and 44% and 87.1% in the pancreatitis group (n = 97). Ca 19-9 elevation, rapid onset jaundice, double duct sign are useful indicators of malignancy both in the setting of normal and inflamed pancreas. Patients without pancreatitis the presence of enlarged lymphnodes or a mass in EUS, weight loss and worsening diabetes are predictor of malignancy. In patients with pancreatitis and without jaundice Ca 19-9 sensitivity for malignancy was 95% and specificity was 39%. In the pancreatitis group, Ca 19-9 sensitivity for malignancy (in patients without jaundice) was 45% and specificity was 86%. IgG4 elevation presented a sensitivity of 83.3% and a specificity of 92% for AIP, where one false elevation was seen in a dusual cholangiocarcinoma.

**Conclusion:** Diagnostic accuracy of EUS is lower in the presence of pancreatitis. Focal autoimmune pancreatitis and paradoxaunal pancreatitis are still confused with pancreatic cancer in the setting of normal or inflamed pancreatic parenchyma. EUS in the setting of a normal parenchyma is an excellent tool to exclude pancreatic cancer. Tumor markers like Ca 19-9 and IgG4 values should be measured in the evaluation of pancreatic masses, also in the setting of chronic pancreatic disease. We recommend EUS-FNA when routine preoperative EUS when performed after contrast enhanced CT in the diagnostic work-up going surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer. In some IPMN cases, they cannot be detected before invasive procedures.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Intraductal papillary mucinous neoplasms (IPMN) are common pancreatic cystic neoplasms often detected by chance, and are sometimes precursors of invasive pancreatic ductal adenocarcinoma [1, 2]. They are heterogeneous lesions because, in addition to cystic components, solid components may be present in the same glandular structure. These lesions are distinct from pancreatic ductal adenocarcinoma (PDA), conventional pancreatic cancer. In some IPMN cases, they cannot be detected before invasive procedures. In other cases, they may be associated with invasive PDA, and detection before invasive processes is crucial. A frequent finding in IPMN is the presence of somatic genetic alterations, and several studies have demonstrated that somatic genetic alterations, especially in IPMN or PDA adjacent to large cystic or solid components, may be involved in the development of PDA [3]. The occurrence of these genetic alterations in IPMN is a critical factor in the decision making process in patients with IPMN. Since the introduction of next-generation sequencing (NGS) technology, the potential of rapid and cost-effective genetic testing has been achieved. However, routine use of NGS in patients with IPMN is still limited, due to the high cost and relatively small number of sequence targets. Moreover, the molecular characteristics of IPMN may be different from those of PDA [4]. Next-generation sequencing using EUS-FNA (endoscopic ultrasound fine-needle aspiration) specimens provides an opportunity to detect somatic genetic alterations in IPMN with high sensitivity. In addition, EUS-FNA is a minimally invasive technique that does not require surgery, and is performed under local anesthesia.

**Aims & Methods:** We analysed IPMN or PDA tissues using NGS and assessed the impact of NGS on clinical diagnosis. From January to December 2015, 14 tissue samples of undiagnosed pancreatic tumours (from 8 male patients, 6 female patients; mean age range, 85–100 years; mean tumour size, 29.6 ± 17.9 mm; tumour size range, 10–66 mm) were collected by EUS-FNA. The locations of the tumours were the head (3), body (4), and tail (5); we obtained their samples through the stomach or duodenum. EUS-FNA was performed using a curvilinear high-frequency scope (GF-UCT 260; Olympus Medical Systems, Tokyo, Japan) and 22- or 25-gauge needles (ProCore; Cook Japan, Tokyo, Japan; Expect; Boston Scientific, Tokyo, Japan). Both slow-pull and negative pressure techniques were used to obtain specimens. We performed whole-genome sequencing using NGS obtained from IPMN and/or PDA tissues using the Comprehensive Cancer panel, and compared their genetic mutations. Additionally, in the case of IPMN, we compared the differences in results between mural nodules and cystic fluids or walls.

**Results:** Pathological diagnoses showed 2 adenocarcinomas, 3 intraductal papillary mucinous carcinomas, 7 intraductal papillary mucinous adenomas; the remaining 2 cases could not be diagnosed. We used minute samples obtained from EUS-FNA, and analysed genetic mutations of 10 cases using NGS. Homogenous genetic mutations were approximately 18% and heterogeneous genetic mutations were approximately 25%. Five of the cases had mural nodules inside the cysts. We could analyse genetic mutations of cystic fluids or walls by the same way as of mural nodules. For the gradually growing IPMN without

Introduction: Circular RNAs (circRNAs) are a novel class of noncoding RNAs that are differentially regulated and play an important role in multiple biological processes. Increasing reports have shown that circRNA dysfunction in neuro system diseases, cardiovascular diseases, human cancers and many other diseases. circRNA is involved in tumorigenicity, proliferation, apoptosis, angiogenesis, cell migration, invasion and metastasis in human carcinoma. circRNA can act as microRNA (miRNA) sponge and regulate the targets of miRNA. Circular RNA HIPK3 (circHIPK3) is originated from second exon of HIPK3 gene, which is upregulated in gastric, liver, esophageal. However, the mechanism remains unclear. Previous studies revealed that signal transducer and activator of transcription 3 (STAT3) as an oncogene that was activated in pancreatic carcinoma. Phosphorylation of STAT3 (p-STAT3) is a downstream target of interleukin 6 receptor (IL6R). Activation of STAT3 leads to malignancy of tumorgenesis, cell proliferation and migration. Knockdown STAT3 induces cell apoptosis by Bax, c-Myc, cyclinD1, etc. circHIPK3 regulates Bxc3 cell proliferation through IL6R/STAT3 pathway. It may be a new target for the therapy of pancreatic carcinoma.

Materials & Methods: Our research is to study whether circHIPK3 can promote proliferation of pancreatic carcinoma cell line, BxPC3, and to explore the mechanism of circHIPK3 in cell proliferation. Cell viability was determined by cell counting kit-8 (CCK-8). Transient knockdown of circHIPK3 using specific siRNA targeting the conjunction of circHIPK3. Overexpression of mir-124 was transfected with synthetic miRNA mimic. Real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed to detect circHIPK3, mir-124 and miRNAs. The expressions of STAT3, p-STAT3, IL-6R were measured by Western blot. Overexpression of STAT3 was monitored with STAT3 plasmid. Dual-Luciferase Reporter Assay was performed to detect the interaction of circHIPK3 and mir-124.

Results: circHIPK3 was upregulated in BxPC3 compared to human pancreatic duct epithelial cells (HPDE6-C7). Knockdown of circHIPK3, which didn’t affect the linear transcript, significantly decreased cell viability of BxPC3. Bioinformatical analysis and luciferase assay demonstrated that circHIPK3 interacted with miR-124. Western blot confirmed that circHIPK3 decreased of miRNA levels of STAT3 and IL-6R and protein levels of STAT3, p-STAT3 and IL-6R. Previous studies confirmed that circHIPK3 negatively regulates STAT3, IL-6R via interacting with 3'-UTR. Recent expression of mir-124 decreased the expression of circHIPK3. circHIPK3 caused decreasing of mRNA levels of STAT3 and IL-6R. Previous studies confirmed that circHIPK3 regulate the expression of STAT3. circHIPK3 regulated Hepatocellular Oncogenesis. Cell. 2011;147(6):1233-47. Indeed, mir-124 repressed BxPC3 cell proliferation which was similar with circHIPK3. In addition, overexpression STAT3 abolished the si-circHIPK3 and mir-124 mimetic induced cell suppression. QRT-PCR and Western blot confirmed that circHIPK3 and both STAT3, p-STAT3 and IL-6R were upregulated in BxPC3 cells than HPDE6-C7 cells while mir-124 was downregulated. mir-124 was negatively correlated with circHIPK3 and STAT3, p-STAT3 and IL-6R.

In this study, we identified circHIPK3 promotes BxPC3 pancreatic carcinoma cell proliferation by targeting mir-124 and its target genes STAT3 and IL-6R. We found that mir-124 was a negative regulator of proliferation in BxPC3. And overexpression of STAT3 could attenuate the anti-proliferation of si-circHIPK3 and mir-124. These results demonstrated that circHIPK3 regulates BxPC3 cell proliferation by acting as mir-124 sponge.

Introduction: Intraductal papillary mucinous neoplasms (IPMN) are precursors of pancreatic ductal adenocarcinoma (PDAC) and are also associated with multicentric lesions (field defect), where concurrent de novo PDA, independent of index IPMN lesion, can also develop. However, there are cases where PDAs arise adjacent to the index IPMNs, and occasionally they are pathologically indistinguishable whether the carcinoma developed from IPMN or was coincidental to the IPMN. A genetic approach can be useful to clarify the origin of each tumor compartment to determine if they shared molecular signatures.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
**Aims & Methods:** Twenty concomitant PDAs and IPMNs (39 samples, including concurrence lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMNs was measured after precise pathological mapping. Target amplion sequencing that covers 18 PDA-associated genes, including KRAS, GNAS, TP53, SMAD4, CDKN2A, BRCA1, RB1, PTEN, ATM, and ATRX, was performed using Ion PGM™ system (Thermo Fisher Scientific). Protein expression of TP53, SMAD4, p16, catenin, and RNF43 was also analyzed immunohistochemically.

**Results:** Fourteen lesions were detected in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. “Adjacent” concomitant PDAs, defined as those that are 5 mm or less away from the IPMN (n = 11), tended to harbor identical KRAS mutations as the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%). Among concomitant non-neoplastic lesions via the main pancreatic duct between PDAs and IPMNs had identical KRAS mutations. In contrast, 7 of 9 “distant” concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n = 9), possessed distinct KRAS mutations from the index IPMNs (78%). Mutations in KRAS were demonstrated in 14/20 (70%) of index IPMNs, and in 29/39 (74%) of all PDAs, but not in PDAs supporting de novo carcinogenesis rather than progression from the IPMNs. PDAs harboring identical mutations in KRAS as IPMNs were significantly closer to the IPMNs (KRAS identical; p = 0.05). The level of KRAS different group had a better prognosis than the KRAS identical group (disease-free survival: p = 0.0245; overall survival p = 0.205).

**Conclusion:** The molecular signature of 18 PDA-associated genes was not significantly different between the two groups. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The pancreatic cancer is a leading cause of death in cancer carriers worldwide.

**Aims & Methods:** To study the polymorphism of the TP53 gene on the suppressor in pancreatectomy and to evaluate proinflammatory cytokines in IL-1β, TNF-α, insulin blood serum levels at patients with various pathologies of the pancreas (cancer (PCa), acute and chronic pancreatitis (OP) and CP) with various genotypes of TP53. 150 patients were followed in a one-stage clinical trial (42 patients with PCa, 16 patients with CP, and 27 with PC). The diagnosis has been verified by clinic methods, ultrasonography, CT. The mean age of patients with PCa was 63.6 ± 4.9 years. In patients with OP, blood sampling was carried out in the first 5 days after admission to hospital, patients with CP were examined at the stage of exacerbation. The concentration of IL-1β, TNF-α, serum insulin was determined by ELISA using the ELISA kit and Monobind Inc., USA. The frequencies of genotypes and alleles of the TP53 gene by exon (exon 4, Arg2Pro) polymorphism were studied by PCR.

**Results:** The distribution of Arg/Arg genotypes of the TP53 gene was 65% in patients with PCa, 49% in the control group. In patients with PCa there was no homozygotic genotype Pro/Pro, in the comparison group - 13%, p < 0.05. The frequency of Arg/Pro genotypes was 35% in patients with PCa and 38% in the comparison group. The frequency of alleles of the TP53 gene in patients with PCa and in the comparison group was: Arg (82.5% and 68%), Pro (17.5% and 32%). The concentration of insulin in different genotypes in patients with PCa did not differ significantly and was 7.5 ± 2.2 μU/ml in Arg/Arg, Arg/Pro – 11.4 ± 1.4 μU/ml, Pro/Pro – 11.4 ± 0.5 μU/ml. In the comparison group, the serum level of insulin was 5.7 ± 1.8 μU/ml. In patients with PCa, the glucose level was significantly higher, compared with patients with OP and CP (8.5 ± 1.4 mmol/l, 5.4 ± 0.3 and 5.1 ± 0.1 mmol/l, respectively, p < 0.05). The level of IL-1β was significantly higher, compared with patients with OP and CP (8.5 ± 1.4, 2.0 ± 0.3 and 1.3 ± 0.2 μU/ml, respectively), p < 0.05. The level of TNF-α in the serum of patients with OP was 3.5 ± 0.5 μU/ml, and did not significantly differ from the serum level of patients with CP and PCa – 4.3 ± 0.7 and 1.1 ± 0.2 μU/ml, respectively. In patients with PDAs, the level of TNF-α was significantly lower than in patients with CP, p < 0.05. The levels of IL-1β in the serum of patients with PDAs with different genotypes of the TP53 gene did not differ significantly and amounted to 1.1 ± 0.2 μU/ml in patients with the Arg/Arg genotype, with Arg/Pro genotypes of 1.2 ± 0.3 μU/ml, p > 0.05. The level of TNF-α in the serum of patients with the Arg/Arg genotype was 1.2 ± 0.2 μg/ml, and did not significantly differ from the level in the serum of patients with the Arg/Pro genotype - 1.3 ± 0.1 μg/ml. 

**Conclusion:** The Pro/Pro genotype of the TP53 gene was significantly more common in patients with PCa than in the patients with CP. We detected significant differences in serum insulin levels in the comparison group and in patients with heterozygous genotypes, p < 0.05. The level of TNF-α in patients with PCa, CP was significantly lower than in patients with OP, and the level of IL-1β was significantly lower in patients with PCa than in patients with CP.

**Contact E-mail Address:** kobataki@med.kobe-u.ac.jp

**Introduction:** Pancreatic cancer (PC) is one of the most lethal diseases due to the difficulty of early detection. There is no effective blood biomarker for screening. Recently metabolomics is considered to be a promising approach to discover disease biomarkers. We previously reported that the serum/plasma levels of 18 candidate metabolites in PC patients were significantly changed compared with those of healthy individuals.

**Aims & Methods:** The aim of this study is to confirm and develop our candidate metabolomic biomarkers in blood of PC patients. Blood samples from PC patients (n = 18), healthy volunteers (HV) were collected from two independent groups consisting of multiple institutions. The 1st set was included 55 PC in stage I and II and 58 HV. The 2nd set was included 16 PC and 16 HV. Sixteen candidate metabolites were selected from previous report. Quantitative analyses were performed by gas chromatography/tandem mass spectrometry (GC/MS) together with their corresponding stable isotopes. In the 1st set, diagnostic models were constructed via multivariate logistic regression analysis. These results were validated using the 2nd set.

**Results:** In the 1st set, the levels of the 15 candidate metabolites differed significantly between PC and HV. Model Y consisting of 2 metabolites, i.e., histidine and xylitol showed high sensitivity (70.4%) than CA19-9. Furthermore, combination of model Y with CA19-9 increased its sensitivity (90.7%) and specificity (89.5%). In the 2nd set, combination of model Y with CA19-9 demonstrated high sensitivity (81.3%) and specificity (93.8%). In particular, it displayed very high sensitivity (100%) for PC in a resectable state.

**Conclusion:** Quantitative analysis using GC/MS/MS confirmed the possibility of metabolomics-based screening methods for PC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0128 COMBINED HISTO-CYTOLOGICAL ANALYSIS OF EUS-FNA SAMPLES FROM SOLID LESIONS USING STANDARD FNA NEEDLES GIVES BETTER DIAGNOSTIC YIELD AND ACCURACY**

**Introduction:** Diagnostic yield from EUS-FNAC (fine needle aspiration cytology) has improved in the past few years with better tissue acquisition techniques. Core biopsy needles are now available but are more expensive than FNAC needles. We assessed the diagnostic yield and accuracy of FNAC samples processed for both cytology and histology.

**Results:** A total of 211 patients (118 male) were included. Samples were sent to cytology (n = 135; 107 pancreas, 10 biliary, 7 lymph nodes, 11 other), or cytology & histology (n = 76; 56 pancreas, 12 biliary, 5 lymph nodes, 3 other). Sample adequacy was 80.7% and 98.7% (p = 0.0004). Diagnostic yield (64.4%, 94.7%) and accuracy (81.3%, 96.1%) was significantly better in the combined (histology & cytology) group (p < 0.0001, p = 0.003). Within the combined group, diagnostic yield and accuracy improved by 20.5% (p = 0.007) and 26% (p = 0.0002) respectively when the sample was processed for both cytology and histology.

**Conclusion:** Our study confirms significant improvement in diagnostic yield and accuracy when samples were sent for both cytology and histology using standard FNAC needles.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: In the revised international consensus guidelines of 2012 for the management of IPMN of the pancreas, resection is recommended for all main pancreatic duct IPMN. While in branch pancreatic duct IPMN (BD-IPMN), the indications for resection are more conservative. Cyst size >30 mm without “high-risk stigmata” can be observed without immediate resection. And EUS observation is recommended to decide a treatment strategy.

Aims & Methods: The present study was a retrospective investigation of surgical indication for BD-IPMN with worrisome features (WF). 466 patients with IPMN underwent pancreatic resection at 3 high volume centers in Japan between 1996 and 2014. Among them, 156 patients with BD-IPMN were enrolled this study. The investigation of predictors of malignancy was done for 10 factors: age at time of surgery, sex, presence or absence of symptoms, serum amylase, CA19-9, CEA, tumor location, size of mural nodules (MN), diameter of main pancreatic duct (MPD) and cyst size of branch pancreatic duct (BPD). In preoperative examination, endoscopic ultrasonography (EUS) and computed tomography (CT) were considered to be essential. As for size of MN, EUS measurements were used in all 156 cases. For diameter of MPD and cyst size of BPD, the CT measurement values were used. The results were: 36 patients had malignant IPMN. The rate of malignancy was significantly higher than that of WF patients (53% (n = 17) - technical failure was only seen in transduodenal puncture (n = 3, 15%). Biopsies were generally of good quality and contributed to the diagnosis in 14 patients (clinical success of 82%). Among these, there were ten cases of intraductal papillary mucinous neoplasia, two serous cystadenomas, two noninvasive cystic adenocarcinomas, and one pseudo-

docyst. Two mild adverse events were recorded (1%), a case of re-admission due to non-specific abdominal pain and a mild acute pancreatitis.

Conclusion: The use of micro-biopsy forceps was until now only reported in case reports of rare edge cases. In a first large scale feasibility study (ERC P), we conclude that the use of the micro-forceps seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

endoscopic ultrasonography fine needle aspiration. One patient developed mild pancreatitis (16.5%).

**Conclusion:** In patients with suspected cephalopancreatic adenocarcinoma referred for ERCP, MPD brush cytology may be performed beyond biliary cytology, as it may improve cytologic diagnosis of malignancy without increasing complications rate.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

**Aims & Methods:** The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 Japanese tertiary referral hospitals between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytologically diagnosed with PM. Kaplan-Meier analysis and Cox’s proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

**Results:** We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n = 61), followed by lung cancer (24.5%, n = 39), colorectal cancer (11.3%, n = 18), sarcoma (6.3%, n = 10), breast cancer (6.3%, n = 10), and other cancers (n = 21). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgical resection, and no surgical resection was performed in 95 patients (60%). Prevalence of isolated pancreatic metastases (PM) was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR = 3.83, CI 1.2–11.8, p = 0.02) compared to the head. Overall CT chest resulted in change in management plan in 9 (2.9%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unresectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic disease in 2 (0.7%) patients. Prevalence of isolated PDA lung metastasis without any other metastasis was 2.8% (8/278).

**Conclusion:** Our study showed that the prevalence of pulmonary metastasis in PDA was clinically relevant and mandate routine staging with CT chest. Prevalence was significantly higher for pancreatic body and tail cancers compared to the head. Staging CT chest resulted in a change in the stage of PDA and management decisions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** National Comprehensive Cancer Network (NCCN) guidelines recommend chest x-ray or chest computed tomography (CT) for the staging of potential resectable pancreatic adenocarcinoma (PDAC). However, there is limited data supporting these guidelines, and the prevalence of lung metastasis is not well defined on staging CT scans. We report our findings of patients with lung metastases during initial staging and follow-up of patients with PDA.

**Aims & Methods:** Data was prospectively collected from May 2013 to September 2016 for PDA patients who were presented at a multidisciplinary pancreas conference (MDPC) at a large tertiary care center. All patients were staged with CT pancreatic protocol, CT chest and Endoscopic Ultrasound. Patients with findings of lung lesions on initial staging chest CT were followed prospectively. Metastatic lung lesions were determined based on definite imaging characteristics with clinical consensus or lung biopsy results.

**Results:** A total 278 PDA patients referred to MDPC were staged with CT chest (Table 1). Out of these, 36 (12.6%) patients were found to have either malignant (N = 6) or indeterminate (N = 30) lung lesions on initial staging CT chest. Out of the six malignant lung lesions, 5 (8.1%) patients had metastatic PDA lesions, and 1 (0.35%) patient had incidental primary lung cancer. On a follow-up of 30 patients with indeterminate lung lesions, 8 patients (26.7%) were later determined to be lung metastasis. The overall prevalence of definite lung metastasis was at least 4.8% (13/278). The prevalence of lung metastasis in pancreatic head cancer was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR = 3.83, CI 1.2–11.8, p = 0.02) compared to head. Overall CT chest resulted in change in management plan in 9 (2.9%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unresectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic disease in 2 (0.7%) patients. Prevalence of isolated PDA lung metastasis without any other metastasis was 2.8% (8/278).

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Introduction: New lesions (metachronous pancreatic cancer) and recurrence may develop in patients after initial resection and Intraductal Papillary Mucinous Neoplasm (IPMN). Endoscopic ultrasonography (EUS) is proved as a more specific and sensitive method for pancreatic lesion. However, there is no report about EUS after pancreatectomy. If it is possible to observe from the anastomotic part to remnant pancreas under the EUS, remnant pancreatic cancer may be pointed out an early stage.

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for remnant pancreas. In this retrospective study, 44 patients who underwent EUS for remnant pancreas were enrolled. The definition of observation under the EUS for remnant pancreas was as follows, total observation for remnant pancreas observed from linear white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent pancreatectomy at the J.A. Omomochi General Hospital between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for remnant pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of remnant pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 22 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIb. The other cases IPMNs were able to perform EUS-FNA for lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (class III), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by Positron emission tomography (PET). EUS was performed in the other 4 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (p < 0.001).

Conclusion: EUS was able to observe remnant pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be performed for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Abbreviations: PDAC, pancreatic ductal adenocarcinoma; SD, standard deviation; HR, hazard ratio; CI, confidence interval.

Conclusion: Second primary pancreatic cancer had a higher rate of resectability, and there was no difference in the effectiveness of curative surgery and chemotherapy between 2nd and 1st PDAC. Therefore, when curative surgery for 2nd PDAC is planned, it should be conducted similarly to curative surgery for 1st PDAC. Considering the increased risk of 2nd PDAC in cancer survivors and the fact that surgery is the only curative treatment for this fatal cancer, more efforts are needed to develop screening programs for second primary pancreatic cancer in cancer survivors.

P0137 ADEQUACY ASSESSMENT OF EUS-FNAB SAMPLES OF Pancreatic Cancer for "Precision Medicine": A COMPARISON OF 22-GAUGE AND 25-GAUGE NEEDLES

Y. Noshizawa1, R. Yamada1, H. Miura1, T. Takenouchi1, T. Tanaka2, N. Horiki2, Y. Takei1
1Department of Endoscopy, Mie University Hospital, Tsu, Mie/Japan
2Endoscopy, Mie University Hospital, Tsu, Mie/Japan

Introduction: The development of new technology including next-generation sequencing has accelerated seeking new biomarkers and implementation of “precision medicine”. Generally, formalin-fixed paraffin-embedded tumor tissues obtained by surgery are used for molecular testing. The problem is that surgery is invasive, therefore, acquisition of adequate specimen by less-invasive procedure is getting significant factor. Endoscopic ultrasonic-guided fine-needle aspiration and biopsy (EUS-FNAB) is the standard technique for diagnosing pancreatic solid tumor. There are several studies that have assessed the diagnostic yield of EUS-FNAB, comparing different needle sizes. Whereas, few reports had focused on the adequacy of sample yield of EUS-FNAB, comparing different needle sizes. Therefore, we investigated the adequacy of sample yield of EUS-FNAB for “precision medicine”, evaluating EUS-FNAB specimens obtained by 22-gauge needles (22G) and 25-gauge needles (25G).

Aims & Methods: The aim of our study was to verify the accuracy and sample yield obtained by EUS-FNAB using 22G and 25G, evaluating the feasibility for immunohistochemistry (IHC) staining. This was a retrospective study in a single tertiary referral center. Between October 2006 and November 2015, we investigated 153 patients of pancreatic ductal adenocarcinoma (PDAC) undergoing diagnostic EUS-FNAB before neoadjuvant gemcitabine-based chemoradiotherapy. EUS-FNAB was performed with rapid on-site evaluation. We compared the adequacy of sample yield of EUS-FNAB by both 22G and 25G.

Results: A total of 597 pancreatic neoplasms (496 with early gastric cancers and 101 with gastric adenomas) in 371 consecutive patients were treated with gastric ESD between January 2010 and October 2016. A total of 102 lesions were excluded from this study: 51 lesions due to anticoagulation therapy; 25 lesions in patients receiving antipatelectomy therapy excluding single-LDA and DAPT; and 26 lesions due to postoperative bleeding at the same time. Thus, a total of 495 patients were enrolled in this study. The patients were categorized according to antipatelectomy therapy (APT). APT was defined as follows: oral administration of single-LDA (aspirin [100 mg/day]) or DAPT (aspirin [100 mg/day] plus clopidogrel [75 mg/day]). Logistic regression analysis was performed for risk factors of bleeding after gastric ESD.

Conclusion: The patients were categorized into two groups: no APT (n=370) and APT (n=125). APT included single-LDA (n=74) and DAPT (n=71) (aspirin plus clopidogrel). Among them, 46 received continuous LDA on single-LDA and 40 received continuous LDA on DAPT. The postoperative bleeding rate in the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; P<0.001). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group (15.2%) and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≥40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; P<0.001) was a sole independent risk factor for postoperative bleeding (Table 1). In subgroup analysis, there was no significant difference in continuous LDA users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding.

Table 1 Multivariate analysis for postoperative bleeding after ESD.

<table>

</tr>
</tbody>
</table>

Conclusion: This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. However, patients with continuous LDA on DAPT should be monitored carefully for postoperative bleeding after gastric ESD because the rate of postoperative bleeding in the continuous LDA on DAPT group was higher than that in the other groups.

Disclosure of Interest: none

Introduction: Peroral endoscopic myotomy (POEM) has been recognized as a viable treatment option for esophageal achalasia. However, the long-term outcomes of POEM remain uncertain. The aim of this study was to evaluate the outcomes of POEM for the treatment of esophageal achalasia with a median follow-up of 4 years.

Results: 60 patients underwent POEM between January 2012 and December 2015. The median follow-up period was 36 months (range, 12–60 months). The median age at the time of POEM was 35 years (range, 19–71 years). The median duration of symptoms was 4 years (range, 1–12 years). The median number of POEM sessions was 1 (range, 1–2 sessions). The median operative time was 170 minutes (range, 120–360 minutes). The median length of hospital stay was 7 days (range, 3–28 days). The procedural success rate was 100% (60/60). The median length of stay was 1 day (range, 1–3 days). The median hospitalization cost was $10,000 (range, $5,000–$20,000). The median follow-up duration was 36 months (range, 12–60 months). The median time to symptom recurrence was 12 months (range, 6–18 months). The median time to resolution of symptoms was 12 months (range, 6–18 months). The median time to normalization of esophageal manometry was 12 months (range, 6–18 months). The median time to normalization of esophageal pH monitoring was 12 months (range, 6–18 months).

Conclusion: POEM is an effective and safe treatment for esophageal achalasia. The long-term outcomes of POEM are promising, with a high success rate and low recurrence rate. Further studies are needed to evaluate the long-term outcomes of POEM.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Peroral endoscopic myotomy (POEM) has received wide acceptance as a feasible treatment for achalasia. However, small and small-scale studies are ample but long-term large-scale studies are few.

Aims & Methods: The aim of this study was to systematically analyze our long-term results of POEM, with particular emphasis on POEM failures and associated risk factors. This is a single center study. Consecutive POEM patients between Aug, 2010 and Dec, 2012 were included. Kaplan-Meier survival function was used to estimate clinical success rate at each year. The Cox proportional hazards model was used to analyze risk factors related to recurrence.

Results: A total of 564 patients were included. Mucosa injuries happened in 93 patients (16.5%) and 36 patients (6.4%) experienced major perioperative adverse events. The Eckardt score and lower esophageal sphincter (LES) pressure were significantly decreased after POEM (median Eckardt score 8 to 2, p < 0.05; median LES pressure 29.7 mm Hg to 11.9 mm Hg, p < 0.05). During a median follow-up period of 49 months (range 3–67 months), fifteen failures occurred within 3 months, 23 between 3 months and 3 years, and 10 after 3 years. The estimated clinical success rates at 1, 2, 3, 4, and 5 years were 94.2%, 92.2%, 91.1%, 88.6% and 87.1%, respectively. Multivariate Cox regression revealed long disease duration (>10 years) and history of prior interventions to be risk factors for recurrence. Clinical reflux occurred in 37.3% (155/416) patients.

Conclusion: POEM is a highly safe and effective treatment for esophageal achalasia with favorable long-term outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0140 PATIENTS WITH CHRONIC GASTROINTESTINAL ISCHEMIA HAVE AN ALTERED SUBLINGUAL MICROCIRCULATION

Introduction: Chronic gastrointestinal ischemia (CGI) results of insufficient blood supply to the gastrointestinal tract. The majority of CGI patients have systemic disorders of the circulatory system including hypertension, diabetes and other cardiovascular risk factors. Studies in patients with acute gastrointestinal ischemia have revealed long disease duration (>10 years) and history of prior interventions to be risk factors for recurrence. Clinical reflux occurred in 37.3% (155/416) patients.

Aims & Methods: This in vivo study attempted to evaluate whether gastrostasis, using conventional narrow band imaging (NBI) endoscopy is equivalent to that determined by histopathology. Fifty (50) consecutive patients with Helicobacter Pylori (H. Pylori) related gastric atrophy selected according to NBI endoscopic findings I. Diagnosis of H. Pylori based on detection of the organism by histopathology assessment. The NBI grade of lower gastric atrophy scored from 0 to 3. The histopathological assessment of lower gastric atrophy was based on OLGA scoring system. Furthermore, we assessed the presence or absence of intestinal metaplasia. The NBI and histology stages of gastric atrophy were assessed using a combination of scores for the antrum and corpus. These stages further classified into low risk (stage 0, I and II) and high risk (stage III and IV). Finally the degree of correspondence between NBI and histopathology, in prediction of gastric cancer risk, was assessed.

Results: The mean age of included patients was 38.7 ±15.6 years, they were 21 (42%) males and 29 (58%) females. 38 (76%) and 13 (26%) patients have pseudopyloric and intestinal metaplasia respectively. Overall 41 (82%) and 9 (18%) patients have low and high gastric cancer risk respectively. The sensitivity of NBI in diagnosis of Helicobacter Pylori infection, gastric atrophy and intestinal metaplasia were 96% (n = 48/50), 100% and 61.5% (n = 8/13) respectively. The degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% (n = 43/50) for the antral intestinal metaplasia. The degree of correspondence between the high risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% (n = 40/50).

Conclusion: NBI is able to approximate histopathological staging of gastritis to achieve complete ESD with a single device. It achieves clear marking, better hemostasis and smoother operation during a procedure without replacing the knife.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early gastric cancer. Development of the ESD device has been conducted recently. Splash M-Knife®, the new multi-functional needle-knife (ESD-C, n = 76) and by ESD with a new device (ESD-N, n = 73) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age (P = 0.006), PORPV of all vessels (median 85.38% vs 95.72%, p = 0.007) and MFI of all vessels (median 3.00 vs 2.80, p = 0.039) compared to healthy controls. After caloric challenge, PVD increased significantly in both in small (PVD) vessels and all vessels (PVD") in patients with CGI (PVD") (median 16.3 (IQR 13.3–22.1) mm²/mm² vs (T1) 12.9 (IQR 14.2–26.2) mm²/mm², p = 0.008; PVD") (T0) median 19.1 (IQR 16.2–23.6) mm²/mm² vs (T1) 22.2 (16.5–28.9) mm²/mm², p = 0.02; PorPV") (median 84.8% (IQR 75.3–90.4) vs (T1) 91.0% (80.1–93.6), p = 0.01). In contrast, no significant changes in microcirculatory parameters were observed after caloric challenge in the healthy controls.

Conclusion: Patients with CGI have impaired submucosal microcirculation compared to healthy controls. They also show significant alterations in the submucosal microcirculation after oral caloric challenge compared to healthy controls. Submucosal microcirculation visualization may offer a fast non-invasive diagnostic tool to diagnose patients with CGI.

2. Sana A, van Noord D, Mensink PB, Kooij S, van Dijk K, Bravenboer B, et al. Patients with chronic gastrointestinal ischemia have low and high gastric cancer risk respectively. The sensitivity of Narrow Band Imaging (NBI) endoscopy is equivalent to that determined by histopathology.

among two groups. As sub-analyses, the cutting time, rate of en-block/complete resection and rates of adverse events were evaluated among two groups.

**Results:** Propensity score matching analysis created 46 matched pairs. Adjusted comparisons between two groups showed a significantly smaller usage rate of hemostatic forceps in ESD-N than that in ESD-C (4.35% vs 8.48%, p < 0.001), and a significantly lower adverse event rate (90.0% vs 78.8%, 0.09%, p < 0.001). According to the Kyoto gastritis classification: diffuse redness, regular arrangement of collecting venules (RAC), fundic gland polyp (FPGP), atrophy, xanthoma, hyperplastic polypl, map-like redness, intestinal metaplasia, nodularity, mucosal swelling, white and flat elevated lesion, sticky mucus, depressive erosion, raised erosion, red streak, and enlarged fold. HP infection status was diagnosed on the basis of the findings. An Olympus H260 and Xp260NS were used for endoscopy. The diagnostic accuracy rate of the Kyoto classification and the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic odds ratio (DOR) for endoscopic findings were determined. This study was registered as a clinical trial in UMIN (UMIN0000166744) and was conducted with the approval of the ethics committee in this hospital.

**Introduction:** Since Helicobacter pylori (HP) eradication therapy is necessary to prevent the development of gastric cancer, evaluation of HP infection status (uninfected, infected, eradicated) by endoscopy has become important. For that purpose, the Japan Gastroenterology Endoscopy Society proposed the Kyoto classification for gastritis. However, the usefulness of the classification in daily clinical practice has not been sufficiently evaluated.

**Results:** The 498 subjects included 376 males and 122 females with a mean age of 53.1 years. HP status was unaffected in 315 subjects, eradicated in 104 subjects and infected in 79 subjects. The diagnostic accuracy rate was 82.9%. The sensitivity, specificity, PPV, NPV and DOR were 88.3%, 92.9%, 95.5%, 82.1% and 99.0%, respectively, for uninfected status, 67.1%, 91.4%, 59.6%, 93.6% and 21.7%, respectively, for infected status. High DORs were obtained for the following endoscopic findings: 32.2 for RAC, 7.7 for FGP and 4.7 for red streak in subjects with infected status, 12.8 for mucosal redness in subjects with eradicated status, and 26.8 for diffuse redness. 13.3 for mucosal swelling, 10.2 for sticky mucus and 8.6 for enlarged fold in subjects with infected status.

**Conclusion:** The Kyoto classification is useful for diagnosis of HP infection. However, it should be kept in mind that there is a high false-negative rate for endoscopy. Thus, considering the high rate of false-negative findings of endoscopy, we recommend using H. pylori serology and the CLO test before endoscopy in daily clinical practice.

**P0143 INTUBATION FAILURE DURING GASTROSCOPY – INCIDENCE, PREDICTORS AND FOLLOW-UP FINDINGS**

K. Siau1, J. L2, N. C. Fisher1, C.J.J. Mulder2, S. Ishaiq1
1Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom
2Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley, United Kingdom
3Dept. Of Gastroenterology, VU University Medical Center, Amsterdam, Netherlands

Contact Email Address: keith@siau.org

**Introduction:** Intubation failure (IF) occurs when a trained endoscopist is unable to progress to upper the oesophagus via the oropharynx. The incidence is unknown, but estimated at 1.8%. There have been no studies exploring IF and follow-up findings. We aimed to assess the incidence, causes of IF, predictors of pathology in patients with IF, and follow-up findings.

**Aims & Methods:** We retrospectively identified all gastroscopies performed at a district general hospital between August 2010–August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopist status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups: ‘failure to tolerate’ (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s chi² and Wilcoxon signed rank test.

**Results:** The incidence of IF was 0.95% (248/26130). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, n = 142), CT (21%, n = 50), repeat gastroscopy (29.4%, n = 70) and no further investigations (19.7%, n = 47). Structural pharyngeal abnormalities were diagnosed in comprising of oropharyngeal hypothyropy (CPH) (58%), Zenker’s diverticulum (ZD) (14.6%), cervical spondylosis (7.3%) and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5-0.9, p = 0.007). Within the IF cohort, predictors of structural causes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, p < 0.001), failure to progress (OR 5.2, 95% CI: 2.3–12.0, p < 0.001) and age ≥ 65 (OR 4.0, 95% CI: 1.8-8.9, p < 0.001). Repeat gastroscopy was successful in 63/70 (2 using nasendoscope) after increasing midazolam dosage (mean increase = 1.5 mg, 95% CI: 1.0-2.0 mg, p < 0.001). Diagnostic yield for barium radiography, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of endoscopy indication and pathology on further investigation for IF was 110/192 (57.5%). In patients undergoing barium radiography and repeat gastroscopy, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal pathology, particularly if associated with age ≥ 65, dysphagia, and failure of endoscopic progression. Barium Radiography is comparable to repeat gastroscopy in terms of diagnostic yield, and may be helpful in evaluating pharyngeal and functional pathology.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Aims & Methods:** The aim of this study was therefore to determine the usefulness of the Kyoto classification for diagnosis of HP infection status. A total of 498 subjects were recruited during the period from January to October 2015 in this study after providing informed consent in writing. HP infection status was determined by the presence of HP-IgG antibody (Eplate II H. pylori antibody, Eiken Chemical Co., Ltd., Tokyo, Japan) and history of eradication therapy. HP infection status was judged to be “eradicated” if there was a definite history of eradication therapy. Without a history of eradication therapy, HP infection status was judged to be “infected” for an HP antibody titer of less than 3 U/ml, “eradicated” for an HP antibody titer of 3-10 U/ml and “infected” for a HP antibody titer of more than 10 U/ml. Seven endoscopists (5 well-experienced endoscopists and 2 trainees) who were blinded to history of eradication therapy performed the endoscopies. The following endoscopic findings determined the diagnosis of HP infection: Helicobacter pylori

**Disclosure of Interest:** All authors have declared no conflicts of interest.

</table>

Re-bleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a non-endoscopic intervention for these still died. The mean time of surgical intervention, during procedure, the percentage of the time that the depth of sedation from the Aldrete score reached 9 or over 9 was 70% and 41% respectively. The median duration of hospitalisation, intensive care and mechanical ventilation was 13 days (1–56), 6.2 days (0.3–362) and 120 hours (1–708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, re-bleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and longer-term survival overall has not significantly improved since studies in the 1970s-1980s despite advances in pharmacological therapy. Current practices of SBT insertion and surveillance are variable and would benefit from further education. Rates of direct visualisation of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

PO146 CONSCIOUS SEDATION FOR ENDOSCOPIC SUBMUCOSAL RESSECTION BY USING DEXMEDETOMIDINE

Department of Gastroenterology, Yamashita Hospital, Ichinomiya, Japan

Contact E-mail Address: e.m.6089@gmail.com

Introduction: To evaluate the feasibility and safety of the dexmedetomidine (DEX) for conscious sedation during endoscopic submucosal dissection (ESD). Aims & Methods: This study was a prospective trial, and was conducted at the Yamashita Hospital. Between January 2016 and December 2016, all 50 patients were enrolled in this study. The inclusion criteria for the study was the presence of esophageal, gastric or duodenal tumors. The criteria for exclusion from this study is as follows: patients who were allergic to the drugs used, a baseline heart rate less than 50 beats/minutes, patients who could not use anticholinergic drugs, and lack of patient’s consent. A total 50 patients who underwent ESD by using DEX for conscious sedation during endoscopic submucosal dissection (ESD) for esophageal squamous cell carcinoma (ESCC) is very important to select appropriate therapeutic procedure. The Japan Esophageal Society (JES) classification using narrow-band imaging with magnification (M-NBI) was efficient for predicting invasion depth of ESCC1. Blue laser imaging (BLI) is an image enhanced endoscopy consisted of two different lasers with wavelength 410 and 450 nm as light source, which can enhance microvascular and microsurface structure. In previous study, BLI with magnification (M-BLI) was useful for evaluating gastro-intestinal neoplasms such as predicting invasion depth or tumor detection2. Aims & Methods: We aim to investigate the diagnostic value of M-BLI by comparing that of M-NBI. Our study was a single center retrospective study and approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. All patients provided informed consent for undergoing both M-BLI and M-NBI. Consecutive 166 patients underwent endoscopic submucosal dissection (ESD) for esophageal tumor at Kyoto Prefectural University of Medicine between April 2014 and March 2016. Endoscopic images of ESCCs were recorded by both M-BLI and M-NBI prior to ESD. ESCCs were pathologically diagnosed by ESD specimens. Three endoscopists with no information of the lesions evaluated invasion depth of ESCCs using M-BLI and M-NBI images according to JES classification. The diagnostic value of each procedure was then evaluated.

Results: 124 ESCCs were analyzed in this study. The numbers of male/female were 104/20, respectively. Median age was 68.5 years old. Median size of tumor was 17.6 mm. The proportion of tumor location at U/M/Lt was 13/70/17(%), respectively. The proportion of macroscopic type for 0-I/0-IIa/0-IIb/0-IIc was 10/66/23(%), respectively. The proportion of invasion depth of the lesions subclassified as EP or LPM, MM or SM1, and SM2 were 80, 13 and 7(%) respectively. The overall diagnostic accuracy of BLI and NBI were 88.7% and 83.9% (P = 0.35), respectively. The interobserver variability of three endoscopists using BLI and NBI was 0.679/0.560/0.559 and 0.568/0.822/0.560, respectively. The intraobserver variability with BLI and NBI was 0.839/0.718/0.531 and 0.517/0.514/0.441, respectively.

Conclusion: M-BLI was efficient for diagnosing invasion depth of ESCC according to JES classification, similar to M-NBI.

Introduction: Endoscopic Ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Cystic neoplastic antigen (CEA) tumor marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (nCLE) has been increasingly used for the diagnosis of PCN. nCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care, EUS alone with combined CEA and nCLE to determine which combination of diagnostic modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Negative Predictive Value (NPV) of EUS alone, EUS with CEA and nCLE combined were evaluated and diagnostic accuracy was compared with pathology using McNemar’s test. Worrisome features (increased cyst size, wall thickness, main pancreatic duct size, and presence of non enhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidean distance and later were used in hierarchical clustering to create two clusters based on Euclidean distance.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.75 and a NPV of 0.88. EUS and CEA had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and nCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, p = 0.000289.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and nCLE. We also found that clustering of worrisome features predicts pathology, however, a larger cohort is required for future studies.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavourable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD. Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric neoplasms were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and/ or others), macroscopic type (protruded, depressed or mixed), size of the resected specimen, preoperative scar, number of preoperative biopsies, (others), and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L: 8, group S: 6.8, P = 0.0231), biopsy visualization of SCJ was 92% (0.0097), and size of the resected specimen >800mm²: 3 points, difficult location: 2 points, the number of biopsies > 7 pieces: 1 point, Group 5 on biopsy diagnosis: 1 point. Cases of 6 points or more was regarded as difficult to remove that takes over 70 minutes. We examined 43 patients who underwent ESD for gastrointestinal neoplasms between August to November 2016 the sensitivity was 87.5% and the specificity was 80%.

Conclusion: Our results suggest that the number of biopsies, size of the resected specimen, biopsy diagnosis, preoperative scar, number of preoperative biopsies, (others), and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

in the lesser curvature (43.9%, 284/647). Posterior EGC was more frequent in the middle third stomach, traction assist contributes to a remarkable reduction of procedure time.

Results: Between July 2015 and September 2016, 640 patients underwent randomization. 316 patients assigned to conventional ESD and 319 patients assigned to DFC-ESD were included in the analysis set. Mean ESD procedure time was 60.7 minutes in the conventional ESD group and 58.1 minutes in the DFC-ESD group (p = 0.45). Perforation was less frequent in the DFC-ESD group (conventional ESD vs. DFC-ESD: 2.2% vs. 0.3%, p = 0.04). Among the lesions in the greater curvature of the upper or middle stomach, mean procedure time in the DFC-ESD group was shorter than the conventional ESD group (conventional ESD vs. DFC-ESD: 104.1 vs. 157.2 minutes, p = 0.01).

Conclusion: This study reveals that traction-assisted ESD does not result in quicker procedures in the entire population, but it can reduce the risk of perforation. Selectively applied to the lesions in the greater curvature of the upper or middle stomach, traction assist contributes to a remarkable reduction of procedure time.

P0152 A STUDY OF THE RECOGNITION OF ENDOSCOPIC IMAGES BY MACHINE LEARNING WITH CONVOLUTIONAL NEURAL NETWORK AND DEEP LEARNING

R. Yamakawa, M. Harada, K. Kawauchi, S. Nuzuki, M. Iwata
Gastroenterology, Kaeantsu Hospital, Niiigata, Japan

Contact E-mail Address: yamakawa_rj@niiigata-min.or.jp

Introduction: The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is underdetermined.

Aims & Methods: The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL.

We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), gastric body (GB), gastric antrum (GA), duodenal bulb (DB) and descending part of the duodenum (DD). Each category had approximately 100 images. These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 8313 by adding additionally rotated images of each five degrees.

We made an ML model with three CNN layers, three Activation Function layers, two Max-Pooling layers and two Dens layers by TensorFlow and Keras. We trained the ML model with the learning group images (n = 8313) and then tested it with the testing group images (n = 327) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same test utilizing the same images.

Results: It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories (n = 327), 77.1% in LP (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.3% in GF (n = 38), 61.5% in GB (n = 39), 52.8% in GA (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% in gastroenterologists (n = 5), 85.2% in junior residents (n = 2), 81.2% in endoscopy nurses (n = 5), 54.4% in medical clerks (n = 5) and 51.8% in floor nurses (n = 4). The percentage of correct answers of the ML model was lower than those of humans who have knowledge about endoscopic images. However, it was higher than those of other humans who do not. Concerning the possibility of the recognition of endoscopic images by ML with CNN and DL. Further study is necessary to confirm the ability of it because this study was conducted in a simple ML model with three CNN layers and a small number of images.

2Dept. De Gastroentérologie, APHM – North Hospital, Marseille/France
3Gastroenterology, Hôpital Nord, Marseille/France

Contact E-Mail Address: diane.lorenzo@gmail.com
Introduction: Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study is to evaluate the different endoscopic approaches.

Aims & Methods: This retrospective study included all patients treated for PSGF in a referral center. Closure management was defined as: initial treatment using covered-metal-stent and/or endoclips. ID management was defined as: initial treatment by nasocystic drain and/or double-pigtail-stent. The failure was defined as: need for surgery, or death.

Results: Between 2007 and 2015, 101 patients (women: N=78; mean age: 42±12years) were included. The mean delay between SG and the first endoscopy was 92±60 days. Overall success of endoscopic treatment was 86% within 6±27months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful).

Conclusion: Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5cm, an internal drainage should be proposed first. A second treatment by nasocystic drain should be associated with long-term care. Management in our center has changed over time with earlier first endoscopy and management of more severe patients.

PO156 CLOSURE BY USING OVER-THE-SCOPE CLIPS AFTER ENDOSCOPIC FULL-THICKNESS RESECTION

J. Guo
Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/China

Contact E-Mail Address: gaoguiyi@hospital.org
Introduction: Endoscopic full-thickness resection (EFR) is a mini-invasive technique for gastrointestinal subepithelial tumors, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastrointestinal fistula closure after EFR is a challenge for endoscopists. In this study, we introduced EFR with fistula closure using the over-the-scope clip (OTSC) system for gastrointestinal subepithelial tumors originating from the muscula propria.

Aims & Methods: We aimed to evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFR with defect closure using OTSC for gastrointestinal subepithelial tumors in our hospital. The patients were selected who underwent EFR for gastrointestinal subepithelial tumors originating from the muscularis propria (tumor diameter ≤3cm) in our hospital from May 2014 to December 2016. After a full-thickness resection of tumors, one or two OTSCs were released to close the defect. The success rate of defect closure with OTSC was observed and the endoscopic follow-up was performed at 1 week, 1 month, 6 months, 24 months after operation to check OTSC closure.

Results: In total 49 patients were included into the study. The full-thickness resection rate of gastrointestinal tumors in the muscularis propria was 100% (49/49), the success rate of defect closure was 100%, and the average time of defect closure was 7.3min (range: 3-27min). All patients experienced no postoperative complications such as bleeding and perforation. The postoperative follow-up time was 1-24 months (mean: 11 months), and no late complications was found.

Conclusion: OTSC can be used to perform EFR with defect closure for gastrointestinal tumors in the muscularis propria (tumor diameter ≤3cm). It is simple, convenient, safe and effective.

Introduction: ESD has been performed on many patients with early stage esophageal squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups chronologically. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (otramiclonel acetone 80mg) injection accompanied with systemic steroid treatment (IT + ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHG group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions.

Aims & Methods: To evaluate the efficacy of this mixture in single center of Beijing, China.

Patients and Methods: In total, 13 patients who underwent more than 2/3 circular or complete circular ESD for esophageal superficial squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups chronologically. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (triamiclonel acetone 80mg) injection accompanied with systemic steroid treatment (IT + ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHG group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions. ST groups started with 30mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT + ST group started with 80mg intraluminal steroid at the end of ESD procedure, and 30mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate and aluminum phosphate gel for prevention of the stricture after endoscopic submucosal dissection for esophageal cancer: a controlled prospective study.

Methods: In total, 13 patients who underwent more than 2/3 circular or complete circular ESD for esophageal superficial squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups chronologically. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (otramiclonel acetone 80mg) injection accompanied with systemic steroid treatment (IT + ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHG group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions. ST groups started with 30mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT + ST group started with 80mg intraluminal steroid at the end of ESD procedure, and 30mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate and aluminum phosphate gel for prevention of the stricture after endoscopic submucosal dissection for esophageal cancer: a controlled prospective study.

Results: There were two complete and two 75% circular ESD cases in IT + ST group, and one complete and five 75% circular ESD cases in OHG group, and one complete and five 75% circular ESD cases in OHG group.

Conclusion: Short period, oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early stage esophageal cancers.

**P0158 LONG-TERM OUTCOMES OF COLD POLYPECTOMY FOR NONAMPULLARY DUODENAL ADENOMAS**

Department Of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba City/Japan

Contact E-mail Address: d.maruoka@bscuit.ocn.ne.jp

**Introduction:** Cold polypectomy has a high incidence of complications such as perforation in endoscopic mucosal resection (EMR) as well as in endoscopic submucosal dissection (ESD), compared with resection of other parts of the digestive tract. We had written the first report on the safety and efficacy of cold polypectomy (cold forceps polypectomy [CFP] and cold snare polypectomy [CSP]) for sporadic SNADETs. However, there is no report on the long-term outcomes of cold polypectomy for sporadic SNADETs. In this study, we aimed to assess the long-term outcomes of cold polypectomy for sporadic SNADETs.

**Aims & Methods:** Patients without polyposis syndrome who underwent cold polypectomy for one or more SNADETs ≤5 mm in size and were diagnosed with adenomas between March 2015 and November 2016, and were followed up by endoscopy for more than 1 year were analyzed. All patients subsequently underwent upper gastrointestinal endoscopy 3 months after the intervention. The presence of residual tumors was evaluated by conducting endoscopic examinations and histopathological tests with tissue samples obtained from the cold polypectomy scars. Subsequently, patients underwent upper gastrointestinal endoscopy annually, and when residual tumors could not be denied, biopsies were taken from the scars.

**Results:** A total of 43 lesions in 33 patients were removed using cold polypectomy. Twenty patients were followed-up for more than 1 year. The mean follow-up period by upper gastrointestinal endoscopy was 13.1 (12–18) months. Of these 20 patients, 12 (60%) were men and the mean age of the subjects was 63 ± 11 years. The number of lesions were 5, 16, and 3 (21%, 69%, 8%) at the location 1st, 2nd, and 3rd portion, respectively, and 2, 3, 13, and 2 (8%, 13%, 54%, 17%) per macroscopic appearance (Isp, Ia, Ia + IIc, and IIc), respectively. Nine lesions in 8 patients were resected using CFP, while 15 lesions in 12 patients were resected using CSP. Seven of 9 (78%) and 14 of 15 (93%) lesions were removed en bloc using CFP and CSP, respectively; the other 3 lesions were removed by piecemeal resection in 2 pieces. All specimens resected using both CFP and CSP were successfully retrieved.

Histopathologic analysis showed that 21 of 24 lesions (88%) were low-grade adenomas and 9 of 24 (38%) were high-grade adenomas. The mean size of the adenomatous lesions was 4.0 ± 1.3 mm (2–6 mm). Eleven of 24 adenomas (46%) were R0 resections; 3 of 9 (33%) and 8 of 15 (53%) were R0 resections using CFP and CSP, respectively. Delayed bleeding and intraprocedural/delayed perforation were not observed in any case. The subjects were identified and biopsied at follow-up endoscopy performed 3 months after cold polypectomy, and no residual or recurrent tumor was detected morphologically or histopathologically. Although there was no recurrent case during the follow-up period, one patient died 6 months after resection because of heart failure.

**Conclusion:** Cold polypectomy is a safe and effective treatment for diminutive and small sporadic SNADETs that have been subjected to long-term follow-up.

**P0160 ARTIFICIAL INTELLIGENCE DIAGNOSIS OF HELICOBACTER PYLORI INFECTION USING LINKED COLOR IMAGING**

H. Nakashima1, H. Kawahira2, H. Kawachi3, N. Sasaki1

1Foundation For Detection Of Early Gastric Carcinoma, Tokyo/Japan
2Center For Frontier Medical Engineering, Chiba University, Chiba/Japan
3Department Of Pathology, The Cancer Institute Hospital, Japan Foundation for Cancer Research, Tokyo/Japan

Contact E-mail Address: nak22515@gmail.com

**Introduction:** Esophagogastroduodenoscopy (EGD) is of growing importance in the diagnosis of *Helicobacter pylori* (HP) gastritis, because HP infection is strongly associated with gastric carcinogenesis. However, the accuracy of endoscopic diagnosis of HP infection may vary according to the experience and technique of the attending endoscopist. Here, we challenged to establish a computer-aided endoscopic diagnosis system for HP infection using two novel technologies. First is a Linkor color imaging (LCI). It is a new Image-enhanced endoscopy (IEE) using a LASER light source to enhance slight differences in tissue color. The other is Artificial Intelligence (AI). Deep Learning has attracted attention in diagnostic imaging. It is a type of AI which imitates neural network in the brain.

**Aims & Methods:** The aim of this study was to establish an AI diagnosis of HP infection using LCI. We designed a prospective study of all patients who underwent EGD and were tested for serum anti-HP IgG antibodies at our medical clinic. Subjects who had a history of HP eradication therapy were excluded in this study. A total of 220 examinees were candidates who underwent EGD and serum antibody testing. The positive IgG antibody titer of each subject was taken as the gold standard for HP infection status for this study. During EGD an endoscopist took 3 LCI pictures of the lesser curvature, greater curvature and antrum of the stomach by EG-L580NW (FUJIFILM Co., Japan). Finally, we used a total of 639 LCI pictures in the study. The specifications of the AI used in this study were as follows: Operating system: Linux (Ubuntu 14.04 LTS), Neural network: GoogleLeNet2, Framework: Caffe3, and Graphic processor unit: Geforce GTX TITAN X (NVIDIA Co., Japan). We used the convolutional neural network (CNN) architecture, and we used R (version 3.3.2.) for all statistical analyses.

**Results:** The area under the curve (AUC) of receiver operating characteristics (ROC) was 0.95 for the lesser curvature. Compared to this, the AUC of the greater curvature and antrum was 0.81 and 0.67, respectively. The AUCs obtained in the lesser curvature was significantly larger than that in the greater curvature and antrum (P < 0.01).

**Conclusion:** The results demonstrate that the AI has excellent ability to diagnose HP infection using LCI in the lesser curvature. The authors believe that AI technology with IEs is likely to become a useful image diagnostic tool.

**P0159 ENDOSCOPIC TREATMENT OF BOERHAAVE SYNDROME: A SURPRISINGLY QUICK HEALING**

G. Sakizlis, D. Karagianannis

Gastroenterology, Iatrikon Medical Center, Athens/Greece

Contact E-mail Address: sakizlis@gmail.com

**Introduction:** Endoscopic treatment of Boerhaave Syndrome: A Surprisingly Quick Healing. Endoscopes (snakes) have a high incidence of complications such as perforation in endoscopic mucosal resection (EMR) as well as in endoscopic submucosal dissection (ESD), compared with resection of other parts of the digestive tract. We had written the first report on the safety and efficacy of cold polypectomy (cold forceps polypectomy [CFP] and cold snare polypectomy [CSP]) for sporadic SNADETs. However, there is no report on the long-term outcomes of cold polypectomy for sporadic SNADETs. In this study, we aimed to assess the long-term outcomes of cold polypectomy for sporadic SNADETs.

**Aims & Methods:** Patients without polyposis syndrome who underwent cold polypectomy for one or more SNADETs ≤5 mm in size and were diagnosed with adenomas between March 2015 and November 2016, and were followed up by endoscopy for more than 1 year were analyzed. All patients subsequently underwent upper gastrointestinal endoscopy 3 months after the intervention. The presence of residual tumors was evaluated by conducting endoscopic examinations and histopathological tests with tissue samples obtained from the cold polypectomy scars. Subsequently, patients underwent upper gastrointestinal endoscopy annually, and when residual tumors could not be denied, biopsies were taken from the scars.

**Results:** A total of 43 lesions in 33 patients were removed using cold polypectomy. Twenty patients were followed-up for more than 1 year. The mean follow-up period by upper gastrointestinal endoscopy was 13.1 (12–18) months. Of these 20 patients, 12 (60%) were men and the mean age of the subjects was 63 ± 11 years. The number of lesions were 5, 16, and 3 (21%, 69%, 8%) at the location 1st, 2nd, and 3rd portion, respectively, and 2, 3, 13, and 2 (8%, 13%, 54%, 17%) per macroscopic appearance (Isp, Ia, Ia + IIc, and IIc), respectively. Nine lesions in 8 patients were resected using CFP, while 15 lesions in 12 patients were resected using CSP. Seven of 9 (78%) and 14 of 15 (93%) lesions were removed en bloc using CFP and CSP, respectively; the other 3 lesions were removed by piecemeal resection in 2 pieces. Resolution White Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and EGGIM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathologic evaluation in specialized labs. The diagnostic performance of EGGIM was then compared to OLGIM (gold standard) and sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated. Results: IM was staged as OLGIM 0, 2, 3 and 4, respectively; 32 (41.0%), 23 (29.5%), 17 (21.8%), and 6 (7.7%) pts (no patients with OLGIM 1 were found). Table 1 shows detailed the EGGIM scores compared to OLGA. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGIM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. Eight of 6 patients were positive results using the EGGIM classification were H. pylori positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGIM was: sensitivity 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGIM classification were H. pylori positive. A high agreement between EGGIM and OLGIM scores was observed (83.3%).

Conclusion: The EGGIM classification showed a high diagnostic performance compared to OLGIM, in particular in patients with OLGIM 3 and 4. A possible confounding factor leading to overestimation of presence of intestinal metaplasia might be the presence of H. pylori infection. This approach could be used to simplify the surveillance of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS

Z. Liu1, X. Zhang1, Q. Li1, P. Zhou1
1Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai, China

Contact Email Address: liuzq16@fudan.edu.cn

Introduction: Peroral endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on its learning curve are limited. A comprehensive evaluation based on risk factors is needed.

Aims & Methods: This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM procedures performed in Zhongshan Hospital were analyzed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.

Results: Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, full-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representativeness of the operative experience, is also an independent risk factor for a longer procedure time and hospital stay.

Conclusion: For POEM operators, seventy cases might be considered a threshold for learning, i.e., technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.

CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS

L. Liu, W. Liu, Z. Fan
Digestive Endoscopy Center, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Contact Email Address: kit9178@sina.com

Introduction: Gastrintestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40%–70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFR) and combined endoscopic and laparoscopic surgery.

Aims & Methods: Our study is aimed to assess the safeness and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 162 patients with gastric stromal tumor who underwent endoscopic treatments from June 1, 2011 to July 31st 2015 were analyzed retrospectively. The mean diameter of the tumors was 1.5 cm (0.3–5.0 cm). 104 patients received endoscopic submucosal dissection, 58 patients received endoscopic full-thickness resection. Among them, 4 operations were failed under the monitor of laparoscopy.

Results: Complications were observed in 8 patients (4.9%): bleeding during operation: 3 patients, post-operation perforation: 3 patients, respiratory tract infection: 2 patients. The mean post-operation feeding time was 2.67 days (range 1–9 days) and post-operation hospital stays were 5.39 days (range 2–10 days). The mean time of follow-up was 26.4 months (range 5–51 months). The follow-up showed that 6 patients kept on treating with oral administration of imatinib. No patient was found recurrence or death.

Conclusion: Endoscopic treatments were demonstrated as safe and effective ways to resect gastric stromal tumors in this study.

Disclosure of Interest: All authors have declared no conflicts of interest.

GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AUGIB ENDOSCOPY TRAINING?

S. Budihal1, P. Wurm1
1Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Contact Email Address: shivbudihal@yahoo.co.uk

Introduction: Much concern surrounds Gastroenterology Specialist Registrar (SIR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AUGIB). Recent evidence suggests there has been a decline in experience and exposure in AUGIB endoscopy.1 In July 2013 our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AUGIB endoscopy training after its implementation.

Aims & Methods: Endoscopy reports of patients presenting with haematemesis, melena or both who had undergone surgery during the period of 1st of May 2012 to 31st August 2013 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where SIRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/08/2012)

Results: A total of 7 SIRs (5 Full Time and 2 Less than Full Time) performed gastroscopies on AUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastroscopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. In cases of hematemesis cases Haemospray was used. On average each SIR on an average able to perform one case of oesophageal varical banding and one case where Haemospray was utilised. Data from the 2012 cohort in comparison showed a total of 66 gastroscopies over 6 months with 13 EI. On average 13 procedures and 2–6 EI were performed by each SIR. Dual therapy was applied in only 28.5% of the cases.

Conclusion: The introduction of the Registrar of the Week Service provides a valuable opportunity for SIRs to be trained in endoscopic haemostasis and augmentation to their exposure to AUGIB patients. As per this study each SIR on an average performed endoscopy on 24 AUGIB patients. If this is extrapolated, each SIR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of EI, on average a SIR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in 5 year program. This is significantly better than in the previous cohort and other centres1. Hospitals should consider developing similar services not only to meet demands for 24/7 Consultant led AUGIB endoscopy service but provide adequate endoscopic training provision for current specialist registrars in order to ensure future competent and confident consultants.

Disclosure of Interest: All authors have declared no conflicts of interest.

HIGH PERCENTAGE OF VISIBLE LESIONS IN PATIENTS WITH BARRETT’S ESOPHAGUS REFERRED WITH DYSPLASIA IN RANDOM BIOPSY

L. C. Noordzij1, W. L. Curvers1, J. Van Linschoten2, C. J. Huygen3,4, E. J. Schoon1
1Gastroenterology And Hepatology, Catharina Hospital, Eindhoven/Netherlands
2Eurhopat Of Pathology And Medical Microbiology, PAMM, Eindhoven/ Netherlands
3Laboratory Of Pathology And Medical Microbiology, PAMM, Eindhoven/ Netherlands

Contact Email Address: irma.noordzij@catharinaziekenhuis.nl

Introduction: Endoscopic recognition of dysplasia or early cancer in Barrett’s esophagus (BE) is difficult. Experience in recognition of early neoplastic lesions is thought to increase the detection of visible dysplastic lesions. A previous study reported that endoscopists in community hospitals detect neoplastic lesions at a significant lower rate than referral centres. The aim of the study was to assess the significance of dysplasia in random biopsies in BE, in the absence of reported visible lesions as well as the final outcome of pathology.

Aims & Methods: We retrospectively analysed all patients referred from 19 community hospitals to our tertiary referral centre with the diagnosis of BE with dysplasia or early adenocarcinoma (EAC) between February 2008 and April 2016. All patients underwent a dedicated imaging endoscopy with high-definition endoscopy supplemented with virtual chromoendoscopy and/or acetate acid staining at the discretion of the endoscopist. All procedures were performed by an endoscopist with extensive experience in the detection of early neoplastic lesions in BE. During endoscopy all visible lesions were noted and biopsied and/or removed by endoscopic resection (ER). Patients were included for analysis in case of absence of reporting visible lesions at referral.

Results: In total 184 patients were referred with dysplasia or EAC of which 82 patients (45.6%) referred with LGD, a visible lesion during imaging endoscopy was detected. Two cases of histology proved EAC and one confirmed LGD. In twenty-six of 31 patients (60.5%) referred with HGD, a visible lesion with histology specimens corresponding to HGD (10) and EAC (16) were found.
respectively. All cases of EAC were detected (7/7). In 18/75 (24%) patients referred with dysplasia (LGD/HGD) without a visible lesion, the referral diagnosis was thus upstaged to EAC. Overall, 41/82 (50%) lesions were found additionally.

**Conclusion:** The presence of any grade of dysplasia in random biopsies in BE screening in community hospitals is a potential marker for more severe focal pathology after endoscopic work-up in an expert centre. Training in Barrett imaging is mandatory for non-expert endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0169 ENDOSCOPIC MANAGEMENT OF BENIGN ESOPHAGEAL FISTULAS**

A. Debourdeau, J. Gonzalez, A. Benezech, M. Barthet
Gastroenterology, Aix Marseille University, AP-HM, Hôpital Nord, Marseille; France

**Contact E-mail Address:** antoine.debourdeau@hotmail.com

**Introduction:** Nonmalignant esophagogastric fistulas (ERF) are rare but frightening clinical situations. They usually involve surgery, but the morbidity and the mortality is high. The knowledge about the modalities and outcomes after endoscopic management of ERF remain limited.

**Aims & Methods:** The aim of this study was to describe and assess the endoscopic management of benign ERF in our center. This was a retrospective study involving patients manage for benign ERF in our tertiary center between July 2012 and December 2016. The inclusion criterion was the presence of communication between esophagus and bronchial tree diagnosed and treated by endoscopy, and malignant ERFs were excluded. The ERFs were classified into three groups of sizes: punctiform (if the orifice was no larger than a straight catheter), medium and large (with visibility of bronchial tree). The primary endpoint was to document any clinical success defined as the closure of the fistula confirmed by endoscopy and persisting >6 months. The secondary endpoints were to document the characteristics of endoscopic treatment, the functional success and death, and to identify factors associated with success and death.

</tbody>
</table>

**Results:** A total of 22 patients were included and analyzed. The endoscopies of ERF were esophageal surgery in 12 patients (54.5%), esophageal dilatation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 93 procedures were performed with a mean of 4.2±4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSC) placement and seven had OTSC associated with esophageal stent. The clinical success rate was 45.5% (n = 10), and 55% of the patients had a functional success (n = 12). Serious adverse events occurred in 9 patients (40.9%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impaction (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctiform ERF (p = 0.193), 50% of medium ERF (p = 1) and 14% of large ERF (p = 0.17). The factor associated with the failure of endoscopic treatment was the persistence of the fistula after 6 months (OR = 44; IC95: 3.38–573, 4; p = 0.004 multivariate analysis). The orifice’s size was associated with the mortality with 71% of death among large fistulas (p = 0.001 univariate analysis).

**Conclusion:** Endoscopic treatment of ERF can lead to 45.5% of clinical success and 55.5% of functional success. However, this outcome appears associated with the size of the fistula. Moreover, the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and has to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0170 CLINICAL UTILITY OF NARROW BAND IMAGING MAGNIFYING ENDOCOPY FOR MM/MM1 ESOPHAGEAL SQUAMOUS CELL CARCINOMA**

M. Inoue1, T. Omori1, K. Nastu1, K. Aiura1
1Department Of Surgery, Kawasaki Municipal Kawasaki Hospital, Kawasaki; Japan

**Contact E-mail Address:** masaz.inoue@gmail.com

**Introduction:** Esophageal squamous cell carcinoma (ESCC) is common in Asia. Predicting invasion depth of superficial ESCC is crucial in determining the pre-operative examination because of the lymph node metastasis increases in proportion of the invasion depth of the carcinoma. According to Japanese guidelines for diagnosis and treatment of esophageal cancer, superficial invasions are divided into 5 categories: carcinoma in situ (EP), tumors invades lamina propria mucosa (LPM), lamina muscularis mucosa (MM), the submucosa to a depth of 200 μm or less from the muscularis mucosa (SM1), and the submucosa to a depth more than 200 μm (SM2). The rate of lymph node metastasis is extremely low in EP/LPM tumors, and esophageal resection (ER) is certified as precise treatment. On the other hand, the rate of lymph node metastasis in MM/MM1 tumors are reported to 10-20%, and both operation and ER are considered as their treatment. Accurate pretherapeutic diagnosis of MM/MM1 tumor is very important for selection of appropriate treatment and interests of patients. In this point, endoscopic diagnosis is very important diagnostic approach.

**Aims & Methods:** The purpose of this study is to investigate the utility of Narrow Band Imaging (NBI) magnifying endoscopy for the diagnosis of MM/MM1 ESCC. From January 2011 to April 2017, 23 patients were diagnosed as pathologically MM/MM1 ESCC in our hospital. We retrospectively analyzed their endoscopic findings and pathological findings. The depth of invasion was diagnosed by NBI magnifying endoscopy according to the Japan Endoscopy Society (JES) magnifying endoscope classification. Diagnostic criteria are based on the degree of microvascular irregularity in the target lesion observed by NBI magnifying endoscopy. Microvessels are grouped into 2 types. Type A microvessels are normal intrapapillary capillary loops or abnormal microvessels without severe irregularity. Type B microvessels are abnormal vessels with severe irregularity and highly dilated abnormal vessels, and subclassified into B1, B2, and B3 based on the running pattern or degree of dilation of severely irregular microvessels. When target lesions have B1 vessels, the invasion depth is predicted as EP or LPM. When B2 or B3 vessels are seen, the invasion depth is predicted as MM or SM1 or SM2 or deeper, respectively.

**Results:** In 23 pathologically MM/MM1 cases, clinical type diagnosed by endoscopy was 0-Hc in 16 cases (70%), 0-Hb in 3 cases (13%), 0-Hb in 3 cases (13%), and 0-Hp in 1 case (4%). Predicted depth of invasion by NBI magnifying endoscopy based on the JES classification was EP in 2 cases (9%), LPM in 7 cases (30%), MM in 10 cases (43%), SM1 in 3 cases (13%) and SM2 in 1 case (4%). Total diagnostic accuracy of MM/MM1 was 57% (13/23). When the B2 vessels were observed, diagnostic accuracy of MM/MM1 was 90% (9/10). In the cases that MM or SM1 invasion remained pathologically quite localized, B2 vessels could not be observed by NBI magnifying endoscopy. And also, in the cases with inflammation or keratinizing epithelium, precise diagnosis of microvessels were difficult.

**Conclusion:** Our data indicate that diagnosis of MM/MM1 ESCC by NBI magnifying endoscopy based on the JES classification is useful when the abnormal microvessels are observable by NBI. NBI magnifying endoscopy is essential method for pretherapeutic examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0171 PER-ORAL ENDOSCOPIC PYLOROVOMYOTOMY (POEP) IN THE TREATMENT OF REFRACTORY GASTROPARESIS – A SINGLE CENTRE EXPERIENCE**

R. Hustak1, Z. Vackova1, J. Spicak2, L. Jurgos3, J. Martinek2
1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Dept. Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
3Poliklinika Myrina, Bratislava/Slovak Republic

**Contact E-mail Address:** rhustak@gmail.com

**Introduction:** Gastroparesis is a chronic, debilitating motility disorder. Effective treatment is challenging especially in patients with severe symptoms. POEP is an
emerging modality for refractory gastroparesis with promising preliminary results.

Aims & Methods: The aim of this prospective case series was to assess our first (single center) experience with POEP. Main outcomes were: 1) the efficacy defined by improvement of GCSI score; 2) gastric emptying evolution and 3) satisfaction. From Nov 2015, a total of 7 patients underwent POEP. The etiology of gastroparesis was post-operative in 4, diabetic in 2 and idiopathic in 1 patient. One patient underwent POEP for gastroparesis following a multivisceral transplantation; one patient underwent both POEP and POEM (as a single procedure) for coexisting refractory idiopathic gastroparesis and achalasia. All patients had severe gastroparesis as defined by elevated GCSI score and delayed gastric emptying scintigraphy. Follow visit at 3, 6, 12-months were completed in 7/7 (100%), 5/7 (71%) and 1/7 (14%) patients, respectively. Upper GI endoscopy and scintigraphy were performed 3 months after the procedure.

Results: POEP was successfully performed in all patients. Mean procedure time was 70 minutes (range 63–106). After POEP, mean GCSI decreased from 3.0 ± 1.2 to 0.8 ± 0.7 (at 3-months) and 0.9 ± 0.8 (at 6-months). One woman developed a delayed follow maintaining excellent outcome. Treatment success was reached in 6/7 (85%) of patient, one female patient with diabetic gastroparesis did not have a major symptomatic improvement despite normalisation of gastric emptying study. Gastric scintigraphy normalized in all patients, mean half emptying time decreased from 108 ± 30 min to 62 ± 25 min; and mean bolus retention at 4 hours decreased from 17 ± 9.2% to 2.0 ± 2.0%. One patient developed bleeding ulcer 10 days after POEP, this adverse event was successfully managed endoscopically (clips) and by parenteral proton pump inhibitor.

Conclusion: We report our first experiences with POEP for refractory gastroparesis, demonstrating its feasibility and safety with promising clinical efficacy.

Conclusion: We have developed the first internally validated simple classification system for the diagnosis of Barrett’s neoplasia using BLI. The classification criteria demonstrated high sensitivity and specificity particularly with regards to mucosal pit and vessel patterns. We aim to use the proposed classification in future studies for real time optical diagnosis of Barrett’s neoplasia.

P0173 TREATMENT OF MULTIPLE GASTROINTESTINAL SUBMUCOSAL TUMORS BY SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

J. Liu, W. Qin, Y. Huang, Z. Ren, P. Zhou
Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: liu.jingzheng@zs-hospital.sh.cn

Introduction: Submucosal tunneling endoscopic resection (STER) is a novel technique to remove the gastrointestinal submucosal tumors. Previous studies mainly focused on technical feasibility for patients with one single gastrointestinal submucosal tumor. No systematic studies about multiple upper gastrointestinal submucosal tumors synchronously removed by STER are addressed. The aim of this study was to evaluate the safety and outcome of STER in treatment of multiple gastrointestinal submucosal tumors.

Aims & Methods: From January 2011 to January 2017, 42 patients with multiple gastrointestinal submucosal tumors undergoing STER were included. Variables of each tumor and patient were analyzed. Detailed tumor characteristics included max size, sum of max size and number of tumors, and longest distance of tumor. While detailed technique information included number of tunnels, tunnel length, hospital stay, procedure time, complication, follow-up, recurrence, and metasta.

Results: Among all the cases, 96 lesions of upper gastrointestinal submucosal tumors were removed by STER. The median procedure time was 50 min (range 13.6–84.9 min). The median number of tumors was 2 (2–4). The median max size of each tumor was 1.8 cm (range 0.7–3.5 cm) and the median sum of max size of each tumor of each patient was 3 cm (range 1.3–8.6 cm). Six patients had perforative complications (14.2%), with 3 pneumothorax/hydrothorax (7.2%), 1 mucosal injury (2.4%), 1 pneumonia (2.4%), and 1 major bleeding (2.4%). Patients with different number of tunnels had similar tumor characteristics and techniques. There were significant differences in longest distance of tumors comparing two groups (p < 0.001). No local recurrence or distant metastasis was detected with a median follow-up of 33 months.

Conclusion: STER is a safety and feasible technique for multiple upper gastrointestinal submucosal tumors no matter in one tunnel or two tunnels resection. Based on the longest distance of tumors, different number of tunnels can be performed with similar procedure technique and prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0174 COMPARISON OF THE LINKED COLOR IMAGING (LCI) TECHNOLOGY AND CHROMOENDOSCOPY WITH ACETIC ACID FOR DIAGNOSIS OF BARRETT’S ESOPHAGUS

H. Neumann1, H. Neumann Sen2, P. Grimminger3, E. Corvinus1, F. Rahman1, F. Thieringer1, G.E. Tontini4, P. R. Gale4
1Universitätssmedizin Johannes Gutenberg University Mainz, Mainz/Germany
2Gastroenterologische Schwerpunktpraxis, Bad Salzuflen/Germany
3Department Of General, Visceral And Transplant Surgery, University Medical Center Mainz, Mainz/Germany
4Interdisciplinary Endoscopy, University Medical Center Mainz, Mainz/Germany

Introduction: LCI is a new imaging technique based on 4 independently acting LEDs that is enhancing the mucosal vascular pattern and surface pattern morpholgy. To date, chromoendoscopy with acetic acid is considered the gold standard for diagnosis of Barrett’s esophagus. Aims & Methods: The aim of this prospective study was to evaluate the recently introduced LCI technique compared to conventional dye spraying with acetic acid for diagnosis of Barrett’s esophagus. Therefore, consecutive patients with Barrett’s esophagus from the Prague classification and prospectively included. All Barrett segments were carefully evaluated by using high-definition white-light imaging, followed by LCI and acetic acid spraying. At each examination targeted biopsies were taken from all visible lesions, followed by random four-quadrant biopsies were applicable. Results: The diagnostic yield of conventional dye spraying was significantly higher for diagnosis of Barrett’s esophagus compared to high-definition white-light imaging. Of note, no significant difference for diagnosis of Barrett’s esophagus was noted between acetic acid chromoendoscopy and the LCI technique. LCI diagnosis was always consistent to traditional dye spraying (100% concordance). The random four-quadrant biopsy protocol did not add additional biopsies and corresponded to the one already obtained by using LCI. Conclusion: The newly introduced LCI technique is superior to high-definition white-light endoscopy for diagnosis of Barrett’s esophagus and equally effective to acetic acid dye spraying. Therefore, the LCI technique has the potential to facilitate the diagnosis of Barrett’s esophagus and to overcome the limitations of a random 4-quadrant biopsy protocol. Disclosure of Interest: All authors have declared no conflicts of interest.

P0175 ALBERTA FAMILY PRACTICE ELECTRONIC ENDOSCOPY STUDY (AFPEE)

M. Kolber1, L. Green1, N. Olivier1, R. Torrie2, O. Babenko1
1Family Medicine, University of Alberta, Edmonton/Canada/AB
2Tabor Medical Clinic, Tabor/Canada/AB

Contact E-mail Address: mkolber@ualberta.ca

Introduction: In Canada, gastroenterologists and general surgeons perform 97% of all colonoscopies. There are a number of rural Canadian Family Physicians involved in performing colonoscopies. These gastroenterologists may improve access for rural patients who require endoscopy and help improve provincial endoscopy wait times. Although some studies demonstrate that adequately trained Family Physicians are able to perform quality endoscopy, other studies question the quality of colonoscopies performed by non-gastroenterologists. Aims & Methods: The Alberta Family Physician Electronic Endoscopy Study (AFPEE) study aimed to examine the quality of colonoscopies performed by Family Physicians in Alberta, Canada. Primary outcomes include the proportion of males and females completing colonoscopies (ranging from 95.2 to 100%) The proportion of males and females who completed colonoscopies (ranging from 95.2 to 100%) The proportion of males and females who completed colonoscopies (ranging from 95.2 to 100%). Results: In this six-month study, 9 Family Physicians performed 1769 colonoscopies in 11 rural Alberta sites. The proportion of successful cecal intubations was 97.9% (95% CI: 97.2, 98.5). All physicians had over 90% successfully completed colonoscopies (ranging from 95.2 to 100%). The proportion of males and females aged 50 years old with an adenoma on a first-time colonoscopy was 67.4% (95% CI: 62.4, 72.7) and 51.1% (95% CI: 45.5, 56.7) respectively. All physicians achieved benchmarks of 30% of males and 20% for females having at least one adenoma. From all colonoscopies in the study there were 2099 pathologically confirmed adenomas or SSA of 628 advanced adenomas and 17 cancers, corresponding to 120 adenomas, 36 advanced adenomas and 1 colon cancer per 100 colonoscopies. There were 2 post-polypectomy bleeds, no perforations and no deaths. Conclusion: Alberta Family Physician colonoscopists are meeting benchmarks in endoscopy quality. Ongoing electronic collection of endoscopy quality markers should be encouraged. Supporting and training rural Family Physicians who perform endoscopy may help alleviate current wait times and improve access for rural Canadian patients. Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: helmut.neumann@unimedizin-mainz.de

Introduction: In a randomised controlled trial, flexible sigmoidoscopy (bowel scope) reduced colorectal cancer incidence and mortality in a population aged 55-64.[1] Patients progressed to colonoscopy based on ‘high risk’ features (Table 1).[1] Based on these pivotal findings, the UK bowel scope (BS) surveillance programme was introduced in 2013 to individuals aged 55. The Wolverhampton Bowel Cancer Screening Centre was the first UK site to roll out the programme. The prevalence of BS findings and subsequent colonoscopy has not previously been evaluated in this specific cohort. Aims & Methods: We prospectively collated data from all BS patients at our centre and identified those undergoing colonoscopy between August 2013-2016. We assessed conversion rates, compliance with BS protocol and correlated endoscopic and histological findings to identify predictors of detection of pathology at colonoscopy. Univariate analysis was performed using Pearson’s chi². Results: 11,711 bowel scopes were performed, with an adenoma detection rate (ADR) of 8.5%, and conversion to colonoscopy in 421 patients (3.6%). 386 were included for analysis after excluding incomplete colonoscopy/histology. All patients were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 1.5% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), polyt ≥10mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, p < 0.001). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, p = 0.002), and male gender (OR 2.35, p < 0.001). These factors also significantly predicted new ≥10mm adenoma. 57 (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, p = 0.003). After adjusting for high risk indications, changing the conversion criteria from any villous to villous only histology altered sensitivity from 27.2% to 83.3%, and specificity from 84.5% to 80.5%. Table 1: Indications for progression from BS to colonoscopy (in bold), and indication of new adenoma detection. Patients in multiple categories are included multiple times. **p < 0.05

Introduction: Cold snare polypectomy is an established method for the resection of small colorectal polyps (SCPs); however, significant incomplete resection rates still leave room for improvement. We aimed to assess the efficacy of cold snare polypectomy with submucosal lift (SL-CSP) versus endoscopic mucosal resection (EMR), for non-pedunculated polyps 6–10 mm (ClinicalTrials.gov NCT02678663).

Aims & Methods: Dual-center, randomized, noninferiority trial. Consecutive adult patients with at least one nonpedunculated polyp 6–10 mm were enrolled. Eligible polyps were randomized (1:1) to be treated with either SL-CSP or EMR. The primary noninferiority endpoint was histologic eradication, with a noninferiority margin of –1. Evaluation of histologic complete resection relied on a postpolypectomy biopsy protocol (4 biopsies obtained in a 4-quadrant fashion from the polypectomy site margins; 1 biopsy from the base). Secondary outcomes included occurrence of intraprocedural bleeding (IPB; defined as any immediate episode requiring endoscopic haemostasis), clinically-significant postprocedural bleeding (CSPPP; any episode requiring emergency department presentation, hospitalization, or reintervention within 30 days of the procedure) and perforation.

Results: Among 689 patients screened, 155 patients with 164 eligible polyps (SL-CSP: n = 83, EMR: n = 81) were included. The overall rate of histologic complete resection was 92.8% (77/83) in the SL-CSP group and 96.3% (78/81) in the EMR group (difference 3.5%; 95% CI, –4.1 to 11.6), showing noninferiority of SL-CSP versus EMR. The SL-CSP technique was noninferior to EMR for polyps measuring 6–7 mm (SL-CSP, 93.3%; EMR, 100%; 95% CI, –7.95 to 21.3) and those 8–10 mm (SL-CSP, 92.5%; EMR, 94.7%; 95% CI, –7.91 to 13.16). By multivariate analysis, female gender (OR, 0.15; 95% CI, 0.02–1.06; P = 0.07) and Parts 0–IIa morphology (OR, 0.12; 95% CI, 0.01–1.19; P = 0.07) were marginally significant predictors correlating negatively with complete resection. Rates of IPB were similar between the two groups (SL-CSP, 3.6%; EMR; 1.2%, P = 0.3). No CSPPP or perforation occurred in either group.

Conclusions: SL-CSP appears to be an effective modification of standard cold snare technique, obviating the need to use diathermy for 6–10 mm colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO177 ASSESSMENT OF TRAINING NEEDS AND DEVELOPMENT OF A SIMULATION BASED TRAINING PROGRAMME FOR SEMI-AUTOMATED ROBOTIC COLONOSCOPY

M. Kopczynska1, R. Hopps1, S. Smith1, N. Warren2, S. Goddard1, X. Ye2, S. Dolan2

Introduction: Early diagnosis of colorectal cancer whether through a symptomatic or screening pathway results in better outcomes for patients. Various studies have reported barriers to screening amongst non-responders as well as delays due to diagnostic pathways. Current constraints in the NHS include delays in diagnostic pathways. Current constraints in the NHS include access to and engagement with non-responders (1, 2).

Aims & Methods: This project forms part of the development of a training programme with the use of a simulation based training model to understand the specific training needs and methods of fulfilling these for the potential ultimate users of community-based robotic colonoscopy. This study involved participants with varying degree of skills and background knowledge in the field of colonoscopy. We enrolled three expert endoscopists, three trainee endoscopists, two novices and two experienced video gamers. All participants performed colonoscopy on a validated ‘surgical’ simulator model developed at Welsh Institute for Minimal Access Therapy (WIMAT) centre. Before testing each participant received both verbal and written instructions on the goals of the study and information about the semi-automated robotic scope along with a familiarisation period with the device. Quantitative parameters were recorded related to procedure times and lesion detection during the procedure. Afterwards participants filled out a questionnaire evaluating the robotic
colonscope. Some operators participated in a follow up session in order to assess the effect of the robotic microvasculature on their diagnostic accuracy.

Results: On average, experts required the shortest time to reach the caecum, followed by video gamers, trainees then novices. Polyp detection rate (as a proportion of total number in the model simulator colon) was the highest in the novices (91.67%) followed by the experts (86.11%), then equally, trainees and video gamers (79.17%). Four out of nine participants attended the second session where they were asked to repeat the procedure from the first session. Each participant had a lower caecal intubation time during session 2 in comparison with session 1, with a median improvement of 40% and 80%, respectively. Each of the participants also had the same or higher polyp detection rate with range of improvement between 0% and 25%. Qualitative assessment of feedback from all participants indicated that most operators felt that the role of the novel test would likely be greater in a diagnostic polyp search in an out of hospital setting. Expert operators felt that training in the device was easier but also provided less ability to torque steer due to automated sequences.

Conclusion: This is the first step in identifying specific training needs and potential for use in early diagnosis of cancer. This study also evaluated the potential to reduce the length of time for skills acquisition associated with standard colonoscopy training through the use of semi-automated robotic devices.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0183 ACHIEVING ADEQUATE LEVEL BOWEL PREPARATION WITH EVENING/MORNING OR MORNING-ONLY SPLIT-DOSING REGIMENS OF NER1006 VERSUS STANDARD 2L PEG WITH ASCORBATE: POST HOC ANALYSIS OF A PHASE 3 TRIAL

R. Biscops1, L. Clayton2
1Gastroenterology, Katholieke Universiteit Leuven, Leuven/Belgium
2Clinical Development, Norgine Ltd., Harefield, Uxbridge/United Kingdom

Contact E-mail Address: raf.biscops@uliege.be

Introduction: Effective colonoscopy requires effective bowel preparation. For detection of polyps larger than 5 mm, an adequate” segmental cleansing level has recently been defined as ≥2 or more on the Boston Bowel Preparation Scale (BBPS). The Phase 3 trial MORA compared NER1006 as an evening/morning split-dosing or a morning-only dosing regimen, against 2L PEG with ascorbate as an evening/morning split-dosing regimen (2L PEG + Asc). Treatment-blinded central readers assessed the bowel cleansing efficacy using both the Harefield Cleansing Scale (HCS) and the BBPS. This post hoc analysis shows the BBPS scores for the two primary endpoints, in those patients who had a readable colonoscopy.

Aims & Methods: In the MORA trial, 784 patients aged 18–85 were randomised to bowel preparation with morning-only or evening/morning split-dosing using either NER1006 or 2L PEG + Asc. Adequate level cleansing success was assessed according to the BBPS for both overall colon (all segments ≥2) and right colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Results: A total of 792 patients were analysed. When using an evening/morning split-dosing, 249/262 (95%) patients on NER1006 achieved adequate level overall colon cleansing compared to 232/260 (89%) on 2L PEG + Asc (Table 1). Using morning-only dosing, 243/270 (90%) patients on NER1006 achieved the same. Using evening/morning split-dosing, 254/262 (97%) patients on NER1006 achieved adequate level right colon cleansing compared to 242/260 (93%) on 2L PEG + Asc. Using morning-only dosing, 253/270 (94%) patients on NER1006 achieved adequate level right colon cleansing. Adequate level cleansing success was achieved significantly more often with NER1006 evening/morning split-dosing than 2L PEG + Asc, both in the overall colon (P = 0.013) and in the right colon (P = 0.042). The slight improvement seen with NER1006 morning-only dosing in the cleansing rate of the overall colon and right sided colon was not statistically significant. Table 1: Adequate level cleansing of the overall colon and right colon segments scores 2–3 as determined by treatment-blinded central readers.

Disclosure of Interest: R. Biscops: Norgine, self: salary, speaking and teaching; funded attendance by Norgine for Investigator’s Meeting trip for the MORA trial.

Aims & Methods: We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathological results from another DB were extracted and merged together in a separated DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polyp detection rate, caecal intubation rate, quality of bowel preparation (using the Boston bowel preparation scale) and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was mandatory. The completeness of recording was evaluated and compared between both periods, and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and to published targets.

Results: During the 6 months "mandatory-filling" period (July-December 2016), 1802 colonoscopies were performed with a QI tab fully filled in 100% of cases compared to 63.1% after the "free-filling period" (p = 0.0001). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.76 with 86.9% of cases with adequate preparation (Boston score ≥ 5; 89.9% among outpatients and 81.9% among inpatients). Colonoscopies were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0%-55.7%). The polyp detection rate was 44.4% with a mean of 1.19 polyp removed by colonoscopy. The positive predictive value (PPV) of CTC in terms of the outcome “detection of ACN” was also calculated, comparisons were made after considering patients in all included studies.

Discussion of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CF-H190i (Olympus Medical Corp., Tokyo, Japan). The videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion used to validate the CAD algorithm and 21 for in vivo evaluation of CAD algorithm) were used to evaluate the performance of the CAD algorithm. The validation samples were analyzed using the CAD algorithm and its output as the probability of the presence of a lesion in each video was computed. A receiver operating characteristic (ROC) analysis was performed to evaluate the efficacy of the CAD algorithm.

Results: The mean probability of a poly positive video was 62.1 ± 27.9%, whereas that of a poly-negative video was 18.1 ± 24.6% (P < 0.001). The area under the ROC curve for probability estimation was 0.87, which was statistically significant from chance level (P < 0.001). The present CAD algorithm could detect a polyp with 90.9% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions.

P0191 MOTORIZED SPIRAL COLONOSCOPY (MSC) – A FIRST FEASIBILITY TRIAL

T. Beyna, M. Schneider, D. Pullmann, H. Neuhaus
Department Of Internal Medicine, Evangelisches Krankenhaus Düsseldorf, Düsseldorf/Germany

Contact E-mail Address: tobien.beyna@evk-duesseldorf.de

Introduction: Colonoscopy is widely accepted for the diagnosis and treatment of colon diseases. Accepted quality parameters for colonoscopy include a cecal intubation rate of ≥ 90%, 10% of all colonscopies are difficult and intubation of the cecum can sometimes be impossible. The novel motorized endoscope was recently developed (Olympus Medical Systems Corporation, Tokyo, Japan) to overcome some of the limitations of standard colonoscopy with push technique by actively pleating the bowel onto the endoscope with motorized rotation of the spiral overtube. This may have advantages in cases of difficult standard colonoscopy to facilitate cecal intubation on the one hand and in all colonscopies in terms of patient comfort, sedation and also in therapeutic situations.

Aims & Methods: To evaluate feasibility and safety of MSC for diagnostic colonoscopy. Secondary endpoints were ileum intubation rate, procedure time, need for sedation and external compression, patients' pain and satisfaction, adenoma detection rate (ADR) and feasibility of therapeutic interventions. 30 consecutive patients with indication for colonoscopy meeting the inclusion criteria at a single tertiary referral center were enrolled in the trial between December 2016 and January 2017. The study was conceived as proof of concept trial with the primary aim to achieve a cecal intubation rate of at least 90% according to quality guideline recommendations.

Results: 13 male and 17 female patients were enrolled. Mean age was 68.9 years (30–90), health status was ASA-1: 16.7%, ASA-2: 36.7% and ASA-3: 46.6%. 42% of the patients had comorbidities. Indications for colonoscopy were clarification of indeterminate iron deficiency anemia (IDA, n = 5), lower gastrointestinal bleeding (GIB, n = 6), surveillance after previous polypectomy (n = 6), screening for polyps and colorectal cancer (n = 11) and others (n = 2). Sedation level (Ramsay Sedation Scale) in all patients was 3 (deep sedation). Mean amount of propofol was 305 [130–880] mg. Mean procedure time was 20.8 [11.4–55.3] min. Cecal intubation rate (technical success) was 96.7% (29/30). One incomplete colonoscopy occurred due to an unexpected postinflammatory stricture of the sigmoid. All colonscopies reaching the cecum also successfully intubated the ileum (96.7%). Only in one case external compression was needed. Adenoma detection rate was 46.7%. EMR was performed in 9 cases, 5 patients had forceps polypectomy. One case of incidental finding of submucosal invasive adenocarcinoma in EMR specimen was histologically proven to have R0 en-bloc resection. All other therapeutic interventions could also successfully be conducted (clip n = 3, argon plasma coagulation n = 1, tissue sampling n = 2). Two mild adverse events were recorded (mild superficial mucosal lesions without proctitis were observed).

Conclusion: This study represents the first clinical evaluation of the novel motorized spiral endoscope for examination of the colon. Our data show that it is effective and safe for diagnostic and therapeutic colonoscopy. It may also have potential advantages over standard colonoscopy technique in terms of effectiveness and convenience of colonoscopy.

P0192 TREATMENT OUTCOMES OF COLD FORCEPS POLYPECTOMY FOR PATIENTS WITH DIMINUTIVE POLYPS: A PROSPECTIVE FOLLOW-UP STUDY

H. Hasegawa1, S. Bambu2, H. Han1, H. Imaeda1, A. Nishida1, O. Inatomi2, M. Sasaki1, M. Sugimoto1, A. Andoh1
1Dept. Of Gastroenterology, JCHO Shiga Hospital, Otsu,Japan

Contact E-mail Address: hiroyase@belle.shiga-med.ac.jp

Introduction: The results of the National Polyp Study are premised on the removal of all adenomatous lesions. Cold forceps polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (<5 mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated by CFP from June 15 to March 2017. Multifocal polypectomy was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: 246 patients were enrolled for total 515 polyps from 277 patients. The size of the polyps was <3 mm/3+mm/5 mm = 379/101/35. The rate of one-bit polypectomy for adenoma was <3 mm/4 mm/5 mm = 79%/54%/33%. There was no significant difference in the one-bit rate between endoscopists’ experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antiplatelet drugs was found in 14% (72/485), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There are no polyps on surveillance. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 13 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rate of newly discovered polyps in the same segment were 2% and 23% in groups A and B, respectively. The rates of newly discovered polyps in the different segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of <5 years/5–9 years/more than ten years, the rate of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42% (8/18)/37% (11/30), respectively.

Conclusion: The rate of one-bit polypectomy was significantly higher for diminutive polyps especially less than 3 mm. Importantly there are no polyps suspicious residual or recurrent lesion. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0193 EFFICACY OF CIMETROPIUM BROMIDE ON POLYP DETECTION DURING COLONOSCOPIC WITHDRAWAL: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED, CLINICAL TRIAL

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of

Contact E-mail Address: salsuplu@naver.com

Introduction: Colonoscopy is the most effective method for preventing colorectal cancer, as it offers easy detection and resection of polyps. Cimetropium bromide
results in colonic spasmylosis and may improve polyp detection. We studied the effect of cimetropium bromide on polyp detection during colonoscopic withdrawal.

Aims & Methods: Patients undergoing colonoscopy for screening examinations were included and randomized at cecal intubation to receive either 5 mg cimetropium bromide sublingual tablets or placebo. We evaluated the polyp detection rate (PDR), adenoma detection rate (ADR), and advanced ADR (AADR) in the right side colon as well as in the cecum.

Results: A total of 181 patients were analyzed in this study. Cimetropium group comprised of 90 patients and placebo group consisted of 90 patients. PDR, ADR, and AADR were not statistically different in cimetropium and control groups (62.6% vs. 66.6%, P = 0.571; 51.6% vs. 47.7%, P = 0.603; 3.2% vs. 7.7%, P = 0.187; respectively). Similarly, PDR and ADR in the right side colon were not significantly different between the groups (46.1% vs. 47.7%, P = 0.827; 32.9% vs. 35.5%, P = 0.714; respectively).

Conclusion: Cimetropium bromide does not improve the PDR or ADR in the right side colon or the cecum. Thus, administration of cimetropium bromide can be used in colonoscopic withdrawal.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: kawamura@kyoto2.jrc.or.jp

Introduction: Cold snare polypectomy (CSP) has grown in popularity worldwide due to its ease and safety with a low incidence of adverse events, such as hemorrhage and post-polypectomy syndrome. However, there are concerns regarding tumor residue with CSP because it does not use electrocoagulation, thereby eliminating its burning effect. European Society of Gastrointestinal Endoscopy (ESGE) clinical guideline suggests CSP for subcentimetre sessile polyps because of its safety despite lack of evidence for efficacy compared to HSP. The aim of this study was to investigate the success rate of CSP for complete resection of subcentimetre colorectal adenomatous polyps compared to that of HSP.

Aims & Methods: This was a prospective, multicentre, randomised controlled, non-blinded study in 12 Japanese endoscopy units. Patients aged >20 years, undergoing elective colonoscopy/polypectomy, and who provided written informed consent were included. Patients who were taking anti-thrombotic agents and undergoing hemodialysis were excluded, as well as those with inflammatory bowel diseases, polyposis, and pregnancy. Endoscopically diagnosed sessile adenomatous polyps, 4–9 mm in size, were randomly assigned to the CSP or HSP group. After complete removal of the polyp using the allocated technique, biopsy specimens from the resection margin after polypectomy were obtained. The primary endpoint was the completion rate, defined as no evidence of adenomatous tissue in the biopsied specimens, among all pathologically confirmed adenomatous polyps (full analysis set: FAS). Pre-planned subgroup analyses for the size of polyp were also conducted. The sample size was calculated according to the incomplete resection rate seen in previous articles and the required sample size was estimated at 780 lesions, including drop out cases. The protocol was approved by the institutional review board in each institution. Results: A total of 796 eligible polyps were detected in 538 of 912 patients screened for eligibility between September 2015 and August 2016. Three hundred and ninety-four lesions were assigned to the CSP group and 402 lesions were assigned to the HSP group. One hundred and nine lesions (56 in the CSP group and 53 in the HSP group) were excluded for FAS analysis. Background characteristics of the lesions (size, location, morphology, and institution) were similar in both groups. The complete resection rate for CSP was 98.2%, compared to 97.4% for HSP. The between group difference in complete resection rate was +0.8%, favouring CSP (90% CI of –0.5–2.7, p < 0.0001). Resection time, overall, was significantly shorter with CSP than with HSP (60 vs. 83 s, respectively, p < 0.001). Postoperative bleeding resided within 24 hours in 99% of the HSP group (95.5%, 2 of 402 cases). Subgroup analysis according to the size of the polyp (4–5 mm and 6–9 mm) showed a comparable complete resection rate for CSP and HSP for both subgroups of polyps.

Conclusion: The complete resection rate of CSP is not inferior to that of HSP. CSP can be one of the standard techniques for subcentimetre colorectal polyps. (Study registration: UMIN000018328)

Disclosure of Interest: All authors have declared no conflicts of interest.
with a defined AE. Treatment options, including none required, were taken from 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient’s safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the impact of LM involvement on local recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, en bloc resection and R0 resection.

Results: The ER was aborted in 5 cases (perforation n = 3; technical difficulties n = 2). Surgical intervention was needed after ER because of submucosal or linfonvascular invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range 10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sm1-Vienna 5. En bloc resections were obtained in 44 cases (57.7%); 33 ESD (48%) and 11 KAR (14.7%). The ER finished as p-KAR in the 31 remaining lesions (41.3%). R0 resections (n = 23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR [OR = 8.9 (CI 95%: 2.8–28.3); p < 0.0001]. The median follow-up period was 16 months (1–91). Local recurrence occurred in 11 cases: 9 of the latter throughout the first year (81.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p = 0.03). When results were stratified according to histology and en bloc resections, no significant differences were found in the recurrence rate. When en bloc resections in pT1a (sm1); (y – v); (v) pTVM0 lesions (n = 44) were analysed separately, the LM distribution with LM0 (52.3%), 18 LM1, 6 LM2 and 3 LM3 (6.8%). There was a non-significant trend concerning the recurrence rate when LM0 (n = 23) lesions were compared with LM1/LMx (n = 21): 0% vs. 14.8% at 3 years; p = 0.06.

Conclusion: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

Introduction: Performing CR-ESD remains challenging in Western countries and surveillance studies in this setting are not fully described. KAR has been advised as a reasonable strategy for non-expert endoscopists and difficult lesions. However, some KAR eventually requires a piecemeal resection (p-KAR). A direct comparison between these two techniques is lacking. Additionally, when the specimen is resected en bloc regardless of what procedure is used, and the only pathological risk factor for recurrence is lateral margin (LM) involvement, its implications concerning the recurrence rate should be assessed.

Aims & Methods: 1) To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD “intention-to-treat” basis, in a Western European setting where CR-ESD is performed by non-experts. 2) To evaluate

Main characteristics of the resected lesions by procedure

Conclusion: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

P0201 ASSOCIATION BETWEEN SIZE, LOCATION AND HISTOLOGICAL CHARACTERISTICS OF COLORECTAL LATERALLY SPREADING TUMOURS
1. F. L. Mota1, J. F. Loureiro1, L. S. N. Da Costa2
2. Digestive Endoscopy Department, Hospital Sírio-Libanés, São Paulo Brazil

Contact E-mail Address: lucasndc@gmail.com

Introduction: Laterally spreading tumours (LST) are important precursors of colorectal cancer (CRC)1. The endoscopic characteristics of the LSTs, such as size and location, appear to correlate with the histological findings2,3, which is an essential data for the decision of the best therapeutic procedure to be carried out4,5.

Aims & Methods: To determine the association between size, location and the histological characteristics of colorectal LSTs by reviewing the colonoscopy and histopathological reports of the LSTs endoscopically removed between October 2013 and June 2015 at the digestive endoscopy department of a tertiary hospital. The Vienna revised classification was used for the adenomatous lesions6, and the World Health Organization (WHO) classification for the ‘sessile serrated adenomas’ (SSA)7. The regions of the colon were referred to

References
Results: A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.69 cm. The rectal/proximal colon was the most common location (73.4%) of occurrence of the LSTs, with 34% being at the ascending colon. The most common histological type was the low grade dysplasia adenoma (Vienna 3), followed by the SSA without dysplasia with 21.6%. There was significant correlation between size and histology (p < 0.005), where the adenomatous lesions were found to be larger than the other categories. The SSAs, however, did not show this association. We identified association between location and histological type (p < 0.005): the adenomas with low grade dysplasia were most prevalent in the proximal colon. However, when the subdivision of the colon into anatomical segments was considered, the SSA without dysplasia was the most common type at the ascending colon.

Conclusion: There is association between the size and the histological characteristics of colorectal lesions with high grade dysplasia were found to be larger than the other classifications. This association, however, is not observed between SSAs lesions. There is association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eFTR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0203 VASCULAR AND PIT-PATTERN ANALYSIS ACCORDING TO KUDO, SANO AND NICE CLASSIFICATIONS: IMPROVES AFTER AN IMAGE-BASED TRAINING PROGRAM

Introduction: Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

Aims & Methods: The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopic unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colo-rectal neoplasms, before and after a 30-minutes image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colo-rectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endoscopists. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colorectal neoplasms’ surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colorectal neoplasms’ evaluation before and after the training was also calculated using the McNemar test. A value of p < 0.05 was considered statistically significant.

Results: A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ± 0.03) and Sano (0.12 ± 0.04), and poor for the NICE classification (0.24 ± 0.05). Diagnostic accuracy was 0.33 ± 0.07, 0.54 ± 0.12 and 0.60 ± 0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification (p < 0.0001) and to good for Sano and NICE classifications (p < 0.0001). Diagnostic accuracy increased significantly, too, with values of 0.60 ± 0.05, 0.76 ± 0.05, 0.80 ± 0.05 for Kudo, Sano and NICE classifications, respectively (p < 0.0001).

Conclusion: To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colo-rectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

P0202 SAFE AND SUCCESSFUL RESECTION OF DIFFICULT GI LESIONS USING A NOVEL SINGLE-STEP FULL-THICKNESS RESECTION DEVICE (FTRD)

P.V. Valli1, J. Mertens2, P. Bauerfeind3
1Division Of Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland
2Department of Surgery, University Hospital Zurich, Zurich/Switzerland
3Division of Gastroenterology and Hepatology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the novel full-thickness resection device (FTRD®) opens a new dimension of possibilities for endoscopic resection.

Aims & Methods: Sixty patients underwent therapeutic endoscopic full-thickness resection (eFTR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD, Ovesco® Endoscopy AG, Tübingen), is fitted onto a therapeutic endoscope. The endoscope with the FTRD® is advanced to the previously marked lesion. Grasping forceps are used to take hold of the target lesion and carefully pull it into the plastic cap of the FTRD®. Immediately after deployment of the OTSC®, eFTR is performed using the hyperthermic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

Results: EFR was performed for the following indications: 1. Recurrent adenomas (n = 22.3%) with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary non-lifting sign on saline injection (n = 2.3%). 2. Non-lifting base after extensive piecemeal resection of a spreading adenoma (n = 2.3%). 3. Diverticulosis (n= 4.3%). 4. Polyps the cecal appendix (6.7%). 5. Submucosal lesions (n = 5.8%). 6. Early carcinoma (n = 7.1%). 7. Follow-up resection of a malignant polyp (n = 6.0%). 8. EFR over endolaparoscopic resection (n = 2.3%). In 97% (58/60) of the interventions, the FTRD®-mounted endoscope reached the previously marked lesion and eFTR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up histology was even higher (88%). The following adverse events occurred: Appendicitis of the residual cecal appendix after eFTR of an appendiceal adenoma (1/58.2%). Minor bleeding at the eFTR site (2/58.3%). EFR performed accidentally without proper prior deployment of the OTSC® (1/58.2%). There was no secondary perforation or eFTR-associated mortality.

Conclusion: To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colo-rectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

P0204 YIELD OF 2ND SURVEILLANCE COLONOSCOPY IN "INTERMEDIATE RISK" PATIENTS. COULD SURVEILLANCE INTERVALS BE REDEFINED?
M. Balakrishnan, B. Adeoti, S. Cerys, S. Catnach, A. King, B. Macfarlane, J. Landy
Gastroenterology, West Hertfordshire Hospitals NHS Trust, Watford/United Kingdom
Contact E-mail Address: jonathan.landy@whht.nhs.uk
Introduction: Data regarding the yield of 2nd surveillance colonoscopy after index procedure findings of advanced colonic neoplasia (ACN) are limited. The yield of ACN at 2nd surveillance is associated with high risk index or 1st surveillance findings (1). However, previous studies have heterogeneous and definition of ACN include characteristics of both "intermediate" (IR, >3 adenomas or any adenoma >10 mm) and "high risk" groups (HR, >5 adenomas or >3 adenomas with at least 1 >10 mm) as defined by BSG guidelines.
Aims & Methods: We aimed to evaluate the differences in yield of advanced colonic neoplasia at 2nd surveillance colonoscopy (S2) between “intermediate” and “high” risk patients at index colonoscopy in our unit. ACN was defined as ≥5 adenomas, any adenoma ≥1 cm, tubulovillous histology or high grade dysplasia, or cancer. Patients with HR or IR index procedures undertaken by 3 experienced, accredited bowel cancer screening colonoscopists and at least 2 surveillance colonoscopies, were identified from our local database between 2008 and 2016. Findings at 1st and 2nd surveillance procedures were assessed for the presence of ACN. Statistical analysis was undertaken using Graphpad Prism 5 using Fisher’s exact test. All tests were two tailed and a p value of <0.05 was considered significant. ORs with a 95% CI were calculated for significant findings.
Results: 218 patients meeting inclusion criteria were identified. 53% of patients had IR index findings. The median time to S2 was 49 months (IQR 48–49) for HR index patients and 72 m (IQR 70–73 m) for IR index patients. 11% of all patients had ACN at S2. 4% of IR patients v 18% of HR patients had ACN at S2. OR 0.4 (95% CI 0.2–0.6). 3% of IR patients without ACN at S1 had ACN at S2 v 15% of IR patients with ACN at S1 (ns). 11% of HR patients without ACN at S1 v 37% with ACN at S1 had ACN at S2; OR 0.2 (95% CI 0.07–0.6).
Conclusion: Stratification of high-risk index findings into HR and IR groups identifies a low-risk group at second surveillance colonoscopy. The second surveillance interval for IR patients without ACN at first surveillance might be increased as ACN is infrequently detected in this group.

P0205 SAFETY OF COLD SNARE COLON POLYPECTOMY IN PATIENTS ON ANTIITHROMBOTIC MEDICATION
M. Matsumoto
Dept. Of Gastroenterology, Hokkaido Medical Center, Sapporo/Japan
Contact E-mail Address: miosakura@outlook.jp
Introduction: Cold snare polypectomy (CSP) has been increasingly used in recent years because post-polypectomy bleeding is less common with this technique than with conventional polypectomy. According to the 2012 update of the Japanese guideline for periprocedural management of antithrombotic medications issued by the Japan Gastroenterological Endoscopy Society, procedures with a low risk of hemorrhage may be performed with a short interruption or continuation of antithrombotic medication. However, the guideline does not refer to periprocedural antithrombotic management for CSP.
Aims & Methods: The objective of this study was to determine the safety of CSP in patients on antithrombotic medication. The subjects were patients who underwent CSP at this hospital between April 2014 and March 2016. Post-CSP bleeding rates were examined in relation to the use of antithrombotic medication. CSP was indicated for non-pedunculated polyps smaller than 10 mm, excluding lesions with worrisome invasion and suspected of being cancers at the preprocedural diagnostic evaluation.
Results: CSP was performed to remove 2466 polyps in 1003 patients; cancerous lesions accounted for 0.2% of them, but all had negative margins. There were 549 patients who had been taking antithrombotic medication before CSP (antithrombotic group), and 1971 (77.7%) in 817 patients not taking antithrombotic medication (non-antithrombotic group). In the antithrombotic group, 106 patients with 283 polyps continued taking the antithrombotic medication; specifically, aspirin in 41 patients with 113 polyps, clopidogrel in 13 patients with 17 polyps, dual antiplatelet therapy (DAPT) in 13 patients with 18 polyps, antiplatelet agents other than clopidogrel in 17 patients with 68 polyps, anticoagulant agents in 20 patients with 56 polyps, and antiplatelet plus anticoagulant combination therapy in 2 patients with 11 polyps. Heparin bridging was used in 13 patients with 38 polyps. Post-CSP bleeding occurred in patients on other antiplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p<0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% vs clipping vs. 0.34% without clipping; p=0.55).
Conclusion: CSP is a safe procedure even in patients on antithrombotic medication. The post-CSP rate of bleeding after CSP was not high compared with that after biopsies in patients on antithrombotic medication (post-procedural bleeding rate, 0.09–0.61%), suggesting that CSP can be virtually categorized as a procedure with a low risk for hemorrhage in the guideline for periprocedural antithrombotic medication.

P0206 OPTICAL ENHANCEMENT FOR THE IN VIVO PREDICTION OF COLORECTAL POLYP HISTOLOGY
E. Klenske, C. Neufert, A. Nagel, S. Zörgl, M. F. Neurath, T. Rath
Department Of Medicine 1 University Hospital of Erlangen, Erlangen/Germany
Contact E-mail Address: entcho.klenske@uk-erlangen.de
Introduction: Diminutive polyps are a common finding among surveillance colonoscopies without having high prevalence of advanced histology, making their standardized removal cost-, time- and risk-intensive. Based on these considerations, the American Society of Gastrointestinal Endoscopy (ASGE) proposed the so called PIWI statement, in which diagnostic thresholds are defined that new technologies used for the real-time assessment of colorectal polyp histology should meet. Optical enhancement (OE) is a novel endoscopic pre-processing optical filter technology, in which the spectrum of the emitted wavelengths is reduced, thereby leading to enhanced visualization of the mucosal and vascular pattern.
Aims & Methods: In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIWI criteria. A total of 106 colorectal polyps from 49 patients undergoing diagnostic or surveillance colonoscopy were included. The in vivo histology prediction using OE was compared to results of histopathology as a reference standard.
Results: The overall accuracy of OE for real-time prediction of polyp histology was 94.3% with a sensitivity, specificity, positive (PPV) and negative prediction value (NPV) of 100%, 95.3%, 85.4% and 100%, respectively. When including only high confidence (HC) predictions, the accuracy of OE increased to 96.5%. Sensitivity, specificity, PPV and NPV were 100%, 94.5%, 91.2% and 100%, respectively. In distal colorectal polyps the accuracy was 93.3% with sensitivity, specificity, PPV and NPV being 100%, 91.3%, 80% and 100%, respectively. The post-polypectomy colonoscopy surveillance intervals were predicted correctly in ≥90% of patients with OE.
Conclusion: Optical enhancement allows to accurately predict the histology of diminutive colorectal polyps in vivo in real-time and meets the PIWI thresholds for expanding training programs to diagnose and discarding diminutive polyps without histological assessment and for leaving distal diminutive colorectal polyps in place. Hence, optical enhancement can potentially reduce time, risk and costs associated with removal and histopathological assessment of diminutive polyps.

P2007  BLUE LASER IMAGING OPTICAL DIAGNOSIS OF COLORECTAL POLyps: ACCURACY OF THE NICE, SANO AND WASP CLASSIFICATIONS

S. Rhiere, J. Dreanic, M. Barret, M. Camus, M. Dior, B. Brieau, S. Leblanc, F. Prat, R. Coriat, S. Chaussade

Department Of Gastroenterology, Cochin Hospital, Assistance Publique-Hôpitaux de Paris, France

Contact E-mail Address: sophieclm.rhiere@gmail.com

Introduction: Imaging (BLI) is a new image-enhanced endoscopic technique, meant, in association with magnification endoscopy, to help differentiating between neoplastic and non-neoplastic colorectal polyps. A variety of endoscopic classifications have been developed to guide optical diagnosis of colorectal polyps, including the NICE, WASP and Sano classifications for the optical diagnosis of colorectal polyps using Blue Laser Imaging and magnification.

Aims & Methods: Between May 2014 and December 2015, 181 colorectal polyps in 65 patients were imaged and resected in our single center study. Each polyp was evaluated using white light endoscopy, BLI with and without magnification. An independent expert reviewed the pictures and the videos of the polyps and staged them using NICE, Sano and WASP classifications: his conclusions were compared with the actual histology of the polyps. Diagnostic performances of BLI and magnification were calculated with each endoscopic classification.

Results: 181 polyps were studied, among which 125 adenomas, 24 sessile serrated adenomas/polyps, 25 hyperplastic polyps, 2 adenocarcinomas and 11 normal colorectal mucosal samples. The median polyp size was 7 mm. Overall, the NICE, Sano and WASP classifications were comparable in terms of diagnostic performances for the optical diagnosis of colorectal adenomas (p=0.7). However, magnification provided the best results with significantly higher specificity, positive and negative predictive value, and diagnostic accuracy for the diagnosis of adenoma of 0.93 (95% CI 0.86 to 0.97), 0.80 (95% CI 0.66 to 0.91), 0.93, 0.80 and 0.9. In the rectosigmoid, negative predictive values for the diagnosis of adenoma were 0.77; 0.91; and 1.0 using NICE, Sano and WASP classifications.

Conclusion: Our work suggests that BLI with magnification is a promising technique for the optical diagnosis of colorectal polyps with a diagnostic accuracy of 80-90%. Our study did not establish significant difference between the three classifications. However, the ASGE criteria for the implementation of the "resect and discard" strategy were met for the classifications of Sano and WASP with a negative predictive value for the diagnosis of adenoma beyond 90% in the rectosigmoid.

Introduction: Colonoscopy is difficult procedure, largely due to unpredictable looping during insertion. If the endoscopist is able to see the colonoscope on the image display, fewer attempts are needed to straighten the shaft of the scope. A prototype Fiber BRag Grating(FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination.

Methods: The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonoscopy using FBG. In the first part of the study, the FBG sensor was inserted into the working channel of a routine colonoscope in the first 70 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movement of the scope. In the second part of the study, patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. Fluoroscopy was used in all investigations for comparison.

Results: In the first part of the study, the results showed that the shape sensor was compatible with our FBG system and the greatest tip curvature of 80 mm. The average tip error was 1.722±1.678 mm, which corresponds to 1.50±1.46% of the total length of the sensor. Scope movement and loops were detected correctly in all cases through the monitor. The prototype used in the second part of the study showed the high correlation and little discrepancy with the comparative findings at fluoroscopy.

Conclusion: Scope-guided endoscopy using FBG sensor can be successfully used to display colonoscopy configuration. This flexible, thin and almost weightless new technology would be a novel technique for identification of colonoscopy shape.

Contact E-mail Address: borakeum@hanmail.net

Introduction: Irreversible electroporation (IRE) is a promising novel technique for tumor ablation using energy current pulses. IRE can effectively remove useless cells without thermally damaging surrounding tissue. Multiphoton microscopy for evaluated the response of cancer cell to IRE ablation and found apoptotic process after applying IRE.

Aims & Methods: By using multi-photon (MP) probes, that is ABI-Nu for nucleus and PMT for mitochondria, we were focusing on these two vital intra-cellular organelles for examining the real-time phenomenon of IRE-induced apoptosis. The study was conducted in three stages. Colon cancer cell lines and normal colon mucosa and colon neoplasm tissues obtained during colonoscopic biopsy from 10 patients were stained with multi-photon (MP) probes that is ABI-Nu for nucleus and PMT for mitochondria. We evaluated the feasibility of using multiphoton microscopy (MPM) to observe IRE response. First, the IRE responses of colon cancer cell lines were compared before and after IRE. Electrical pulses were administered with a Harvard apparatus, and the changes in the intensity of the nucleus and mitochondria were observed with time. Second, the IRE response of normal colon and colon cancer tissue obtained from same patient were evaluated before and after IRE same with previous method. Also, the 3-D images of the tissues co-labelled with ABI-Nu and PMT were reconstructed. Third, to assess apoptosis, colon cancer cells were stained with the fluorescent dye Annexin V or propidium iodide (PI) after applying electroporation at the same energy used earlier. Also, in order to determine whether IRE induce apoptosis, membrane blebbing of colon cancer cell lines were examined after apply IRE.

Results: MPM images of cancer cells stained with MP probes revealed that ABI-Nu and PMT for mitochondria, we were focusing on these two vital intra-cellular organelles for examining the real-time phenomenon of IRE-induced apoptosis. The study was conducted in three stages. Colon cancer cell lines and normal colon mucosa and colon neoplasm tissues obtained during colonoscopic biopsy from 10 patients were stained with multi-photon (MP) probes that is ABI-Nu for nucleus and PMT for mitochondria. We evaluated the feasibility of using multiphoton microscopy (MPM) to observe IRE response. First, the IRE responses of colon cancer cell lines were compared before and after IRE. Electrical pulses were administered with a Harvard apparatus, and the changes in the intensity of the nucleus and mitochondria were observed with time. Second, the IRE response of normal colon and colon cancer tissue obtained from same patient were evaluated before and after IRE same with previous method. Also, the 3-D images of the tissues co-labelled with ABI-Nu and PMT were reconstructed. Third, to assess apoptosis, colon cancer cells were stained with the fluorescent dye Annexin V or propidium iodide (PI) after applying electroporation at the same energy used earlier. Also, in order to determine whether IRE induce apoptosis, membrane blebbing of colon cancer cell lines were examined after apply IRE.

Conclusion: Here, we observed using MPM that nuclear staining occurred quickly due to increased cell membrane permeability and bleb was formed after electric pulse exposure. These results are expected to challenge the understanding of the
permeability process after IRE by providing the real-time images. Additionally, Magnetic resonance imaging was performed using a Siemens 1.5 T scanner, including a 3T FITE and STI imaging. This MRI protocol would dramatically increase the accuracy of diagnostic techniques by providing in vivo cell images.

**P0211 LARGE (>30MM) POLYP ENDOSCOPIC MUCOSAL RESECTION: OUTCOMES AND PREDICTORS OF SUCCESS**

K. Sia1, E. Karunananda2, A. Kaweza3, S. Ishag1
1Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom
2Department Of Surgery, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Contact E-mail Address: keith@sia.org

**Introduction:** Endoscopic mucosal resection (EMR) is an established therapeutic option for large (>30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

**Aims & Methods:** We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2006–2016 in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMSA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMSA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

**Results:** Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colon in 81%. Bleeding occurred in 16.5%, all of whom achieved haemostasis. The 30-day complication rate was 1.1% (delayed bleeding in 1 patient), 54 (59%) were fully resected in one session, with overall EMR success in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile polyp morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured malignant polyps with R0 endoscopic resection. The overall malignant histology rate in this cohort was 11/91 (12%). In this cohort, the R0 EMR success rates was 4/11 (36%), with no recurrence after 60 months of follow-up. The overall 12-month recurrence rates following complete EMR was 1.5%, with no significant factors affecting EMR durability identified.

Table 1: Predictors of complete resection on first EMR attempt. p-values derived from bivariate regression, with bold values significant if *p < 0.05.

Conclusion: Large polyp EMR is a safe and effective alternative to surgical resection of large polyps. Endoscopist experience, polyp morphology, and benign histology are the complete predictors at index EMR. Further data are required to evaluate the longer-term outcomes of malignant polyps.

**Introduction:** Though numerous research has enabled decrease of the bowel preparation solution volume, it is still a major complaint of patients preparing for colonoscopy. There have been studied that additional administration of laxatives could lessen the amount of various formula with prokinetic effect. Prucalopride is a serotonin (5-HT4) receptor agonist which stimulate colonic mass movements and provide main propulsive force for defecation.

**Aims & Methods:** The aim of this study is to compare 2-L PEG-Asc and 1-L PEG-Asc plus prucaloprside while probe for quality of bowel cleansing while comparing the colonoscopy and patient compliance. Two hundred patients were prospectively enrolled. Patients referred for colonoscopy were divided into group A (the split-dose 2-L PEG-Asc) and group B (1-L PEG-Asc + prucalopride) randomly. During colonoscopy, each patient’s bowel preparation quality was evaluated with The Boston Bowl Preparation Scale (BBPS) and Arowchick Preparation Scale (APS). The tolerability and satisfaction of patients was determined based on a questionnaire-based survey.

Results: One hundred patients received either 2-L PEG-Asc or 1-L PEG-Asc with prucaloprside. Regarding colon cleansing outcome (BBPS and APS), the 1-L PEG-Asc with prucalopride group showed similar, but non-inferior results compared to the 2-L PEG-Asc group on both BBPS (7.63 ± 1.27 vs. 7.52 ± 1.40, p = 0.586) and APS scales (93.3% vs. 95%, p = 0.717). Tolerability was similar for both 1-L PEG-Asc with prucalopride and 2-L PEG-Asc.

**Conclusion:** 1-L PEG-Asc plus prucalopride preparation showed comparable result to traditional 2-L PEG-Asc preparation. 1-L PEG-Asc plus prucalopride preparation method could be an alternative method for bowel preparation which can relieve patient discomfort.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Colon EMR follow-up rate

Mean (±SD) 8.2 months (2.6) 10.4 (9.1)

Colon EMR follow-up rate of 6–9 months, % (n)

CI [0.54%–0.73%], (25)

Conclusion: These preliminary results suggest significant improvement in SC1 compliance with our intervention. We believe that continuing these efforts and further refining the intervention process, requiring less personnel resources, may be helpful to improve the follow-up time until 3–6 months interval while also enduring as a sustainable change for our practice.

P0214 META-ANALYSIS SUGGESTS: INSPECT TWICE TO INCREASE RIGHT COLON ADENOMA DETECTION RATE

K. Triantafyllou, P. Gkolafas, G. Tzatzios, G. D. Dimitriadis
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktiriani@med.uoa.gr

Introduction: Missed adenomas in the right colon are of major concern for interval colon cancer (CRC) development. There is evidence from cohort and randomized controlled studies (RCTs) that a second examination of the right colon – either in direct view or in retroflexion- increases the diagnostic yield of the procedure. However, data are not accepted unanimously.

Aims & Methods: The aim of this meta-analysis was to examine the effect of a second, back-to-back mucosa inspection on the diagnostic yield of colonoscopy in the ecum and the ascending colon. We performed literature searches in MEDLINE to identify studies evaluating the effect of a second pass endoscopic examination on adenoma detection rate (ADR) and advanced ADR (AADR) in the right colon. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95%CI]. Heterogeneity was measured using the I2 statistics. Publication bias was assessed by funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 8 studies (5 cohort and 3 RCT, with 9 sets of data and 5639 subjects – mixed CRC screening/surveillance and symptomatic population) that reported on the aforementioned outcomes. Two sets of data examined the yield of the second direct view as compared to that of a single inspection, one set examined the cumulative yield of two passes compared to that of an extended (timely) inspection of the right colon and six sets of data evaluated the yield of the second examination of the right colon with scope retroflexion compared to that of the single direct view. We were moderate risk of bias studies; suspicion for publication bias was detected in the direct view arm of the analysis. As compared to a single pass, the second right colon inspection significantly increased ADR (1.31 [1.15–1.49], I2 = 49%). The effect size of ADR was higher in the direct view second pass arm (1.73 [1.41–2.12], I2 = 0%) as compared to the retroflexion arm (1.17 [1.06–1.29], I2 = 0%). Sensitivity analysis with removal of one study each time did not identify a single study responsible for the detected heterogeneity. Our analysis did not show significant increase in right colon AADR (1.5 [0.76–1.56], I2 = 0%) after the second exam.

Conclusion: In comparison to a single pass, the second inspection of the right colon either in direct view or with scope retroflexion increases ADR in this colon segment. However, results should be interpreted cautiously due to the small number of meta-analyzed studies with mixed indications populations, and the detected moderate levels of heterogeneity and risk for bias.

Introduction: Endoscopic treatment of malignant colorectal polyps is often challenging, especially for early rectal cancer (ERC) localized close to the dentate line. Conversely, the surgical approach may result in temporary or definitive stoma and in frequent post-surgical complications [1–2]. Endoscopic Full Thickness resection (EFTR) is a novel technique that, besides having other indications, appears to be promising for wall-thickness excision of intestinal T1 carcinoma following incomplete endoscopic resection [3–4].

Aims & Methods: Follow-up data on patients treated with this device are scarce, particularly for ERC. We enrolled six consecutive patients with T1-ERC. They were treated with the EFTR, after appropriate staging, and their long-term outcomes were evaluated based on a detailed clinical and instrumental assessment. Results: The endoscopic en bloc full-thickness resection was technically feasible in all patients. The histopathologic analysis showed a complete endoscopic resection in all cases, and a full-thickness excision in four. Neither complication, nor disease recurrence was observed during the one-year follow-up performed. Conclusion: EFTR is a promising tool for treating ERC featuring a residual risk of disease recurrence after incomplete endoscopic mucosal resection in patients unfit for surgery or refusing surgical approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Contact E-mail Address:** jorgevasquez11md@gmail.com

**Introduction:** Colorectal Endoscopic Submucosal Dissection (CR-ESD) is technically difficult, time-consuming, and has a long learning curve for Western endoscopists. Several factors related with greater difficulty while performing this technique have been described. Generally, during the learning curve phase, we select simple lesions while initiating the technique.

**Aims & Methods:** Our goal was to assess those factors associated with greater difficulty during untutored DSE-CR without prior selection of less difficult lesions. All patients who attended the complex colorectal polyps consultation were included consecutively. No polyps regardless of their size, morphology, location or any characteristic of greater technical difficulty were ruled out. All CR-ESDs were performed by an endoscopist with previous animal model experience. The demographic and clinical characteristics of the patient, the morphology of the lesion and factors related to the technique were collected. A complex technique...
was defined as that dissection that is not done en bloc and/or had complications.

**Results:** 112 lesions were selected, discarding 4 due to deep invasion. We evaluated in this study 108 DSE-CR, 27 (25%) of which were compatible with our definition of "complex" ESD. In Table 1 you can see the characteristics of each group. Univariate analysis showed that variables such as size over 35 mm (63% vs. 27.2%); OR 4.56 (95% CI: 1.81–11.46); P = 0.001; absence of CO2 (55.6% vs. 19.8%; OR 5.08 (95% CI: 1.99–12.94); P < 0.001), presence of serious fibrosis in the submucosa (48.1% vs. 7.4%; OR 11.61 (95% CI: 3.78–35.69); P < 0.001) and presence of fatty tissue in the submucosa (9.3% vs. 22.2%; OR 5.09 (95% CI: 2.01–12.90); P = 0.001) were related to a "complex" ESD. Finally, in the multivariate analysis, those variables were associated with a complex technique with an Odds Ratio of 7.42 for severe fibrosis (p = 0.039), 6.34 for non-CO2 insufflation (p = 0.030), 5.79 in the presence of fatty tissue in the submucosa (p = 0.035) and 3.74 in size greater than 35 mm (p = 0.025). There was no relation with the complexity of the technique the demographic-clinical characteristics of the patient, nor the location-morphology of the lesions. The duration of the technique was an average of 48 minutes longer in cases of a complex technique.

**Conclusion:** In our series the difficulty of CR-ESD was associated with factors described in other studies such as the size, the non-insufflation of CO2 and the presence of severe fibrosis in the submucosa. Our results describe the presence of fatty tissue in the submucosa as a new predictor of technical difficulty. In our study, we did not select the location to begin the technique, and in our learning curve we did not find significant differences in the performance of ESD in the proximal colon, distal or rectum.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0217 PERSISTENT PAIN AFTER COLONIC ENDOSCOPIC MUCOSAL RESECTION: PREDICTORS, A MANAGEMENT ALGORITHM AND OUTCOMES**

I. Desomer, J. T. Tate, H. Awadie, L. Pillay, G. Aldensteil, M. J. Bourke
Department Of Gastroenterology And Hepatology, Westminster Hospital, Sydney/ Australia/NW

**Contact E-mail Address:** lobkedesomer@gmail.com

**Introduction:** Endoscopic mucosal resection (EMR) of large (>20 mm) laterally spreading colon lesions (LSSL) is safe, effective and superior to surgery. This advantage is based on a day stay model of care; however, the most common adverse event is abdominal pain and this is a major impediment to its efficiency. No prospective data exist on the optimal selection of analgesics, the necessary upgrade of analgesics to fentanyl, with a starting dose of 25 micrograms (mcg) and 50 mcg in 1.75 mcg in 1 and 100 mcg in 2.

**Aims & Methods:** To develop a simple and effective management algorithm for patients with PP based on the need for analgesics in recovery. Data on consecutive patients based on the need for analgesics in recovery. Data on consecutive patients with a LSSL referred for EMR at a single, tertiary referral centre were included. We developed a simple and effective management algorithm for patients with PP based on the need for analgesics in recovery. Data on consecutive patients with a LSSL referred for EMR at a single, tertiary referral centre were included.

**Results:** No prospective data exist on the optimal selection of analgesics, the necessary upgrade of analgesics to fentanyl, with a starting dose of 25 micrograms (mcg) and 50 mcg in 1.75 mcg in 1 and 100 mcg in 2. A CT scan was performed in the 2 patients requiring 100mcg of fentanyl, showing serositis in 1 patient and no abnormalities in the other. Both patients were admitted and managed conservatively (discharge day 6 and 2 respectively). The other 5 patients were discharged home on the same day after extended recovery. Predictors of PP were lesion size ≥45 mm (P = 0.003), Paris classification (P = 0.22) and intra-procedural bleeding requiring endoscopic control (IPB, P = 0.042). Lesion size ≥45 mm and IPB were also independent variables on multivariate analysis with an odds ratio of 2.8 (95% confidence interval 1.3–6.3, p = 0.012) and 2.3 (95% confidence interval 1.05–5.2, p = 0.042 respectively (Table 1).

**Conclusion:** Pain after EMR occurs in 20% of patients and is associated with larger lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the stepped down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0219 META-ANALYSIS AND OWN EXPERIENCE IN THE TREATMENT OF RECTO-URETINAL FISTULA USING THE OVER-THE-SCOPE CLIP (OTSC)

M. Raithel1, M. Vetter2, A. Braun3, T. Vasilakis3, A. F. Hagel2
1St. Marien Waldkrankenhaus, Erlangen/Germany
2University Clinical Center Erlangen, Erlangen/Germany

Introduction: The transmural OTSC is used to achieve a full-thickness, serosa-to-serosa apposition (emergency & elective cases) for closure of GI wall defects (perforation, leak, fistula) with reported mean closure rates of 62–100% (range 0–100%), depending on the size of perforation, type and nature of lesion and the endoscopists’ experience3. However, recto-uretinal fistula may arise from a variety of etiologies and are mostly leaks or fistula of chronic nature, rarely acute perforations with vital wound tissue. They may occur in Crohn’s disease, but can also be a consequence of abdominal surgery, traumatic lesions or post-radiation damage.

Aims & Methods: To further explore the role of the OTSC in this particular type of fistula we analyzed own cases and 21 reports from the literature dealing with any type of recto-uretinal fistula. In total, 25 patients were identified with closure of a recto-uretinal fistula using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal n = 10, rectovesical n = 7, rectourethral n = 2, other rectal fistula n = 3).

Results: In most situations a previous interdisciplinary discussion was reported before an OTSC attempt, or patients refused to undergo re-operation. However, special characteristics of these leaks were reported to make more difficult the OTSC procedure compared with other GI locations, e.g., the site of the fistula is nearby located to L. dentata and anal sphincter, it includes a localization with little space for endoscopic manipulation, fibrous and scarry tissue is around the fistula in rectum or anastomosis and there may be sometimes suture material in situ. Thus, the tissue is often fixed and there is not so much tissue for grasping tissue into the OTSC.

The diagnosis of recto-uretinal fistula was usually made by endoscopic visualization and radiologically documented extravasation of contrast media into the vagina, urethra, bladder or into other adjacent tissue. For fistula closure traumatic OTSC was mostly used, but sometimes other adjuvant therapeutic modalities were also combined locally (e.g. histoacryl injection, fibrin glue, argon plasma coagulation, brushing etc) or systemically (e.g. ascorbic acid 7.5 g i.v.) to stimulate wound healing. The procedural success of occluding various types of fistula in rectum or anastomosis and there may be sometimes suture material in nearby located to L. dentata and anal sphincter, it includes a localization with little space for endoscopic manipulation, fibrous and scarry tissue is around the fistula in rectum or anastomosis and there may be sometimes suture material in situ. Thus, the tissue is often fixed and there is not so much tissue for grasping tissue into the OTSC.

Conclusion: In conclusion, recto-uretinal fistula may be a potential indication for OTSC application, after interdisciplinary consensus, when re-operation is avoided, deemed to be too risky or cumbersome. Although this type of fistula carries some difficulties because of little space, tissue tension and fibrous or postop changes, long-term success may be achieved in around half of all patients. Further improvements should focus on increasing healing potency of the fistula or better after performing anastomosis creation (ascorbic acid?), to avoid postoperative recto-uretional leaks.

Disclosure of Interest: All authors have declared no conflicts of interest.

31st Department Of Medicine, Ostallb-Klinikum Aalen, Acad. Teaching Hospital, University of Ulm, Aalen/Germany

Introduction: While ESD in the upper GI tract is well established, it is as yet not standard of care in the colorectum. Contrary to Japan, western experience is limited and only relatively few case series have been published in Europe (e.g. Deissel et al. 2017). Aims & Methods: For the period 5/2012-1/2017 the first fifty-one consecutive patients with colorectal (n = 18/17/6 rectum/left/right hemicolon) neoplasias (diameter > 27 ± 1.3 mm, ≤ 2 cm; low grade dysplasia: n = 86; serrated/tubular/villous; high grade dysplasia: n = 12; malignant: n = 4) or hyperplastic polyps (n = 4) receiving ESD according to predefined protocol (hook or knife dual, Olympus Medical Systems, Hamburg, Germany; procedure time 162.5 ± 3 min, ≥ ≥ SD) are reported. ESD was performed by a single investigator (G.K.) trained previously by Japanese experts and in experimental models. ESD was complete (n = 22) or complemented by snare resection of a remaining stalk (n = 25) or cancelled (n = 4) with subsequent alternative treatment.

**Introduction:** Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Colonoscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration room due to not meeting real-time constraints (40 ms max per image). In this abstract, we present a methodology to adapt and evaluate a real-time still frame-based method [3] to video analysis.

**Aims & Methods:** The still frame detection system used as reference [3] was based on an active learning method. We base the adaptation to video analysis on two aspects: (i) influence of the type of information used for polyp candidate characterisation, and (ii) introduction of spatio-temporal coherence. The former study whether the combination of different types of information may lead to improve system performance whereas the latter fosters stability in the position detection of the detector output between consecutive frames. The learning stage of the method involves the use of a public still-frame database (CVC-Clinic, 612 images) whereas the testing was done on a new set of 18 sequences with a polyp (10,294 images) collected with an Olympus colonoscope CIF-H190 at Hospital Clinic, Barcelona. Performance was evaluated using two groups of metrics: (i) standard information retrieval. Recall and Precision (ii) ad-hoc learning metrics (assessing the clinical usability). Among the latter group we define: a) Polyp Image/Video Metrics: Precision, Recall and F1-Score (ii) Ad-Hoc Clinical Metrics. Performance was evaluated using two groups of metrics: (i) standard of the detector output between consecutive frames. The learning stage of the method involves the use of a public still-frame database (CVC-Clinic, 612 images) whereas the testing was done on a new set of 18 sequences with a polyp (10,294 images) collected with an Olympus colonoscope CIF-H190 at Hospital Clinic, Barcelona. Performance was evaluated using two groups of metrics: (i) standard information retrieval. Recall and Precision (ii) ad-hoc learning metrics (assessing the clinical usability). Among the latter group we define: a) Polyp Image/Video Metrics: Precision, Recall and F1-Score (ii) Ad-Hoc Clinical Metrics. Performance was evaluated using two groups of metrics: (i) standard information retrieval. Recall and Precision (ii) ad-hoc learning metrics (assessing the clinical usability).

**Results:** Table 1 shows the influence of local features on the overall performance and how the combination of both types of features can lead to an overall improvement in Recall and RT, which we interpret as local descriptors complementing each other.

**Conclusion:** Work presented in this abstract shows how a real-time still-frame-based polyp detection method can be successfully adapted to video analysis. Clinical usability metrics along with a new fully annotated video database were introduced to completely assess method performance. Results show methodology potential regarding clinical deployment as it detects all different polyps with a small RT. Results show that the sole use of shape features allows to meet real-time constraints but that a combination with a computationally efficient texture descriptor might improve frame-based performance.

Introduction: Cold forces polypectomy (CFP) is commonly used to remove diminutive colorectal polyps (<5mm). In addition, jumbo biopsy forceps are superior to standard forceps for removing colorectal polyps. However, problems remain for CFP with regard to residual adenomatous tissue on histological evaluation after a complete endoscopic cold forceps polypectomy.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of jumbo forces biopsy using narrow-band imaging endoscopy in patients with diminutive polyps. In addition, we evaluated the factors related to one-bite resection using Cox’s regression model.

Results: A total of 503 patients were prospectively assessed, and 1015 polyps were resected. The median age of the patients was 65 years. The patients comprised 329 men (65%) and 174 women (35%). The polyp morphologies were 0-Is lesions in 886 cases (87.7%), 0-IIa lesions in 65 (6.4%), 0-IIp lesions in 63 (6.2%) and 0-IIp lesions in 1 (0.1%). Polyps were most often resected in the ascending colon (289 lesions) or transverse colon (262 lesions). Of all the polyps, 88% (896 lesions) were adenomas, 10% (100 lesions) were hyperplastic, and 0.3% were adenocarcinomas. The mean procedure and treatment times were 26.5 and 20.4 minutes, respectively. The complete resection rate was 99.3%. The rate of one-bite polypectomy was 71.8%, which included rates of 100%, 91.5%, 81.8%, 56.9%, and 40.5% for lesions 1, 2, 3, 4, and 5 mm in diameter, respectively. Delayed bleeding that required endoscopic hemostasis occurred in only one case, but no other adverse events occurred. The most important factor related to one-bite polypectomy was polyp size (≤3mm; OR: 5.58), followed by macroscopic type of polyps (non-Ha; OR: 1.95).

Conclusion: In this large-scale multi-center prospective study, 99.3% of all diminutive polyps were completely resected by using jumbo forces biopsy and magnified endoscopy with NBI. In addition, we were able to do one-bite polypectomy for more smaller polyps (≤3 mm). Jumbo forces biopsy appears to be adequate for resecting diminutive polyps if no residual tissue is visible by using magnified endoscopy with NBI.

P0225 PERIOPERATIVE MANAGEMENT OF ORAL ANTICOAGULANTS WITHOUT HEPARIN BRIDGING THERAPY FOR PATIENTS UNDERGOING ENDOSCOPIC SURGERY: A PILOT STUDY

1Division Of Endoscopy, Hokkaido University Hospital, Sapporo/Japan
2Department Of Gastroenterology, Hokkaido National Hospital, Hakodate/Japan
3Department Of Gastroenterology And Hepatology, Hokkaido University Graduate School of Medicine, Sapporo/Japan
4Department Of Gastroenterology And Hepatology, Hokkaido University Graduate School of Medicine, Sapporo/Japan
5Division Of Endoscopy, Hokkaido University Hospital, Sapporo/Japan

Contact E-mail Address: onosho@med.hokudai.ac.jp

Introduction: Heparin bridging therapy (HBT) is recommended for patients administered anticoagulants who have a high thrombotic risk and who undergo a high bleeding-risk procedure such as endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR). However, HBT is actually related to a high frequency of delayed bleeding4-8. Aims & Methods: Our aim is to analyze bleeding and coagulation markers in the periprocedural periods of patients with or without HBT during the perioperative periods of ESD and EMR. Patients who underwent ESD or EMR and received warfarin or a direct oral anticoagulant (DOAC) during the period from January 2013 to March 2017 were analyzed. Generally, administration of warfarin was continued within the therapeutic range of the international normalized ratio (INR) during the periprocedural periods and DOACs were not administered on the day of the procedure. HBT was conducted only for patients who had a hypercoagulable condition. The rates of delayed bleeding in patients who received warfarin and patients who received DOACs were compared, and coagulation molecular markers including soluble fibrin (SF), thrombin-antithrombin complex (TAT), prothrombin fragment 1 + 2 (F1 + 2) and D-dimer (DD) were compared before and after the procedures in 13 patients.

Results: Among the patients who underwent ESD or EMR during the study period, 5 patients received warfarin and 49 received DOACs. Delayed bleeding occurred in 6 patients (11.8%) in the warfarin group and in 8 patients (16.3%) in the DOAC group, and there was no significant difference. Only one patient with continued administration of antiplatelet agents had delayed bleeding among the patients in whom administration of warfarin was continued within the therapeutic range (5.3%, 1/19). Six (15%) of the 40 patients in the DOAC group for whom the DOAC was not administered only on the day of the procedure had delayed bleeding, and 23.8% (5/21) of the patients who received HBT had delayed bleeding. No thrombotic events occurred from one month after the procedures. One patient in whom the DOAC was not administered on the day of the procedure became positive for TAT, F1 + 2 and DD after ESD and had a hypercoagulable condition.

Conclusion: For perioperative management of anticoagulants in patients undergoing ESD or EMR, continuous use of warfarin within the therapeutic range is recommended. However, DOACs should be carefully managed with attention to hemorrhagic risk and coagulable condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: It remains unknown if colorectal lesions detection rates as quality indicators of the colonoscopy, behave in the same way in relation to colonoscopy indication.

Aims & Methods: The aim of this study was to evaluate the adenoma detection rate (ADR), serrated polyt detection rate (SDR), advanced adenoma detection rate (AADR) and colorectal cancer detection rate (CRCDR) depending on the colonoscopy indication. A total of 6912 colonoscopies have been prospectively included in the QUALISCOPIA project, an observational, multicenter and prospective study, developed in 12 centers in Spain. The ADR, SDR, AADR and CRCDR have been calculated. These data were analysed according to the colonoscopy indication adjusted by sex, age, colic intubation, adequate cleansing (Boston scale score of 2–3 in all segments) and sedation use.

Results: The results can be seen in Table 1. In colonoscopies performed due to positive fecal immunochemical test (FIT+), the ADR was 54.0% (p < 0.001, aOR 3.0, 95%CI 2.6–3.4). In those performed because of post-polypectomy surveillance, 49.3% (p < 0.001, aOR 3.4, 95%CI 2.2–5.3), and, those due to direct screening, the ADR was 31.6% (p < 0.005, aOR 1.4, 95%CI 1.1–1.7) compared to 28% in patients with gastrointestinal symptoms. Regarding the serrated polyps, in procedures performed due to FIT+, the SDR was 1.9% (p = 0.005, aOR 0.9, 95%CI 0.3–2.5), 4.2% in surveillance colonoscopies (p = 0.001, aOR 3.8, 95%CI 2.3–5.3), and 3.3% in direct screening (p < 0.001, aOR 2.8, 95%CI 1.6–5.0), compared to 1.2% of patients with digestive symptoms. Moreover, the AADR in colonoscopies performed due to FIT+ was 36.8% (p < 0.001, aOR 3.9, 95%CI 3.3–4.6), compared to 23.1% in surveillance colonoscopies (p < 0.001, aOR 1.8, 95%CI 1.5–2.2), and 14.9% in direct screening (p = 0.023, aOR 1.3, 95%CI 1.1–1.8). However, the SDR was 12.8% in patients with digestive symptoms. Finally, the CRCDR was 5.8% in patients with gastrointestinal symptoms (p < 0.001, aOR 11.6, 95%CI 4.7–28.7), 4.8% in those with FIT+ (p < 0.001, aOR 13.4, 95%CI 5.4–33.2), and 1.8% in direct screening (p < 0.005, aOR 5.1, 95%CI 1.6–15.6), compared to 0.5% in post-polypectomy surveillance.

P0228 THERAPEUTIC ERCP USING A SHORT SINGLE-BALLOON CHOLANGIOSCOPY IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

K. Masu, K. Ito, T. Ohira, S. Koshita, Y. Kanno, T. Ogawa

Gastroenterology, Sendai City Medical Center, Sendai, Japan

Contact E-mail Address: k-masu@openhp.or.jp

Introduction: Recently, we have performed therapeutic ERCP using a newly developed short single-balloon enteroscope (sSBE) (working length of 152 cm, working channel of 3.2 mm) in patients with surgically altered anatomy.

Aims & Methods: We aimed to evaluate the usefulness and safety of sSBE for therapeutic ERCP in patients with surgically altered anatomy. We analyzed the data from patients with surgically altered anatomy who underwent therapeutic ERCP using a sSBE between August 2011 and February 2017 who were included in this study.

Patient anatomy consisted of Roux-en-Y anastomosis (R-Y) (n = 82), hepatocaco- lysticostomies (HC) (n = 11), subtotal stomach-preserving pancreaticoduodenectomy (SPPD) (n = 11). The indications for ERCP were choledocholithiasis (88: R-Y cases), malignant bile ducts (20: R-Y 14, HC 7, SSPD 4), intraductal stones (9: HC 7, SSPD 2), and anastomotic stenosis (7: SSPD 5, HC 2).

The success rate of reaching the target site was 91% (95/104), and the overall technical success rate was 79% (80/104). Biliary interventions included 64 stone extraction (R-Y 58, HC 5, SSPD 1), and 12 metallic biliary stent placement (R-Y 7, HC 1, SSPD 4). Of 17 unsuccessful cases, nine with choledocholithiasis underwent surgical operation (R-Y 6, HC 2, SSPD 1) and EUS-guided drainage was successfully performed in six with anastomotic stenosis (SPPD 3, R-Y 2, HC 1).

The adverse event rate was 10% (4: cholangitis 4, mild pancreatitis 3, perfora- tion 2, aspiration pneumonitis 1). The two perforation cases required urgent operation but remaining eight cases were managed conservatively.

Conclusion: Therapeutic ERCP using a sSBE is safe in patients with surgically altered anatomy and considered to be safe and effective.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0229 USEFULNESS OF SPYGLASS PERORAL CHOLANGIOSCOPY FOR THE DIAGNOSIS AND TREATMENT OF BILE-DUCT DISORDERS: EXPERIENCE FROM A LARGE-VOLUME CENTER

X. Tang, D. Zhang, C. Xu, X. Zhang

Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou, China

Contact E-mail Address: solitude834@hotmail.com

Introduction: SpyGlass single-operator peroral cholangioscopy (SOC) has been designed to overcome some limitations of conventional cholangioscopy, and demonstrated improved diagnostic and therapeutic abilities of complex pancreato- ductal obstructions.

Aims & Methods: To assess the clinical efficacy and safety of the SpyGlass system for diagnosis and treatment of bile-duct disorders in a large-volume center. All patients undergoing SOC in our department between January 2013 and May 2016 were retrospectively identified from a prospectively collected database. The baseline characteristics, including age, gender, presenting symptoms, indication and others were recorded. Procedure-related parameters of SOC for detecting malignant lesions and the stone clearance rate were calculated.

Results: During the study period, a total of 68 patients underwent 78 SOC procedures: 26 (38.2%) with indeterminate strictures, 7 (10.3%) with indetermi- nate filling defects, 31 (45.6%) with difficult bile stones, and 4 (5.9%) with cystic lesions. SpyGlass was technically successful in 63 of 68 patients (92.6%). The mean SpyGlass procedure time was 52 ± 12 mm. In patients with indeterminate biliary strictures, 6 cases of definite diagnosis (stones, varices) was made by SOC evaluation. Twenty patients underwent SOC-directed biopsy, and samples were adequate for histologic diagnosis in 17 patients (85%). The preliminary accu- racy of SpyGlass-directed biopsy to diagnose malignancy were 76%. For the patients with biliary stone, SpyGlass-guided holmium laser lithotripsy or electro- hydraulic lithotripsy succeeded in 15 of 15 patients (100%). There were 6 procedure-related adverse events occurred (8.8%), and resolved uneventfully.
Conclusion: SpyGlass cholangioscopy system can be safe and useful for definite diagnosis with a high accuracy in patients with indeterminate biliary lesions, and successfully guided stone therapy. Further prospective multicenter clinical trials of the system are warranted in the future.

P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY

T. Xang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic disorders in pediatric patients.

Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indications, ERCP findings, ERCP interventions performed and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common biliary obstruction (n = 153, 54.2%), recurrent or chronic pancreatitis (n = 64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was choledocholithiasis (n = 146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n = 204), including sphincterotomy (n = 97), stone extraction (n = 55), and stent insertion (n = 52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS’ EXPERIENCE AT A LARGE CENTER IN CHINA

T. Xang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy were compared with high accuracy in our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.8%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrostomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236). The overall success rate was 88.2% (204/236). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n = 146), sphincterotomy (n = 44), stent placement (n = 57), papillary balloon dilatation (n = 27) and mechanical lithotripsy (n = 23). The adverse event rate was 7.2% (17/236). Mild pancreatitis occurred in 3% (7/236) of cases, perforation occurred in 2.5% (6/236) of cases, and asymptomatic hyperamylasemia occurred in 1.7% (4/236) of cases.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYNDROME RECURRENCE TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESECTION: A PROPENSITY SCORE ANALYSIS

1Department of Gastroenterology and Hepatology, Mayo Clinic, Jacksonville, Florida/United States of America/FL
2Biostatistics, Mayo Clinic, Rochester/United States of America/MN

Contact E-mail Address: danielaguerrerotorres@gmail.com

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size ≥20mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPB), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to compare the efficacy of the newer 190 colonoscopes versus standard 180 colonoscopes for complete resection of lateral spreading lesions (LSS) ≥20mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT score) in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscope series from 2010 to 2016. Lesions ≥20mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p = 0.85). Adenoma size (p = 0.002) and concomitant need for supplemental APC (p = 0.001) were risk factors for recurrence. SERT > 0 lesions had a higher risk of recurrence during follow-up (OR 1.71; 95% CI 1.00–2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0233 INCIDENCE AND RISK FACTORS FOR PANCREATITIS IN EMERGENCY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: A PROSPECTIVE MULTICENTER STUDY

Introduction: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy were compared with high accuracy in our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.8%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrostomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236). The overall success rate was 88.2% (204/236). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n = 146), sphincterotomy (n = 44), stent placement (n = 57), papillary balloon dilatation (n = 27) and mechanical lithotripsy (n = 23). The adverse event rate was 7.2% (17/236). Mild pancreatitis occurred in 3% (7/236) of cases, perforation occurred in 2.5% (6/236) of cases, and asymptomatic hyperamylasemia occurred in 1.7% (4/236) of cases.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Endoscopic necrosectomy (EN) in walled-off necrosis (WON) is a labor intensive, high-risk, non-standardized technique that is associated with significant morbidity and mortality. This observational study included 45 consecutive patients with WON who had undergone EN versus an algorithmic approach that is tailored to the extent and location of the WON: While WON extending to the flanks and more proximate (P < 0.001) increased the risk of PEP in emergency ERCP. Conclusion: The incidence of PEP was lower in emergency ERCP than in elective ERCP. Multivariate analysis showed that contrast injection into the PD (OR: 4.51, 95%CI: 1.64–12.40, P = 0.003) increased the risk of PEP in emergency ERCP. Multivariate analysis showed that contrast injection into the PD (OR: 4.51, 95%CI: 1.64–12.40, P = 0.0035) increased the risk of PEP in emergency ERCP. Disclosures: All authors have declared no conflicts of interest.

P0234 WALLED-OFF NECROSIS (WON): OUTCOMES OF AN ALGORITHMIC APPROACH TO NECROSECTOMY

J.Y. Bang1, U. Navaneethan1, M. Hasan, R. Hawes, S. Varadarajulu
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Endoscopic necrosectomy (EN) in walled-off necrosis (WON) is a labor intensive, high-risk, non-standardized technique that is associated with significant morbidity and mortality. Aims & Methods: To evaluate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERCP) for the treatment of pancreas divisum (PD) associated with recurrent acute pancreatitis (RAP) in children. We retrospectively analyzed patients of PD associated with RAP who were younger than 18 years old from January 2011 to December 2015 in our center. All the patients were diagnosed and treated with ERCP. Patients of complete PD associated with RAP underwent endoscopic sphincterotomy (ESCS). Patients of incomplete PD underwent biliary and pancreatic duct stenting (Bi-E-ESCS). ERCP-related data, complications and other relevant data were collected. The median time follow-up was 3 months (from 2 to 6 months). Results: A total of 227 pediatric ERCPs were performed for 117 pediatric patients during this period. Of which 24 were PD cases. The endoscopic detection rate of PD was 20.5%. Of the 24 patients, 12 were PD associated with RAP, among which 10 were complete PD and 2 were incomplete PD. A total of 21 therapeutic ERCPs were performed for these cases. All procedures were successful with 100% (21/21) of cannulation rate of the minor papilla. The mean interval of changing pancreatic dorsal duct stent is 3 months (from 2 to 6 months). ERCP-related complications were mild with a rate of 9.5% (2/21). One was acute mild pancreatitis and the other was hyperamylasemia, both of which were managed conservatively. During follow up from 15 to 74 months (mean 33.9 months), all patients had pain relief with a relief rate of 100%, of which 10 were asymptomatic with no longer onset of acute pancreatitis. During follow-up, the presence of more dilatation of the minor ducts in all children and presented normal in weight, growth and intelligence.

Conclusion: The techniques of ESCS and Bi-E-ESCS under ERCP are safe and effective methods to manage PD associated with RAP in pediatric patients. It seems very vital for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP.

Disclosures: All authors have declared no conflicts of interest.

P0235 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE MANAGEMENT OF PANCREAS DIVISUM ASSOCIATED WITH RECURRENT ACUTE PANCREATITIS IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA

G. Cui, J. Yang, X. Tang, J. Yang, X. Zhang
Gastroenterology And Hepatology, Hangzhou First People’s Hospital, Hangzhou, China

Contact E-mail Address: zxs837@163.com

Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Most PD patients are asymptomatic, but a few may present symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatic-type pain. It is imperative to treat PD associated with RAP as early as possible to prevent it from developing CP. Unfortunately, to date, most PD-related studies have been concentrated on adults. Researches of PD in children are rare.

Aims & Methods: To determine the predictive risk factors for PEP in emergency ERCP using univariate and multivariate analyses. Results: A total of 1677 cases were enrolled in this study. Study 1 > PEP developed in 20 of 429 cases (4.7%) from the emergency group and in 101 of 1248 cases (8.1%) from the elective group. The incidence of PEP was significantly lower in the emergency group than in the elective group (odds ratio [OR]: 0.56, 95% confidence interval [CI]: 0.32–0.92, P = 0.017). Endoscopic sphincterotomy, stone removal, papillary balloon dilation, and intraduodenal ultrasound sono-graphy were performed significantly more often in the elective group than in the emergency group (P < 0.001). Placement of a biliary stent was significantly more common in the emergency group than in the elective group. In addition, the procedure time was significantly longer (P < 0.001) and the number of endoscopists who had more than five years of experience was significantly higher (P = 0.04) in the elective group than in the emergency group. < Study 2 > PD cases with no native papilla (n = 183) were excluded from the analysis of risk factors for PEP because no PEP was observed in these cases. Only cases with native papilla (n = 248) were analyzed. Univariate analysis showed that contrast injection into the PD (OR: 4.20, 95%CI: 1.64–10.80, P = 0.0028), more than four contractions (OR: 2.83, 95%CI: 1.12–6.98, P = 0.028) and placement of a biliary stent (OR: 0.028, 95%CI: 0.11–0.88, P = 0.028) decreased the risk of PEP in emergency ERCP. Conclusion: The incidence of PEP was lower in emergency ERCP than in elective ERCP, and it was largely unaffected by the endoscopist’s experience and the procedure time. This may be associated with a tendency to avoid invasive proce-dures, and it is consistent with the idea that only placement of a biliary stent contributes to a decrease in the development of PEP. Close attention should be paid for contrast injection into the PD, particularly when attempt of cannulation for native papilla are required.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0236 ENDOSCOPIC BILIARY SPHINCTEROTOMY IN MALIGNANT BILIARY OBSTRUCTION: IS IT INDICATED IN CASE OF STENT PLACEMENT? A META-ANALYSIS

The overall rate of biliary stent insertion was not significantly different: 384/392 excluded leaving 6 prospective studies (total of 711 patients).

Results: 14 papers were assessed via full text for eligibility, 8 articles were excluded leaving 6 prospective studies (total of 711 patients). Technical success: The overall rate of biliary stent insertion was not significantly different: 384/392 patients (98%) in the no-EBS group versus 331/339 (97.6%) in the EBS arm (OR: 1.05; 95% CI, 0.42–2.63). Early complications: The overall early AEs developed in 43/392 (11%) of patients without EBS versus 68/339 (20.1%) of patients who received EBS, with a significantly different (OR: 0.55; 95%CI: 0.33–0.92). Post-ERCP pancreatitis (PEP) was no significantly different in the two groups: 24/392 (6.1%) in no-EBS group versus 24/392 (6.1%) in EBS (OR: 0.65; 95%CI: 0.25–1.7). The bleeding was significantly different in patients without EBS: 0/351 of patients in no-EBS group versus 15/259 (5%) in the EBS group (OR: 0.05; 95% CI, 0.01–0.29). Early mortality rate was 0% in both groups. Late complications: No significantly difference occurred in the overall late adverse events in the two groups: 50/251 patients (19.9%) in no-EBS group vs 38/210 subjects (18.9%) in the EBS group (OR: 0.93; 95% CI: 0.56–1.53). No significantly differences in late cholangitis (11.6% patients in no-EBS vs 11.4% in EBS) and late AEs (p = 0.42). No significantly differences in stent migration (4% in no-EBS group vs 5.5% - OR: 0.81; 95% CI: 0.29–2.25). No significantly differences in late cholangitis (2.6% in no EBS vs 0% in EBS group - OR: 1.83; 95% CI: 0.17–19.85). Long-term mortality was not significantly different (2.5% in no-EBS group and 2.9% in the EBS arm - OR: 1.18; 95% CI: 0.22–6.29).

Conclusion: Our meta-analysis showed no significantly differences in technical success and in PEP. In consideration of the significantly increase of the overall AEs in the EBS group, and in particularly of the bleeding and cholangitis, the EBS seems not be recommended in patients not suitable to surgery undergone biliary stenting.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO237 ENDOSCOPIC PANCREATIC SPHINCTEROTOMY COMBINED WITH PANCREATIC DUCT STENT CAN EFFECTIVELY PREVENT RECURRENCE OF ACUTE RECURRENT PANCREATITIS CAUSED BY BILIARY MICROLITHIASIS — A SINGLE-CENTER STUDY FROM BEIJING, CHINA

Y. Huang, X. Yan, W. Liu, Y. Zhang, W. Yao, K. Li Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/China

Introduction: Acute recurrent pancreatitis (ARP) refers to a clinical entity characterized by episodes of acute pancreatitis which occurs on more than one occasion. Biliary microlithiasis plays an important role in the etiology of ARP. Bile sludge may induce acute pancreatitis as a consequence of transient papillary edema that can obstruct the pancreatic juice flow. The established treatments of ARP includes with ARP. In this case, we analyzed the efficacy of endoscopic pancreatic sphincterotomy (EPS) and empirical cholecystectomy. However, ESP may increase the morbidity of biliary reflux or cholecystitis recurrence. We hypothesized that endoscopic pancreatic sphincterotomy (EPS) can save the function of biliary sphincter and prevent the recurrence of ARP.

Aims & Methods: The aim of the study is to evaluate the effectiveness of EPS combined pancreatic duct stent for preventing ARP caused by biliary microlithiasis. 67 patients with ARP from 2005 to 2016 were diagnosed as biliary microlithiasis by endoscopic retrograde cholangiopancreatography (ERCP), bile microscopy or intraductal ultrasonography (IDUS). The whole was divided into two groups according to endoscopic therapy by EST or EPS with pancreatic stent. Rate of pancreatitis recurrence, early complication of post ERCP pancreatitis (PEP), and late complication (3 months after the treatment) which included cholangitis, cholecystitis, or cholecystolithiasis were compared between the two groups.

Results: (1) 38 and 29 patients were included in EST and EPS group, respectively. The mean age and follow-up duration of EST and EPS were 48.4 ± 15.1yrs, 45.7 ± 36.5months and 45.6 ± 15.2yrs, 24.1 ± 36.3months, respectively. (vary from 2months to 115months). (2) The mean episodes of ARP in EST and EPS group before endoscopic therapy were 3.9 ± 3.3 times and 7.9 ± 11.8 times. (3) Four patients in EST group and 6 patients in EPS group suffered PEP after the endoscopic therapy (P = 0.418). (4) 15 patients in EST group and 3 in EPS group suffered recurrent pancreatitis. The efficiency in EST group and EPS group is 68.4% and 89.6% respectively (P = 0.039). (5) The incidence of late complications are 18.4% in EST group and 10.3% in EPS group (P = 0.567).

Conclusion: EPS combined with pancreatic stent is a promising strategy to prevent recurrence of ARP due to biliary microlithiasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO238 OUTCOME OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH PERIAMPULLARY DIVERTICULUM

Introduction: Periampullary diverticulum (PAD) is frequently asymptomatic, usually encountered in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP).

Aims & Methods: The aim of this study was to investigate the association of PAD with bile duct stones, biliary cannulation success and different types of PAD. A total of 1164 ERCP procedures were performed in 833 patients in a single center by single operator from January 2012 to October 2016 after excluding patients with bile duct stent, biliary cannulation failure and different types of PAD. Patients with PAD had mean age 59.10 years (range 18 to 84 years) 17 were < 50yrs while 32 > 50yrs, compared to controls mean age 52.74 yrs (range 12 to 95 yeras) 230 were < 50yrs while remaining more than 50yrs. P-value (< 0.05) compared with controls.

Results: PAD identified in 49 (4.2%) cases, PAD type (1 the diverticulum) was found in 7 pts (14.3%), Type II (at (edge) brim) in 34 pts (69.4%), Type III (adjacent near diverticulum) (16.3%). Patients with PAD had mean age 59.10 years (range 18 to 84 years) 17 were < 50yrs while 32 > 50yrs, compared to controls mean age 52.74 yrs (range 12 to 95 yrs) 230 were < 50yrs while remaining more than 50yrs. P-value (< 0.05). PAD predominantly occurred in > 50yrs, compared to controls.

Patients with PAD had increased prevalence of gallstone/biliary stone disease compared with controls, 71.4%vs 33.1% (p < 0.01) compared with controls. Easy cannulation of CBD without difficulty (PRECUIT/Pancreatic cannulation/stenting) was more frequent in patients controls (82.3%) compared to PAD group (75.5%) p < 0.05. However, CBD clearance was same in both groups >90% (p value not significant) Incidence of complications in PAD group bleeding (2%), Pancreatitis (2%) and one small retroduodenal perforation (2%) all managed conservatively. In without PAD group bleeding 0.6%, pancreatitis 0.7% and no perforation.

Conclusion: PAD is seen with advanced age, predominantly in female and frequently associated with bile duct stones. In this case control study PAD did not appear to be a barrier for successful ERCP with acceptable complication rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Dysplasia may persist at the termination of the common bile duct (CBD) after endoscopic ampullectomy. Radiofrequency ablation (RFA) could be an alternative intervention to reduce the risk of invasive cancer with less morbidity.

Aims & Methods: The aim of the study was to evaluate the efficacy and morbidity of endo-biliary RF for the treatment of residual endo-biliary dysplastic lesions after endoscopic ampullectomy. A prospective open-label multicenter study

References

P0239 COMPARISON OF DIGITAL VS FIBEROPTIC CHOLANGIOSCOPY IN PATIENTS REQUIRING EVALUATION OF BILE DUCT STONES

Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERCP procedure (examination time, endoscopic biliobiliary tract obstruction (EST)), post-ERCP pneumonia, death within 30 days after ERCP procedure, anesthesia-related complications (blood pressure decrease, pulse reduction, respiratory depression).

Results: We examined 69 males (92.3%) and 6 females (7.7%) Women underwent endoscopy for a larger proportion in the super-elderly group (71% vs 40%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERCP procedures (moderate, 32; severe, 22) against 124 ERCP procedures (moderate, 104; severe, 20) in non-super-elderly group, and similar results observed in the super-elderly group were statistically significant (p < 0.001). Regarding comorbidities, chronic heart and renal failure were statistically dominant in the super-elderly group. However, no difference was seen in the incidence of other diseases receiving anticoagulant medication between the two groups. The causes of acute cholangitis were common in both groups with common bile duct stone (46% vs 46%), followed by malignant obstruction (9% vs 12%) and benign stenosis (0% vs 5%), but no difference was found. Regarding the ERCP procedure, the examination time was longer in the super-elderly group (35.7 ± 28.1 min vs 29.2 ± 24.0 min, p = 0.044), but there was no difference in the procedure success rate (93% vs 97%, p = 0.249) and the presence of peripapillary diverticula. The patients were sedated using midazolam (MDZ) plus pentazocine (PTZ). The amount of anesthetic used was less in the super-elderly group (MDZ: 2.2 ± 3.3 mg, p < 0.001, PTZ: 3.1 ± 5.4 mg, p = 0.005).

Regarding (i) ERCP-related and (ii) anesthesia-related complications, these were higher in the super-elderly group ([i] 15% vs 9%, p = 0.293, (ii) 17% vs 7%, p = 0.086). The incidence of anesthetic complication improved in the super-elderly group, and no intravascular or surgical treatment was required.

Conclusion: Acute cholangitis in super-elderly patients was more likely to become severe and the complications were higher than that in non-super-elderly patients. When performing an emergency procedure in super-elderly patients, we should particularly pay attention to developing complications in patients with moderate or higher acute cholangitis, according to TG13.

Disclosure of Interest: All authors have declared no conflicts of interest.
included 20 patients with low-grade dysplasia (DBG) or high grade (DHG) lesions. ERCP was performed by a double-balloon enteroscopy, in relation to a residual adenomatous bud after endoscopic ampullectomy for ampullary adenoma. The lesions should extend to a maximum length of 20 mm in the CBD. Endoscopic retrograde cholangio-pancreatectomy (ERCP) was performed with the Habib™ EndoHPB probe (EMcision, UK) (effect 8, power 10Watts, 30 s). Biliary: pancreatic stent were placed at the end of the procedure. The primary endpoint was the rate of residual neoplasia (eg, DBG, DHG or invasive carcinoma) at 1 year after treatment. Secondary endpoints included neoplasia at 6 months after treatment; 2) rate of surgery at 12 months; 3) adverse events.

Results: The mean age (±SD) was 67 years (±11), with 12 men and 8 women. RFA was performed on average (±SD) 1.9 years (±3.5) after ampullectomy. The mean resected adenoma size (±SD) was 24.9 mm (±10.2), and 7 patients had adjacent duodenal mucosectomy at the time of ampullectomy. The histology of the resected ampullary adenoma was DBG for 7 patients, DHG for 12 patients, and in situ carcinoma for 1 patient. Lateral margins were R0 in 20 patients (95%). CBD recurrence was diagnosed predominantly on ERCP and/or endoscopic ultrasonography surveillance procedures with an estimated mean infiltration height (±SD) of 11.2 mm (±4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radiopaque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had bilary stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (±25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DBG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients had angiography requiring bilary stent replacement. 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoescopy and biological tests). At M12, one patient presented with a bilary stricture resolved by dilatation and a calibration bilary stent.

Conclusion: Endoscopic RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

Introduction: Simulation-based training has become an important pillar in competency building and learning in medicine, especially in training novice endoscopists. Several simulators have been validated and implemented in training curricula pertaining gastrointestinal endoscopy. Surprisingly, limited data are available on simulators on ERCP training, despite the fact that ERCP seems to be an ideal candidate for simulation-based training due to its technical complexity. The available simulators are difficult to implement in training settings due to the lack of realism or use of live animals or ex-vivo components. Recently, the Boskoski™ cutting papilla available simulators are difficult to implement in training settings due to the lack of an ideal platform for simulator-based training due to its technical complexity. The purpose of this study was to evaluate the didactic value and added competence-based learning in medicine, especially in training novice endoscopists.

Aims & Methods: The aim of our study was to determine the expert validity of this cutting papilla and its didactic value for training sphincterotomy, as judged by experts. Expert participants with more than 2500 ERCPs lifetime were invited to perform the simulation and fill out a questionnaire on the realism of the sphincterotomy procedure and its didactic value.

Results: A total of 40 ERCP experts were included. All experts were men, originating from 16 different countries with a mean age of 49.6 years (range 37–65). Twenty-seven experts were gastroenterologists (92.5%), 3 participants were surgeons (7.5%). The mean number of years of endoscopic experience was 20.9 (range 10–40). Experts' opinion on realism of performing a sphincterotomy was evaluated on a four-point scale. The potential as a training tool of the cutting papilla in training novices was rated 3.93 on a four-point scale, and there was a high agreement among the experts to include the papilla in the training of novices (3.93 on a four-point scale).

Disclosure of Interest: M.J. Bruno: We have received a unrestricted research grant from Cook Medical, Limerick, Ireland. All other authors have declared no conflicts of interest.

P0243 MEDICO-LEGAL CLAIMS IN GASTROINTESTINAL ENDOSCOPY: DOES PROCEDURE RISK RELATE TO SUCCESSFUL OUTCOMES?

S. Budihal, J. F Maybery
Dignostics Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Complications in endoscopy can lead to adverse clinical events. The likelihood of developing a complication depends on the degree of risk associated with a certain procedure. It is generally noted that riskier the procedure larger is the chance for a complication and higher the likelihood for medico legal issues. This is relevant as in the event of the risk materialising, patients make seek legal redress. The aim of this study was to investigate the degree of success of medico legal claims based on the nature of the endoscopic procedure and the outcome of the claims.

Aims & Methods: The National Health Service Litigation Authority (NHSLA) database in U.K was searched using a Freedom of Information request (F2403) in 2010/11 and 2014/15. The term "Gastroscopy", "Sigmoidoscopy", "Colonolesscopy", "PEG" and "ERCP" were used to search the database. They were then analysed for procedure type, characteristics and outcomes. StatsDirect statistical software was used for statistical analysis.

Results: A total of 291 claims were notified to the NHSLA during this period. 107 (36.7%) of claims still remain open. Analysing outcomes by procedures reveals a success rate of 44%, 44%, 37%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmoidoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used).

Conclusion: A significant number of claims remain open leading to concern and worry among endoscopists. The impact on practitioners after a successful claim is unknown and merits further investigation. Procedures considered as dangerous like ERCP and Colonoscopy have the least successful claims. It is imperative that clinicians remain vigilant. Performing Gastroscopy is dangerous and so is undertaking a Percutaneous Endoscopic Gastrostomy. Endoscopists should tighten their approach to all procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0244 VISUALIZATION OF INTRA-AMPULLARY CHOLEDOCHOCELE WITH CONTRAST MEDIUM FOR EVALUATING TECHNICAL DIFFICULTY IN ERCP

N. Nishino
Gastroenterology Center, Southern Tohoku Hospital, Koriyama/Japan

Contact E-mail Address: nishinon@tim.hi-ho.ne.jp

Introduction: Choledochocele has been rarely recognized. We focus on intra-ampullary choledochocele (IAC). We had experienced some cases with IAC as refractory access to bile duct (BD). IAC has small cyst within ampulla regulated by Oddi’s sphincter, so the BD axis has changed via IAC. The cases with IAC would require a high technical skill for axis alignment or alternative strategy such as infundibulotomy or precut. We propose advantage of conventional ERCP (cERCP) with contrast medium, which provides images of IAC and leads to evaluation of the difficulty in cannulation.

Aims & Methods: This study aims to recognize the morphology of intra-ampullary bифurcation of bile duct (BD) and pancreatic duct (PD). Its variation allows the elucidation of the reason for difficulties in cannulation. The current study is a retrospective consecutive case study that is conducted in a single facility, with a study period of 8 years. Our strategy for ERCP was carried out with the contrast medium injected via a catheter, but without guide wire (GW) seeking. Intra-ampullary bифurcation was particularly visualized with the contrast medium, and X-ray images were magnified sequentially 5–10 times each. The eligibility criteria were: it must be naif papilla and both of BD and PD must be visualized. The following factors were evaluated: ampulla shape, number of orifices, angle of intra-ampullary bифurcation and presence of IAC. The Location, size and shape of IAC were used to search the database. They were then analysed for successful outcome of IAC visualization.
Results: There were cases of 1223 naïve papilla out of 2226 cases in total. The success rate to access BD with naïve papilla was 97.6% (1195/1223) and overall post-ERCP pancreatitis (PEP) was 1.3% (29/2226). The eligible patients were 908 (505 male and 403 female), among whom IAC was identified in 6.0% (54/908). The prevalence of IAC in the L/N, D and F types were 9.9% (48/542), 1.2% (4/338) and 4.1% (7/170) respectively. IAC was significantly higher in the L/N (p < 0.01) and F (p < 0.05) types than in the D type. The choledochocele shapes of Sp, Sh and Ow were 59.3%, 13.0%, 27.8%, respectively. The average size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were 60.1% (274/456) and 39.9% (182/456) respectively. In Ac, the IAC was found with LN shape only. Patients of 53.7% (29/54) required GW placement on PD to access BD. IAC was alternately seen on MRCP in 10% (3/30).

Conclusion: Choledochocele is rarely seen on even cERCP, in addition the visualization of IAC has been rarely reported. IAC could be actually visualized with prudent contrast medium injection. Our results showed aminosalicylates in the intra-ampullary images. IAC would require refractory pursuit of the axis alignment due to its unexpected pathway within ampulla to access BD. Moreover, 6.0% prevalence of IAC should not be ignored. IAC can be one of the factor of refractory cannulation. cERCP with focus on ampulla could the difficulty in cannulation. On the other hand, WGC would not do. The previous randomized control trials showed no difference to access to BD between WGC and cERCP. However, both procedures still remained cases with refractory cannulation. It has been reported that refractory cannulation might cause PEP1). Therefore careful attention should be paid while passing through IAC to avoid PEP. According to ampulla shapes, especially of L/N and F, cERCP would be recommended to identify the presence of IAC. It will be a warrant strategy to choose.

P0245 ENDOTHERAPIES FOR DUCT-TO-DUCT BILIARY ANASTOMOTIC STRICATURE AFTER LIVER TRANSPLANTATION (BASALT STUDY GROUP): INTERIM ANALYSIS AND MEDIUM-TERM OUTCOMES OF A RETROSPECTIVE NATIONWIDE ITALIAN SURVEY

P. Cantu,1, I. Parzanese1, R. Rosa1, G. Santi1, F. Barbaro2, E. Forti3,4,5,6,7,8,9,10

Introduction: Most appropriate endotherapy of biliary anastomotic strictures (AS) remains to be defined.

Aims & Methods: Aim is to retrospectively report the endotherapy for duct-to-duct AS in 2013, procedure related complications and medium-term outcome results in Italy. A questionnaire was sent to the Endoscopy Units working with Italian Liver Transplantation Centers (BASALT study group).

Results: At present sixteen of the 19 Units (84%) returned the questionnaire. Complete endotherapy data and follow-up are available for 182 pts. One-hundred and two patients have been treated with plastic multistenting (PM), 27 with fully covered SEMS and 53 with single stenting (SS). Radiological success was achieved in 144 pts (79%), i.e. 86% of PM, 89% of fully covered SEMS and 60% of SS (p < 0.01 vs PM). Recurrence occurred in 31 pts, i.e. 21% of pts in whom radiological success was achieved: 11% of PM (p < 0.001 vs SEMS and p < 0.05 vs SS), 41% of fully covered SEMS and 17% of SS. After failure of first-line endotherapy (36) or recurrence (31), patients were re-treated with endotherapy (75%), surgery (21%) or percutaneous balloon dilatation (7%), one patient dropped out because of death unrelated to endotherapy. Second-line endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22% of pts and radiological success was achieved in 82% of them (in 86%, 89%, and 66% with PM, SEMS and SS respectively). Procedure-related complications occurred in 7.8% (51/665), i.e. 2.4% pancreatitis (1 severe leading to death), 4.1% cholangitis and 0.9% bleeding. Overall clinical success was achieved in 85% after a median f-up of 23 mos and no need of surgery in 92% of patients.

Conclusion: Endotherapy is confirmed as the preferred first-line and rescue option for AS. Progressive multi-stenting is most frequently used. Single stenting has suboptimal results and should be abandoned. Use of SEMS is effective, but recurrences seem to be frequent, although a larger patients’ sample needs to be evaluated.

P0246 COMPARATIVE EVALUATION OF TWO PORCINE EX-VIVO MODELS FOR TRAINING IN ENDOSCOPIC ULTRASOUND- GUIDED DRAINAGE OF PANCREATIC FLUID COLLECTIONS

F. MorosuÈse,1 S. Leblanc2, A. Bertucat3, A. LaquieÈre4, E. Coron5,6,7,8,9,10,11,12,13,14,15

Disclosure of Interest: needs to be evaluated.

Introduction: EUS-guided Cysto-Enterostomy (EUCE), technique indicated for drainage of symptomatic pancreatic pseudocysts and other peri-enteric fluid collections, requires specific skills for which dedicated models are needed. Based on a compact EASE model (Active Simulating for Interventional Endoscopy) we developed two ex-vivo porcine models of retrogastric cysts and evaluated learning performance within the frame of a structured training program.

Aims & Methods: The first model was made of porcine colon (i.e. “natural cyst”), and second one was made with an ostomy bag (i.e. “artificial cyst”). All procedures were achieved with EUS scope under fluoroscopy. Both models were evaluated prospectively over a 2-days session involving 14 students and 5 experts. Results: “Natural cyst” and “artificial cyst” were prepared respectively within 10 and 16.5 minutes (p = 0.05). More than 10 EUS procedures were done in each model. Model grading (analogic scale) showed no significant difference for primary endpoint of global satisfaction (p = 0.60). Radiological endpoints, however, showed significant differences (p = 0.05) whereas it was significant favoring “artificial cyst” in terms of ability to teach procedural steps (p = 0.01) and ease of puncture (p = 0.03) because of less elasticity. Moreover, experts considered it useful to improve students’ proficiency superior with “artificial cyst” (p = 0.008)

Conclusion: Both “artificial and natural cysts” are efficient for EUCSE training in terms of global satisfaction. However, the “artificial cyst” model appears to make procedure easier and it can help to teach procedural steps improving students’ proficiency. Larger applications of this model are needed to validate as a standard of training.

P0247 A COMPARATIVE STUDY OF SUCTION METHODS DURING ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION (CONVENTIONAL SUCTION VERSUS CAPILLARY SUCTION)

K. Yamakita,1 Y. Kitano2, Y. Hswamoto2, K. Takahashi2, K. Wada2, S. Otake2, Y. Ota2, Y. Tamaki2, M. Okada2, K. Aso2, Y. Makino2

Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is essential for the diagnosis of various malignant and non-malignant conditions. However, aspiration efficiency is highly variable and the aspiration technique is an important factor. Various aspiration techniques have been reported and the best aspiration technique to improve aspiration efficiency remains to be defined. In the current study, we compared the conventional aspiration method (CA) using syringes with the aspiration method (AM) using capillary suction catheters (CSC) during EUS-FNA.

Materials and Methods: The study was approved by the ethical committee of our institution and all patients provided written informed consent at the time of the procedure. A total of 60 procedures (25 in each group) were conducted by one experienced investigator. Patients were randomized into two groups: the CA method group and the AM method group. After the CA method group was aspirated, the AM method group was aspirated by the same investigator. Aspiration was considered successful if any amount of fluid was obtained. The aspiration efficiency was assessed by the volume of the aspirated fluid and the number of aspiration attempts.

Results: The mean aspiration efficiency was 252.8 ± 79.8 µl in the CA method group and 307.0 ± 90.7 µl in the AM method group (p = 0.004). The number of aspiration attempts was 4.2 ± 1.7 in the CA method group and 3.5 ± 1.4 in the AM method group (p = 0.006). The number of successful aspirations was 25/25 in each group.

Discussion: The aspiration method using capillary suction catheters improved aspiration efficiency compared with the conventional aspiration method. The aspiration method using capillary suction catheters is recommended for use in daily practice, as it allows saving aspiration attempts and aspirating more tissue.
EUS guided tissue acquisition using a 25G-gauge core biopsy needle without an on-site cytology showed high accuracy for definitive diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0250 A COMPARATIVE STUDY BETWEEN EUS-GUIDED BILARY DRAINAGE AND PERCUTANEOUS BILIARY DRAINAGE IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION AND FAILED ERCP

Department Of Gastroenterology, Hangzhou First People’s Hospital, Hangzhou, China

Contact E-mail Address: zacharylu@126.com

Introduction: Patients with malignant biliary obstruction conventionally undergo percutaneous transhepatic biliary drainage (PTBD) after failed endoscopic retrograde cholangiopancreatography (ERCP) (1). While PTBD is effective, it is associated with significant morbidity, such as bile leakage, bleeding, and pneumothorax, and involves uncomfortable external drainage (2). Endoscopic ultrasound-guided biliary drainage (EUS-BD) is a minimally invasive endoscopic procedure increasingly offered to patients with malignant biliary obstruction after failed ERCP (3). Although a recent meta-analysis reported better clinical efficacy and superior safety of EUS-BD when compared to PTBD, there are still no high-quality clinical data (4).

Aims & Methods: We aimed to compare efficacy and safety of EUS-BD to PTBD in patients with malignant biliary obstruction after failed ERCP at a single tertiary referral center from mainland China. From November 2011 through December 2015, consecutive patients undergoing EUS-BD or PTBD for malignant biliary obstruction after failed ERCP were included. Demographical, biochemical, and outcome data were registered for each group. The primary outcomes included technical success rate and incidence of complications, the secondary outcomes were clinical success rates and re-intervention rates.

Results: A total of 93 patients (mean age 68 ± 13.5 years, 49 males) were included, 33 in the EUS-BD group and 60 in the PTBD group. Both groups were similar in terms of age, gender, baseline bilirubin and functional status. Technical success was achieved in 32 (97.0%) of 33 patients in the EUS-BD group and in 57 (95.0%) of 60 patients (p > 0.05) in the PTBD group. The clinical success (jaundice relief: reduction in serum bilirubin by 50% within the first month) was achieved in all patients with technical success (32/32, 100% EUS-BD vs. 57/57, 100% PTBD).

Disclosure of Interest: All authors have declared no conflicts of interest.
P0251 A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOLGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MASSES

P.N. Desai, M. Kabrawala
Endoscopy, Surat Institute Of Digestive Sciences, Surat/India

Contact E-mail Address: drp.desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used up till now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for attaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with a certain diagnosis in almost 81% and a suspicious diagnosis in 19%.

Results: Total number of cases 56 Age (range) 57.2±13.6 Male to Female 40:16 Total Needle Bi ulcerin (0mg/dl) 5.9±6.4 Mean size of the mass 12 mm (7 mm to 30 mm). Mean Number of passes with FNA needle 2.5 (2 to 5 passes). Mean number of passes with cytology brush 2 (2 to 5). Positive diagnosis obtained With FNA 47 (83.9%). Positive Diagnosis obtained by brush 34 (60.7%).

Discussion:

With EUS the tumors were sometimes difficult to locate and identify. But giving some time and instilling water in duodenum were useful techniques to identify the masses. Only a 25 G needle was used as the FNA had to be taken almost always from the duodenum and with difficult angles. But we succeeded in taking FNA from all cases.

Conclusion: EUS FNA is a very effective method for diagnosis of distal bile duct masses with a certain diagnosis in almost 81% and a suspicious diagnosis in around 19% cases. Its efficacy is better than ERCP guided brush cytology. Even small masses are amenable to FNA using EUS guidance. Male over 57 years with jaundice and distal bile duct obstruction has a very high likelihood of having a distal CBD cholangiocarcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0253 TRANSM AORTIC ENDOSCOPIC ULTRASOUND GUIDED FNA IN THE DIAGNOSIS OF LUNG CANCERS AND MEDIASTINAL LYMPH NODES

P. Somani, M. Sharma
Department Of Gastroenterology, Jaywant Rai Speciality Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Obtaining a tissue diagnosis from a lung tumour or a mediastinal lymph node located lateral to the aorta (para-aortic) is a diagnostic challenge because of the interposition of the aorta. Invasive surgical procedures like mediastinotomy, thoracotomy, or video-assisted thoracic surgery is required for the diagnosis of these lesions. Lymph node stations immediately anterior to the aortic arch and lateral to the descending aorta are difficult to access. Lymph nodes on the “far-side” of major blood vessels can be visualized by endoscopic ultrasound(EUS), however Fine needle aspiration(FNA) is avoided due to concern for bleeding complications. Tumours and mediastinal lymph nodes located in the para-aortic region can easily be visualized by esophageal EUS, because the aorta provides an excellent medium to transfer ultrasound waves.

References

G. Macedo

84%; p required another EUSTD attempt. Complete resolution of PFCs with DPPS was drainage with a different modality (surgery/percutaneous drainage) and 8 cases lesions was 92 mm (IQR: 74–120). The overall technical success rate was 78% EUSTD of PFCs using DPPS and FCSEMSs.

Aims & Methods:

We aimed to evaluate the feasibility, yield, and safety of EUS-guided lung tumours and pancreatic fluid collections (PFCs). We undertook a retrospective case series of 12 consecutive patients with suspected lung cancer or tuberculosis who underwent transaortic FNA during a study period of 7 years. In all cases, the para-aortal lesion was the only site suspect lung cancer or tuberculosis (other lesion/lymph node if present were negative). Based on CT/ PET imaging, a transesophageal FNA performed through the aorta was considered as the only option to diagnose or stage these patients by means of a minimally invasive procedure. Seven patients had left-sided lesions, 1 case had a lesion in the right lower lobe and 1 in left upper lobe. Four patients had enlarged para-aortic lymph nodes (mean size 18 mm, range 8–22 mm), suspicious for ISLSCC stations 5(n=1) and 6(n=3). One patient had anterior mediastinum mass. EUS was performed with a linear echoendoscope. All aspirates were obtained under real-time US guided FNA by using a 22/25-gauge needle. A single real-time FNA of the lung mass or lymph node was performed. The para-aortal area was observed on EUS for 5 minutes to assess for immediate procedure-related complications.

Results:
The final diagnosis was known in 11 patients (5 non-small-cell lung carcinoma [NSCLC], 2 small-cell lung carcinoma [SCLC], 3 tuberculosis and 1 thymolipoma). EUS-FNA established diagnosis in 9 of 12 patients (75%) (4 NSCLC, 1 SCLC, 3 tuberculosis and 1 thymolipoma). One aspiration revealed reactive nodal tissue, and one demonstrated nonrepresentative material. One procedure was abandoned due to complication. Three patients in whom diagno- sis was not established by transaortic FNA underwent subsequent surgical stag- ing (1 throracotomy, 1 mediastinotomy, and 1 VATS), and malignancy was found in 2 of the 3 patients. Trans aortic FNA was found to be safe. In one patient, EUS images after FNA were suspicious for a small para-aortic hema- toma. This patient recovered without any adverse event.

Conclusions:

This study confirms the feasibility and probable safety of single EUS guided transaortic aspiration in para-aortic lesions. The diagnostic yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure include day care procedure, less invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transaortic FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

P2054 ULTRASOUND-GUIDED ENDOCUTOCR TRANSDUGAL DRAINAGE FOR PANCRA TIC FLUID COLLECTIONS

M. Sibila1, S. Lopes1, A. Peixoto1, F. Vilas-Boas1, P. Moutinho-Ribeiro1, G. Macedo2

1Gastroenterology, Hospital São João, Oporto/Portugal
2Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: marccostasilva87@gmail.com

Introduction:

Ultrasound-guided endoscopic transgastric drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPPS) requires placement of multiple stents and can be restricted by inadequate drai- nage and leak risk. Recently, the use of fully covered self-expanding metal stents (FCSEMSs) has been reported as an effective alternative.

Aims & Methods:

We aimed to evaluate the successful placement of stents, the impact of endoscopic ultrasound (EUS)-guided sampling in gastroenterology: disclosure of interest, more data is required. At present, Transaortic FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures. Definitive diagnosis with full histological assessment including IHC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36% (72/malignant. SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinoid, 1 SEL-like adenocarcinoma, 1 schwannoma, 1 benign SEL (leiomyoma), 4 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95%CI 70.2–94.3), 100% (95%CI 58.7–100%), 100% (95%CI 85.1–100%), and 62% (95%CI 27.7–84%), respectively. No major complications requiring additional care have been observed. Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G needle is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-approach anatomical locations. Comparative studies with different needle sizes are awaited.

P2055 COMPARISON OF NATURAL COURSE VERSUS EUS-GUIDED ETHANOL ABLATION FOR PANCREATIC CYSTIC LESIONS

1Department Of Internal Medicine And Liver Research Institute, Seoul National University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: pseudo.jh@gmail.com

Introduction: Endoscopic ultrasound-guided(EUS)-guided ethanol ablation for pancreatic cystic lesions (PCLs) is a recently introduced treatment option for PCLs. The aim of this study was to compare the clinical outcomes of EUS-guided ethanol ablation with those of the natural course of PCLs. Aims & Methods: We performed retrospective study of patients with PCLs divided in two groups: EUS-guided ethanol ablation group (n = 118, performed between June 2006 to August 2015) and natural course group (n = 458, diagnosed between January 1993 to August 2015). The propensity score-matching analysis
between the two groups was applied in order to minimize the effect of selection bias. There was a larger rate of significant reduction in size (≥ 20% of initial size). The secondary outcomes were the rate of significant growth in size (> 10 mm), complete remission rate, and surgical resection rate.

**Results:** In a propensity matched analysis of 88 pairs, the mean initial cystic size of EUS-guided ethanol ablation group and natural course group was 23.72 ± 10.99, 23.16 ± 13.15 mm and the mean follow-up duration was 75.45 ± 38.12, 82.12 ± 59.06 months respectively. Significant reduction in size was detected in 53 (60.2%) of the EUS-guided ablation group and 17 (19.3%) in the natural course group (p = 0.001). Significant growth in size was detected in 6 (8.9%) of ablation group and 11 (12.5%) of natural course group. (p = 0.202). Seven patients (7.95%) underwent surgical resection in the EUS-guided ablation group and 17 patients (19.3%) in the natural course group (p = 0.080) during follow-up. Overall 28.8% patients (34 of 118) who underwent EUS-guided ethanol ablation achieved the complete remission.

**Conclusion:** PCLs that underwent EUS-guided ethanol ablation can be seen the likelihood of getting clinical benefits such as reduction of the cystic size, the chance for surgical resection and the natural course of them. It is also expected to achieve a certain level of complete remission for PCLs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0257 RANDOMIZED TRIAL COMPARING THE FRANSEN AND FORK-TIP NEEDLES FOR EUS-GUIDED FINE-NEEDLE BIOPSY**

J.Y. Bang, S. Hebert-Magee, M. Hasan, U. Navaneethan, R. Hayes, S. Varadarajulu

Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL.

**Contact E-mail Address:** jybang213@gmail.com

**Introduction:** Fine-needle tissue comprising both tumor and desmoplastic stroma is required for molecular profile-based personalized chemotherapy in pancreatic cancer. Recently, a three-plane symmetric needle with Fransen geometry and a Fork-tip biopsy needle have been developed for histological tissue procurement.

**Aims & Methods:** We aimed to compare tissue acquisition between the 22G Fransen and 22G Fork-tip needles in patients undergoing EUS-guided sampling of pancreatic masses.

**Results:** In 50 patients randomized to undergo EUS-guided sampling, the diagnosis was pancreatic cancer in 43, neuroendocrine tumor in 2, lymphoma in 1 and chronic pancreatitis in 4 patients. There was no significant difference in total tissue area (median 6.1 mm² [IQR 3.5–10.5] vs. 8.2 mm² [IQR 4.0–13.0], p = 0.53), presence of desmoplastic stroma in tumors (100 vs. 83.3%, p = 0.23), sizes of diagnostic cell block (96.0 vs. 92.0%, p = 0.68) and diagnostic adequacy at ROSE (94.0 vs. 98.0%, p = 0.62) between the Fransen and Fork-tip needles, respectively.

**Conclusion:** Both the Fransen and Fork-tip needles appear equally effective in yielding histological tissue. By virtue of their ability to yield a diagnostic cell block in greater than 90% of patients, the new generation FNB needles may obviate the need for ROSE during EUS-guided tissue sampling.

**P0258 THE SUCCESS RATE OF DOUBLE BALLOON ENDOCOPIC CHOLANGIOGRAPHY IN PATIENTS WHO UNDERWENT THEIR INITIAL SURGERY AS INFANT IS SIGNIFICANTLY LOWER THAN OTHER PATIENTS**

K. Yokoyama1, T. Yano1, J. Ushio2, K. Tamada1, A. K. Lesor2, H. Yamamoto3

1Department Of Gastroenterology, Jichi medical university, Tochigi/Japan
2Department Of Gastroenterology, Jichi Medical University, Tochigi/Japan

**Contact E-mail Address:** r7060k@jichi.ac.jp

**Introduction:** To evaluate the success rate of double-balloon endoscopic retrograde cholangiopancreatography (DBERCP) to reach the anastomosis in patients with surgically altered gastrointestinal anatomy.

**Aims & Methods:** We review 346 patients with surgically altered anatomy who underwent DBERCP from April, 2002 to December, 2016 (47 patients with biliary atresia (BA) after living donor liver transplantation (LDLT), 33 with LDLT without BA, 45 with biliary resection and choledochojejunostomy, 111 with gastric resection and Roux-en-Y bypass, 48 with gastric resection and Billroth-II resection, 18 with pyloro-preserving pancreaticoduodenectomy, and 42 others). We evaluate the success rate according to the type of gastrointestinal anastomosis, age, and age at surgery.

**Results:** The success rate for reaching the biliary anastomosis (or papilla of Vater) in all 346 patients (66y.o (3–91)) was 83%. The rate in 47 patients with BA after LDLT (12y.o (3–39)) was 57%. In the remaining 299 patients the rate was 87%.

The success rate of reaching the biliary anastomosis in patients with BA after LDLT was significantly lower than other patients (p < 0.01). There was no significant difference between the success rate in the patients over or under 13 years at the time of ERCP (50% vs 56%, p = 0.70). The success rate was lower in patients who underwent initial surgery as an infant (Kasai hepatoportoenterostomy) than in those past infancy (54% vs 88%, p < 0.01). When reaching the biliary anastomosis is successful, the success rate of cannulation in the patients after LDLT is high (92%). When the success rate for reaching the biliary anastomosis in patients with BA after LDLT is significantly lower than other patients. The age at the time of ERCP did not affect the success rate of reaching the biliary anastomosis, but the success rate was lower in patients who underwent their initial surgery as infants.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0259 EUS-GUIDED RADIOFREQUENCY ABLATION OF DIFFICULT SITES IN THE LIVER: A PRECLINICAL STUDY**

N. Junya, T. Tamura, M. Itonaga, R. Shimizu, Y. Ida, M. Kitano

Second Department Of Internal Medicine, Wakayama Medical University, Wakayama/Japan

**Contact E-mail Address:** jybang213@yaho.co.jp

**Introduction:** Liver tumors such as hepatocellular carcinoma and liver metastases sometimes occur in positions in which treatment using percutaneous radiofrequency ablation (RFA) is difficult, such as the caudate lobe and surface of the liver. EUS-guided RFA (EUSRATM) can offer an alternative treatment by accessing these tumors through the stomach or duodenum. To the best of our knowledge, only one report has described EUS-RFA of the liver in an animal model, using a 19-gauge EUS-FNA needle with an umbrella-shaped array at the tip.

**Aims & Methods:** We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. EUSRATM needle and a VIVA combo™ generator (TaeWoong Medical, Gimpoo, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-mm, and 20-mm exposed tips) were used. After the echoendoscope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at 5-40 W for 2–6 min in each mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrato lobe of the gallbladder through the bulb of the duodenum.

**Results:** All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect were evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

**Conclusion:** In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0260 CYANOACRYLATE INJECTION THERAPY OF SMALL BOWEL VARIANCES BY DOUBLE-BALLOON ENTEROSCOPY (DBE): A TERTIARY CENTRE EXPERIENCE**

A. Murino1, N. Koukia2, E. Vlachou1, K. Planché2, D. Patch1, E. J. Despot1

1Digestive Free Unit For Endoscopy at The Royal Free Hospital and University College London (UCL) Institute for Liver and Digestive Health, London/United Kingdom
2Department Of Radiology, The Royal Free Hospital and University College London (UCL) Institute for Liver and Digestive Health, London/United Kingdom

**Contact E-mail Address:** albertomurino@yahoo.it

**Introduction:** Small bowel varices (SBV) occur as a consequence of portal hypertension and may result in life-threatening mid-gut bleeding. First line management usually involves radiological intervention (RI) (e.g. TIPS, stenting of occluded mesenteric veins +/- embolisation of culprit varices). In cases where RI is impossible, management options become very limited.

**Aims & Methods:** This case series evaluated the usefulness of DBE facilitated cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV at our institution (December 2015 to August 2016). Demographic, clinical, endoscopic and radiological findings, interventions and follow-up data were analysed.

**Results:** Seven DBEs were performed in 5 patients (3 women, median age: 73-years). Four patients had previous surgery (hemi-hepatectomy (n = 2); SB resection (n = 2)); one patient had a history of intra-abdominal sepsis in childhood causing portal vein thrombosis. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase CT mesenteric angiography. At DBE, a total of 10 nests of SBV were identified.
and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications. A median size of 80 mm was developed and then removed by a congenital jejunal cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route and 1 patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for treading of further patent proximal SBV. At 30-day follow-up post-therapy, only 1 patient had exhibited a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options are not available.

Contact E-mail Address: n.ogata@hotmail.co.jp

Introduction: The development of balloon endoscopy and capsule endoscopy has made observation of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with 80x magnification has been recently developed. Aims & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal crohn’s disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to February 2015. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo). Magnifying NBI was performed, and the images were evaluated by assessing vascularity, increased vascularization, and the increased caliber of capillaries into three grades as follows: Normal, Visible and Irregular. Normal was indicative of inactive disease, while Visible and Irregular were indicative of acute inflammation in our study. The outcome measures included the diagnostic ability of magnifying NBI findings to distinguish active CD from inactive CD on the basis of histological activity.

Results: Twenty-four patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman’s r = 0.54, p < 0.05).

Conclusion: The NBI findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0262 SINGLE-INCISION LAPAROSCOPIC-ASSISTED DOUBLE BALLOON ENTEROSCOPY: A NOVEL TECHNIQUE TO MANAGE SMALL BOWEL PATHOLOGY

Introduction: Double balloon enteroscopy (DBE) has revolutionised the diagnosis and treatment of small intestinal conditions. However, in even expert hands, deep small bowel (SB) insertion can be challenging, especially in patients with a history of abdominal surgery. Moreover, if the findings at DBE are not amenable to endoscopic therapy, a further surgical procedure is usually required to provide definite treatment. Laparoscopic-assisted DBE (LA-DBE) using a standard multi-port technique has previously only been reported in a small series of 3 patients with Peutz-Jeghers Syndrome (PJS).

Aims & Methods: This case series reports the development of LA-DBE using single-incision laparoscopic surgery (SILS) applied to a wide range of clinical indications. Retrospective review of LA-DBE procedures performed in a single tertiary centre over a 6 year period. Demographics, indication, findings, diagnostic and therapeutic interventions were recorded. Completion, complication rates and hospital length of stay were also captured.

Results: 17 procedures were performed over 6 years in 17 patients who had failed standard DBE. Mean (range) age was 40 (17-73) and 41% of patients were male. The enteroscopic approach was oral in 13/17 patients and rectal in 4/17. Laparoscopic approach was standard (multipor) in the first 4 cases, SILS was then used in all subsequent patients (13/17). The mean (range) procedure time was 147 (84-210) mins. Indications were PJS (n = 10), suspected submucosal/ intramural lesion at small bowel imaging (n = 5) and obscure gastrointestinal bleed (OGBB) with vascular abnormalities seen at capsule endoscopy (n = 2). In 15/17 procedures the target pathology was reached using laparoscopic assistance only and 1/17 was converted to intraoperative enteroscopy (IOE). In 1/17 the suggested pathology at magnetic resonance enterography (MRE) was not identified. Therapy was applied in 15/17 (88%) cases. 7 underwent endoscopic therapy of which 6 polyectomy and 1 ablation with argon plasma coagulation (APC). 4 required limited SB resection and 4 underwent both endoscopic polyectomy and small bowel resection for a second polyp that could not be removed endoscopically. A total number of 57 polyps were removed with the largest measuring 40 mm. The range of length of surgically resected SB was 4-17 cm. Diagnoses were PJS polyps (n = 9), neuroendocrine tumour (NET) (n = 2), PJS polyps and NET (n = 1), transection arteriovenous malformation (n = 1), angioectasia (n = 1), inflammatory polyp (n = 1), leiomyoma (n = 1), Meckel’s diverticulum (n = 1). Median length of stay post procedure was 2 (1-19) days. 8/17 patients were discharged at 24 hours. 3/17 patients developed complications: 1 small bowel leak, 1 perforation, 1 deep vein thrombosis, 1 patient had repeated post surgery rebleeding requiring blood transfusion and 1 patient that was readmitted 8 days post procedure with subacute SB obstruction which resolved with conservative management.

Conclusion: LA-DBE appears to be a safe, effective and minimally invasive procedure that can be applied for the management of small bowel polyps surveillance and treatment in patients with Peutz-Jeghers syndrome.

P0263 GASTRIC EMPTYING IN CROHN’S DISEASE – EVALUATION BY SMALL BOWEL CAPSULE ENDOSCOPY

A.M. Singeap1, A. Trifan1, S. Chirila1, I. Giaurca1, I. Cucureanu2, C. Staniciu2

Introduction: The complex relationship between small bowel inflammatory disease (IBD) and motility disorders of the digestive tract is a complex area of study, so far incompletely elucidated. The association between Crohn’s disease and gastric emptying time modification has been relatively less studied. However, there is no single standardized method to study gastric emptying, one particular investigation that could bring direct information in this field being the small bowel capsule endoscopy (SBCE).

Aims & Methods: We aimed to study gastric emptying by small bowel capsule endoscopy in patients with suspected and confirmed Crohn’s disease. We evaluated gastric passage time showed by SBCE in patients with small bowel Crohn’s disease, compared to patients without IBD, investigated by SBCE (PillCam), following recognized indications, in the Institute of Gastroenterology and Hepatology of Iasi, tertiary center in North-East of Romania.

Results: 144 SBCE studies were included, 24 were cases of suspected and confirmed Crohn’s disease. The mean time of gastric passage in patients with Crohn’s disease was 51±21 minutes, longer than in patients without inflammatory bowel disease, in which the mean gastric passage time was 24±16.6 minutes.

Conclusion: Gastric passage time, evaluated by SBCE, is prolonged in patients with Crohn’s disease compared to patients without IBD, suggesting a relationship between chronic inflammation and gastric motor disorders. Globally, the values correlated with those considered as physiological by other exploration methods. SBCE studies may provide additional data on gastric motility (and in general gut motor disorders), with special usefulness in some individual cases, as particular symptoms or variations in the bioavailability of small bowel released drugs.

P0264 META-ANALYSIS SHOWS THAT PURGATIVE PREPARATION INCREASES SMALL BOWEL VIDEO CAPSULE ENDOSCOPY DIAGNOSTIC YIELD AND IMPROVES THE QUALITY OF SMALL BOWEL MOTILITY ASSESSMENT

P. Gkolfinakis, G. Triantziou, G. D. Dimitriadis, K. Triantafylloiu
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: The value of purgative preparation (PP) before small bowel video capsule endoscopy (VCE) remains controversial and it has been recently challenged.

Aims & Methods: The aim of this meta-analysis was to examine the effect of PP on small bowel VCE outcomes. We performed literature searches in MEDLINE and Cochrane Library to identify randomized-controlled trials (RCTs) evaluating the effect of small bowel preparation –purgative (PEG, sodium phosphate, United European Gastroenterology Journal 5(5S)
compared to clear liquids diet, PBP significantly increased small bowel VCE DY and improves VQ without affecting exam's CR. However, the positive effect of PBP on VCE DY is mainly derived from two relative small, old (2004 and 2009) RCTs and disappears if only PEG preparation studies are meta-analyzed. Heterogeneity was measured using the I2 statistics. Publication bias was assessed by funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 9 eligible RCTs with 12 sets of data, including 1029 subjects. They were low risk of bias trials and no publication bias was detected. As an entirely visual medium it depends on the qualitative scale, most of the bowel preparations were considered reasonable for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at ±10% contrast. Results are detailed in the table below.

P0265 INTER-OBSERVER AGREEMENT IN BROTZ CLEANING SCALES FOR CAPSULE ENDOSCOPY

Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal  
Contact E-mail Address: malufada_m_p_sousa@hotmail.com

Introduction: The diagnostic yield of capsule endoscopy (CE) depends on the adequate visualisation of the mucosa. As with colonoscopy, cleaning scales should be described in the report in order to better interpret results. In 2009, Brote et al proposed and validated 3 different cleaning scales in 40 patients.

Aims & Methods: A hundred CE videos (Mirocam®) were reviewed by 2 authors at a fixed frame rate of 100 frames per second in quadruple view (Miroview Client). The CE were evaluated according to Brotz scales: (1) Overall adequacy assessment (adequate/inadequate) (2) Qualitative scale (excellent, good, fair, poor) and (3) Quantitative scale (0–10 score, graded from 0–2 visualization of the mucosa, fluids, bubbles, bile and luminosity). The aim of this study was to evaluate the inter-observer variability of this cleaning scales. The kappa coefficient was used to calculate the inter-observer agreement in overall adequacy assessment and the intra-class correlation coefficient was used to evaluate the concordance of the qualitative and quantitative scales.

Results: In overall adequacy assessment, the quality of bowel preparation was classified as adequate by observer 1 in 83% and by observer 2 in 73%, with an inter-observer kappa index of 0.76 (p < 0.001) suggesting strong agreement. In the qualitative scale, most of the bowel preparations were considered reasonable (40% observer 1 vs 36% observer 2), with an intra-class coefficient of 0.89 (p < 0.001). In the quantitative scale, the mean score of the two observers was 6.5 and 6.7, resulting in an intra-class agreement of 0.78 (p < 0.001).

Conclusion: The optimization of quality of bowel preparation and the diagnostic yield of the CE requires, first, a well-validated cleaning scale. Brotz's rating scales has strong inter-observer agreement. The qualitative scale is easier to apply and has better inter-observer agreement, so the authors propose that it should be used routinely in the CE report.  

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy (CE) is the prime mode of investigation for small bowel (SB) pathology. However, as an entirely visual medium it depends heavily on image quality. The definition of optimal image quality remains unstandardised between studies and poses significant limitations to the quality of study reporting. As yet, there is no widely-accepted or integrated method for scoring SB cleanliness during CE reporting. This pilot study aims to quantify the image properties contributing to adequate visualisation quality in CE images.

Aims & Methods: Five clear images of SB pathology were obtained using MiroCam® (Intromedic, South Korea), image resolution 320×320 pixels(px): P1 and P2 angioectasias, ulcer, aphtha and polyp. Each image was processed using GIMP2 image editing software (www.gimp.org) for 3 parameters: (1) opacity (opacity filter matched in colour to commonly-seen SB contents, 10–90% in 10% increments), (2) blur (Gaussian blur, radius 1–10px), (3) contrast (-50% to 50% in 10% increments). Gaussian blur was used to simulate the effects of rapid capsule movement as well as to affect image definition. A set of 5 original and 190 edited images was obtained. A web-based survey was created using Google Forms and 9 expert CE readers were asked to indicate whether each image was adequate or not for diagnosis. The order of images was randomised for each reader. For each type of pathology, we determined the threshold of image quality which was deemed adequate for diagnosis.

Results: For image opacity, both aphtha and the polypoid lesion were adequately visualised below 40% opacity whereas the threshold was lower for both the ulcer and aphtha (10% opacity). Increasing blur radius significantly impacted the acceptability of images for reaching a diagnosis with confidence; for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at ±10% contrast. Results are detailed in the table below.

Introduction: Inflammatory bowel diseases (IBDs) are chronic inflammatory diseases that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic evaluation of these parts is essential to assess disease extent and severity. The small bowel capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

Aims & Methods: The aim was to evaluate SBC-CE system functionality in suspected or established IBD (Crohn’s disease [CD] and Ulcerative Colitis [UC]) patients. This was a prospective 5 center feasibility study assessing the practicality and software and capsule performance. Subjects enrolled in the study ingested the new capsule after standard bowel preparation plus boosts. Contraindications for its use included obstruction, dysphagia or swallowing disorders, pacemakers etc. GI patency was assured using the patency capsule. The procedure characteristics, (3) clinical outcomes, (4) adverse events.

Results: Overall reading time, over all video quality and occurrence/severity of adverse events. Points were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events.

Conclusion: The new SBC capsule is a friendly, minimally invasive capsule allowing complete evaluation of the entire gut of IBD patients. The system may be used to assess disease severity and extent and for follow up of IBD patients.

P0268 THE UTILITY OF A NOVEL TRANSPAPILLARY DILATATION TECHNIQUE WITH A DIATHERMIC CATHETER FOR SEVERE MPD STRicture DUE TO CHRONIC PANCREATITIS

S. Kato, M. Kuwatai, R. Sugiuira, I. Sano, K. Kawakubo, N. Sakamoto

Gastroenterology And Hepatology, Hokkaido University Hospital, Sapporo/Japan

Contact E-mail Address: shinchan1231@gmail.com

Introduction: Transtabilary dilation for severe main pancreatic duct (MPD) stricture is sometimes difficult and diathermic dilation is now getting attention as a salvage technique for severe stricture; however its efficacy and safety remains unclear.

Aims & Methods: To evaluate the efficacy and safety of a novel transpapillary dilation technique with a wire-guided 6Fr diathermic catheter for severe chronic pancreatitis. Between April 2011 and March 2017, 143 patients with chronic pancreatitis underwent endoscopic transpapillary stent placement for MPD. MPD dilatation was indicated in 18 patients, and diathermic dilation was required in nine patients. We evaluated (1) the patients’ characteristics, (2) procedure characteristics, (3) clinical outcomes, (4) adverse events.

Results: (1) Six patients were men and three were women (mean age, 50.1 years).
(2) Alcohol 8, unknown 1. The strictures were in the head of pancreas: 8, body: 1.

The mean length of stricture was 20.2 mm (range, 10.3–38.8). The mean MPD diameter at the distal side of the stricture was 6.2 mm (range, 2.0–12.7). The success rate of dilatation (55.6%) among them had no former procedure for MPD including stenting. (2) A wired-guided 6Fr diathermic catheter with 30 W power was used for all cases. All cases underwent diathermic dilation as salvage procedure subsequent to conventional dilation. One to 7 diathermy procedures (mean 2.9) were applied in all patients in passage through each stricture. (3) Passage of the diathermic catheter and stent placement was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). Recurrence of stricture was observed in 2 patients (22.2%). One of them needed diathermic dilation again. (4) Two adverse events (22.2%) were observed and both of them were mild pancreatitis. Multiple diathermy procedures (6 times and 4 times, respectively) and relatively long duration of total diathermy procedures (39 sec. and 25 sec. respectively) were observed in cases with pancreatitis.

Conclusion: Transtabilary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. This technique should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

References
EUS-BD using transmural covered metal stent with antimigration periods. The stent patency duration was 275.2 (147.8–402.7) days. During stent occlusion was observed in 5 patients. Neither proximal peritoneal stent abscess in patients with malignant biliary stricture. Late adverse event that segmental duct in 18 patients. Among them, percutaneous transhepatic biliary drainage methods after unsuccessful ERCP. Among these procedures, CDS and RVS require the echoendoscope reaching duodenum. However, HGS and CAS are indicated in cases with inaccessible duodenum. However, HGS is associated with a higher risk of adverse events, compared with the other methods. When the stent dysfunction occurs, re-intervention is more difficult after AGS alone than after HGS or CAS. Thus, we started to add AGS during HGS in a single session from April 2011.

Aims & Methods: The aim of this study was to assess the efficacy and safety of HGS combined with AGS for malignant biliary strictures induced obstructive jaundice. Between Jan. 2006 and Dec. 2014, ERCP was attempted in patients with obstructive jaundice, which was successful in 641 patients and impossible in 154 patients (101 cases due to post-surgical altered anatomy or duodenal stenosis, 53 cases due to difficult cannulation). A total of 145 patients received EUS-BD, HGS and AGS were attempted in 42 (Group A; from Jan 2006 to Aug 2011) and for malignant biliary stricture patients who underwent EUS-BD after failed ERCP were enrolled. The technical and functional success rates, adverse events rate, re-intervention rate, procedure time, overall patient survival time, and time to stent dysfunction or patient death. In Group A, technical success of HGS was defined as successful stent deployment between the left hepatic bile duct and the stomach. In Group B, technical success of HGS with AGS was defined as successful stent deployment at bile duct stricture (AGS) in addition to success of HGS. Functional success for obstructive jaundice was defined as a decrease in bilirubin levels to <40% of the pretreatment value within 2 weeks. The incidence rate of adverse events such as peritonitis, bile leakage, bleeding, stent migration, and stent occlusion was assessed. The re-intervention was defined as any endoscopic, surgical, or percutaneous procedure that was required to improve symptoms after placement of the stent. Time to stent dysfunction or patient death was defined as the time from stent deployment to biliary re-intervention due to stent dysfunction or from the time to stent deployment to patient death. Groups A and B were compared in the technical success rate, adverse events rate, and re-intervention outcomes, the procedure time, the overall patient survival time and time to stent dysfunction or patient death. For subgroup analysis in patients who underwent chemotheraphy the Groups A and B were compared in the overall patient survival, time to stent dysfunction or patient death and adverse events rate.

Results: Technical success rate of Group A was significantly higher than Group B (97.6% vs 83.8%, p = 0.03). The two groups were comparable for the functional success rate (98.2% vs 90.3%, p = 0.25), although the rate of adverse events tended to be higher in Group A than in Group B (26.1% vs 13.5%, p = 0.10). The re-intervention rate tended to be higher in Group A than in Group B (16.7% vs 8.1%, p = 0.25). Groups A and B did not differ significantly in terms of median overall patient survival (75 days vs. 72 days, p = 0.70), and median time to stent dysfunction or patient death (68 vs 63 days, p = 0.08). In patients who underwent chemotherapy, there were no difference in the overall patient survival time (121 vs 137 days, p = 0.08) between the two groups although the time to stent dysfunction or patient death was significantly shorter in Group A than in Group B (71 vs 95 days, p = 0.02).

Conclusion: Technical success rate of HGS with AGS was lower than HGS, although HGS with AGS is superior to HGS in terms of stent patency in patients undergoing chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Long-term outcomes of endoscopic ultrasound-guided right intrahepatic duct drainage with transmural covered metal stent

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been regarded as an effective alternative in cases of endoscopic retrograde cholangiopancreatography (ERCP) failure or inaccessible papilla. However, EUS-BD for right intrahepatic duct obstruction (EUS-BDR) remains challenging, although recent studies showed promising result. The aim of current study was to evaluate the feasibility and long-term outcomes of EUS-BD with transmural covered metal stents for right intrahepatic duct obstruction. Aims & Methods: Retrospective study, a total of 24 consecutive patients who underwent EUS-BDR after failed ERCP were enrolled. The patients were consisted of 12 cases of benign strictures and 12 cases of malignant strictures. The biliary stents used in this study was covered metal stent with anchoring flaps (4.5-6.5 mm, fully covered metal stent with anchoring flaps). The technical success rate, clinical success rate and adverse events were evaluated.

Results: The technical success rate was 91.7% (22 cases) and 80.8% (18 cases) in benign and malignant stent deployment. Time to stent dysfunction or patient death was 75.2 days (147.8-402.7 days). During follow-up period, stent revision due fistula tract was successful and additional percutaneous biliary drainage for right intrahepatic duct obstruction was not required in all patients who achieved clinical success.

Conclusion: EUS-BD using transmural covered metal stent with antimigration properties for right intrahepatic duct obstruction may be technically feasible, effective and relatively safe for both benign and malignant strictures by expert hands. Furthermore, the route of hepatocoduodenotomy created by covered metal stent was durable and endoscopically easily managed. Disclosure of Interest: All authors have declared no conflicts of interest.

Utility of EUS-guided hepaticogastrostomy for malignant biliary obstruction of ERCP inability

H. Inai, M. Takenaka, M. Kudo Gastroenterology And Hepatology, Kindai University, Osaka, Japan

Contact E-mail Address: codenagemenchan1023@gmail.com

Introduction: Endoscopic ultrasound guided transmural gall-bladder drainage (EUS-GBD) with covered metal stent has become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-GBD with covered metal stent and conventional percutaneous cholecystostomy. Aims & Methods: This is a single-centre, retrospective study of long-term outcomes of EUS-GBD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-GBD for acute cholecystitis is obtained from prospective collected EUS database of the hospital. In percutaneous cholecystostomy group, the electronic medical record of patients who underwent percutaneous cholecystostomy was reviewed and analyzed. Demographics and procedure related outcomes including early, late adverse events and need for re-intervention in each group was compared. Results: A total of 181 patients (74 in EUS-GBD group and 107 in percutaneous cholecystostomy group) were enrolled in this study. The cause of cholecystitis and ASA class were similar in both groups. The technical/clinical success rate was 100%/98.6% in EUS-GBD group and 99.1%/97.2% in percutaneous cholecystostomy group (P = 0.591). However, early adverse events such as migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis was more frequently observed in percutaneous cholecystostomy group (5.7% in EUS-GBD group and 21.07% in percutaneous cholecystostomy group, P = 0.017). Percutaneous cholecystostomy tube was indwelled for....
median 20 days (14.0–45.2) after the procedure. A total of 7 patients in EUS-GBD intervention for all of them were conducted successfully. The patients who underwent percutaneous cholecystostomy more frequently received re-intervention for adverse event or recurrence of cholecystitis after removal of cholecystostomy. (7/74 vs. 23/106, P = 0.041).

Conclusion: EUS-GBD and percutaneous cholecystostomy were both effective interventions to urgent drainage for acute cholecystitis. However, EUS-GBD might be beneficial than percutaneous cholecystostomy in long term management for the patients with acute cholecystitis who are not suitable for cholecystectomy.

Disclose of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We retrospectively analyzed the data of DLDT patients with duct-to-duct anastomotic biliary strictures who underwent endoscopic treatment at our center within the last 3 years. FcSEMSs were inserted in 23 patients (13 male, 10 female, mean age: 51 ± 9 years) who were managed with MPSs insertion (Group-2). In Group-1, secondary branch ducts were prophylactically drained with insertion of plastic stent(s) in order to prevent the development of cholangitis due to their occlusion. FcSEMS and plastic stent(s) were left in place for 2 months. In Group-2, maximum number of plastic stents were inserted and replaced every 3 months. Patients with a follow-up duration of at least 3 months after stenting were included to the study. Primary end-points were the number of endoscopic procedures and the time required for structure resolution. The secondary end-point was the recurrence rate of the stent.

Results: FcSEMSs were successfully deployed in all cases. The diameter of the Fc-SEMSs was 10 mm in 22 patients and 8 mm in 1 patient. The length of the Fc-SEMSs was 15 cm in 13 patients, 10 cm in 8, and 5 cm in 2 patients. Secondary branch ducts were prophylactically drained with a single plastic stent in 12 patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The median number of endoscopic procedures was 2 (2–4) in Group-1 and 4 (2–9) in Group-2 (P = 0.001). The time required for structure resolution was shorter in Group-1 (65.7 ± 18.2 days) than in Group-2 (240.1 ± 183.4 days) (p < 0.001). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%) (P = 0.57) after a follow-up period of 315 ± 290 and 378 ± 96 days, respectively. Conclusion: FcSEMS is an effective method for the treatment of anastomotic biliary strictures after LDLT.

Disclose of Interest: All authors have declared no conflicts of interest.

Aims: The aim of this study is to investigate the feasibility of our GI bypass device in animal. Before animal study, we performed an experimental study for durability test under simulated intestinal fluid flow. And next, we performed an animal study with 10 Yorkshire pigs. The stents were placed on pylorus with fixation by clippings or on duodenal bulb without fixation. Follow up endoscopy was done per one week after implantation. After they were sacrificed, gastric, duodenal, and jejunal tissues were harvested and examined for histologic assessment of any device or procedure-related effects.

Results: The overall clinical success rate for GI bypass in in vivo model was 10 (100%). The mean follow up time was 8 weeks (range: 6–10 weeks). Two patients were operated at 8 weeks after implantation.

Conclusion: New GI bypass stent was an effective alternative to surgical bypassing. We developed a new endoscopic gastrointestinal (GI) bypass stent and designed a preclinical study to assess the safety in a porcine model.

Disclosure of Interest: All authors have declared no conflicts of interest.

BLEEDING STENTS FOR REFRACTORY VARICEAL BLEEDING – A P0278 OUTCOME AFTER THE USE OF SX-ELLA DANIS
Eur J

Results: Forty-eight patients (296 dilations) were evaluated (median of 4 dilations/patient): 85% were male, mean age of 62 years-old, 60% belonging in Group II. Therefore, between different dilations of 5 weeks. Discrimination dysphagia Mellow-Pinks score and luminal calibre were 3 ± 1 and 7 ± 2, 8mm, respectively. Twenty-eight patients (out of 30 live patients non-submitted to additional therapies) answered to the interview: a) 96% had improved, b) 60% had better quality of life, c) 85% had a worse prognosis. Even though retrospective we present the longest follow-up in 12 of 13 patients (clinical success rate, 92.3%). Stent migration was found in a mean of 29, 2 (range: 0–13) days. Therefore the new method to inhibit stent migration is needed for more frequent, ulcers/necrosis of the esophagus were rare with a dwell time of 5 days. The most common adverse events were stent dislocations (n = 13; 37.1%), while ulcers/necrosis of the esophagal mucosa was seen in only 4 (11.4%) patients.

Disclosure of Interest: All authors have disclosed no conflicts of interest.

Introduction: Current guidelines favour the use of bleeding stents over balloon tamponade for the management of variceal hemorrhage (VBV). However, data on the efficacy of and outcomes after the placement of an SX-ELLA – Danis-Stent” are limited.

Aims & Methods: Retrospective multicenter study including cirrhotic patients receiving Danis-Stents for massive/refractory EVB at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenanstalt Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic band ligation (EVL) prior to Danis-Stent placement. Danis-Stent controlled EVB in 80% (28/35) of patients. In the remaining uncontrolled bleeders (n = 7), 3 patients had subsequent EBL, while in 3 patients the stent had to be replaced and 1 patient received a Linton-tube. Among these patients with initial Danis-Stent failure, 4 died of uncontrollable EVB. 2 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control. In total, early-rebleeding within 6 weeks occurred in 14.3% (including n = 1 while Danis-Stent was still in place and n = 5 after Danis-Stent was removed); 3 under- went venous ligation and received a subsequent Danis-Stent, and 1 patient was treated with a Sengstaken tube. Moreover, among n = 14 patients without early rebleeding within 6 weeks, only n = 3 (21.4%) showed rebleeding later during follow-up: n = 2 patients were treated with a Sengstaken-Tube (both experienced bleeding-related death) and n = 1 had another Danis-Stent placed (successful bleeding control). Only n = 11 (31.4%) patients did not experience any rebleeding after Danis-Stent removal, while n = 8 patients died with the Danis-Stent in situ. Notably, “early-TIPS” was performed in this study, but 4 (11.4%) received an NIPS during follow-up. 5 patients (14.3%) died due to uncontrolled bleeding (≤5days) and n = 10 died within 6 weeks (bleeding-related mortality: 28.6%). Overall, n = 22/35 (62.9%) patients died. The median survival was 10.5 (IQR:82) days after Danis-Stent placement. Median Danis-Stents dwell time was 5 (range: 0–13) days. The most common adverse events were stent dislocations (n = 13; 37.1%), while ulcers/necrosis of the esophaghal mucosa was seen in only 4 (11.4%) patients.

Conclusion: Danis-Stent controlled trauma bleeding/massive EVB in 80% of patients but bleeding-related mortality was as high as 45%. While stent dislocations are frequent, ulcers/necrosis of the esophagus were rare with a dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome in patients with Danis-Stent placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Benign anastomotic strictures are common adverse events of gastrointestinal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic strictures are balloon dilatation and bougination. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continuous expanding effect for a long period. But, It has problem of frequent stent migration, because of slow stent expanding, 2–3 days. Therefore the new method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stenosis. From May 2013 until February 2015, patients with benign anastomotic structure after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), double-layered, were inserted. We made two nylon thread loops at the proximal bared section of the stents. After stent placement, stent fastening with loop and clip method was performed. Patients’ symptoms and oral intake were assessed once or twice a week with a clinical check-up or telephone interview. After two weeks, the loop and stent removals were done.

Conclusion: The new method with fastening the stent with loop and clip can reduce the risk of stent migration.
Our fasting method can be feasible and useful technique for postoperative analysis of subcutaneous fat. Additionally, with some studies estimating the rate at around 20%14,15. We report a single-centre, retrospective cohort study on the use of SEPs, and aimed to establish risk factors for stent migration.

Aims & Methods: Case note review was undertaken retrospectively on all patients who had fully covered SEPS inserted at a high-volume tertiary oesophageal cancer centre between Jul 13 to Feb 17. All SEPS were placed under fluoroscopic guidance by experienced endoscopists. Stent migration was confirmed endoscopically or radiologically and was defined as displacement of the stent from the stomach or the baseline stent location. Loss of the recanalised lumen. Shapiro-Wilk testing showed non-normal distribution of data. Non-parametric testing by logistic regression was therefore performed.

Results: 188 stents were inserted to palliate malignant strictures. 75% in males. We observed a migration rate of 20% (39) in our cohort. We observed a significant association between predilation (within 7 days of the stent procedure) and subsequent stent migration (31% in dilated vs 13% in undilated stents). This also met Bonferroni correction for significance. We demonstrate a trend towards shorter strictures being associated with an increased risk of migration [OR 1.14 CI1.12–1.164 (p=0.032)]. There were no significant associations between migration and whether patients received previous chemo-radiotherapy, or whether the stent crossed the GOJ.

Conclusion: Endoscopic placement of SEPS is a safe and effective procedure in the management of malignant dysphagia with a low risk of complications. Predilation of lesions within 7 days of SEPS insertion carries a risk of subsequent stent slippage – suggesting that a cautious approach to dilation may be prudent. Further, larger studies may demonstrate an association with shorter stents and migration Rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0282 COMBINED RESSECTION IN ESOPHAGEAL CANCER: MYTH OR REALITY
D. Rusanov1, K. Pavelets2, M. Antipova3, M. Protchenkov1, M. Pavlovs1, U. Drozd1, A. Sokolova1, G. Florovsky1
1 Faculty Surgery Named After Prof. A.a. Rusanov, Saint-Petersburg State Pediatric Medical University, Saint-Petersburg/Russian Federation
2. Contact E-mail Address: Rusanov_vergeltung@yandex.ru
Introduction: Esophageal cancer is one of the 10 most common malignant diseases of the digestive tract and ranks 7th in the structure of mortality. The indicators of 5-year survival, at the present stage, rarely overcome the threshold of 15-20% in the course of the disease. Most patients are considered inoperable by the time of admission to hospital due to the spread of the tumor process. Local-regional spread of the tumor is the reason for refusing to perform radical surgical intervention. Taking into account the data for the last 10 years, only 1.6% of patients had different types of combined and surgical treatment. According to various authors, chemoradiotherapy is offered as an alternative to surgical intervention in locally advanced forms of esophageal cancer. In addition, there is no consensus between “western” and “eastern” authors about the issues of lymphodissection in esophageal cancer. Thus, for the optimal primary staging of esophageal carcinoma and planning of surgical treatment, the surgeon needs a preoperative, spatial picture of the prevalence of the tumor process in patients suffering from esophageal cancer.

Aims & Methods: To analyze the proportion of tumor using computer 3D-model of mediastinum and long-term results of treatment. Describes the experience of treatment of 190 patients with esophageal cancer from 2010 to 2015. Of them to 52 (27.3%) performed CT, to 37 (19.5%) EUS. Besides, CT to 101 (53.1%) and MRI 7 (0.1%) with subsequent DCE-MRI. 1 group- 123 (64.7%) patients, performed surgical treatment based on resection of thoracic part of esophagus, fundamental part of stomach and two-field lymphodissection. To 15 (7.9%) performed combined operations. The data obtained were compared with intracorporal findings and pathohistological examination. H group- 67 patients (35.3%) used palliative treatment: 31 (16.3%) - esophageal stenting, 26 (13.7%) - argon-tumor recanalization, 10 (5.3%) - argon-tumor recanalization with esophageal stenting.

Results: On data of all 59 (100%) 3D-models, were estimated, localization and length of esophagel tumor, its relationship with the structures of the mediastinum, severity of intraabdominal and intrathoracic lymphadenopathy. In most cases, according to the data 3D model, as well as intraoperative, met defeat of middle and lower esophagus. Severity of involvement of mediastinal structures rated at 48 patients (81.4%). At 35 (59.3%) and 37 (62.7%) cases amafed fiber mediastinoscdi, at 8 (8.5%) patients - invasion to the main bronchi, At 13 (22.0%) and 11 (18.6%) combination of anatomical structures of mediastinum defeat.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Seventy of intrahepatic and intraabdominal lymphadenopathy: mediastinal lymph node at 19 (12.2%) and 20 (33.9%) patients, combined of 38 (64.4%) and 35 (59.3%). At pre-operated staging mostly met advanced form of cancer: T4N1 at 16 (27.1%), T4N2 at 23 (38.9%). Sensitivity in staging of tumor 89.8%. Long-term results: 1-year survival at I group 96.1%, 3-year is 42.3%, 5-year 16.7% II group 1-year survival 6.45%.

Conclusion: The use of 3D-modeling performed using MRI, spiral CT and EUS, allows to planning the optimal surgery and lymph node for locally common form of esophageal cancer, and improve the results of survival. The scope of surgical intervention is advised to plan taking into account the constructed 3D-models, which helps to solve the problem of the possibility of surgical intervention in esophageal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0283 INFLUENCE OF CONTINUOUS ADMINISTRATION OF LOW-DOSE ASPIRIN FOR INTRAOPERATIVE BLEEDING ON GASTRIC ENDOSCOPIC GASTRIC DISSECTION: A PROPENSITY SCORE MATCHING ANALYSIS

Y. Horikawa, N. Mimori, H. Mizutani, Y. Kato, S. Fushimi, S. Okubo, S. Sato
Gastroenterology, Hiraka General Hospital Dept. of Gastroenterology, Yohoku Japan

Contact E-mail Address: horikawa_01@me.com

Introduction: Endoscopic submucosal dissection (ESD) was a promising method for the resection of superficial gastric neoplasms. The patient with antithrombotic agents has increased for first or secondary prevention of cardiovascular or cerebral disease. Continuous administration of low-dose aspirin (LDA) during ESD was recommended in American, British and Japanese guidelines. However, the influence of this drug for the hemostasis condition during ESD procedure is still unclear. Therefore, we performed this study for addressing intraoperative bleeding risk without cessation of LDA.

Aims & Methods: In this retrospective study, we assessed the hemostasis condition during ESD that were treated for superficial gastric lesions between January 2014 and March 2017. Patients with antithrombotic therapy by LDA (n = 42) and those with no antithrombotic therapy (n = 187; Control) were compared using propensity score matching. Primary outcome was frequency of intraoperative major bleeding. Secondary outcomes included procedure time, Hb reduction rate, En bloc resection rate, and adverse event rate.

Results: The propensity score analysis yielded 39 matched pairs. Adjusted comparison between the two groups showed similar with regards to major bleeding, median [range]: 0.0% vs 0.0%, x2 (1) = 0.0, p = 0.062. Procedure time was prolonged in aspirin group by 16.7% without significant differences. Other aspects were the same in both groups with low incidence of adverse event; perforation (0%), thromboembolism (0%).

Conclusion: This study indicated the feasibility of gastric ESD with continuous administration of LDA including little intraoperative bleeding and adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0284 WEEKDAY OF CANCER SURGERY IN RELATION TO PROGNOSIS

P. Lagergren, F. Mattsson, J. Lagergren
Department Of Molecular Medicine And Surgery, Karolinska Institutet, Stockholm,Sweden

Contact E-mail Address: pernilla.lagergren@ki.se

Introduction: Later weekday of surgery seems to reduce the prognosis in oesophageal cancer, while any such influence on other cancer sites is unknown. This study aimed to test whether weekday of surgery influences prognosis following curative gastrectomy. This nationwide Swedish population-based cohort study from 1997-2014 analysed weekday of elective surgery for 10 major cancer groups in relation to disease-specific and all-cause mortality. Cox regression provided hazard ratios with 95% confidence intervals (CI) adjusted for the covariates age, sex, year of surgery, patient volume, calendar year, and tumour stage.

Results: Included were 228,927 patients. Later weekday of surgery (Thursday and even more so Fridays) was associated with increased mortality rates for gastrointestinal cancers. The adjusted hazard ratios for disease-specific mortality comparing surgery on Friday with Monday were 1.57 (95% CI 1.31-1.88) for oesophago-gastric cancer, 1.49 (95% CI 1.17-1.88) for liver-pancreatic-biliary cancer, and 1.53 (95% CI 1.44-1.63) for colorectal cancer. Existing mortality during the initial 90 days of surgery made little change to these findings, and the all-cause mortality was similar to the disease-specific mortality. The associations were similar in analyses stratified for covariates. No consistent associations were found between weekday of surgery and prognosis for cancer of the head-and-neck, lung, thyroid, breast, kidney-bladder, prostate, or ovary-uterus.

Conclusion: The scope of surgery has increased in recent years and it is essential to plan Taking into account the constructed 3D-models, which helps to solve the problem of the possibility of surgical intervention in oesophageal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0285 IMPACT OF POSTOPERATIVE COMPLICATIONS AND PERIOPERATIVE ONCOLOGICAL TREATMENTS FOR GASTRIC CANCER PATIENTS AFTER GASTRECTOMY

S. Kamiya1, F. Klevebro1, J. Rovellas1, M. Lindblad1, L. Lundell2, M. Nilsson2

2Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: satoxi_ki@hotmail.com

Introduction: Recently, multidisciplinary treatments such as perioperative chemo/ radiotherapy have been introduced to improve the prognosis of gastric cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastric cancer patients.

Aims & Methods: Consequent gastric cancer patients who underwent curative gastrectomy in Karolinska University Hospital between 2006 and 2016 were enrolled. Patients’ characteristics, surgical data, postoperative courses and prognostic evaluations were evaluated according to Clavien-Dindo classification. The significance of postoperative severe complications and perioperative oncological treatment for overall survival (OS) was evaluated by the Cox proportional hazard model.

Results: 1,954 patients were examined in this study. 89 (52.7%) and 66 (39.1%) patients had neoadjuvant and adjuvant treatment, 85 (50.3%) and 84 (49.7%) underwent distal and total gastrectomy, respectively. 24 (14.2%), 16 (9.5%) and 5 (3.0%) were diagnosed as grade III, IV, V complications. The prognosis of the patients with grade III or higher complication was significantly worse (3-year OS: 66.6% vs 47.3%, p = 0.001). Subgroup analysis by pathologic stage showed that the prognosis of pStage III/IV patients with postoperative complications was significantly poorer than the patient with no grade III or higher complications (3-year OS: 45.3% vs 7.5%, p = 0.001).

Conclusion: Regarding to the postoperative severe complications, the Cox proportional hazard model indicated the significant impact on overall survival (p < 0.001). Postoperative severe complications had considerable impact on the OS, especially for pStage III/IV gastric cancer patients. Perioperative oncological treatment may be able to prevent the prognosis from deteriorating due to postoperative complications.

Introduction: Duodenal papillary tumor as rare gastrointestinal neoplasm is essential for curative therapy due to its malignant potential. Endoscopic papipoolctomy as an alternative approach to surgery in select cases. Endoscopic papillotm is a relatively difficult endoscopic technique mainly performed by experienced endoscopists. Stable standard endoscopic procedures for endoscopic papipollctomy have not been established.

Aims & Methods: We aimed to investigate the clinical value of endoscopic papipollctomy for duodenal papillary tumor based on the endoscopic and clinical characteristics. Between 2006 and 2017, seventy-five patients with duodenal papillary tumor under endoscopic papipollctomy in the gastrointestinal endoscopic center of Chinese PLA General Hospital were included. These patients were diagnosed of duodenal papillary tumor by the clinical manifestation, laboratory tests, CT, MRC, endoscope, EUS, ERCP along with biopsies and histopathologic tests. During the detailed clinical assessment combined with patients’ wishes, endoscopic papipollctomy and followed ERCP procedures were performed successfully, and the clinical data of these patients were retrospectively analyzed.

Results: 75 patients (50 males and 25 females) with a median age of 58.6 yrs (range 27 to 82 yrs) were evaluated. The main clinical symptoms were predomi- nated by abdominal pain followed by cholestasis and cholangitis, but nine cases were non-abdominal symptoms. Endoscopic papipollctomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists. The majority of excised tumors were exogenous (90.7%, 68/75), and the tumor size ranged between 8 and 55 mm. The final histopathological diagnosis included 12 cases of intraductal papilloma (37.3%, 28/75), pT1a grade, with high-grade intraductal neoplasia (18.7%, 14/75), adenoma with low-grade intraductal neoplasia (26.7%, 20/75), adenoma combined with local carcinoma (16%, 12/75), and neuroendocrine tumor (1.3%, 1/75). En bloc resection was achieved in 53 cases (70.7%) and the piecemeal resection was performed in 22 cases (29.3%). After endoscopic papipollctomy, the ERCP procedures were performed in 70 cases (93.3%). The pro- phyllactic pancreatic duct stent was placed in 30 cases (40%) for preventing pancreatitis, the biliary plastic stent or nasobiliary drainage tube in 16% (12/ 75), the combined of both in 17.3% (13/75), and no stent placement in 26.7% (20/75). Moreover, intraoperative hemostasis was performed in 47 cases (62.7%), including pure endoscopic clip placement, followed by injection therapy, thermal therapy or in combination. Regarding to the postoperative adverse events,
hernorrhage was identified in 11 patients (14.6%) but mainly cured by endoscopic hemostasis, followed by percutaneous (9.3%, 7.75) but cured with medical treatment.

Conclusion: Endoscopic papillectomy can be considered as a feasible and reasonable treatment option for suitable patients with tumors of duodenal papilla.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diverticulitis is a common gastrointestinal disease in developed countries, especially among elders. It is classified into five stages according to the severity of the inflammation with stage 3 involving perforation as a consequence. Perforation and abscess formation occur with 30% to 40% and up to 32%. This indicates that acute diverticulitis is an emergency case requiring rapid management. However, the surgical interventions of diverticulitis vary according to its grade and severity, there is a controversy about the preferable surgical procedure of these different complications.

Aims & Methods: We aimed to systematically review and meta-analyze randomized controlled trials (RCTs) comparing outcomes and complications between different surgical approaches for acute diverticulitis and its complications. Nine electronic databases, including PubMed, Scopus, Google Scholar, ISI Web of Science, WHO Global health library (GHL), POPLINE, Virtual health library (VHL), NYAM (New York Academy of Medicine), and SIGLE (System for information on grey literature in Europe), were searched for RCTs comparing different surgical procedures for different grades of diverticulitis. Out of 1738 articles, we included 14 studies with 1076 patients. The primarily assessed outcomes were post-surgical mortality rate besides short- and long-term post-surgical complications. The risk of bias was assessed using the Cochrane Collaboration tool. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated in the meta-analysis using the RevMan platform. The protocol was registered in PROSPERO (CRD42015032290).

Results: Nineteen RCTs compared laparoscopic sigmoid resection (LSR) (n = 247) versus open sigmoid resection (OSR) (n = 237) for treatment of acute complicated diverticulitis with minimal heterogeneity. For short-term outcomes, there was no significant difference in postoperative overall morbidity (RR 0.89, 95% CI [0.61–1.31]; P = 0.56), all major postoperative morbidity (RR 0.79, 95% CI [0.12–5.07]; P = 0.80), and all minor postoperative complications (RR 0.98, 95% CI [0.62–1.57]; P = 0.94). Similarly, there was no difference between the two procedures regarding the long-term postoperative recurrence and mortality (RR 0.83, 95% CI [0.57–1.21]; P = 0.37) and mortality (RR 0.78, 95% CI [0.46–1.31]; P = 0.34), and mortality (RR 0.95, 95% CI [0.04–24.59]; P = 0.98). In other four RCTs compared laparoscopic laveage with resection (sigmoidectomy) for treatment of perforated diverticulitis with peritonitis, the postoperative mortality rate was non-significant in both short-term (RR = 1.55, 95% CI [0.79–3.04]; P = 0.21) and long-term (RR = 0.67, 95% CI [0.29–1.58]; P = 0.36) follow up. Interestingly, the short-term reoperation rate and long-term precese of intra-abdominal abscesses were significantly higher in OSR (RR = 1.74, 95% CI [1.01–3.02]; P = 0.05) and (RR = 1.74, 95% CI [1.03–3.02]; P = 0.92) respectively. The remaining five RCTs compared between different procedures, like primary anastomosis versus non-restorative resection, RP-LASR versus NRP-LASR, and primary versus secondary resection, for different situations and reviewed qualitatively.

Conclusion: The superiority of LSR over OSR was non-significant in the treatment of acute symptomatic diverticulitis regarding postoperative complications, short-term and long-term perioperative morbidity, and mortality. However, the cosmetic advantage of LL is significant. Regarding perforated diverticulitis with purulent peritonitis, our results showed that LL is as safe as resection (either Hartmann’s operation or sigmoidectomy with primary anastomosis) regarding short- and long-term post-operative outcomes especially in long-term, hospital stay, and overall mortality. Hence, LL is feasible and can act as definitive treatment. Further RCTs are still needed to make a decision regarding these and other procedures.

and liver metastases in newly diagnosed patients with CRC. Three hundred patients with CRC undergoing curative resection were included in this cross-sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and PLR was estimated by ROC curve.

**Results:** Our results suggest that there was high statistically significant difference between NLR (p = 0.003) and PLR (p = 0.002) and tumor stages (I to IV). ROC curve analysis showed high diagnostic accuracy of NLR (AUC 0.774, 95%CI = 0.683–0.790) and PLR (AUC 0.698, 95%CI = 0.663–0.742) for synchronous lymph node and liver metastases. Also combination of NLR and PLR improved diagnostic efficacy (AUC 0.841, 95%CI = 0.811–0.863) for synchronous liver and lymph node metastases.

**Conclusion:** Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential use in early recognition of different stages of CRC.

**P0291 DEVELOPING AND VALIDATING OF RAMATHIBODI APPENDICITIS IN SUSPECTED APPENDICITIS PATIENTS**

**Contact E-mail Address:** champhon.wil@mahidol.ac.th

**Introduction:** Diagnosis of appendicitis is still clinically challenge where resource is limited. The purpose of this study is to develop and externally validate Ramathibodi Appendicitis Score (RAMA-AS) in aiding diagnosis appendicitis. Aims & Methods: Two-phase cross-sectional study (i.e. derivation and validation) was conducted at Ramathibodi Hospital (for derive), Thammasat University Hospital and Chaiyaphum Hospital (for validation). Patients with abdominal pain and suspected of having appendicitis were enrolled. Multiple logistic regression was applied to develop parsimonious model. Calibration and discrimination performances were assessed. In addition, our RAMA-AS was compared with Alvarado’s score performances using ROC curve analysis. The study was conducted and reported according to Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis Or Diagnosis (TRIPOD) statement.

**Results:** The RAMA-AS consisted of 3 domains 7 predictors including symptoms (i.e. progression of pain, aggravation of pain, and migration of pain), signs (i.e. fever and rebound tenderness), and laboratory (i.e. white blood cell count (WBC) and neutrophil). The model fitted well with data and it performed better discriminate than the Alvarado score with C-statistic of 0.842 (95% CI: 0.804, 0.881) versus 0.760 (0.710, 0.810). Internal validation by bootstrap yieldedSommer’s D of 0.686 (0.608, 0.763) and C-statistics of 0.848 (0.846, 0.849). The C-statistics of two external validations were 0.853 (0.791, 0.915) and 0.813 (0.736, 0.892) with fair calibrations.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0292 IS HAEMORRHHOECTOMY SAFE IN PATIENTS WITH ULCERATIVE COLITIS?**

**Contact E-mail Address:** vocalcord@hanmail.net

**Introduction:** Haemorrhoidectomy in ulcerative colitis (UC) have been considered to be potentially dangerous, but the evidence is poor.

**Aims & Methods:** A study was conducted to ascertain the safety of haemorrhoidectomy in patients with ulcerative colitis and synchronous liver metastasis. Retrospective review of 44 UC patients from 2004 to 2014. Patient demographics and clinical characteristics (anorectal symptoms, prior non operative haemorrhoidal therapy, whether done UC preoperatively (BD) and unproven preoperatively (AD), whether to use azathioprine, presence of other perianal disease, and activity, anatomic location of UC) were recorded. Postoperative complications, and between BD and AD were analysed.

**Results:** The patients were 29 males (65.9%), median age 44 (range, 19–72) years. Preoperative symptoms were bleeding and prolapse (n = 24; 54.5%), prolapse only (n = 6; 13.6%), bleeding only (n = 14; 31.8%). 17 patients (BD, 38.6%) were diagnosed with UC prior to surgery. 4 patients (9.1%) had haemorrhoidal therapy before surgery. There was no other perianal disease. Disease was limited to the rectum (n = 33; 75%), left-sided (n = 9; 20.5%), and extended to right-sided (n = 2; 4.5%). During follow-up, there were no complications such as sepsis, anal stenosis, abscess and fistula formation, and recurrence. There was no difference in complications and other clinical characteristics between BD and AD. There was no difference in complications according to disease extent (p = 0.15).

**Conclusion:** Our data suggest that haemorrhoidectomy may be performed safely in UC patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Aims & Methods: In this study, we investigated the current state of inguinal hernia treatment at our hospital. Surgical indication of inguinal hernia in our department is as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand on the left and right sides of the patient, respectively, anesthesiologist stands at the patient’s head, and a nurse stands caudal to the assistant.

Aims & Methods: This method. Application after carefully deciding the indication may be important for inguinal hernia and introduction of the TAPP method. In expert hands it represents an effective technique for the treatment of acute diverticulitis complicated by diffuse peridiverticulitis. Length of hospital stay was 7.8 ± 2.8 days and we have not recorded any readmissions in patients discharged within 60 days after surgery. The rates of postoperative complications were 6.8% and 2.3% for grade III and V according to the CDCS respectively.

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m2. No conversion to open surgery was registered. The mean operative time and estimated blood loss were 184.3 ± 32.7 minutes and 81.2 ± 7.2 ml respectively. All the specimens showed diverticulitis with peridiverticulitis. Length of hospital stay was 7.8 ± 2.8 days and we have not recorded any readmissions in patients discharged within 60 days after surgery. The rates of postoperative complications were 6.8% and 2.3% for grade III and V according to the CDCS respectively.

Disclosure of Interest: All authors have declared no conflicts of interest.

lower abdomen. The bowel extraction was performed by invagination transrectal. After the extraperitoneal distal linear stapling of the sigmoid, the colonic anastomosis was completed by applying a circular stapling device transrectally, assisted by a transcutaneous inserted grasper. Function testing was performed by the coloscope. Gastric access closure was performed by OTSC clip.

Results: The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic healing with a stenosis and consecutive prestenotic dilatation in one case. These animals were excluded. No more peritoneal abscess beside the anastomosis. Gastric closure was healed and the OTSC clip still in situ in all animals. In one case we used two OTSC clips for gastric closure, there were severe adhesions with two perigastric abscesses.

Conclusion: The use of an operating platform like the Anubiscope has the advantage of flexible preparation in opposite position of the instruments. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Flexible colonoscopy provided a fixed reference frame for the investigation and dissection. For resection and anastomosis, an additional transcutaneous access was necessary.

Introduction: Postmenopausal tuberculosis (TB) is an advanced ovarian cancer, two conditions with different management and prognosis, have many similarities: ascites, complex adnexal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also common to these two entities.

Aims & Methods: The aim of this study was to analyze patients' characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-posterioral TB in post-menopausal women who presented with mimicking ovarian malignant from 2004 to 2014 in a Tunisian center.

Results: The mean age was 59.8 (46–87 years). Three patients have personal or family antecedents of TB. The women presented with abdominal pain and distensions of varying duration of 1 month to 6 months. Eleven patients had reduced appetite and weight loss, and four women gave a history of low-grade fever. A CT scan showed the presence of solid-cystic adnexal masses ranging rom 3 cm to 15 cm in diameter in 100% and ascites in 90.4%. Ascitic fluid analysis was done in 19 patients. The culture was used in 12 and the cytological was performed in all cases. The cytological was divided into tuberculous and inflammatory. In 13 cases, the cytological was tuberculous while in 6 cases the cytological was diagnostic of peritonitis or inflammatory (in %) in the lamina propria. The study implied investing the cellular composition of the inflammatory infiltrate in the lamina propria. Depending on the density of the inflammatory infiltrate, the presence of tuberculous granuloma was confirmed.

Conclusion: The presence of tuberculous granuloma in peritoneal biopsy was considered as a strong evidence for tuberculous peritonitis. The current study is the first report that has considered the tuberculous peritonitis as an initial presentation of ovarian malignancy in our population.

P0300 REGULATORY B CELLS CONTRIBUTE TO THE ALLEVINATION OF COLITIS INDUCED BY DEXTRAN SULPHATE SODIUM AFTER H. PYLORI INFECTION

X. Li1, N. Wang1, Q. Xue1, J. Tan1, J. Wang1 1Department Of Gastroenterology, Peking University, People’s Hospital, Beijing/China

Contact E-mail Address: lixiajy@163.com

Introduction: Epidemiological studies have showed that there was an inverse correlation between Helicobacter (H. pylori) infection and the incidence of inflammatory bowel disease (IBD). Our previous research indicated that the regulatory immune responses induced by H. pylori infection were not limited to gastric mucosa, IL-10-producing Breg cells and Foxp3+ Treg cells expanded in spleen and mesenteric lymph nodes (MLN), the balance of intestinal mucosal immunity was influenced to a skewed regulatory immune response.

Aims & Methods: A murine model with H.pylori infection and acute and chronic colitis induced by dextran sulphate sodium (DSS) was established to explore the function of regulatory B cells (Breg cells) in the alleviation of inflammatory bowel disease (IBD). All authors have declared no conflicts of interest.

P0299 INSULINLIKE GROWTH FACTOR IGF-I AND INFLAMMATORY RESPONSE IN THE COLONIC MUCOSA IN ULCERATIVE COLITIS

V. Pavlenko, F. Urasova, G. Eseneva, A. Pavlenko, N. Korabina Starropolitan State Medical University, Starropolitan Russian Federation

Contact E-mail Address: pavlenkow@yandex.ru

Introduction: Peptide growth factors including the IGF family are expressed in the colon and are thought to have proliferative activity of the intestinal epithelium in ulcerative colitis (UC) and Crohn’s disease (CD). At the same time, IL-8 is one of the main triggers behind the immunoinflammatory process in the colonic mucosa (CM) in UC, and its level may be of prognostic value in determining the illness course.

Aims & Methods: The aim of the study was to identify the role that IGF-I plays in colonic inflammation in 35 patients with different clinical (Rahmihlech index) and endoscopic (Mayo index) activity of UC. The treatment was administered in view of the severity of UC. 20 healthy volunteers were the control group. IGF-I levels in peripheral blood were determined by ELISA (Mediagnost, Germany). The results were expressed as mmol/l. The spontaneous and E. Coli LPS-induced synthesis of IL-8 in rectal biopsy samples were studied via ELISA.

Results: The results were expressed as picograms per 1 mg of wet tissue (pg/mg). The severity of the disease in the method of IGF-I levels in the blood plasma decreased (15.16±1.35 mmol/l (P < 0.05 to control)), while spontaneous production of IL-8 chemokine in rectal biopic samples went up (300.0±6.0 pg/ml, P < 0.05). In case of the LPS stimulation the production of IL-8 (450.0±10.0 pg/ml, P < 0.05 vs control) in the CM went up markedly (750.0±30.0 pg/ml, P < 0.001 vs control). There was significant inverse correlation (rs) detected between the IGF-I levels in the blood plasma, on one hand, and indicators of the UC clinical, endoscopic activity and the intensity of the inflammatory infiltrate in the CM, on the other. Direct regulatory levels of spontaneous and LPS-induced production of the IL-8 chemokine and the density of the inflammatory infiltrate in the CM of patients with active UC. Through the period of the clinical remission development (an average of 8 weeks) the IGF-I levels increased up to 94.25±28.18 mmol/l (P < 0.05 vs control), yet have not reached the control value (P < 0.05 to control). Induction of the clinical remission was associated with a decrease to the level of the central values for spontaneous and LPS-induced IL-8 production, regardless of UC activity.

Conclusion: The intensity of the inflammatory process in the CM depends on the level of IL-8 produced by respective cells. Evidently, IL-8 has a capacity of inhibiting the production of IGF-I at the peak of inflammation (acute UC). Improvement of synthesis of IGF-I and reduced IL-8 in remission facilitates regeneration of the damaged mucosa.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD was unclear. The aim of our study was to clarify the gut fungal composition in IBD patients with different treatment strategies.

Aims & Methods: 73 IBD patients were divided into three groups, Untreatment (n = 21), Antiinflammation (n = 43) and Immunosuppression (n = 9). Antiinflammation was defined as treatment with 5-aminosalicylic acid (5-ASA), salazosulfapyridine (SASP) and Immunosuppression as treatment with Glucocorticoid (GC), azathioprine (AZA), biologics and thalidomide. Noninflamed and inflamed mucosa were collected for 16S and ITS sequencing to explore the fungal and bacterial composition. Inflamed mucosa was utilized for RNA extraction and real-time PCR to detect the expression of IBD-associated biomarkers, such as TNF-alpha, IL-17A, MCP-1, etc. Analysis of Spearman’s correlation was performed to estimate the fungi-bacteria and microbiota-biomarkers correlation.

Results: Compared with noninfamed mucosa, lower diversity and evenness were observed in inflamed mucosa in all IBD patients, but no significance in noninfamed (or inflamed) mucosa of different treatment strategies. Beta diversity showed a treatment-dependent clustering in inflamed mucosa. Fungal microbiota was constituted by fungi from Ascomycota, Basidiomycota and Zygomycota phyla. There was a higher proportion of Zygomycoza in inflamed mucosa than noninfamed mucosa in untreated IBD patients, and Antiinflammation and Immunosuppression significantly altered their abundance. Mortierella from Zygomycoza was the richest fungi in both inflamed and noninfamed mucose of all patients. To analyze the effects of treatment strategies on fungal microbiota in IBD patients, we found Immunosuppression decreased abundance of Akkermansia muciniphila, Lachnospira and Lachnospira, but no significance in noninfamed mucosa decreased Ascomycota in noninfamed mucosa but decreased it in inflamed mucosa. Both Antiinflammation and Immunosuppression increased Zygomycoza in inflamed mucosa, but not in noninfamed mucosa. Fungi-bacteria-biomarkers correlation showed a weak correlation in noninfamed mucosa of untreated IBD patients, and Antiinflammation and Immunosuppression didn’t significantly alter fungi-bacteria correlation patterns in noninfamed mucosa. However, after Immunosuppression, fungi including Candida, Chaetomium, Cladosporium and Cryptococcus were positively correlated to NanoBacteri and Cloacibacterium. Furthermore, Mortierella was negatively correlated with Blautia and Lachnospira in noninfamed mucosa of immunosuppression. In analysis of bacteria-biomarkers correlation, we found bacteria such as Clostridium, Par relat and Par relat and Clostridium, Par relat and Roseolaria, Fecalibacterium, Ruminococcus and Megamonas were significantly correlated to several biomarkers (such as IFN-gamma, IL-10, IL-17A, IL-22, TNF-alpha, etc). Notably, there were different correlation patterns in different treatment strategies, especially, IL-17A was extensively correlated to bacteria such as Enterococcus, Clostridium, Fecalibacterium and Klebhiella in inflamed mucosa of Immunosuppression, but not correlated to Fecalibacterium in Antiinflammation. Additionally, we found a weak fungi-biomarkers correlation in IBD patients, but fungi such as Asterotremella and Verticillium were correlated to biomarkers such as IL-17A, IL-22, IL-8 and MCP-1, and treatment altered microbiota-biomarkers correlation patterns.

Conclusion: Treatment strategies affect fungal composition. To some extent, immunosuppression may aggravate gut fungal dysbiosis in IBD patients, but antiinflammation partially ameliorate it. The bacteria-fungi and microbiota-biomarkers correlation on acute IBD is a treatment-dependent clustering, and treatment change these correlation patterns. Additionally, IL-17A tended to be the main mediator for bacteria to induce inflammation in IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

5Gastroenterology, San Filippo Neri Hospital, Roma/Italy

Introduction: Crohn’s Disease (CD) and Ulcerative Colitis (UC) are two main bowel diseases that, with a complex etiology, including an immune response against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments. Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments (1).

Contact Email Address: gmazzarrini@isa.cnr.it

Introduction: MMP9 is involved in the degradation of the extracellular matrix and its expression is elevated in the inflamed tissue of patients with ulcerative colitis (UC) [1-3]. Pre-clinical models of colitis demonstrate a therapeutic benefit from inhibiting MMP9 secreted by colitogenic colitis [4]. Andecaliximab (previously GS-5745) is a high-affinity IgG4 monoclonal antibody against human Matrix Metalloproteinase 9 (MMP9). In a 36-day Phase 1b study in UC, andecaliximab demonstrated clinical efficacy relative to placebo treatment [5]. Here we describe bacterial microbiota analysis of stool samples collected during the Phase 1b study of andecaliximab in UC.

Aims & Methods: The objective of this study is to examine changes to the bacterial microbiota pre- and post-andecaliximab treatment and relative to therapeutic response. Stool was collected for 36 days post-treatment (Baseline) and at the end of the study (Day 36). Clinical response was defined as a Mayo score reduction ≥3 point and ≥30% reduction from baseline score; accompanying decrease in rectal bleeding sub-score of ≥1 or an absolute rectal bleeding sub-score of 0 or Dory was extracted from fecal samples using a modified CTAB method and 16S rRNA amplicon sequencing was performed on 59 samples (27 paired and 5 unpaired samples). Alpha diversity, beta diversity (calculated in QIIME), and taxonomic differences were examined between placebo and andecaliximab-treatment and between response and non-response.

Results: Compared to placebo-treated patients, those who received andecaliximab trended towards decreased alpha diversity (p = 0.06) at 36 days post-treatment. These changes in alpha diversity were not dose related. At Day 36, a trend towards a significant difference in community beta-diversity was observed between the andecaliximab-treated group relative to placebo (p = 0.07). Andecaliximab treatment was also associated with differences in bacterial taxonomy relative to placebo (p = 0.07). Specifically, the genera Clostridium and Akkermansia represented some of the top organisms enriched post andecaliximab treatment relative to placebo. Andecaliximab treatment exhibited a non-significant expansion of Akkermansia from Baseline to Day 36 (p = 0.15). Amongst the changes in the microbial community, these results are unlikely to be pursued in relation to andecaliximab treatment effects, but may be beneficial as a reference for future trials in inflammatory bowel disease.

P0303 MUCOSAL CYTOKINE PROFILE IN INFLAMMATORY BOWEL DISEASE PATIENTS: A LASER CAPTURE MICRODISSECTION APPROACH
Aims & Methods: This work was designed to investigate the pattern of cytokines that regulate the mucosal immune response occurring in different intestinal compart-
ments of IBD patients, using LCM technology (1). Frozen sections of colonic biopsies were obtained from 5 patients with active CD, 5 patients with active UC and
5 controls. None of the patients with CD or UC had been ever undergone microarray experiments (E) and inflammatory bowel disease (IBD) (LP) were isolated by LCM, RNA from EP and LP samples were extracted and, after a reverse tran-
scription, RNA levels of TNF-a, IFN-g, IL-17, IL-10 and TGF-b were deter-
mimed by quantitative PCR, using glyceraldehyde 3-phosphate dehydrogenase
(GAPDH) as reference gene. Results: We observed a significant increase in gene expression level of IL-17 in the lamina propria of UC patients respect to CD and controls (p < 0.05). TNF-a, IFN-g, IL-10 and TGF-b levels were significantly higher in the LP of CD as compared to controls (p < 0.05). All the cytokines investigated were not significantly up-regulated in the surface EP of both CD and UC patients, when compared to controls.
Conclusion: Our data show that the LP compartment play a key role in the mucosal immune response in IBD patients. In particular, CD seems to be pro-
minently an innate immune response-mediated disease, which is characterized by an increased production of IFN-g, whereas UC seems to be predominantly an innate immune response-mediated disease, which is characterized by an increased production of IL-17. Concurrently with the pro-inflammatory, response, high amounts of the anti-inflammatory cytokines IL-10 and TGF-b are also produced in CD compared to UC patients, suggesting that in UC patients, the immune-regulatory mechanisms could be impaired. This work underlines the importance of LCM as a valuable tool to determine potential inflammatory components involved in IBD pathogenesis.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The gut microbiota play important roles in the development of the ulcerative colitis (UC). Enough evidence has proven the role of intestinal bacter-
bia in UC pathogenesis has not been fully demonstrated. Aims & Methods: Fungal microbiota from the descending colon mucosal samples from 14 active UC patients and 15 healthy subjects (HS) were analyzed by high-
throughput sequencing method. The expression of pro-inflammatory cytokines (IL-1b, TNF-a, INF-g, IL-6, IL-17a, and IF-23) were up-regulated in UC patients, whereas the expression of anti-inflammatory cytokines (IL-10 and TGF-beta) was significantly lower in UC patients compared to HS. Results: The number of fungi decreased significantly in inflamed mucosal tissue compared to HS counterpart while the Shannon diversity did not show significant differences. Fifteen major genera were examined, among which Wickerhamomyces, unidentifed genus of Saccharomycotales, Aspergillus, Sterigmatomyces, and Candida showed increasing trends, whereas Exophiala, Alternaria, Emeriella, Epicoccum, Acremonium, Trametes, and Penicillium showed decreasing trends in UC patients compared to HS. The pro-inflammatory cytokines (IL-1b, TNF-a, INF-g, IL-6, IL-17a, and IF-23) were up-regulated in UC patients. The genera Wickerhamomyces, Sterigmatomyces, and Penicillium were positively correlated with the expression of several pro-inflammatory cytokines in the colonic mucosa, whereas Nigrospora was negatively correlated. Nigrospora and Sterigmatomyces were positively correlated with the Baron and/or Mayo score. Conclusion: The fungal microbiota in the colonic mucosa of UC patients was different from that of HS. Alterations in fungal composition might be associated with mucosal inflammation and pathogenesis of UC. Further studies are needed to define the fungal composition in detail and identify the role of different fungi in the gut, and determine the mechanism of the host-fungal inter-
action underlying the development of UC.

Introduction: Although the etiology of ulcerative colitis (UC) has yet to be char-
acterized, it is increasingly accepted that the cause of UC might well be related to commensal enteric bacteria in a genetically susceptible patient. Anti-inflamma-
tory drugs and immune system suppressors are usually prescribed for UC treat-
ment, and we previously demonstrated that triple antibiotic combination therapy with oral amoxicillin (1500 mg/day), tetracycline (1500 mg/day) or fosfomycin (3000 mg/day), and metronidazole (750 mg/day) (ATM/AFM), for two weeks, induces remission in more than 27% of patients with active UC including those with steroid-refractory or dependent disease, suggesting ATM/AFM to be possibly effective for achieving UC remission.
Aims & Methods: Thirty-two patients with UC given ATM/AFM therapy for two weeks on average were enrolled in this study. The clinical conditions of these UC patients were evaluated by Mayo score. Fecal samples were obtained prior to, after therapy and at three months after treatment comple-
tion. Gut microbiota were compared employing metagenomic analysis of fecal samples.
Results: Of the 32 patients, 17 and eight, respectively, experienced complete and partial remission over three months in response to ATM/AFM therapy, whereas ATM/AFM showed no efficacy in seven patients. The metagenomic analysis revealed abundant human DNA to correlate positively with the disease activity indicated by the Mayo score. Furthermore, dramatic gut microbiota changes were observed at an early stage, i.e. just two weeks after starting ATM/AFM therapy. Comparison of the metagenomic data suggested that the dysbioses through the expression of Wnt ligands (Mucosal Immunology, 2016). We have recently reported that STAT6 deficiency favours fibrosis in a murine model of TNBS colitis (P031, ECCO 2016).
Aims & Methods: We aim to characterize here the functional relevance of the macrophage phenotype in fibrosis development. WT or STAT6 (-/-) mice were given TNBS (0.5, 0.5, 0.75, 0.75, 1, and 1 mg intrarectally) or saline weekly and they were sacrificed 3, 5 or 7 weeks after the first TNBS administration. The percentage of CD206+CD68+ cells was analyzed by flow cytometry in F4/80+ macrophages isolated from the intestinal mucosa. The mRNA expression of Wnt ligands was evaluated in F4/80+ CD16+ macro-
phages isolated from the mucosa, 7 weeks after the first TNBS administration and results are expressed as fold induction vs vehicle-treated mice. The mRNA expression of CD16 and fibrosis markers were evaluated in the colonic mucosa. The percentage of CD16+ cells was similar between TNBS-WT and TNBS-STAT6 (-/-) mice. In CD16+ macrophages isolated from TNBS-STAT6 (-/-) mice the mRNA expression of canonical and non-canonical Wnt ligands was significantly increased compared with cells isolated from TNBS-WT mice (Table). A positive and significant correlation between CD16 and Vimentin (r = 0.0088*, p = 0.51), a-SMA (r = 0.0044*, r = 0.55) and MMP2 (r = 0.0002*, r = 0.67) was detected in TNBS-STAT6 (-/-) mice but not in WT animals. Table

Conclusion: The expression of Wnt ligands from CD16 positive cells, which are accumulated in the mucosa, may be involved in murine intestinal fibrosis.

Introduction: STAT6 plays a crucial role in M2a macrophage polarization in vitro and these cells mediate mucosal healing in an acute model of TNBS-colitis

Conclusion: We observed a significant increase in gene expression level of IL-17 in the lamina propria of UC patients respect to CD and controls (p < 0.05). TNF-a, IFN-g, IL-10 and TGF-b levels were significantly higher in the LP of CD as compared to controls (p < 0.05). All the cytokines investigated were not significantly up-regulated in the surface EP of both CD and UC patients, when compared to controls.

before treatment in the active stage to possibly be associated with increased proliferation of Bacteroides, Parabacteroides, Rickenella, Clostridium, Flavonifractor, Pelagibacter, Bordetella, Massilia and Picricickea species. In responders after treatment, populations of Bifidobacterium and Lactobacillus species were significantly increased. In this study, there was an especially strong negative correlation between Bacteroides and Bifidobacterium both before and after treatment.

Conclusion: These results suggested metagenomic analysis results to be associated with a remarkable change in gut microbiota after antibiotic combination treatment. In non-responders in association is associated with increased levels of Neisseria and Lactobacillus species and a decrease in Bacteroides.

Introduction: Classically, enteroendocrine cells (EEC) are regulated for facilitating gastrointestinal motility, secretion, and insulin levels by release of peptide hormones. Via receptors and transporters, EEC are capable of sensing the lumina propria and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin hormone glucagon-like peptide 1 (GLP-1) is increasingly recognized to exert direct effects on immune cells and to orchestrate a metabolic-inflammatory response. In inflammatory bowel disease (IBD), a role for EEC in disease pathogenesis is suggested by the observation that reduced numbers of EEC are associated with reduced numbers of colorectal cancer cells. Moreover, GLP-1 receptors (GLP-1R) are expressed on NETs in a plethora of neutrophil-mediated thromboinflammatory conditions [1-3]. Ulcerative colitis (UC) is characterized by infiltration of neutrophils into the affected mucosa and increased risk of thromboembolic events; however, the mechanism behind the thrombophilic state of UC has not been clearly elucidated yet [4, 5].

Aims & Methods: We aimed to investigate for the first time the role of neutrophils/NETs through TF expression in the pathophysiology of UC. Neutrophils, sera and colon biopsies were obtained from 10 naïve patients with active UC (6 male and 4 female, mean age 34.6 ± 19.1 years, mean Mayo score 8.5 ± 1.4). Furthermore, NETs from UC patients were compared to control NETs obtained from patients suffering from active Crohn disease (CD) (7 male, 3 female, mean age 34.2 ± 18.5, CDAI > 220). Additionally, 10 sex- and age-matched healthy subjects, were served as control subjects (5 male, 5 female, mean age 38.2 ± 15.8). Ex-vivo findings regarding peripheral blood neutrophils and colon tissue specimens were verified using appropriate in-vitro stimulations of control neutrophils with corresponding sera and intestinal tissue-conditioned media, respectively. Identification and quantification of NETs were performed with immunoluminescence confocal microscopy (IHC), flow cytometry, and PCR methods. DNA complex ELISA. The expression of TF on neutrophils/NETs was determined using ICM, qRT-PCR and western blot analysis. The bioactivity of TF on NETs was assessed by measuring thrombin-antithrombin complex levels with ELISA.

Results: Neutrophils from patients with active UC are characterized by increased NET formation in both the peripheral blood and affected colonic mucosa, compared to controls. Furthermore, NETs in UC are decorated with functional human TF and the amount of TF-bearing NETs was reduced from the inflamed to normal colon. In-vitro stimulations of controls neutrophils with sera or intestinal tissue-conditioned media corroborated the findings obtained ex-vivo. 

Conclusion: NETs expressing bioactive TF may be involved in the induction of intestinal inflammation and systemic thrombosis in UC probably constituting a novel candidate diagnostic and/or therapeutic target.

Introduction: Recent studies have revealed that the intestinal epithelium is a multicellular interface that is completely renewed every 3–5 days. Pluripotent stem cells reside at the crypt bottom giving rise to transient amplifying cells and subsequently differentiated intestinal epithelial cells (IEC) of all subtypes. Phases of cellular and functional transitions are characterized by distinct metabolic identities, reflected by changes in mitochondrial activity. Alterations in mitochondrial function and mitochondrial unfolded protein response (MT-UPR) activation are associated with various chronic pathologies including inflammatory bowel diseases (IBD) and cancer. We have previously shown that MT-UPR and mitochondrial function itself is involved in the regulation of cell cycle progression and intestinal stemness. Here, we present evidence that impaired mitochondrial proteostasis is sufficient to drive differentiation of Lgr5+ stem cells (ISC) into Paneth cells.

Aims & Methods: To depict the impact of imbalances in mitochondrial proteostasis on ISC, we used mice with a tamoxifen-inducible ISC or IEC-specific conditional knockout allele for the mitochondrial chaperone Hsp60 and the mitochondrial protease Ccp3. Molecular consequences of the gene deletions in the different models were further characterized ex vivo using intestinal organoid culture. In situ hybridization, IHC and combinations of both as well as IF were performed to illustrate alterations of IEC subtypes. Readouts were complemented with single-cell RNA expression and bioinformatic approaches. 

Results: Ccp3-knockout as well as chemical inhibition of the respiratory chain in intestinal organoids led to diminished Lgr5 expression confirming our results from ISC and IEC specific Hsp60-deletion. In vivo, the ISC-specific loss of Hsp60 resulted in a transient drop in Lgr5+ cells with Lgr5 expression being reduced from day 2 after end of tamoxifen treatment and signals reappearing from day 4. Cells positive for the stem cell markers Olfm4 and Hopx expanded at day 2, indicating reserve stem cell populations compensating for the Lgr5- ISC loss. Minimal numbers of Lgr5+ stem cells at day 2 were further paralleled by increased numbers of Lgr5- Paneth cells and no signs of enhanced cell death, indicating differentiation of ISC into Paneth cells. Lgr5- Paneth cells displayed a premature phenotype with diffuse Lyz staining in the cytoplast.
Concomitantly, these cells were positive for the WNT ligand WNT10A and autophagy/mitophagy- associated LC3, suggesting autoregulatory mechanisms for the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

**Conclusion:** Our results indicate that mitochondrial function not only reflects IEC phenotypic changes but seems to be the driving force in differentiation processes. Mitochondrial function might therefore represent a key player at the edge of intestinal tissue homeostasis and repair/healing processes in the context of diseases.

**P0310** **METABONOMIC PROFILING OF ULCERATIVE COLITIS PATIENTS: RESULTS FROM AN INCEPTION COHORT TIME SERIES ANALYSIS**

R. Misra1, M. Sarafian2, N. S. Ding3, E. Holmes2, G. Faiz2, N. Arebi2

1Gastroenterology, St. Marks Hospital, London/United Kingdom
2Centre For Computational And Systems Medicine, Imperial College, London/United Kingdom
3Gastroenterology, St. Vincent's Hospital, Melbourne/Australia

**Aims & Methods:** We aimed to examine the metabolic profile in a newly diagnosed cohort of UC patients recruited from St. Marks Hospital, London, UK. Patients were stratified by ethnicity (SA, Caucasian, Other), treatment (None, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Metabonomics analysis was applied according to principal component analysis (PCA) and orthogonal partial least squares -discriminant analysis (OPLS-DA) for small metabolites (hydrophilic liquid chromatography, HILIC) and for bile acids (BA) platforms. Univariate (UV) and multivariate (MV) data analysis was implemented to build models using principle component analysis (PCA) and orthogonal partial least squares -discriminant analysis (OPLS-DA) to find metabolites that were expressed in significantly different concentrations between SA and Caucasian groups. There are several possible reasons but two important factors are differing microbial metabolism and diet between the two groups. We are conducting further studies incorporating dietary data and 16S microbial analysis in this cohort. In combination with matching disease extent (left-sided vs colonic disease) may help to identify possible explanations for the different disease phenotype in this group.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Patients with active inflammatory bowel disease have elevated myeloid lineage leucocytes1 including the CD14+CD16+ DR+E phenotype known as proinflammatory monocytes, and a major source of tumour necrosis factor-α.2 Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) is expected to promote remission or enhance drug efficacy. However, studies in ulcerative colitis (UC) patients have reported contrasting efficacy outcomes, ranging from an 85%3 to statistically insignificant level.4 Patients’ baseline demographic features may guide to selecting responder patients.

P0312 THE EFFECTS OF GLIAL-DERIVED NEUROTROPHIC FACTOR PRODUCED BY ENTERIC GLIAL CELLS ON DENDRITIC CELL AND ITS ROLES IN DEXTRAN SULPHATE SODIUM INDUCED COLITIS

Y. Huan
West China School of Medicine of Sichuan University, Chengdu/China

Contact E-mail Address: yuhuan86@126.com

Introduction: Much research has demonstrated that tolerogenic dendritic cell (DC) and the capacity to induce regulatory T cells (Treg) play an important role in maintaining immune tolerance and has been proposed for treatment of inflammatory bowel disease (IBD). In this study, we report on the use of glial-derived neurotrophic factor (GDNF) produced by enteric glial cells (EGCs) as a new approach to induce tolerogenic DCs with capacity to generate Treg, to restore immune tolerance in vivo, and to ameliorate experimental colitis.

Aims & Methods: DCs were generated from rat bone marrow (BMDC) in the absence or presence of GDNF (DCGDNF) and additionally stimulated with LPS to induce maturation (mDC). The expression of major histocompatibility complex II (MHC-II), CD40, CD80, and CD86 was determined by flow cytometry. Levels of IFN-γ, interleukin-4 (IL-4), and IL-10 in the culture supernatants were determined by ELISA. The induction of GDNF receptor-α1 (GFR-α1) in DCs was detected by immune-fluorescence staining. The expression of GFR-α1 and ERK1/ERK2 in DCs was tested by Western Blot. SD rats were fed with 5% Dextran Sulphate Sodium (DSS) to induce experimental colitis, the colitis induction therapy was examined. The clinical signs of the disease including weight loss, diarrhea, colitis, histopathology were evaluated, and the mechanisms involved in the potential therapeutic effect of DCGDNF, such as inflammatory cytokines and chemokines (IL-4, IFN-γ, TNF-α, IL-1β, IL-17), the generation of IL-10–secreting Treg (Treg1), and the level of Treg1/Th2 demonstrated a higher level of Treg1/Th2 was investigated.

Results: GFR-α1 was expressed in BMDC, and the expression of GFR-α1 was significantly up-regulated after treatment with GDNF. DCGDNF did not up-regulate MHC-II, CD40, CD80, and CD86, and induced very low levels of proinflammatory cytokines (IFN-γ, IL-6) but secreted significant levels of the anti-inflammatory cytokine IL-10 after LPS stimulation, as compared with DCcontrol. CD4 T cells primed with DCGDNF resulted in weak proliferation and exhibited a Tr1-like cytokine profile, which characterized by IL-10; whereas DCcontrol induced a strong proliferation, exhibited a phenotype characterized by IFN-γ, IL-4. DCGDNF injection significantly ameliorated weight loss, diarrhea, and colonic histopathologic injury in rat, and DCGDNF injection strikingly reduced the production of inflammatory factors such as IL-4, IFN-γ, TNF-α, IL-1β, and IL-17, generated Treg1 with suppressive capacity on autoreactive T cells, and demonstrated a higher level of Treg1/Th2, Treg1/Th17.

Conclusion: GDNF could induce tolerogenic DCs through ERK1/ERK2 signal pathway, and DCGDNF could alleviate the severity of DSS induced colitis in rats. The mechanism may be related to down-regulation of inflammatory and immune response, generating Treg1 and restoring immune tolerance.

P0313 DETERMINANTS OF REDUCED GENETIC CAPACITY FOR BUTYRATE SYNTHESIS BY THE GUT MICROBIOME IN CROHN’S DISEASE AND ULCERATIVE COLITIS

1School Of Microbiology, APC Microbiome Institute-University College Cork, Cork/Ireland
2Department Of Laboratory Medicine, Virgen de la Salud Hospital, Toledo/Spain
3School Of Microbiology & School Of Pharmacy, APC Microbiome Institute-University College Cork, Cork/Ireland
4School Of Biochemistry & Cell Biology, APC Microbiome Institute-University College Cork, Cork/Ireland

Introduction: Alterations in short chain fatty acid (SCFA) metabolism have been reported in inflammatory bowel disease (IBD). Among SCFA, butyrate has been described as a potent communicator to the immune system eliciting an anti-inflammatory response and other positive effects to human health1. A reduction of faecal butyrate levels has been reported in IBD but results have been conflicting or discrepant because of small study numbers and failure to distinguish disease type, activity or other variables such as diet. Microbiota is receiving increasing attention as a key environmental factor influencing IBD2, and butyryl-CoA:Acetate-CoA-transferase (BCoAT) is considered the main enzyme involved in butyrate synthesis by gut microbiota3.

Aims & Methods: We performed a comparative assessment of the capacity of the microbiota for butyrate synthesis by quantifying BCoAT gene content in stool from patients with Crohn’s disease (CD; n = 71), ulcerative colitis (UC; n = 58) and controls (n = 75), and determined whether it was related to disease activity, inflammatory, microbial diversity and composition and/or dietary habits. BCoAT gene content was quantified by qPCR. Disease activity was assessed clinically and faecal calprotectin concentration measured as biomarker of inflammation in the gut. Microbial composition was determined by sequencing 16S rRNA gene. Dietary data were collected using an established food frequency questionnaire.

Results: Reduced butyrate-synthetic capacity was found in patients with active and inactive CP (p < 0.001 and p < 0.01, respectively), but only in active UC (p < 0.05). In patients with UC, low BCoAT gene content (below 9.5 log10 copies BCoAT/g) was associated with active disease, increased inflammation, lower microbial diversity, greater microbiota compositional change and decreased butyryloxigenic taxa, while no major changes were observed between patients with UC grouped according to BCoAT gene levels. Reduced BCoAT gene content in patients with CD was, in part, linked with lower intake of certain foods containing fibre (vegetables, fruits, high-fibre cereals, brown/wholemeal bread and nuts).

Conclusion: Reduced butyrate-synthetic capacity by the microbiota is more evident in CD than UC and may relate to reduced fibre intake. The results suggest that simple replacement of butyrate per se may be therapeutically inadequate, whereas manipulation of microbial synthesis perhaps by dietary means may be more appropriate and profitable for patients with CD.

Introduction: Inflammatory bowel disease (IBD) is a group of gastrointestinal tract diseases consisting mainly of Crohn’s Disease (CD) and Ulcerative Colitis (UC). Various etiological factors contribute to the pathogenesis of IBD, including modulation of microbiota, epithelial barrier disruption, genes and environment. Recently, the treatment of both diseases comprises several groups of drugs the choice of which is made based on disease activity and extent. The treatment options include: analogs of 5-aminosalicylic acids, glucocorticoids and other immunosuppressive drugs such as azathioprine. Biological therapy with anti-tumor necrosis factor alpha (TNF-α) are considered when conventional therapy fails. In portion of patients surgical approach is necessary. Therefore novel pharmacological targets are sought in order to improve the remission rate with anti-tumor necrosis factor therapy. In this context, the expression of GPR18 (Coupled Receptor 18 receptor of the endogenous cannabinoid system family which may be implicated in the indices after treatment with the agonist. We also showed that GPR18 is expressed in the colon of patients with IBD.

Aim: To assess the anti-inflammatory and anti-microcobic actions of GPR18 in the intestinal inflammation.

Methods: GPR18-dependent colonic mucus secretion was regulated by exogenous endocannabinoids, which already earned its place in the pathogenesis of IBD. GPR18 was found to be implicated in protection against bacterial infection and organ injury. Reports indicate that it may also be connected to the obesity/diabetes-related inflammation. As we lack data regarding its association with intestinal inflammation we attempted to shed some light on this phenomenon.

Aims & Methods: We aimed to clarify how GPR18 affects the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin (VCM), and neomycin or a combination of ABPC, VCM, and neomycin (A-V) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Metabolites and short chain fatty acid (SCFA) in the feces were measured by a chromatography-tandem mass spectrometry. Fecal microbiota was determined by 16S rRNA sequencing and metagenome analysis.

Results: In mice treated with A-V, GPR18 antagonist PSB-KK-1415 secreted butyric acid. Decreased inflammation indices. Study in the mouse model of TNBS-induced colitis demonstrated that GPR18 is another receptor of the endogenous cannabinoid system family which may be implicated in the pathogenesis of IBD and intestinal inflammation overall.

P0318 APPLICATION OF NEW SINGLE NUCLEOTIDE POLYMORPHISMS TO THE IDENTIFICATION OF ADHERENT-INVASIVE E. COLI (AIEC)

Biology Department, Universitat de Girona, Girona/Spain
Contact E-mail Address: c.camprubi4@gmail.com

Introduction: This thesis constitutes an adherent-invasive Escherichia coli (AIEC), a pathotype associated with Crohn’s disease, still needs to be deciphered. Obtaining new molecular tools for AIEC identification would be of great significance, as current techniques based on phenotypic screening of cultured bacteria are time consuming (1).

Aims & Methods: Our aims were: (i) to search for genetic elements putatively involved in the AIEC phenotype in order to find specific signature sequences and (ii) to determine the distribution of these elements to assess their usefulness in AIEC identification. AIEC-specific sequences were identified through comparison of genomes of three E. coli strain pairs (from different phylogroups) displaying different AIEC phenotype but identical pulsetype. Pair-end libraries of Illumina HiSeq and PacBio of the six strains’ genomes were combined de novo and assembled by SPAdes. Differences in gene content between pairs were accomplished with OrthoVenn. Harvest was performed to compare strain pairs against an AIEC reference genome (UM146). Only non-synonymous single nucleotide polymorphisms (SNPs) between the strains of the D-phylogroup pair, 17 in the B2-pair and 30 in the B1-pair that met the selection criteria. Of those, 24 SNPs (found in 13 genes) were confirmed and further analysed in the strain collection. Three of the SNPs encompassing genes were related with adhesion/invasion and two with stress tolerance. Three SNPs resulted in differential nucleotide distribution between AIEC and non-AIEC strains, respectively. After a median follow-up of 8.6 years, clinical recurrence was seen in 57%, and surgical recurrence in 26%. A significantly increased recurrence rate was seen in patients with active inflammation at the distal resection margin whereas recurrence rates were comparable for inflammation at the proximal site and radical surgeries (87%, 61%, and 50% respectively, p < 0.001). Active inflammation at the distal resection margin (HR: 3.189 (1.635–6.220); p = 0.001) and smoking (HR: 2.502 (1.331–4.703; p = 0.004) were the only independent predictors for clinical recurrence. The incidence of surgical small bowel to perianal fistulas was much higher in patients with previous AIEC-related disease, in particular women.

Disclosure of Interest: No authors have declared no conflicts of interest.
incident rate of microscopic colitis appeared to increase with time (Table). The incidence of microscopic colitis in 2016 was twice that observed in 2009 (incidence rate ratio 1.86; 95%CI 1.41, 2.46). There was a strong, independent graded association between the incidence of microscopic colitis and the number of lower GI endoscopy procedures undertaken (p = 0.03).

Conclusion: Microscopic colitis diagnosis is becoming more common. It is unclear whether microscopic colitis itself is increasing or greater numbers of lower GI endoscopy are being undertaken causing an ascertainment bias. Further work is required to explore environmental exposures such as drugs associated with microscopic colitis and to observe its natural history.

Introduction: Data on extra-intestinal manifestations (EIM) and their impact on disease course of ulcerative colitis (UC) in population-based cohorts are scarce, particularly in paediatric- and elderly-onset UC patients.

Aims & Methods: The aims of this population-based study were to assess 1) the occurrence of EIM in paediatric- and elderly-onset UC; and 2) their impact on long-term disease outcome. Paediatric-onset (<17 years at diagnosis) and elderly-onset UC patients (>60 years) from a French prospective population-based Registry (EPIMAD) were included. Data on EIM and other clinical factors at diagnosis and at maximal follow-up were collected.

Results: 158 paediatric- and 470 elderly-onset patients were included (median age at diagnosis 14.5 and 68.8 years; median follow-up 11.2 and 6.2 years, respectively). EIM occurred in 8.9% of childhood- and 3% of elderly-onset patients at diagnosis and in 16.7% and 2.2% of individuals during follow-up (p < 0.01). The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset). Presence of EIM at diagnosis was associated with more severe disease course (need for immunosuppressive or biologic therapy or colectomy) in both paediatric- and elderly-onset UC (HR = 2.0, 95%CI: 1.0-4.2 and HR = 2.8, 0.9-7.9). Extensive colitis was another independent risk factor in both age groups.

Conclusion: Elderly-onset UC patients had lower risk of EIM either at diagnosis or relapse compared to pediatric-onset UC patients. All authors have declared no conflicts of interest.

Introduction: Data on long-term natural history of microscopic colitis (MC), including collagenous (CC) and lymphocytic colitis (LC) are lacking.

Aims & Methods: All new cases of UC diagnosed in the Somme area, France between January 1st, 2005 and December 31th, 2007 were prospectively included. Colonoscopic biopsies from all patients were reviewed by a group of 4 expert gastro-intestinal pathologists to assess the diagnosis of CC or LC. Demographic and clinical data were retrospectively collected from diagnosis to February 31th, 2017.

Results: One hundred and thirty cases of MC, 87 CC and 43 LC were included (median age at diagnosis 70 and 48 years, respectively). The median follow-up was 9.6 years (Q1 = 7.6; Q3 = 10.61). By the end of follow-up, 37 patients (28%) developed steroid-dependency, 21 patients (16%) were hospitalized for a disease flare and 32 (25%) presented with another disease flare. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticosteroid-resistant. Only one patient was treated by immunosuppressants. By the end of follow-up, 37 patients (28%) developed steroid-dependency, 21 patients (16%) were hospitalized for a disease flare and 32 (25%) presented with another disease flare. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticosteroid-resistant. Only one patient was treated by immunosuppressants.

Conclusion: This population-based study showed that after diagnosis, two third of patients with MC observed long term clinical remission. Age at diagnosis and disease exposure (HR 0.40; 95%CI, 0.18–0.90; p = 0.02) and budesonide exposure (HR 0.64; 95%CI, 0.18–0.90; p = 0.03) were significantly associated with relapse.

Introduction: It has been demonstrated in many chronic conditions, including inflammatory bowel disease (IBD), that better patients’ knowledge about pathology and treatment improves the course and management of disease. The aim of this study was to develop an updated self-questionnaire to assess patients’ level of knowledge of IBD.

Aims & Methods: The IBD-INFO included 3 parts: an original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohns’ and Colitis Knowledge score (CCKNow) (Q2) and Crohn’s and Colitis Pregnancy Knowledge score (CCPKNow) (Q3). The reliability and discriminatory ability of the questionnaire were validated with 3 groups of non-IBD volunteers with various theoretical knowledge levels. The final questionnaire (64 validated questions) was then tested on 364 in- and out- IBD patients from 4 French university hospitals. The score for each part of the questionnaire was calculated and factors associated with low scores were identified by uni- and multivariate logistic regression analyses.

Results: The scores obtained by the 3 non-IBD volunteer groups differed significantly (p < 0.0001) and the IBD-INFO questionnaire showed excellent internal reliability and consistency (α = 0.98). The median total score obtained by the IBD patients was 27/64 [0–59], and scores for Q1, Q2 and Q3 were, respectively, 10/23
Investigation of the average disease activity in 5-year-intervals in UC patients

F. Cordes

STUDY WITH MATCHED COHORTS

THE DISEASE COURSE IN PATIENTS WITH INFLAMMATORY

P0324 IMPACT OF PRIMARY SCLEROSING CHOLANGITIS ON

the incidence of UC-PSC and CD-PSC patients was assessed. Data were evaluated using standard statistical methods. In matched-pair analyses, IB patients with and without PSC were matched at the ratio of 3:1 by sex, disease entity, age at diagnosis, time from diagnosis to first presentation, and duration of follow-up.

Time to event analysis was performed using survival analytic methods including Kaplan-Meier method and Log-rank test.

Results: PSC was diagnosed in 77 and 10 patients out of 781 UC (9.8%) and 1033 CD patients (1.0%), respectively. Age at UC onset was significantly lower in UC-PSC patients than in patients without PSC (23.3 vs. 29.3 years; p = 0.001). Extensive disease manifestation was observed in 46% of UC patients, whereas pancolitis was more frequently diagnosed in UC-PSC patients (75%, p = 0.001). Concerning CD, all patients with coincident PSC showed colonic involvement, while only 69% of the CD patients without PSC had colonic manifestation (p = 0.044). Interestingly, IB patients without PSC presented more frequently with active disease, as compared to IB-PSC patients (p = 0.036; p = 0.055), respectively. Convenietly, average disease activity assessed by complete Mayo score, was significantly higher in UC patients with acute flare as compared to UC-PSC patients (7.3 vs. 6.2; p < 0.001).

Investigation of the average disease activity in 5-year-intervals in UC patients revealed a stronger disease activity in UC patients without PSC, especially within the first 10 years after UC onset. Furthermore, biological therapy including vedolizumab and anti-TNF antibodies was initiated more frequently (25% vs. 0.05% to 0.084) and earlier (20.4 vs. 28.6 years after onset, respectively) in UC without PSC than in those with coincident PSC. Colorectal high grade intraepithelial neoplasia (HGIEN) and CRC were detected in 25 IB patients without PSC and in 7 IB-PSC patients (4 UC and 3 CD patients) (1.45% vs. 8.00%). Of note, in IB-PSC patients, HGIENCRC occurred significantly earlier than in IB patients without PSC (20-year-risk: 9.6% vs. 5.6%; p = 0.003).

Conclusion: In our large cohort study, IB patients with coincident PSC showed a distinct disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.

Disclosure of Interest: All authors have declared no conflicts of interest.
There was a similar, significant increase for codeine (chi2 for trend, p analysis. in patients with inflammatory bowel disease in the English primary care database. for prescriptions of tramadol at any prescription density in CD or UC. associations were for heavy users of strong opiates in patients with CD (HR 2.18, patients with IBD. Any opiate use in patients with UC was associated was with surgery, biological therapy and hospitalization after 1 and 5 years follow-up in the EpiCom-cohort). We included 3517 patients with CD and 5349 with UC. Opiate prescribing for cancer and non-cancer pain has increased dramati- shortly in recent years but there is a paucity of data on prescription trends for individuals with IBD. The only population-based study is from Canada where 5% of subjects with IBD became heavy opiate users after 10 years of diagnosis and there was a strong association between heavy opiate use and mortality (OR 2.91, 95% CI 1.58–5.02). In this study we explore trends in the prescription of opiate medications and assess the association between prescription and mortality in English primary care cohort of patients with IBD. we defined 3 groups of prescription density as none/infrequent users, moderate and heavy users as < 1, 1–3 and > 3 prescriptions per calendar year respectively. We examined the trend in opiate prescriptions for all IBD patients in 4 year blocks from 1990-2014 using chi2 for trend as a significance. Separate trends were produced for each of our opiate classes. We calculated a propensity score estimating the conditional probability of being prescribed an opiate medication based on pre-defined characteristics which may influence the prescription of opiates. All analyses were performed for each opiate medication class in CD and UC patients. Results: We included 3517 patients with CD and 5349 with UC. Opiate prescrip- tions increased from 10% in 1990 to 30% in 2014 (chi2 for trend p < 0.005). There was a similar, significant increase for codeine (chi2 for trend, p = 0.008), tramadol (p < 0.005) and strong opiates (p < 0.005) when analyzed separately. Table 1 shows the association between opiate use and all-cause mortality in patients with IBD. Any opiate use in patients with UC was associated with increased mortality ((HR 1.67, 95% CI 1.25–2.23). The strongest associations were for heavy users of strong opiates in patients with CD (HR 2.18, 95% CI 1.20–3.95) and UC (HR 3.30, 95% CI 1.77–6.18). There was no association for prescriptions of tramadol at any prescription density in CD or UC. Table 1: – The association between opiate prescription and all-cause mortality in patients with inflammatory bowel disease in the English primary care database Research One. Propensity score matched, Cox proportional hazards regression analysis. Any opiate medication

Crohn’s disease Hazard ratio (95% CI) Ulcerative colitis Hazard ratio (95% CI)

None/infrequent use (< 1 prescription per year) 1 1

Moderate use (1–3 prescriptions per year) 1.10 (0.89–1.36) 1.10 (0.89–1.36)
Heavy use (≥ 4 prescriptions per calendar year) 1.20 (0.97–1.48) 1.20 (0.97–1.48)

Table 1 Continued

None/infrequent use (< 1 prescription per year) 1 1
Moderate use (1–3 prescriptions per year) 1.09 (0.86–1.37) 1.10 (0.89–1.36)
Heavy use (≥ 4 prescriptions per calendar year) 1.21 (0.98–1.48) 1.21 (0.98–1.48)

Table 1 Continued

Conclusion: Our study is the largest population based study of opiate use in patients with IBD. We have shown a significant increase in the prescription of opiates since 1990, with 30% being prescribed an opiate medication between 2010 and 2014. Prescriptions of codeine in UC and strong opiates in both CD and UC were associated with increased all-cause mortality. There appears to be a dose association as heavy users of strong opiates had the largest association with mortality. Observational studies are not proof of causality and there may be residual confounding. A dose response is a strong indicator that opiates could be responsible for the associations seen, which is consistent with other studies investigating opiates used for non-cancer pain in chronic disease. Randomised controlled trials would be unethical and not feasible to investigate this potential effect so population-based observational studies may provide the best estimate. Opiate prescriptions are increasing worldwide for chronic non-cancer pain, and individuals with IBD can now be included. Clinicians managing pain in individ- uals with IBD should consider the potential implications of prescribing, or continuing with opiate prescriptions as they are a marker for increased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In a prospective 6-months study, dental examination was performed in IBD and in 19 healthy controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth (the severity of gingival inflammation). Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis.

Results: Among the 54 included patients, 44 had Crohn disease (81%) and 31 were women (55%). At the time of dental examination, median age was 33 years (Q1 = 26; Q3 = 41), 20 (36%) were smokers and the median IBD duration was 8.4 years (3.4–16.3). Eleven (20%) were treated by corticosteroids, 27 (49%) by anti-TNF, 6 (10%) by other biologies and 8 had no IBD treatment. IBD was significantly associated with periodontitis (81% vs 27%; Odds Ratio 2.9, 95% CI: 1.6–3.2). Mild, moderate and severe periodontitis were respectively observed in 34 (63%), 8 (15%) and 3 (5%) IBD patients. As compared to healthy controls, IBD patients had significant increase of BOP index (p = 0.008), probing death (p = 0.03), and REC index (p = 0.01). Patients with active IBD (Harvey Bradshaw index > 3 or Mayo Score > 1) had a significant increase of BOP index (p = 0.007) as compared to patients with inactive disease. A significant correlation between BOP and Harvey-Bradshaw index was observed (r = 0.44, p = 0.0018). Anti-TNF therapy was significantly associated with lower BOP index (p = 0.02). All patients with diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with pidovone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Conclusion: Inflammatory bowel diseases were associated with an increased risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of active periodontal disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn’s disease is a chronic, immune mediated inflammatory condition which affects the gastrointestinal tract. NOD2/Card15 mutations have been linked to an increased risk of Crohn’s disease and to some of its phenotypes. This study aimed to determine the presence of the above mutations in Arab patients suffering from Crohn’s disease in Kuwait.

Aims & Methods: Blood samples were obtained from 103 Arab patients with Crohn’s disease and 100 Arab control subjects. The genomic DNA was isolated from the samples using Qagen DNA Blood mini kit. The isolated DNA were used in Polymerase Chain Reaction (PCR) using four sets of primers specific for the mutations in the NOD2/Card15 sequence of 17 (16.5%) Arab patients with Crohn’s disease compared to 32 (32.0%) normal controls (p < 0.05). This difference was statistically significant if the mutation was heterozygous (p < 0.001) but not in homozygous. This mutation in rs2066845 (SNP8, Exon 8227G > C) was found in 24 (23.3%) patients and 10 (10.0%) controls (p < 0.05). This difference was statistically significant if the mutation was homozygous (p < 0.05) but not in heterozygous. The mutation in rs2066844 (SNP8, Exon 8202C > T) was found only in one patient and no controls and rs2066847 (SNP13, Exon 11302mc) was not detected in any of the patients or controls. Table 1. Mutations in SNP5, SNP8, SNP12 and SNP13 of the NOD2/Card15 gene in Arab patients with Crohn’s disease and control subjects.

Conclusion: The results suggest that mutations in SNP5 and SNP13, Exon 8227G > C occurs more frequently in Arab patients with Crohn’s disease compared to controls, but the disease is associated only with the homozygous mutation. The mutation in rs2066842 (SNP5, Exon 802C > T) occurs more frequently in controls compared to patients and the heterozygous mutation appears to have a protective effect against Crohn’s disease in the Arab population. Mutations in rs2066844 (SNP8, Exon 8202C > T) and rs2066847 (SNP13, Exon11302mc) were not seen in this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin D receptor gene (VDR) associated with disorders of innate and adaptive immunity, as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the VDR gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism of the VDR gene with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene (rs154440) in UC among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method (“SNPexpress” reagents, Lytech Co., Ltd., Russia) with electrophoretic separation of amplification products. Statistical analysis was performed using the X2 and Mann-Whitney tests. In the presence of statistically significant differences (p < 0.05), odds ratios (OR) with 95% confidence interval (CI) were calculated.

Results: It was found that the frequency of the allele B polymorphism of the VDR Bsm I gene was higher among patients with UC than in the control group (44% vs. 26%, p = 0.02), which increases the risk of this pathology by 2.2% (95% CI: 1.2-4.1). In the case of carriers of the B/B genotype, the risk of developing UC increased up to 3.5 times in comparison with the control group (21% vs. 7%, p = 0.02, 95% CI: 1.4-8.6), whereas in b/b genotype the risk of UC decreased (33% and 54%, respectively, p = 0.02, OR = 0.4, 95% CI: 0.2-0.7). Significant differences between carriage of the B allele Bsm I polymorphism and the features of the clinical course of the UC have not been established. However, it has been shown that in carriers of allele B, the clinical implementation of UC develops significantly later than in patients with the b/b genotype (43 and 28.5 years, respectively, p = 0.04).

Conclusion: For the carriers of the B allele Bsm I polymorphism of the VDR gene is a predictor of a high risk of ulcerative colitis with an increase in the age of diagnosis. Genotype b/b Bsm I polymorphism of the VDR gene has a protective effect in the development of ulcerative colitis among the residents of the Kemerovo region of the Russian Federation.

References:
and decreased UPRE promoter activity. ORMDL3 overexpression induced the increased cleavage of ATF6a and augmented ERSE promoter activity. Mechanistically, we show that ORMDL3 colocalizes and directly interacts with ATF6a. Furthermore, ORMDL3 overexpression induced the PERK pathway by elevating -deficiency was observed to be beneficial in the course of chronic colitis: compared to their wild-type littermates, Ormd3+/- mice showed less body weight loss and an improved survival rate. 

Conclusion: This study demonstrates for the first time the modulatory functions of ORMDL proteins as regulators of all three UPR signaling pathways. Above results suggest that ORMDL proteins constitute a precise fine-tuning mechanism of the UPR determining cell fate decisions in response to ER stress.

Introduction: Inflammatory bowel disease (IBD) is one of the most frequent inflammatory disorders affecting the digestive tract. Leman score was designed by Leman in 1990 to develop a comprehensive assessment of the structural bowel damage, including strictureing lesions, penetrating lesions (fistulas and abscesses), and surgical resection. (1)

Aims & Methods: To calculate Leman score in a cohort of Egyptian patients according to its ability to assess the structural damage caused by CD in Egyptian patients, score was calculated using excel computer software based on the original paper by Pariente. B et al in a cohort of Egyptian patients with CD (2) in 2013 - August 2015. The temporal relation between Leman score and disease duration was also assessed.

Results: A total of 100 Egyptian patients were enrolled, 69% males and 31% females. Median age was 32 years, 36% were smokers. The clinical presentation varied between abdominal pain occurring in 90% followed by 69% with chronic diarrhea, 52% with weight loss. Few patients (26%) presented with extraintestinal manifestations. According to ECCO classification of disease severity 73% of our patients had mild disease, 17% had moderate disease, 10% had severe disease. According to Montreal classification, 25% of patients were A1, 55% A2, 13% A3, 70% L1, 5% L2, 26% L3, & only 4% had perianal disease. According to CDAI, 83% were in clinical remission, 11% mild “CDAI 150-220”, 4% moderate “220-450”, 2% severe “CDAI > 450” disease activity. When assessing structural damage of upper GIT, 4% had strictureing lesions, 2% grade 1 & 2 grade 2 lesions. The small bowel showed strictureing lesions in 65%; 39% grade 1, 23% grade 2, 3% grade 3 lesions. 25% of patients had grade 3 penetrating lesions, 5% had surgery which was resection in all the cases. As regards the assessment of strictureing lesion in the colon, 5% showed stricteing lesion of this structure in 3%, 2% in grade 1, 0.5% in grade 3 lesions; ascending colon showed strictureing lesions in 20%, with 7% grade 1 lesions, 11% grade 2 & 2 grade 3 lesions; transverse colon showed strictureing lesions in 1%; sigmoid colon showed strictureing lesions in 2%; rectum showed strictureing lesions in 1; while in only 1% whole colon showed grade 1 strictureing lesions affecting the 6 segments. In addition, 12% had grade 3 penetrating lesions while 9% had history of surgery mainly intestinal resection. In the anal canal, only 3% of patients had grade 3 penetrating lesions. The mean Leman score was 4.02 ± 2.6 of the median of patients in whom Leman score was statistically positively correlated with disease duration of ≤ 2 years & > 2 - ≤ 10 years and >10 years respectively. (r = 0.343 & p < 0.001) (KW = 9.235(0.01)). The current study showed that affection of the GI tract was (5%, 92%, 41%, and 3% with upper tract, small bowel, colon/rectum, & anus CD location, respectively). There is an increase in median Leman score with increase in disease duration (global test p < 0.001): 0.60, 2.50, 6.40 for disease duration of ≤ 2 years & > 2 - ≤ 10 years and >10 years respectively; These results are in concordance with what was published by Pariente B et al. (1)

Conclusion: Crohn’s disease affection pattern in our Egyptian cohort is mainly in the small bowel (92%) followed by the colon (41%) with the upper GI and the anal canal representing only 5% and 3% respectively. Leman score designed by Le’mann score was designed to develop a comprehensive assessment of the structural bowel damage, including strictureing lesions while 9% had history of surgery mainly intestinal resection. In the anal canal, only 3% of patients had grade 3 penetrating lesions. The mean Le’mann score was 4.02 ± 2.6 of the median of patients in whom Le’mann score was statistically positively correlated with disease duration of ≤ 2 years & > 2 - ≤ 10 years and >10 years respectively. (r = 0.343 & p < 0.001) (KW = 9.235(0.01)). The current study showed that affection of the GI tract was (5%, 92%, 41%, and 3% with upper tract, small bowel, colon/rectum, & anus CD location, respectively). There is an increase in median Leman score with increase in disease duration (global test p < 0.001): 0.60, 2.50, 6.40 for disease duration of ≤ 2 years & > 2 - ≤ 10 years and >10 years respectively; These results are in concordance with what was published by Pariente B et al. (1)

Conclusion: Crohn’s disease affection pattern in our Egyptian cohort is mainly in the small bowel (92%) followed by the colon (41%) with the upper GI and the anal canal representing only 5% and 3% respectively. Leman score designed by

Introduction: The most relevant scope of serologic antibodies in Crohn’s disease [CD] is to stratify the risk of complicated disease course. Significance of distinct antibody class and their characterization was rarely considered. We aimed to address these concerns.

Aims & Methods: Sera of 266 well-characterized CD patients [m/f:112/154, median age: 25 yrs, BI:80.1%, PI:18.0%] and 155 controls were assayed for serological ASCA and OMP antibodies, defined as the Endoscopic healing was defined as the absence of mucosal ulcers and/or stenosing (IP/S) complications and subsequent surgical interventions. A novel flow cytometry test system was established for characterisation of IgA type ASCA to reveal possible origin of the antibody.

Results: A total of 65.7% and 46.2% of the CD patients were positive for ASCA IgA and anti-OMP antibodies. Both ASCA types occurred equally. However, in controls the ASCA IgA positivity was more frequent (15.4% vs. 5.4%, p<0.001) and sIgA were increased [median, 51 vs. 29 μg/ml, p<0.001] in CD compared to controls. They were also associated with presence of IgA type anti-microbial antibodies. Contrary, ratio of IgA2/A1 in CD corresponded with the value of the controls. In Kaplan-Meier analysis, development of perianal penetration (PP) with IgG type ASCA (p LogRank = 0.025 respectively), while development of perianal penetration (PP) with IgG type ASCA (p LogRank = 0.008). Performance OMP IgA was equal to ASCA IgA, however sIgA not. Anti-microbial antibodies remained independent predictors in multivariate Cox-regression analysis comprising relevant clinical factors.

Introduction: Achievement of endoscopic healing is a key treatment goal in patients with Crohn’s disease (CD). We previously reported that magnetic resonance enterography (MRE) could exactly assess small bowel (SB) active lesions such as ulcers using balloon assisted enteroscopy (BAE) reference [1, 2]. Aims & Methods: We aimed to evaluate whether MRE could predict patient prognosis in prospective observational study. From July 2012 to December 2015, 139 CD patients in clinical and serological remission were followed up after BAE and MRE procedure. Two endoscopists performed BAE and assessed the endoscopic findings, while two radiologists assessed the MRE findings. Both the endoscopists and radiologists were blinded to the patient’s clinical presentation and results of other studies. We used Simple Endoscopic Score for CD (SES-CED) for endoscopic evaluation and Magnetic Resonance Index of Activity (MRIA) for MR evaluation. Endoscopic healing was defined as the absence of ulcerative disease (SES-CDA ≤ 5). Primary endpoints were clinical relapse and serological relapse. The relationship between endoscopic SB lesions and endpoints was evaluated. Moreover, whether MRE findings could predict patient outcome was assessed.

Results: The median duration of follow-up was 27 months (range, 12-48). Clinical and serological relapse occurred in 30 (21.6%) and 62 (44.6%) patients, respectively. SB endoscopic healing (SES-CDA ≤ 5) was achieved in 76 (54.7%) patients. Multiple logistic regression analysis of BAE findings and the absence of SB endoscopic healing (ulcerative disease; SES-CDA ≤ 5) was an independent risk factor for clinical relapse (Hazard ratio [HR] = 4.78; 95% CI: 1.94-11.80; P = 0.001) and serological relapse (HR = 2.84; 95% CI: 1.63-4.99; P = 0.001). The MRE analysis, patients who did not achieve endoscopic healing were at a significant risk of worse outcomes (clinical relapse, P < 0.001; serological relapse, P < 0.001). MR ulcer healing (MzRIA score <11) showed a high sensitivity (82.5%, 95% confidence interval [CI] 74.4%-88.2%) and specificity (85.5%, 95% CI: 79.2%-90.0%) for detection of endoscopic healing. On Cox’s proportional hazards analysis, MRE findings of ulcer healing were associated with a low risk of clinical relapse (Hazard ratio [HR]: 0.47; 95% CIs: 0.29%-0.78%; P = 0.003) and serological relapse (HR: 0.47; 95% CIs: 0.29%-0.78%; P = 0.003).

Conclusion: The absence of endoscopic healing (ulcerative disease) were seen in a considerable number of CD patients who were in clinical-serological remission, and SB lesions were at risk factor for worse prognosis. MRE could evaluate SB endoscopic healing with a high diagnostic accuracy and could predict patient outcomes.

Introduction: In Crohn’s disease (CD), accurate evaluation of location and small bowel involvement are necessary at the time of diagnosis for prognostic concern and planning of treatment strategy. Since Double Balloon Endoscopy (DBE) enables us to examine deep small bowel either oral or anal it could be of great utility in the management of Crohn’s disease patients.

Aims & Methods: We aimed to evaluate the diagnostic yield and therapeutic impact of DBE on small bowel CD. The medical records of 180 CD patients from September 2009 to April 2013 were retrospectively reviewed. Patients were included if they had known CD based on clinical, colonoscopic and histological findings and had been subjected to DBE. If one patient underwent more than one DBE examination only the first evaluation was considered. The primary end point of our study was to evaluate small bowel involvement that is beyond the reach of conventional colonoscopy. The secondary endpoints were to determine the impact of DBE findings on management strategy of CD. The diagnostic yield of DBE in small bowel CD was determined. In addition, the changes in medical treatment, endoscopic intervention and surgical procedures, within three months after DBE, were analysed.

Results: Among 180 patients with CD, 90 patients underwent 168 DBE examinations and were included. The mean age of included patients was 40 ± 13.6 years. They were 63 males and 27 females. Eighty-nine (91%) patients with established CD underwent DBE for evaluation of small bowel involvement and 8 (9%) patients underwent DBE because of suspicion of CD and had been newly diagnosed. The overall diagnostic yield of DBE was 69%, DBE revealed small bowel involvement proximal to the terminal ileum in 40 (64.5%) patients; of them 17 (42.5%) patients had isolated small bowel CD. Within 3 months after DBE examination the management strategy of CD had changed in 47 (52.2%) patients, based on DBE findings. The medical treatment escalated in 20 (32%) patients, and decreased in 7 (11%). Fourteen (24%) patients underwent DBE-assisted balloon dilatation, and 6 (9.6%) patients underwent CD-related surgery.

Conclusion: DBE is able to detect small bowel involvement in a significant proportion of CD patients. The DBE findings modified the management strategy in at least one half of CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

A study assessed adherence in patients with Crohn’s disease and found that lower adherence was associated with an increased risk of treatment failure.

**Results:**

- Of 181 patients evaluated, the median age was 47 ± 16 years; 98 (54.1%) were males and 32 (17.7%) were active smokers. 82 (45.3%) patients had CD and 99 (54.7%) had UC. The mean disease duration was 10.21 ± 8.5 years. Most patients were in remission (87.8%). In relation to the treatment, 35.9% were taking mesalazine, 2.8% steroids, 29.3% immunomodulators and 30.4% biologics. The oral route was the most frequent (52.5%), followed by rectal route (17.1%) and subcutaneous or intravenous (30.4%). Based on MMAS-4, almost half of our patients (42%) had high adherence to IBD treatment, 56 (30.9%) had medium and 41 (22.7%) had low adherence. In relation to factors associated with adherence, univariate analyses showed that patients with high adherence were older (52.0 ± 7.1 years vs 42.5 ± 14.4; p < 0.001) and their disease had a longer duration (13.2 ± 9.7 years vs 8.5 ± 7.1; p = 0.004) than patients with medium or low adherence. However, smokers had a lower adherence (p = 0.007). Multivariate analysis confirmed that age was associated with high adherence (OR:1.04, CI95% 1.01-1.06; p = 0.002) and being smokers with low adherence (OR:3.47, CI95% 1.36-9.00; p < 0.01). Other factors as sex, anxiety, depression, quality of life, disease activity, type of drugs or administration route were not significantly associated with adherence.

**Conclusion:** Only active smoking and age were predictors of insufficient adherence to drugs in IBD. Efforts for reinforce adherence should be especially directed to young patients. Quitting tobacco could improve adherence.

*the number of liquid or very soft stools per day. SES-CD, Simple Endoscopic Score for Crohn’s Disease. HCT, hematocrit. NA, not applicable.

Conclusion: From data with moderate to severe CD and evidence of mucosal ulceration in EXTEND supported previous findings that the CDAI was only weakly correlated with SES-CD, as assessed at 12 and 52 weeks. When SF was significantly correlated with SES-CD at week 12, the strongest correlation was for SF (r = 0.46) and the addition of AP to SF did not increase the correlation (Table). At week 52, SF, hematocrit, and SF + AP were significantly correlated with SES-CD. At week 12, the correlation of SES-CD with SF was similar regardless of whether the patient had disease of the ileum (r = 0.44 [P < 0.001] with ileal disease; r = 0.48 [P < 0.001] without ileal disease), while SES-CD correlated more strongly with AP in those with ileal disease (r = 0.237 [P < 0.005]) than those without ileal disease (r = 0.16 [P = 0.233]).

**Introduction:** The success of colonoscopy is dependent on efficient bowel cleansing. Inadequate bowel cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and potentially delay appropriate treatment. The increasing frequency of the incidence of colorectal cancer arising in the ascending colon necessitates effective cleansing of this area; additionally these cancers are often associated with poorer prognoses. Data suggest that detection in the ascending colon is more dependent on higher grades of cleansing, perhaps due to the nature of polyps present, which may be more likely to be sessile or serrated. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The NOCT study (a multicentre randomised Phase 3 clinical trial investigating bowel cleansing efficacy of NER1006 vs trisulfate solution) reported bowel preparation quality assessed by central readers. This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision making; hence this study may be more relevant for clinical practice than previous studies.

**Aims & Methods:** In the NOCT study, 523 patients who underwent a colonoscopy and had a site colonoscopist assessment did not show a statistically significant difference in bowel cleansing on the HCS was also assessed by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopist. For both preparations, site colonoscopist findings demonstrated similar very high rates of cleansing success for the overall colon (>93%) and high rates of high-quality cleansing of the ascending colon (>73%), however, statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists are notably higher than those previously reported by central readers.

**Introduction:** The efficacy of colonoscopy is dependent on the quality of bowel cleansing. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel cleansing solution and is a patented combination optimised for effective bowel cleansing. The DAYB study was a European multicentre, randomised trial that tested the hypothesis that NER1006 would be non-inferior to sodium picosulfate and magnesium citrate (NaPic + MgCit) in terms of overall bowel cleansing and high-quality cleansing of the ascending colon plus caecum [1]. Bowel cleansing was assessed using the Harefield Cleansing Scale (HCS) [2]. The primary endpoints of the study were assessed by video review by a central reader. Bowel cleansing on the HCS was also assessed by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopists.

**Aims & Methods:** In the DAYB study, 515 patients (aged 18–85, median age: 55.0 years) underwent screening, surveillance, or diagnostic colonoscopy and were randomly assigned in a 1:1 ratio to receive either NER1006 or trisulfate solution, each administered as an overnight split-dose. Data from the 523 patients who underwent a colonoscopy and had a completed assessment by the site colonoscopist were included. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the Harefield Cleansing Scale, following segmental scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Cleansing of the ascending colon was graded from 0 to 4; grades 3 and 4 were judged as high-quality cleansing.

**Results:** As Table 1 shows, the bowel preparation quality of NER1006 when assessed by site colonoscopists did not show a statistically significant difference to trisulfate for the overall colon (93% vs 94%, P = 0.681; 95% CI: −5.1–3.3%) or ascending colon (80 vs 74%, P = 0.079; 95% CI: −0.7–13.6%). There was, however, a numerical advantage in favour of NER1006 on the proportion of patients achieving high-quality cleansing success in the right colon.

**Table 1:** Successful colon cleansing rates when treated with NER1006 or trisulfate solution.

Several studies in recent decades have revealed new roles for vitamins—especially as a regulator of the immune system and suppressor of fibrostenosis. However, no reports have demonstrated this relationship seen with NER1006 is of clinical relevance. The trial lived up to the expectations in the analysis. The trial satisfied the patients and was considered to be important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several studies in recent decades have revealed new roles for vitamin D. For example, vitamin D plays a role in regulating skeletal muscle, as well as in cardiovascular and renal physiology, producing antinflammatory effects, suppressing fibrosis, and as a regulator of the immune system. In light of these new roles, especially as a regulator of the immune system and suppressor of fibrosis—vitamin D deficiency is considered to be related to disease activity and intestinal fibrosis, including that seen in Crohn’s disease (CD). Several reports have demonstrated a relationship between vitamin D deficiency and CD activity according to clinical parameters such as Crohn’s disease activity index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship using endoscopic parameters such as endoscopic activity, mucosal inflammation, and intestinal fibrostenosis.

Aims & Methods: The aim of this study was to clarify the relationship between vitamin D deficiency and CD by using endoscopic parameters, as well as clinical parameters. Of the CD patients visiting Nagaoya University Hospital from May 2011 to February 2016, 82 patients were enrolled in this study. Serum 25-hydroxyvitamin D (25(OH)D), disease activity, and clinical factors of the subject were investigated prospectively. Endoscopic findings of 52 of the 82 total patients enrolled were investigated retrospectively from endoscopic records. This study design was approved by the ethics committee of Nagoya University Hospital. Clinical remission was defined as CDAI ≤150. Mucosal healing was defined as a simple endoscopic score for Crohn’s disease (SES-CD) ≤1. Moreover, to evaluate endoscopic activity from two aspects (mucosal inflammation and fibrostenosis), we divided SES-CD score into endoscopic mucosal inflammation score and endoscopic fibrostenosis score. We used the simplified Crohn’s disease endoscopic index (CDEI) in the analysis. The trial lived up to the expectations in the analysis. The trial satisfied the patients and was considered to be important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

Results: Mean age of the subjects was 41.11, and the male/female proportion was 64/18. The mean serum 25(OH)D level of subjects was 17.1 ng/mL, and 61 cases (74.4%) were classified as severe deficiency or deficiency. Mean serum 25(OH)D levels of the clinical remission and clinically active groups were 18.7 ± 8.1 ng/mL and 12.4 ± 3.6 ng/mL, respectively (P < 0.001). In a multivariate analysis, low levels of 25(OH)D and serum albumin and positive C-reactive protein (CRP) results were correlated with clinical activity. Mean serum 25(OH)D levels in the mucosal healing and no mucosal healing groups were 24.0 ± 9.8 ng/mL and 15.1 ± 6.6 ng/mL, respectively (P < 0.001). Mean serum 25(OH)D levels for the no mucosal inflammation and mucosal inflammation groups were 21.6 ± 9.6 ng/mL and 14.3 ± 5.5 ng/mL, respectively (P < 0.001); and those of the no fibrostenosis and fibrostenosis groups were 20.2 ± 4.8 ng/mL and 14.2 ± 6.7 ng/mL, respectively (P < 0.001; Mann-Whitney U test). In a multivariate analysis, low serum 25(OH)D levels were related with mucosal inflammation and intestinal fibrostenotic score of CD (P < 0.05; logistic regression analysis).

Conclusion: This study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing of inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

Introduction: Inflammatory bowel diseases (IBD), such as ulcerative colitis (UC) and Crohn’s disease (CD), are chronic gastrointestinal diseases that are associated with protein-energy malnutrition (PEM). Although the frequency of altered body composition, such as reduced fat-free mass or skeletal muscle volume, has been shown to be high in patients with IBD, the relationships between skeletal muscle volume and the prognosis are yet to be elucidated.

Aims & Methods: We have conducted a retrospective study on 61 IBD patients who have admitted due to exacerbation of the disease. We have enrolled IBD patients with abdominal computed tomography and assessed the nutritional indices, such as the Onodera’s prognostic nutritional index (O-PNI) and control-nutritional status (CONUT). O-PNI was calculated based on the serum albumin and total lymphocyte count, using the following equation:

\[
O-PNI = \frac{\text{serum albumin (g/dl)}}{20} + \frac{\text{total lymphocyte count (x10^9/ml)}}{1000}
\]

The L3 skeletal muscle area (SMI) which is the cross-sectional area of the skeletal muscle at the level of the third lumbar (L3) vertebra normalized by the height squared is used to identify sarcopenia.

Results: Sarcopenia defined as low SMI were observed in 44% of all IBD patients (29% in CD, 54% in UC). In UC patients, the O-PNI, CONUT, height and albumin were significantly lower than the CD patients. Spermans’ rank correlation revealed that the SMI has a strong correlation to body weight and O-PNI in IBD patients. Multivariate analysis using Cox regression model demonstrated the SMI has a strong correlation to body weight and O-PNI in IBD patients. The L3 skeletal muscle volume can be a prognostic factor of intestinal resection in IBD, especially in CD. The results may originate from the fact that CD patients present other gastrointestinal diseases which accumulate intestinal deformity.

Introduction: Crohn’s Disease (CD) spans a wide spectrum of severity, from mild to severe, and can avoid under- as well as overtreatment of the patient if determined properly. While factors determining bad prognosis are studied in detail, factors predicting a mild course with the chance of simple treatments are less known. Here we show first results of a prospective evaluation of a retrospectively created score (JCC 2013;7:263) for prediction of mild CD which consists of age at diagnosis, CRP, an endoscopy score, presence of perianal lesions and complications.

Aims & Methods: This is a prospective, ongoing study performed in 12 IBD-specialized private gastroenterology practices (outpatients only) in Germany. All consecutive newly diagnosed CD patients (diagnosis ≤6 weeks) are included. An annual screening ileocolonoscopy with histology, investigation of the perianal area, laboratory tests including CRP are performed and CD complications (stenosis, fistula, extraintestinal manifestations or fever > 38 °C) evaluated to complete of the above quoted score. Patients are treated at the discretion of the physician. In case of a score indicating a good prognosis (≤3) or of mild clinical appearance mesalazine is started. In all other cases patients are treated according to guidelines. 5 year follow up is planned for all patients. If initial therapy fails, treatment is escalated. Source data verification is performed by external monitors. Primary aim of the study is to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalazine therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This interim analysis presents preliminary data.

Results: Currently, 78 patients (33 male, 45 female; age 16-72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up 2-8 weeks (mean 8.5 months), mean age 35 years, female 21 mean, CRP 12.2 mg/l were included into the interim analysis. In 28 patients with a score from 0-2 step-up treatment occurred in 7%, whereas in 28 patients with a score >2, step-up rate was 43% (p=0.0043). Differences between patients with a score 0-2 or >2 were age (41 vs. 28 years, p=0.0011), CRP <2 mg/l (17/28 patients vs. 0, p < 0.0001), endoscopic score 1.4 vs. 2.7, p < 0.001, perforation 1/28 vs. 4/ 28, stenosis 1/28 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and lever.

Conclusion: In this early analysis of a prospective study planned with a 5-year follow-up, we present a significant proportion of patients with mild CD and simple mesalazine therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

P0350 USEFULNESS OF REPEATING TESTING FOR LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD): CORRELATION BETWEEN TUBERCULIN SKIN TEST (TST)/BOOSTER AND QUANTIFERON-TB (QFT)

1Gastroenterology, Hospital Virgen Concha, Zamora/Spain
2Pediatrics, Hospital Virgen Concha, Zamora/Spain

Contact E-mail Address: amfoncor@gmail.com

Introduction: The Spanish Working Group on Crohn’s Disease and Ulcerative Colitis (GETECCU) and other international guidelines recommend testing of latent tuberculosis infection (LTI) before anti TNF therapy by screening with tuberculin skin test (TST) and, in a potential state of energy, double screening by TST and interferon-gamma release assays (IGRAs) or two-time tuberculin test (TST/booster). Routine repetition is not recommended.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and IGRAs using QUANTIFERON-TB (QFT) and the usefulness of repeating periodic (annual or biannual) screening in a population of IBD patients of Zamora (Spain). In a single cohort of IBD patients attended in the department of gastro-entorology of Zamora Hospital, we implemented a questionnaire and collected TST/booster performed previously to February 2015. Afterwards, prospectively, between February 2015 to February 2017, TST and QFT were performed at the same day, and the TST-booster 7 days after. Finally we compared the results of the LTI screening performed prospectively with the screening of the retrospective cohort.

Results: A total of 404 patients were included with a mean age of 51.5 (SD 16.6), 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%), 60/355 (16.9%) were smokers. The prevalence of LTI and the correlation between TST/booster and QFT is shown in table 1.

Table 1: Prevalence of LTI and correlation between TST/booster and QFT.

<table>
<thead>
<tr>
<th>Prevalence of LTI</th>
<th>Prevalence of LTI in patients on immunomodulator or anti-TNF therapy</th>
</tr>
</thead>
<tbody>
<tr>
<td>TST/booster or QFT (+)</td>
<td>130/399 (32.6%)</td>
</tr>
<tr>
<td>TST/booster positives</td>
<td>116/371 (31.3%)</td>
</tr>
<tr>
<td>TST/booster(+) /QFT(+)</td>
<td>12/272 (10.3%)</td>
</tr>
<tr>
<td>QFT positives</td>
<td>40/264 (15.5%)</td>
</tr>
<tr>
<td>TST/booster(+) /QFT(+)</td>
<td>12/272 (10.3%)</td>

<tr>
<td>TST/booster(+) /QFT(+)</td>
<td>3/39 (8%)</td>
</tr>
<tr>
<td>QFT positives</td>
<td>40/264 (15.5%)</td>
</tr>
</tbody>
</table>

Prevalence of LTI in patients on immunomodulator or anti-TNF therapy: TST/booster or QFT (+) 130/399 (32.6%), TST/booster positives 116/371 (31.3%), TST/booster(+) /QFT(+) 12/272 (10.3%), QFT positives 40/264 (15.5%), TST/booster(+) /QFT(+) 12/272 (10.3%), QFT positives 40/264 (15.5%).
Prevalence of LTI in retrospective testing was of 54.246 (22.0%). Prospective testing was (26.7% CD, 27.6% UC). Using the follow up, 30.191 (15.7%) patients who were negative for screening before 2015 were converted in positive for LTI (95% CI [10.2–21.1]).

Conclusion: The prevalence of LTI in our area is high (32.6%). The simultaneous presence of the stool test, an booster and QFT are useful for the detection of LTI. The CEC increases the detection of LTI even when is performed in patients without immunosuppressive treatments, in whom is not routinely recommended.

P0351 MAGNETIC RESONANCE ENTEROGRAPHY GLOBAL SCORE ALLOWS FOR ACCURATE QUANTIFICATION OF SMALL BOWEL INFLAMMATION IN CROHN’S DISEASE – A COMPARISON WITH CAPSULE ENDOSCOPY

1Diagnostic Imaging, Sheba Medical Center, Ramat Gan/Israel
2Gastroenterology Department, Sheba Medical Center, Ramat Gan/Israel
3Chaim Sheba Medical Center, Tel Aviv University, Tel Aviv/Israel

Contact E-mail Address: ukopylov@gmail.com

Introduction: Magnetic resonance enterography (MRE) and capsule endoscopy (CE) are prime modalities for evaluation of small bowel in patients with Crohn’s disease (CD). However, detection of proximal (jejenum and proximal ileum) small bowel inflammation by MRE is challenging. Current quantitative scores such as Magnetic Resonance Index of Activity (MaRIA) do not incorporate proximal small bowel data and were validated against ileocolonoscopy. Magnetic resonance enterography global score (MEGS) was designed for quantitative evaluation of the entire digestive tract; however, it was only validated against ileocolonoscopy and its accuracy in the proximal small bowel was not assessed. CE allows for accurate assessment of the entire small bowel and is the modality of choice for evaluation of the proximal small bowel.

Aims & Methods: We aimed to compare the quantitative evaluation of the small bowel inflammation by MEGS score and the Lewis capsule endoscopy score. Patients with known quiescent small bowel (CD) for at least 3 months (CDAI < 150) were prospectively recruited and underwent magnetic resonance enterography (MRE) and capsule endoscopies (CE). MEGS score was calculated for each bowel segment and the entire small bowel. MEGS is based on the involved segment length, wall thickness, mural enhancement, mural and perimesal edema and extra-intestinal findings. In addition, MARIA score was calculated for the terminal ileum. Small bowel inflammation on CE was quantified using the Lewis score (LS) (LS < 135– mucosal healing; LS ≥ 790 – moderate to severe inflammation). Proximal small bowel was defined as jejunum and duodenum on MRE and as 1st and 2nd tertiles LS on CE. Distal small bowel was defined as terminal ileum on MRE and 3rd tertile LS on CE. Fecal calprotectin (FCP) levels were measured and correlated with all scores.

Results: Fifty patients were included in the study. There was a strong correlation between LS and CECDAI (Pearson’s r = 0.67, p < 0.001), CECDAI > 11.1 corresponded to moderate to severe inflammation (LS ≥ 790) by linear regression. There was a moderate correlation between both scores and FCP levels that was somewhat stronger for CECDAI (r = 0.39, p < 0.002 vs r = 0.53, p = 0.001 for both). There was a weak correlation between LS and CRP levels (r = 0.27, p = 0.04) and none for CECDAI and CRP (r = 0.21). There was no correlation between MRE based scores and CECDAI.

Conclusion: In our prospective study, CECDAI and LS strongly correlated and performed similarly for quantitative assessment of mucosal inflammation in established CD.

P0354 THIOPURINE MAINTENANCE THERAPY FOR IBD: WHICH IS THE BEST METHOD TO MEASURE MEDICATION ADHEREANCE?

A. Ochien, V. George, C. Selinger
Gastroenterology, St James Hospital, Leeds/United Kingdom

Contact E-mail Address: odouri.ochien@nhs.net

Introduction: For the majority of patients with IBD long-term therapy is required to maintain remission, yet 30–45% of patients do not adhere to their IBD medication. Medication adherence can be assessed with prescription refill rates, biological measures (metabolites, trough levels) and patient self-report tools. There is currently no accepted gold standard and the feasibility and utility of different adherence assessment tools in the routine outpatient clinic setting have not been fully examined. The aim of this service improvement project was to test the acceptability of self-report tools assessing thiopurine adherence in the IBD clinic and to correlate the results with thioguanine-nucleotide (TGN) levels.

Aims & Methods: Consecutive outpatients on thiopurine maintenance therapy for IBD for >3 months were recruited from clinic. Patients selfreported adherence using a visual analogue scale (VAS), the validated Morisky adherence tool (MOR) and the validated Medication Adherence Report Scale (MARS). TGN levels were classified as complete non-adherence (<100 and MMP low), partial adherence (TGN 100-235 and MMP low) or full adherence (>235 or MMP high). Correlation analysis was performed using Pearson tests.

Results: Of 100 approached patients none refused participation and TGN levels were available for 96. These included 38 women. Diagnoses were Crohn’s disease in 27, ulcerative colitis in 41 and IBD-U 3 cases. Concomitant therapy included 5/ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant tool report tool 71% (TGN), 87% (VAS), 87% (Morisky) and 77% (MARS). VAS (Pearson 0.315, p = 0.005) and Morisky (Pearson r = 0.363, p = 0.001) correlated moderately with TGN, but MARS (Pearson r = 0.393) did not. The patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had 15–25 TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

Conclusion: Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective TGN levels are problematic for routine use in all patients. TGN require a more invasive and expensive approach. Furthermore, TGN cannot detect “white coat adherence” (patients take medication only around appointments), which is the most likely explanation for normal TGN levels in patients reporting to be poorly adherent. Neither TGN levels nor self-report tools can be seen as the gold standard at present.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNFa therapies have improved outcomes in patients with inflammatory bowel disease. Their use has been associated with improved clinical endpoints, reduced hospitalisation and rates of surgery. However secondary loss of response (LOR) to both infliximab (IFX) and adalimumab (ADA) is a significant problem, leading to further flares of disease, disease progression and poorer outcomes. Therapeutic drug monitoring (TDM), which involves measurement of an anti-TNFα trough level, offers the opportunity of exploring an immune basis behind LOR, and potentially adjusting doses or switching therapies to help regain clinical response.

Aims & Methods: The aim of this study was to evaluate whether TDM can help predict secondary LOR to infliximab and adalimumab and whether dose adjustments based on this information can help patients regain clinical response. This was a prospective, single-centre, cohort study from April 15, 2014 to April 2016, at our institution. Patients with Ulcerative colitis (UC) and Crohn’s disease (CD) were enrolled, if they were clinically (based on Harvey-Bradshaw Index (HBI) or partial Mayo scores) felt to be experiencing a secondary LOR to either infliximab or adalimumab maintenance therapy. Patients with inflammatory bowel disease were followed for a one-year period, from their initial assessment for secondary LOR to assess outcomes.

Results: 24 patients were recruited, 40 CD with Harvey-Bradshaw Index (HBI) >4 points and 6 patients with UC with Partial Mayo Score (PMS) > 2 points. Mean age was 46 years, 38% female and 62% with CD. The majority of patients were on IFX (95%) or ADA (95%). The therapeutic strategy chosen for each group was: 23.9% no change in treatment, 26.1% increase anti-TNFa dose or decrease infusion interval, 19.6% switch to another anti-TNFa drug, 15.2% switch to non anti-TNFa (ustekinumab). For patients who had doses adjusted, clinical response (decrease of HBI ≥ 3 points for CD) was reached in 77.8% of patients and remission (HBI ≤ 4 for CD) in 55.6% at the end of follow-up.

Conclusion: Secondary LOR to anti-TNFα therapy has a significant impact on patient outcomes. Therapeutic drug monitoring is helping us predict secondary LOR and for facilitating dose adjustment or switch in therapy in a clinically guided fashion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Gastroenterology Unit, Inserm U954, Nancy University and Hospital, Nancy/ France

Contact E-mail Address: mariangela.allocca@humanitas.it

Introduction: Bowel Ultrasound (US) and Magnetic Resonance Enterography (MRE) are accurate in assessing disease activity and complications in Crohn’s disease (CD) patients. The comparative accuracy of US versus MRE + Colonoscopy (CS) in assessing disease activity and complications and influencing the decision-making process in CD is unknown.

Aims & Methods: Ileo-colonic CD consecutive patients seen in a tertiary referral Center (Humanitas Research Hospital, Milan, Italy) were prospectively assessed by MRE, CS and US, within 1 week. Sensitivity, specificity, accuracy, positive and negative predictive values (PPV and NPV) of US in assessing localization and extension (bowel wall thickening > 3 mm), bowel wall enhancement (increase of vascularization at power Doppler), strictures (narrowing of the lumen), fistulas and abscesses, and active disease (presence of ulcers at colonoscopy) were calculated using CS in combination with MRE findings as a reference standard. Two independent blinded IBD specialists reviewed separately MRE and US findings, and were asked to decide the therapeutic strategy (continue therapy vs. optimize/change therapy). Kappa agreement between MRE and US was calculated.

Results: Forty-one consecutive CD patients, irrespectively of disease activity and negative predictive values (PPV and NPV) of US in assessing localization and extension (bowel wall thickening > 3 mm), bowel wall enhancement (increase of vascularization at power Doppler), strictures (narrowing of the lumen), fistulas and abscesses, and active disease (presence of ulcers at colonoscopy) were calculated using CS in combination with MRE findings as a reference standard. Two independent blinded IBD specialists reviewed separately MRE and US findings, and were asked to decide the therapeutic strategy (continue therapy vs. optimize/change therapy). Kappa agreement between MRE and US was calculated. United European Gastroenterology Journal 5(3S)
Conclusion: Us was as accurate as the combination CS + MR1 in assessing disease activity and complications in CD patients. Therapeutic decisions based on US findings alone were appropriate in the vast majority of CD patients. US is a non-invasive, easy-to-use tool to manage CD patients in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn’s disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

Aims & Methods: A multicentre cohort study adult patients with IBD (CD, ulcerative colitis UC, inflammatory bowel disease unclassified IBU) attending 18 Austrian outpatient clinics were recruited between May 2014 and July 2015 to complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics. Study outcome was the diagnostic delay defined as the time period from first symptom onset to diagnosis of IBD. A multivariable proportional hazard regressions model based on interval censored latency times was applied to the data.

Results: 1217 patients (CD 779, UC 400, IBU 21, missing 17; females 615) with a median age of 40 years (interquartile range IQR 31–52) and a median disease duration of 10 years (IQR 4–18 years) were analysed. The median diagnostic delay was 0.53 years (IQR 0.29–1.92 years) in CD and 0.28 years (IQR 0.00–0.90 years) in UC. In CD, the median time from first symptom to diagnosis was 0.11–0.86 years) in UC, respectively (p = 0.0001). Diagnostic delay did not differ significantly between CD and UC, but it was associated with older age at diagnosis.

Conclusion: The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

Introduction: Enterobacteria, especially adherent and invasive E. coli (AIEC), are suspected to play a key role in Crohn’s disease (CD). These bacteria are able to highly adhere to the ileal mucosa of CD patients through the CEACAM6 receptor (Caricnoernbryic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice overexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.

Aims & Methods: We aimed to assess the correlation between the level of CEACAM6 in the saliva and the level of CEACAM6 in the ileum in CD patients and to define the best threshold of CEACAM6 in the saliva to detect overexpression of ileal CEACAM6. In addition, we attempted to identify non-invasive biomarkers of AIEC infection. In this prospective multicentre study (8 centers), all the patients requiring ileocoloscopy, regardless the indication, were consecutively included between September 2015 and September 2016. Clinical and endoscopic data were collected on the day of colonoscopy. Blood samples, stool samples (before bowel cleansing, saliva and ileal biopsies from healthy and affected areas) were also collected. CEACAM6 from ileal biopsies and saliva were measured (duplicates) using ELISA assays. AIEC were identified using phenotypic assays.

Results: Overall, 102 patients were enrolled in the study (Table 1).

Table 1: Baseline characteristics of the 102 CD patients included in the study.

(continued)
Ileal CEACAM6 level did not depend on disease severity or the site of biopsies as the median level of ileal CEACAM6 was 584 pg/ml [570.3; 1646] and there was no difference in healthy or ulcerated ileum (756 pg/ml [487; 1617] vs 947 pg/ml [604; 1820], p = 0.86). The median level of CEACAM6 from saliva was 3837 pg/ml [1889; 7388]. There was a positive correlation between the levels of CEACAM6 in saliva and CEACAM6 in the ileum (ρ = 0.47; p < 0.0001) in both macroscopically healthy areas (ρ = 0.53, p < 0.0001) and ulcerated area (ρ = 0.39, p = 0.0082). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal CEACAM6 antibodies. Using a ROC curve (area under the curve (AUROC) = 0.73), the cut-off value of 3800 pg/ml demonstrated the best performance to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9-90.6]) and positive predictive value (67.5% [74.5-93.5]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-consuming and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identified the number of enterobacteria associated to the ileum as a convenient and reliable test to screen CD patients for AIEC bacteria.

Disclosure of Interest: The study was funded by LESAFFRE company. I declare lecture fees for Abbvie, Takeda, Hospira, MSD, Vifor Pharma, SANofi-Aventis and Ferring. I declare consulting fees for Abbvie, Takeda, Hospira.

**Introduction:** Increasingly, immunosuppressive medications such as azathioprine and 6-mercaptopurine (6-MP) have been used in order to prevent a possible remission of inflammatory bowel disease (IBD) patients. It has been reported that such treatments increase the risk of developing all types of skin cancer. Education of these patients is key in order to promote their awareness of their increased risk and it is vital for gastroenterologists to communicate to patients on sun protection strategies on initiating therapy. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician’s lack of knowledge was partly to blame.

**Aims & Methods:** Our aim was to determine Irish IBD clinicians’ knowledge of the skin cancer risk and advised photoprotective behaviours in this cohort. Cross-sectional descriptive study. We invited IBD clinicians via email to fill in an anonymous online survey designed to assess knowledge of skin cancer risk and preventative measures. Surveys were sent out to gastroenterology trainees, general gastroenterology trainees, gastroenterology specialists, and nurse specialists.

**Results:**
- 45% of respondents acknowledged the consequences of sun damage;
- 34 (79.1%) recognised the use of sun protective clothing increased skin cancer risk and almost 100% (44, 98%) knew working outdoors increased risk of skin cancer; and
- only 34 (79.1%) knew sun beds increased skin cancer risk.

Clinician’s knowledge of general factors associated with skin cancer risk and clinical experience was noted. Overall, clinician’s knowledge of general factors associated with skin cancer risk and preventative measures was also lacking; 37 (86%) knew patients should wear SPF 50 but almost half (47% n = 20) thought it should be applied twice daily rather than two hourly (51% n = 23) and only 47% (n = 20) knew patients should stay in the shade from 11am-3pm. Regarding their own practice; 39 (87%) report they emphasise the importance of sun protection in their patients; however, worryingly only 24 (55.8%) had heard of our national skin cancer prevention guidelines “Sunsmart”. Of interest; while physicians had a greater understanding of patient risk factors (p < 0.03), nurse specialists were more likely to emphasise the need for sun protection in clinic (p < 0.0003), and of physicians, trainees had a more complete knowledge of all advised preventative measures (p < 0.03).

**Conclusion:** Our study highlights IBD clinicians’ suboptimal knowledge of immunosuppression risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** dorit.vedel.ankersen@regionh.dk

**Introduction:** Due to the chronic and progressive nature of inflammatory bowel disease (IBD) it is of significant importance to detect and treat a relapse as soon as possible in order to decrease the total inflammation burden and avoid progression of intestinal damage, and possibly improve the disease course. A validated Fecal Calprotectin (FC) home testing kit and smart phone application CalproSmart™ have been added to existent eHealth web-application, enabling patients to perform yearly skin checks on their patients on immunosuppressants. Their knowledge of preventative measures was also lacking: 37% (86%) knew patients should wear SPF 50 but almost half (47% n = 45) knew to be suspicious of changing color and 84% (n = 38) of an irregular border, but shockingly only five (11%) perform yearly skin checks on their patients. Their knowledge of specific immunosuppressant risk was suboptimal; while 82% (37/45) recognised cyclosporine had an increased risk of malignant melanoma. Regards prevention strategies; the majority knew what changes to look for in a suspicious mole; 100% (n = 45) knew to be suspicious of changing color and 84% (n = 38) of an irregular border, while shockingly only five (11%) perform yearly skin checks on their patients. Their knowledge of preventative measures was also lacking: 37 (86%) knew patients should wear SPF 50 but almost half (47% n = 20) thought it should be applied twice daily rather than two hourly (51% n = 23) and only 47% (n = 20) knew patients should stay in the shade from 11am-3pm. Regarding their own practice; 39 (87%) report they emphasise the importance of sun protection in their patients; however, worryingly only 24 (55.8%) had heard of our national skin cancer prevention guidelines “Sunsmart”. Of interest; while physicians had a greater understanding of patient risk factors (p < 0.03), nurse specialists were more likely to emphasise the need for sun protection in clinic (p < 0.0003), and of physicians, trainees had a more complete knowledge of all advised preventative measures (p < 0.03).

**Conclusion:** Our study highlights IBD clinicians’ suboptimal knowledge of immunosuppression risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

**Contact E-mail Address:** darina.kohoutova@seznam.cz

**Introduction:** Ultrafilitic calprotectin (UC) and Crohn's disease (CD) represent a serious medically raised socio-economic problem worldwide. The family of S100 proteins represents a total of at least 25 relatively small calcium binding proteins. S100 proteins have a broad range of functions: they play a role in the regulation of cell proliferation, differentiation, apoptosis, energy metabolism, cellular signalling and calcium homeostasis. S100A4 (metastatin-1, calvasculin) strongly contributes to a process of metatization. Still, the role of S100A4 seems to be more complex as its profibrotic effect has been confirmed in the myocardium, liver parenchyme and in the intestine. Fibroblasts represent the key cell type in the pathogenesis of fibrostenosing/stricturing CD.**

**Aims & Methods:** The aim of this prospective study was to assess serum concentration of S100A4 protein in UC and CD. Study included 118 subjects: 93 patients with CD (44 men, 49 women, aged 22–74, mean 44 ± 14), 16 patients with UC (8 men, 8 women, aged 20–74, mean 39 ± 15) and 9 controls (average patient population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 2 men, 7 women, aged 53 ± 17). CD subgroup was divided according to the Montreal classification: 20/93 (22%) patients had B1 phenotype, 19/30 (20%) B2, 20/31 (20%) B3 and 34/93 (37%) B2 + B3. Perianal involvement was present in 27/93 (29%). L1 involvement was present in 15/93 (16%), L2 in 14/93 (15%) and L3 in 8/93 (11%). Serum concentration of S100A4 protein was investigated by means of Human Protein S100-A4 ELISA kit, the quantitative sandwich enzyme immunoassay technique (purchased from My Biosource, San Diego, California, USA).

**Results:** Serum concentration of S100A4 protein was significantly higher in UC compared to controls (58.8 ± 56.2 µg/L) compared to controls (mean 104.8 ± 40.5 µg/L, p < 0.019 and in CD (mean 154.4 ± 52.1 µg/L) compared to controls, p = 0.007. No difference in S100A4 was revealed between UC and CD, p > 0.05. In CD group, serum concentration of S100A4 in each subgroup (divided according to bowel involvement CD) was significantly higher compared to controls; p < 0.005. No differences in S100A4 were documented between each CD phenotypes. Serum concentration of S100A4 was significantly higher in L2 (mean 144.6 ± 44.2 µg/L) compared to controls, p = 0.041 and in L3 (mean 163.0 ± 52.8 µg/L) compared to controls, p = 0.002. Serum concentration of S100A4 was significantly higher in L2 (163.0 ± 52.8 µg/L) compared to L1 (mean 126.9 ± 47.6 µg/L), p = 0.017. No difference in S100A4 was observed between patients with and without perianal involvement, p > 0.05.
Conclusion: Association of serum S100A4 protein with UC and CD was significantly more common in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VitD deficiency than those in remission. The correlation with activity indexes was statistically significant between normal subjects and those with disease; albumin 42.4 g/L vs 38.9 g/L in normal vs stricturing disease (p < 0.0181 95%CI -0.23–0.02), CRP 8.8 mg/L vs 18.3 mg/L (p < 0.003 95%CI -0.46–0.10) and v 29.2 mg/L (p < 0.002 95% CI -0.43–0.11) amongst normal inflammation and inflammation and strictures respectively. Neither parameter could differentiate between inflammatory and restricting disease. 26 MREs performed with ileal CD had been further assessed; median age = 41yrs, male = 10(38%). RCE > 24% and high T2 signal intensity (SI) 6:26 (23%) and 11:26 (42.3%). RCE > 24% was occurred in only 1 patient with a visible stenosis. Average MRAIAs 2(6.7%) < 7 mild; 3/26 (11.5%) 7–11 moderate; 21/26 (80.7%) >1 severe. MRAIAs did not change significantly between 70 sec and 7 min. As expected T2 SI increased with MRAIAs >11, 26 vs 13 (p < 0.001, 95% CI 7.73–17.27). RCE > 24% correlated with MRAIAs >1, suggesting it as a predictive factor for fibrosis. Consistent with MRE findings, CRP was higher in patients with MacRA >11 (13.3 v 5.2) and lower in patients with RCE > 24% (3.9 v 14). Conclusion: Unlike biochemical markers, MRE may be a useful means to differentiate between inflammatory and restricting disease. Further study is required to assess the long-term predictive value. RCE may be a useful adjunct to current MRE and help detect fibrosis in small bowel lesions and warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

2. Kabbani TA et al. Association of Vitamin D Level With Clinical Status in an Italian IBD cohort in relation to disease activity. Serum 25-hydroxyvitamin D (25OHD) levels were significantly lower in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VitD deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

Contact E-mail Address: ruimorais20@gmail.com
Introduction: Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may relate to severity of the disease.1,3
Aims & Methods: The aim of the study was to determine the Vitamin D (VitD) status in an Italian IBD cohort in relation to disease activity. Serum 25-hydroxyvitamin D was measured in 260 IBD outpatients, not supplemented with VitD (110 Crohn’s disease (CD) and 150 Ulcerative Colitis (UC); 145 males and 115 females mean age 50.7 ± 15 years), and compared to those of 205 healthy blood donors, matched by age (±2– 2 years) and month in which the blood sample was collected. VitD levels were correlated to C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Harvey Bradshaw Index (HBI) and Crohn’s Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.
Results: IBD patients were at higher risk of VitD deficiency (defined as < 20ng/ml) than controls (OR 4.5, 95% CI 2.9-6.9, p< 0.0001). Of 260 IBD patients, 156 (60%) had VitD deficiency, more often in CD than in UC (72.7% vs 48% respectively, p < 0.001). Age < 40 and >60 years, winter/spring season, CRP >0.5mg/dl, ESR >20 mm/h, previous intestinal surgery and HBI ≥5 were significant risk factors for VitD deficiency. No differences were observed in relation to sex, smoking status, BMI, age at diagnosis, localization and behavior of disease, and need of steroids. There was a weak negative correlation between CRP values, HBI scores and VitD levels (R = -0.13, p = 0.037 and R = -0.26, p = 0.006 respectively).
Conclusion: VitD deficiency is significantly more common in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VitD deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

Introduction: The need for upper endoscopy in patients with Crohn’s disease (CD) with no symptoms is controversial. The aim of this study was to establish the prevalence of gastroduodenal involvement, regardless of symptoms, and its prognostic implications.
Aims & Methods: Patients from a single centre with established CD (n=347) were retrospectively evaluated – inclusion criteria: upper endoscopy without treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, cryptic irregularity, erosion/ulceration and granuloma in the absence of Helicobacter pylori (HP) infection).
Results: We included 140 patients - phenotype: 50% inflammatory, 31% structuring and 19% penetrating; Location: 42% ileal, 45% ileocolic and 13% colic. Upper endoscopy was performed in 19% for symptoms and in 81% for staging. Gastric macroscopic findings were detected in 49% (69/140); the most common were erosions (21%) and erythematous mucosa (18%). Biopsies were performed in 56% of patients: chronic gastritis 66%, normal 23%, granuloma 5%, focal gastritis 2% and cryptic microabrasion in 2%. HP was positive in 25% of patients. In the duodenum, endoscopic lesions were observed in 33% of the biopsies were observed in 35% of the biopsies were observed in 33% of the patients (46/ 140); the most common were erosions (16%) and ulcers (9%). Biopsies were performed in 32% and the most prevalent findings were chronic non-specific inflammation 62%, ulcers 17%, granuloma 3% and erosion 3%. Applying macro/microscopic criteria, gastroduodenal involvement by CD was considered in 18% of the patients and was not correlated with the presence of symptoms, phenotype or localization of the disease. The prevalence of gastroduodenal involvement was a significant predictor of hospitalization.
Conclusion: The prevalence of gastroduodenal involvement by CD in this sample was 18%, and a larger percentage have macro/microscopic findings that are not disease specific. The presence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CT enterography is one of the most accurate imaging methods for evaluating Crohn’s disease (CD) extent and intestinal involvement.

Aims & Methods: The aim of this study was to determine the frequency and clinical impact of the incidental findings in CD patients who underwent CT enterography. This was a retrospective study that evaluated patients with CD who underwent CT enterography between January 2012 and December 2016. Incidental findings were defined as previously unknown extraintestinal lesions. The orientation of the patients after their detection was evaluated.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
1. 2016, 111(Jan), 1–8.
5. Helicobacter pylori (HP) infection.
6. United European Gastroenterology Journal 5(58)
Results: A total of 520 patients who underwent CT enterography were identified, with 370 being asymptomatic and 276 of these being women. The median age was 43 (32–53) years and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 59), hepatic cysts (n = 55) and salamioid cysts (n = 46). The findings implicated orientations to another medical specialty in 80 patients (29%), the main ones being Cardiovascular (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); one suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

Conclusion: Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE CARRIAGE IN PATIENTS ON IMMUNOMODULATOR FOR INFLAMMATORY BOWEL DISEASE S.T. Law, W.M. Yip, K.K. Li Department Of Medicine And Geriatrics, Tuen Man Hospital, Hong Kong/Hong Kong Pre

Contact E-mail Address: stil168@hotmail.com

Introduction: Clinical significance of asymptomatic Clostridium difficile (C. difficile) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

Aims & Methods: The aim of this study was to investigate the clinical implication of asymptomatic carriage of C. diff in IBD patients. Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013. Those cases were excluded if they had past history of total colorectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate.

Stool specimen for C. difficile cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrollment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for C. difficile cytotoxin RT-PCR assay was obtained.

The primary outcomes were the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) (graded as follows: <150: remission; 150–220: mild-moderate; 220–450: moderate-severe; >450: severe). The Ulcerative colitis Disease Activity Index (UC-DAI) in ulcerative colitis (UC) (graded as follows: the total index score ranges from 0–12; 0-2: remission; 3-6: mild; 7-10: moderate; >10: severe UC). The study population was partitioned with C. difficile carriage which was defined in the patients with active lower gastrointestinal symptoms accompanying with positive RT-PCR assay of C. difficile at that instant.

Statistical inference of the variables was examined by Mann-Whitney U and 2 test for numerical and categorical parameters respectively.

Results: Of 197 IBD patients (CD: 98 (49.75%); male: 132(67.01%); age (yrs): median 43, minimum 17, maximum 79), 9(4.57%; CD: 6 patients) patients were found to be asymptomatic carriage of C. difficile during the study period. The demographic features, including age, gender ratio, smoking history and the duration of IBD, of the patient group with and without asymptomatic carriage of C. difficile were comparable each other. Four UC patients in the non-carriage group had prior history of anti-TNF exposure in which three were treated as maintenance therapy for the active disease activity, associated axial spondylarthropathy and rectovaginal fistula while the other two patients (one from each group) had received three doses of anti-TNF as rescue therapy for severe disease flare-up.

Incidence rates of the disease flare-up were comparable (11.17 vs. 22.22%, p = 0.313) between the non-carriage and carriage groups in which all these flares were under-controlled by course of high-dose prednisolone.

Clinical characteristics of the IBD patients with and without asymptomatic carriage of C. difficile

<table>

<td>16(5.80)</td>
</tr>
</tbody>
</table>

Data were expressed as median(interquartile range) *: all are UC cases and 3 for maintenance therapy with indications as follows: refractory colitis, spondyloarthropathy, rectovaginal fistula **: case of UC received 3 doses of anti-TNF for severe flare

Abbreviation: IBD, inflammatory bowel disease; C. difficile, Clostridium difficile; ulcerative colitis, UC; ns, non-significant

Conclusion: The incidence of asymptomatic carriage of C. difficile in the IBD patients on immunomodulators was not common. It did not associate with the disease flare-up but a significant portion of them could evolve subsequently into clinical infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to the relapsing and highly variable nature of ulcerative colitis (UC), it would be desirable to have reliable tools for measuring parameters of disease activity in order to monitor response to therapy and to detect relapse. In the past decade it has already been shown that ultrasound (US) is a useful to monitor the disease activity. The hypothesis of the TRUST&UC (TRANsabdominal UltraSonography of the bowel To monitor disease activity in subjects with Ulcerative Colitis) study is that transabdominal US is an easy to use, easily repeatable, and accurate diagnostic tool in the assessment of UC activity, in monitoring the disease course, and response to therapy.

Aims & Methods: TRUST&UC is a German ongoing prospective, observational multi-center study in patients with active UC. The primary objective of this study is the prospective evaluation of bowel wall US in response to therapy in order to assess its value in monitoring UC patients in routine medical practice. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity.

Results: 176 patients with active UC have been enrolled in 37 German IBD study group (GISG) centres until February 2017. 47.2% of the patients were female, median age was 38.9 years (range 19–77) with median disease duration of 152.2 days (range 8–1017). Of all the patients with a clinical flare defined by SCCAI 90.3% showed a bowel wall thickening (BWT), and only 9.7% showed no US signals. At US examination, a BWT in the colon sigmoideum was present in 276 (53%). The median age was 43 (32–53) years and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 59), hepatic cysts (n = 55) and salamioid cysts (n = 46). The findings implicated orientations to another medical specialty in 80 patients (29%), the main ones being Cardiovascular (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); one suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.
stratification was the case in 20.6% of the patients, mesenteric fibro-fatty prolif-
eration more than 50%, had increased signal in the color Doppler US. At baseline systemic steroids were used in 62.1%, azathioprine in
36.2%, and TNFα antagonists in 40.0% of patients (N = 174).
All follow-up patients (N = 104) displayed acute inflammatory symptoms at baseline with active disease and anti-TNF therapy which required an introduction or escalation of treatment. After 12 weeks, the US examination showed signifi-
cant improvements of the following parameters: BWT in colon sigmoideum (87.5% vs 33.7%, p = 0.034) and colon transversum (42.3% vs 15.4%, p = 0.012), loss of haustation (54.8% vs 33.7%, p < 0.001), ascites (9.7% vs 2.9%, p < 0.001), mesenteric lymphadenopathy (31.6% vs 14.3%, p = 0.005), mesenteric fibro-fatty proliferation (40.0% vs 10.0%, p = 0.041) and increased signal in color Doppler US (56.7% vs 23.1%, p = 0.039). A decrease of BWT was significantly accompanied by a decrease in SCCAI (8.0 to 1.5 points, p < 0.001).
Conclusion: In this real-life cohort almost 90% of the patients showed a BWT, a pivotal IBD symptom and within 12 weeks selected bowel US parameters improved significantly from treatment intensification. Therefore, US examination is a useful tool to monitor disease activity and response to therapy in UC patients.

P0370 THE GUT MICROBIOME IN IBD IS CHARACTERIZED BY IMPAIRED METABOLIC COOPERATIVITY AND CAN BE RESTORED UPON ANTI-TNF THERAPY
1Medical Department, University of Kiel, Kiel/Germany

Introduction: Blocking TNFα is an important treatment option for inflammatory bowel disease (IBD). The etiology of the disorder comprises a permanent activation of immune cascades and imbalanced cytokine networks. Evidence has been put forward that alteration of the human gut microbiome may play a critical role in the pathogenesis of IBD. However, the impact of targeted cytokine blockade on dysbiosis of intestinal microbial communities is poorly understood. Here, we investigate the effect of anti-TNFα treatment on gut microbial community structures in a prospective, longitudinal study for 30 weeks. The study compares IBD as a disorder, which primarily affects the gut, with sero-positive and -negative rheumatoid arthritis (RA) and IBD as a rheumatoid disorder (RD) as an inflammatory disease complex, which usually does not affect the intestine.

Aims & Methods: anti-TNFα naïve patients suffering from IBD (n = 12) or RD (n = 17), subject to first-time anti-TNFα therapy were recruited for longitudinal stool sampling at baseline and 2, 6 and 30 weeks after therapy induction. Intestinal microbiota communities were studied by 16S rRNA gene (V4) sequenc-
ing. Changes in microbiota before and after therapeutic interventions were assessed in terms of alpha and beta diversity, indicator species and prediction of metabolic cooperative interactions. Samples from healthy controls (n = 19) were included as a benchmark of healthy microbial profiles.

Results: Intestinal microbial diversity and cooperativity are decreased in both disease entities, IBD and RA. In IBD, anti-TNFα therapy is able to restore microbial diversity and cooperativity. More over cooperative metabolic interaction is significantly increased only in anti-TNFα responder. In RA, anti-TNFα therapy did not significantly restore microbial community structures.

Conclusion: We show that anti-TNFα treatment increases the gut microbial diversi-
ty and coupling of cross feeding metabolic interactions towards the state of healthy individuals. Assessment of metabolic interactions of intestinal microbiota may serve as a marker for clinical response in IBD patients.

Introduction: Faecal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease (IBD). However, until now, commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-
monitoring and eHealth technologies have been evaluated in managing patients with this life-long disease.

Aims & Methods: The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-
monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. The patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

Results: By the end of February 2017, 134 of the 180 included patients had completed the 12 months’ follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 14/91(15%) patients for 12 months. In the control group, 14/89 (16%) patients had filled in the symptom score at baseline and 12 months. There was a significant difference of the adherence between patients stratified for IBD-diagnosis, age, or sex. The satisfaction of the patients with the program as well as the reasons for the discontinuation of the study and influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic in both groups will be evaluated.

Conclusion: The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although the incidence of ulcerative colitis (UC)-related colorectal cancer (CAC) is increased in cases with long duration of disease, it should also be recognized that sporadic tumors (ST) develop as older. Various studies have been conducted on CAC, but there are few clinical studies on ST merged with UC. In
this study, the clinical and endoscopic features of CAC and ST, treatment method, and comparison were compared. Aims & Methods: Among 261 UC patients who underwent colonoscopy (CS) and had neoplastic lesions, the clinical features, treatment and diagnosis were compared between 71 patients (88 lesions) with CAC (including HGD; CAC group) and 47 patients (63 lesions) who underwent local excision (surgical or endoscopic resection) within the presence of the past/present inflammation of UC (ST group). Definition of CAC and ST was performed by conventional pathological and immunohistochemical findings.

Results: The age of UC onset (29.8 vs. 39.0) and tumor detection (45.5 vs. 57.3) in the CAC group were significantly higher than those in ST group (p < 0.01). The CAC group (47.1%) had a higher percentage of chronic persistent type than the ST group (2.3%), and the Mayo endoscopic score is also significantly higher (p = 0.001) in the CAC group (1.43) than ST group (0.38). The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAC group than ST group (p = 0.000). In patients with intraepithelial neoplasia (IEN) or submucosal lesions, flat lesion was found in 15 lesions of CAC group and whereas no flat lesion was observed in ST group. One lesion in ST group could not distinguish the lesions from the surrounding mucosa without magnifying colonoscopy. In ST group who received resections, 4 patients after resections observed ectopic CAC or low-grade dysplasia during follow-up. In CAC group, 50, 5, 4 patients received total colectomy, left colostomy, ESD, respectively, whereas in ST group, 1, 7, 45 patients received total colectomy, local colectomy, EMR and polypectomy, ESD, respectively. Although mortality from cancer was 11.4% (8/70 cases) in CAC group, no death due to cancer observed in patients whose lesions were found as IEN. On the other hand mortality from cancer was 2.1% (1/47 cases) in ST group.

Conclusion: Most sporadic lesions were endoscopically distinct and local resection was enough if inflammation was controlled. After the sporadic lesions were resected in remitting UC patients, regular surveillance colonoscopy is necessary because 8.5% (4/47) of patients was found CAC/dysplasia. Even in CAC group, prognosis is well in patients with IEN.

Contact E-mail Address: zsuzsa.kurti@gmail.com

Introduction: Crohn’s disease (CD) diagnosis between 2004-2015 in Hungary based on the administrative database of the National Health Insurance Fund (OEP). We used the administrative database of the National Health Insurance Fund (OEP), the only nationwide state-owned health insurance provider in Hungary. Newly diagnosed CD patients were identified through previously reported algorithms using the ICD-10 codes for Crohn’s disease in the outpatient, (inpatient, medical, surgical) non-primary care records and drug prescription databases between 2004-2015. Patients were stratified according to the year of diagnosis and maximum treatment step during the first 3 years after the diagnosis.

Results: A total of 6173 (male/female: 46.12%/53.87%) newly diagnosed CD patients were identified during the observational period. Maximum treatment steps did not differ in patients diagnosed before and after 2009 (5-ASA: 11.7% vs. 12.2%, p = 0.157; ST: 46.4% vs. 30.5%, p = 15.6%). Probability of hospitalizations during the first 3-years from diagnosis was lower according to the maximal treatment step in patients diagnosed after 2009 (at 36 ± 30-day period: overall 55.7% vs. 47.4% (p = 0.000), anti-TNF: 73% vs. 66.7% (p = 0.103), 5-ASA: 64.6% vs. 56.1% (p = 0.000), steroid: 44.2% vs. 36.8% (p < 0.007), 5-ASA: 32.6% vs. 26.7% (p = 0.157), respectively. In contrast, surgery rates were not different according to the maximum treatment step (at 36 ± 30-day period: overall 16.0% vs. 15.5% (p = 0.672) anti-TNF 26.7% vs. 27.2% (p = 0.993), IS: 24.1% vs. 22.2% (p = 0.565), steroid 8.1% vs. 7.9% (p = 0.896), 5-ASA 10% vs. 11% (p = 0.816)).

Conclusion: Distribution of maximal treatment steps and surgery rates was not different according to the year of diagnosis and after 2009, although immunomodulators and biologics remained high after 2009. The time from diagnosis to surgery was shorter in CD patients receiving immunomodulators, whereas CD patients receiving biologics had a diagnosis to surgery interval of 12-24 months.

PATIENTS WITH CROHN'S DISEASE TREATED WITH P0377 DYNAMICS OF PROINFLAMMATORY CYTOKINES IN COMBINED STEM CELL AND ANTI-CYTOKINE THERAPY OF CD WITH PERIANAL FISTULAS.

Aims & Methods:
We aimed to compare the efficacy of combined therapy (local and systemic) mesenchymal stem cells (MSCs) of bone marrow, infliximab (IFX) and antibiotics/immunosuppression (IS) on the rate of healing of simple perianal fistulas in Crohn's disease. 36 patients with Crohn's disease with perianal lesions were divided into three groups depending on the method of therapy. The first group of patients aged from 19 to 58 years old (Me=31) received MSCs according to the recommended scheme (Me=29) (n=14). In the 1st group the closure of the fistula was observed in 10/12 patients (83.3%), in the 2nd group healing simple fistulas after 12 months was observed in 8/10 patients (80.0%) (OR=0.83; 95% CI 0.14–4.9; p=0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.11; p=0.32) did not find a fistula. After 12 months of the 1st group patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.6%) with the 2nd group - 7/9 (70.0%) (OR - 1.15; 95% CI 0.32–3.84; p=0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.11; p=0.32) did not find a fistula. After 12 months of the 1st group patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.6%) with the 2nd group - 7/9 (70.0%) (OR - 1.15; 95% CI 0.32–3.84; p=0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.11; p=0.32) did not find a fistula. After 12 months of the 1st group patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.6%) with the 2nd group - 7/9 (70.0%) (OR - 1.15; 95% CI 0.32–3.84; p=0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.11; p=0.32) did not find a fistula.

Introduction: Mesenchymal stem cells (MSCs) are used for the treatment of chronic inflammatory and autoimmune diseases in recent years, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). In most cases, treatment of the IBD patient receiving concomitant immunosuppressive therapy. It is found that immunomodulatory drugs (azathioprine (AZA), methotrexate, 6-mercaptopurine, infliximab (IFP)), regardless of the concentration, do not affect the viability, differentiation, phenotype, and ability to inhibit proliferation of MSCs's penumocytes, R. Gudkova1, E. Dobroliub1, A. Parfenov1

Introduction: The oral delivery of therapeutic concentrations of anti-TNF to affected mucosa of patients with inflammatory bowel disease (IBD) has remained a challenging endeavor despite advances in protein engineering, the attractions of oral dosing for chronic therapies, and the acknowledged benefit of anti-TNF monoclonal antibodies in the management of IBD. As the ileum is commonly involved in Crohn’s disease (CD), it is important to deliver drug there if treatment is to be effective. This is the first report of a domain antibiotic to TNF, V565, engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in the ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorabodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5.

Aims & Methods: Following prior placebo-controlled demonstration of the safety and tolerability of high single and multiple doses of V565, this open label assessment was performed to confirm the delivery of active domain antibiotic to the terminal ileum of human subjects. Four subjects with a terminal ileostomy were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 6 h post dose with further collections 16, 24 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition, serial blood samples were taken for determination of V565 serum concentrations over 24 h.

Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of Crohn’s disease), post dose with further collections 16, 24 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition, serial blood samples were taken for determination of V565 serum concentrations over 24 h.

In addition to the V565 concentrations in ileal fluid, partially dissolved MTs were recovered from the ileostomy bags of all subjects. Each 166.5 mg dose contained a total of 135 MTs. 50 MTs were recovered 2 h post dose from Subject 31001; these MTs were stored as a potential control to provide additional ileal V565 to lesions distal to the ileum. This profile may be beneficial for IBD and merits further investigation as a potential oral treatment.

obviously evaluated by the IBD validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACT-F).

Aims & Methods: The main objective was to assess the efficacy of electroacupuncture (EAc) vs. sham EAc and no treatment for treating fatigue in patients with quiescent IBD in a single-blind randomized controlled trial. Secondary objectives were to assess changes in quality of life, depression, anxiety and sleepiness after treatment with EAc.

Methods: Fifty-two patients with quiescent IBD and severe fatigue (FACT-F ≤ 40) (65.3% female, mean age 42 years) were randomized to EAc vs sham acupuncture. Patients in the EAc group performed a total of 9 acupuncture sessions during eight weeks (2 sessions/first week and one session per week during the after the treatment periods. Results: Both EAc and Sham group improved the FACT-F score post-treatment (EAP -9.53 points, 95% CI (-12.3 to -6.75, Basal Vs 9th session p < 0.001); Sham group (-1.9 to -2.66, Basal Vs 9th session p = 0.063). Depression (8.9, 95% CI from 4.1 to 13.8, Basal Vs 9th session p = 0.002), anxiety (10.6 points, 95% CI from 3.6 to 17.6, Basal Vs 9th session p = 0.006) and sleepiness (1.46 points, 95% CI from 0.096 to 2.83, Basal Vs 9th session p = 0.038). However, the differences in between EAc and sham and control groups were not significant (p > 0.05).

Conclusion: Both targeted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD.

Introduction: Anti-TNFs such as adalimumab (ADA) and infliximab (IFX), have improved the therapeutic care of Crohn’s disease (CD). However their use may be associated with loss of efficacy, adverse events and sometimes primary failure. After the first anti-TNF discontinuation, it is possible to switch to another anti-TNF. In France, three anti-TNF are available in ulcerative colitis (IFX, ADA and golimumab), but only the first two are approved in CD, because golimumab has not been studied in this indication. The aim of this study was to report golimumab efficacy and safety in CD.

Aims & Methods: This national multicenter retrospective study included patients with CD from 12 French tertiary centers who received golimumab and analyzed: clinical response, duration of treatment, tolerance, reasons for discontinuation of treatment, adverse effects and treatments preceeding and associated with golimumab. The main endpoint was the efficacy of golimumab defined by the treatment before failure (need for therapeutic optimization or cessation).

P0383 BIOLOGICS AND BIOSIMILARS: WHAT MATTERS TO PHYSICIANS? A. Molinari1, A. Louiza-Bonnilla2, D. Charles3

Aims & Methods: The purpose of this survey was to determine physicians’ familiarity and comfort level with prescribing biosimilars to patients. The survey was sent to physicians residing in the European Union and specializing in the following clinical fields: dermatology, endocrinology, gastroenterology, oncology, and rheumatology.

Introduction: Biologic medicines and their biosimilar counterparts are effective therapies for many conditions, including inflammatory bowel disease, Crohn’s disease, and ulcerative colitis. The European Medicines Agency (EMA) has approved twenty-two biosimilar medicines, which are derivatives of eight original biologics, and four more biosimilar are scheduled to be reviewed this year. As the number of approved biosimilars rises, regulatory agencies must closely monitor their safety and efficacy.

Results: The majority of survey respondents specialized in endocrinology (19%) and gastroenterology (19%). Respondents were recruited almost equally from the five countries, with France being the most represented country (22%) and the UK being the least represented (18%). The majority (55%) indicated that safety and efficacy is the most important factor in determining whether a patient should be switched from a prescribed biologic therapy to its approved biosimilar. Thirty percent of respondents indicated that clinical trials related to the biosimilar’s condition being treated was the most important factor for switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with immunogenicity.

Conclusion: This survey suggests that the safety and efficacy of biosimilar medicines is of paramount importance to physicians and that physicians highly value clinical trial data for biosimilars. Given that biosimilars are structurally distinct from their original innovator biologics, the EMA should consider requiring more stringent clinical trials data for biosimilars seeking approval. Fifty percent of respondents indicated that clinical trials related to the biosimilar’s condition being treated was the most important factor for switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with immunogenicity.

Introduction: Oral steroids are effective in inducing remission of moderate flares of patients with either ulcerative colitis (UC) or Crohn’s disease (CD). However, we know little about their efficacy in immunosuppressed patients or their possible role in reducing biologics and/or surgical needs in these patients.

**Aims & Methods:** We aimed to determine the efficacy of systemic or low bioavailability immunosuppressive treatment (ADA) for moderate to severe active Crohn's disease (CD) in patients treated according to the local product label. The study was an observational, non-interventional post-marketing registry assessing the long-term safety and effectiveness of ADA-naive patients with moderate to severe active Crohn's disease (CD), with or without prior ADA experience. The registry included patients 18 to 70 years of age with moderate to severe active Crohn's disease (CD) who were treated according to the local product label. The study was conducted in the United States and included 5025 patients evaluated in the registry. Participants were followed for a median of 13 months (0–178). A total of 304 patients (78%) had moderate to severe disease (CD) and 72 (19%) had at least one steroid treatment during follow-up (63% systemic steroid and 37% low bioavailability oral steroid). A median time of steroid treatment of 4 (1–168) months. Average time from IM to steroid treatment was 26 (6–207) months. In CD patients there were no differences regarding sex, age, disease location, gender, disease duration, extra intestinal manifestations, appendectomy, smoking habit, need for steroids at diagnosis and previous abdominal surgery between patients with no need of steroids and patients with steroid treatment during follow-up. In CD patients, biological treatment for perianal disease before IMM (p = 0.009) and fistulizing (B3) behavior (p = 0.005; OR: 2.284) were risk factors for using steroids after IMM treatment. In UC patients, no statistically significant variables were identified. 49 of these 89 steroid treatment patients (55%) needed biological treatment or surgery after a median of 13 months (0–178). 19 (21%) needed more than one steroid treatment (2–5) and just 31 patients (35%) did not need any other treatment. CD patients had higher risk (p = 0.007; OR: 3.529) to receive biological treatment or surgery versus UC patients. Otherwise, the months using steroids in UC patients, the greater risk for biological or surgery treatment (p = 0.009). During follow-up, it's not statistically significant (p = 0.078), we observe that 75% probability of rescue treatment for UC patients in 62 months (0–178) months for CD patients. Conclusion: 23% of CD immunosuppressive patients needed at least one steroid treatment after 6 months of IMM. Previous biological treatment and B2-B3 behavior predicted steroid treatment in CD patients, who had 3.5 times more risk to receive biological treatment or surgery after steroid treatment using it earlier than UC patients. Just 1/3 of patients who needed steroid treatment after IMM did not need any other rescue treatment.

P0386 EFFECT OF ADA rimABUM ON CLINICAL AND HEALTH-RELATED QUALITY OF LIFE OUTCOMES BY DISEASE SEVERITY AND PRIOR TUMOUR NECROSIS FACTOR INHIBITOR USE IN PATIENTS WITH ULCERATIVE COLITIS IN A CLINICAL PRACTICE SETTING: SUBGROUP ANALYSES FROM INSPIRADA

1Oxford University Hospitals, Oxford, United Kingdom
2Robarts Research Institute, London, Canada
3University of Calgary, Calgary, Canada
4Istituto Clinico Humanitas, Milan, Italy
5AbbVie Inc., North Chicago/United States of America
6AbbVie Deutschland GmbH & Co. KG, Ludwigshafen/Germany

Introduction: Adalimumab (ADA) has been shown to improve clinical outcomes and health-related quality of life (HRQoL) significantly in patients (pts) with ulcerative colitis (UC) in a clinical practice setting. Evidence is limited about benefits of ADA among UC pts with different characteristics.

Aims & Methods: The aim was to examine clinical and HRQoL effects of ADA in pts with UC based on disease severity and prior use of tumour necrosis factor inhibitor (TNFi). INSPIRADA details have been published. Pts received ADA 160 mg at week (wk) 0,2 followed by ADA 40 mg at wk 4 through 26. Pts who did not respond to ADA by wk 8 were to discontinue. Pts who lost response or had severe UC pts could escalate to ADA 40 mg weekly. UC pts were categorized into subgroups based on physician global assessment (PGA) of disease severity (moderate [baseline PGA <= 2] vs severe [baseline PGA = 3]) and previous TNFi use (naive vs experienced).

Results: Among pts with moderate UC (n = 386) and severe UC (n = 74), SCCAI response rates were 74.6% vs 74.3%, 80.1% vs 71.6%, and 67.1% vs 64.9% at wk 2, 8, and 26, respectively. Although remission rates were similar between moderate and severe pts at wk 26 (49.5% vs 40.5%, p = 0.16), ADA provided greater disease control for moderate pts at wk 2 (29.8% vs 9.5%, odds ratio [OR] 4.195% confidence interval [CI] 1.8–9.1; p < 0.0001) and wk 8 (52.3% vs 31.1%, OR 2.4, 95% CI 1.4–4.4; p = 0.01) compared to severe pts (Table). The rate of disease escalation (ADA 40 mg weekly) was 28.0% in moderate and 28.4% in severe UC pts. HRQoL outcomes were similar between the moderate and severe cohorts. Among pts who were naive (n = 389) and those experienced to TNFi, remission response rates were 90% vs 74.0%, 80.9% vs 76.2%, 79.2% vs 75.5%, and 66.3% vs 68.4% at wk 2, 8, and 26, respectively. No significant difference was observed in remission rates for naïve vs experienced pts at wk 2 (28.0% vs 19.4%, p = 0.43) and wk 26 (49.4% vs 41.7%, p = 0.23), but naïve pts showed a significantly higher remission rate than experienced pts at wk 8 (52.5% vs 31.9%, OR 2.1, 95% CI 1.2–3.7; p < 0.0001). The rate of disease escalation was 26.5% in naïve vs 36.1% in experienced pts (p = 0.09). In general, HRQoL outcomes were similar between naïve and experienced TNFi pts.

Conclusion: ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFis), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFis.

Cmax ranged from 5016.4 to 14253.6 μg/mL and 10.0 to 23.1 μg/mL, respectively. The next cohort was conducted subsequently from low dose to high dose. The PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety. Bioavailability of CT-P13 SC was approximately 60.6%, (mean range 11.3 to 13.7 days vs. 11.7 to 12.2 days) between SC and IV formulation. Mean AUC0-last and T1/2 values were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in IV administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 male subjects with median age of 23 years (range 19, 30 years) were treated with CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC0-∞, Cmax, Tmax and T1/2.

Results: A total of 38 male subjects with median age of 23 years (range 19, 30 years) were treated with CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC0-∞, Cmax, Tmax and T1/2.

Conclusion: Biological therapy has been highly effective for inflammatory bowel disease (IBD). In addition to anti-tumour necrosis factor (anti-TNF) drugs, a gut-selective anti-inflammatory biologic, vedolizumab (VDZ), has been approved since 2014. However, the real-world comparative effectiveness of VDZ and anti-TNF has not been fully investigated.

Disclosure of Interest: Treatment with intravenous (IV) PT-P13, a biosimilar infliximab (INX) licensed for use in 80 countries, is highly effective and well tolerated. To increase treatment modalities with CT-P13 for patients, a new subcutaneous (SC) formulation was developed.

Aims & Methods: This phase I and open label study, conducted at a single site in Korea, was designed to evaluate safety and pharmacokinetics (PK) of SC administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC0-∞, Cmax, Tmax and T1/2.

Results: A total of 38 male subjects with median age of 23 years (range 19, 30 years) were treated with CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC0-∞, Cmax, Tmax and T1/2.
Disclosure of tumour necrosis factor antagonists (anti-TNF) treatment in this populations is ill-defined.

Aims & Methods: To assess the main adverse events (AE) of this therapy in the elderly population in comparison with the younger patients, we performed a retrospective cohort study of patients with IBD that initiated treatment with anti-TNF agents in October 2003 and 2014, with a follow-up until December 2013. Demographic, clinical and medication data were collected. AE (including opportunistic, malignancy, dermatologic, neurologic, cardiac and vascular, hepatic, infusion reactions and others) occurring during anti-TNF treatment in elderly and younger patients were analysed and both groups were compared. The severe AE definitions from Food and Drug Administration (FDA) and European Medicines Agency (EMA) were used.

Results: Of the 219 patients (55.3% women; average disease duration 13.60 ± 7.74 years), 25 were more than 65 years-old (elderly group, mean age 70.0 years vs. younger group, mean age 41.77 years). Infliximab was used in 174 patients (on average 1585 days) and adalimumab in 93 (on average 1379 days), with a total 1106 years of anti-TNF exposure. In the elderly, azathioprine was used less frequently (80.0 vs. 90.0%, p = 0.008). There were 46 severe AE overall, including 18 cancers and 16 opportunistic infections (5 tuberculosis). Malignancy (20.0% vs. 6.7%, p = 0.039) and cardiovascular events (16.0 vs. 4.1%, p = 0.036) occurred more frequently in the elderly, whereas dermatologic AE were more common in the younger group (4.0 vs. 0.0%, p = 0.044). The severe AE (24.0 vs. 20.1%, p = 0.794) including death (4.0 vs. 2.6%, p = 0.521) was not significantly different between groups.

Conclusion: Despite being at higher risk of malignancy and cardiovascular events, the total number of severe adverse events was not significantly increased in elderly patients. Particular attention to malignancy surveillance and treatment of cardiovascular comorbidities is advised in this population.

P0390 CLINICAL RESPONSE TO VEadoluzumab in IBD Patients is Associated with the Concomitant Use of ImmunoMODulators
I. Parisi, R. Vega, L. Whitely, S. Bloom, S. Mccartney
GI Medicine, University College London Hospitals, London/United Kingdom

Contact E-mail Address: ioannparisis@hotmail.com

Introduction: The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn’s disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naive patients. Multivariate analysis searched for factors associated with response to treatment.

Aims & Methods: All patients with IBD who received at least three doses of Vedolizumab in UCLH since the drug was officially licensed in the UK were included in the study. Demographics, clinical and endoscopic response rates were recorded and analysis was conducted in the whole cohort and in the subgroups of Crohn’s and UC patients separately. Univariate analysis and logistic regression were conducted in order to identify important associations with clinical and/or endoscopic response.

Results: 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn’s disease and the majority (n = 43, 73%) had mainly colonic inflammation (12 colonic Crohn’s, 29 UC, 2 IBDU). Median time from anti-TNF exposure to Vedolizumab initiation was 8 years. 17 (29%) were anti-TNF naive (all UC) and 28 (67%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either Methotrexate (18) or Azathioprine (7). 14 (24%) patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline ≥3 points for Crohn’s patients or a reduction of partial Mayo score ≥2 points for UC patients. The rates of response were similar in Crohn’s and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95%CI 0.07–0.91, p = 0.036). 11(18.6%) patients experienced adverse events while treated with Vedolizumab, five of which related to active IBD. There were two minor allergic reactions and two mild inflections.

Conclusion: Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn’s disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNFα therapies have helped improved response rates, reduced complication rates, and quality of life for patients with inflammatory bowel disease (IBD). However primary loss of response (LOR) is still a big concern. Therapeutic Drug Monitoring (TDM) potential of adjust- dosing of anti-TNFα in a treat to target fashion. The end of anti-TNFα induction therapy is a key time point in the management of IBD. TDM is a useful method to help explore an immune basis behind LOR. In addition anti-TNFα trough levels, are a significant predictor of future likelihood of clinical response and mucosal healing.

Aims & Methods: The aim of this study was to explore the relationship between infliximab (IFX) and adalimumab (ADA) trough and antibody levels with clinical response rates, at the end of anti-TNFα induction therapy. This was a prospective, single-centre study. Patients were recruited from the gastroenterology department at our centre, from July 2015 to August 2016. Inclusion criteria were all patients older than 17 years old with IBD who started treatment with anti-TNFα drugs, either infliximab or adalimumab, during the study period. Patient demographics, medication and clinical history were collected from the electronic hospital information system. Baseline clinical disease activity indexes were per- formed. The Haemorrhage Index for Crohn’s disease (CD), and partial Mayo scores for Ulcerative colitis (UC). Clinical response was defined as reduction in HBI ≤2 or reduction in partial Mayo score ≤4 and ≥30% from baseline. Anti-TNFα trough and antibody levels were measured using standard ELISA techni- ques.

Results: 35 patients were recruited: 23 CD, 12 UC. 18 patients were treated with IFX, trough and antibody levels, are a significiant predictor of future liklihood of clinical response rates. For infliximab, mean trough levels in responders was 16.4 ug/ml (IQR 4.9-22.7) versus 5.5 ug/ml (0.5-8.8) for non-responders (p value 0.026 95% CI 1.24-8.43). Antibody forma- tion occurred in 6 patients (17.1%). The patients who had primary non- response, 18/35 (51.4%) had doses of anti-TNFα escalated, 7/17 (41.1%) for infliximab, and 11/18 (61.1%) for adalimumab. 4 patients required surgical intervention. The proportion of patients with histological remission at week 8 was significantly higher in the budesonide group than in the placebo group (intention-to-treat (ITT) 79% vs 42%; p = 0.001). The difference in clinical remission at week 8 between mesalazine (63%) and budesonide (68%) was not statistically significant (p = 0.099). The proportion of patients with histological remission at week 8 was higher with budesonide (68%) than with mesalazine (26%; p = 0.02) and placebo (21%; p = 0.008). The rate of adverse events did not differ among groups.

Conclusion: Oral budesonide 9 mg once daily is highly effective and safe for induction of clinical and histological remission in lymphocytic colitis, while oral mesalazine 3 g once daily was only numerically, but not statistically signifi- cantly better than placebo.

P0394 PREGNANCY OUTCOMES IN THE TOFACITINIB ULCERATIVE COLITIS OCTAVE STUDIES

1University of California, San Francisco/United States of America/CA
2Department Of Gastroenterology And Hepatology, Charité Medical Center Virchow and Medical School of the Humboldt, University of Berlin, Berlin/Germany
3Icahn School of Medicine at Mount Sinai, New York/United States of America/ NY
4Pfizer Inc, Collegeville/United States of America/PA
5Division Of Gastroenterology, Scripps Clinic, La Jolla, San Diego/United States of America/CA
6Krankenhaus der Barmherzigen Brüder, Salzburg/Austria

Contact E-mail Address: daniel.baumgart@charite.de

Introduction: A pregnant woman with ulcerative colitis (UC), compared with age- matched controls, is at higher risk of adverse outcomes including spontaneous abortion, preterm birth and low birth weight.1,2 Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for UC. Tofacitinib has been shown to be foetidial and teratogenic in both rats and rabbits at exposures 146 times and 13 times, respectively, the human dose of 5 mg twice daily (BD). There is no adequate and well-controlled studies of tofacitinib in pregnant women.

Aims & Methods: We report the pregnancy outcomes from three randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01485951; OCTAVE Sustain, NCT01485874) and one ongoing open-label extension study (OCTAVE long-term study, NCT01470612) of tofa- citinib monoclonal antibody in patients (pts) with moderate to severe UC.3,4 Pregnancy outcomes following maternal or paternal exposure to tofacitinib or 5 mg BD were identified from Pfizer’s internal safety database up to 23 March, 2017, and categorised as: healthy newborn, medical termination, foetal death, congenital malformation, spontaneous abortion or pending/lost to follow-up. Trial proto- cols required use of highly effective contraception for females of childbearing potential, and study drug to be discontinued in any female pts who became pregnant.

Results: A total of 1139 unique pts (incl. placebo) enrolled in the UC OCTAVE trials, of whom 296 were females of childbearing age. There were a total of 25 pregnancies reported with exposure to tofacitinib. Of these, 11 were cases of maternal exposure, all during the 1st trimester, including: 2 (18.2%) spontaneous abortions (5 mg BD, n = 1; 10 mg BD, n = 1), 2 (18.2%) medical terminations (both 10 mg BD), 4 (36.4%) healthy newborns (all on 10 mg BD) and 3 (27.3%) cases of pending/lost to follow up (all on 10 mg BD). Out of the 14 cases of patient exposure, 11 (78.6%) were healthy newborns (5 mg BD, n = 2; 10 mg BD, n = 9) and 3 (21.4%) were pending/lost to follow-up (5 mg BD, n = 1; 10 mg BD, n = 2). Overall, there were no cases of foetal death or congenital malformation.

Reference
Safety assessments were performed on all patients in this study. All adverse events (AEs) during the study period were recorded. AEs for which the causality of tofacitinib could not be ruled out were defined as side effects (SEs). Feasibility problems (FPs) included blood withdrawal difficulty, venous pressure elevation, coagulation in the apheresis system and venous access difficulty. The safety of GMA was investigated in the following six special situation subgroups: the elderly (≥65 years), concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia (haemoglobin <10 g/dl), paediatric (<18 years) and other groups. We also compared AEs, SEs and FPs between the subgroups with/without each special situation by univariate analysis. The efficacy of GMA was also assessed in patients with UC. Patients with a partial UC disease activity index score (pUC-DAI) of ≤3, those with missing pUC-DAI scores and those receiving concomitant treatment with infliximab, adalimumab, tacrolimus or cyclosporine were excluded from efficacy analysis. pUC-DAI scores were calculated at the baseline and then after the final GMA session or when the GMA therapy had to be discontinued because of AEs or FPs. Remission was defined as a pUC-DAI score of ≤2 with no individual sub-score exceeding 1 point. Patients who received additional treatment by the final GMA session, including infliximab, adalimumab, tacrolimus and cyclosporine, were considered non-responders to GMA.

Results: This study included 363 patients (304 UC, 59 CD). Among these patients, SEs and FPs were observed in 3.0%, 10.7% and 16.3% of the patients, respectively. There were 105, 112, 103, 89, 43 and 39 patients in the elderly, concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia, paediatric and other groups, respectively. The incidence of AEs was significantly higher in patients on multiple concomitant immunosuppressants compared with those not receiving them. Likewise, the incidence of AEs was significantly higher in patients of the anaemia group compared with patients with haemoglobin ≥10 g/dl. The incidence of FPs was significantly lower in patients of the retreatment group with GMA than in those who received non-responders to GMA. The pUC-DAI score significantly decreased from 6.2 at baseline to 3.4 after the final GMA session (P < 0.001) and the remission rate at the final GMA session was 43.5%.

Conclusion: This multi-centre observational study showed that GMA has an acceptable safety profile in IBD patients and sufficient effectiveness in UC patients who have special situations. However, care should be taken when GMA is used in patients with anaemia or those who have received concomitant treatment with multiple immunosuppressants.

state-wide hospital records. Psychological support was offered where scores on HADS and/or K6 indicated likely need.

Results: 506 patients were approached during the 12-month screening phase; 50.6% were male, 70.8% used clean intermittent catheterization, mean disease duration of 11.4 years, 43.3% in clinical remission, and 9.8% current smokers (Australia’s average 13.3%). Of these 506, 67% participated in psychological screening, 38% scored within the clinical range, and 17% accepted psychological support. Gender was a significant predictor of participation in psychological screening: women were 62% more likely to participate than men. Analogies and/or mental health medication increased the likelihood of scoring within the clinical range nearly fivefold (analyse use OR = 5.32, p = .030; psycho OR = 6.94, p = .001). Significant predictors of accepting psychological treatment included older age (OR = 1.03, p = .041), anxiety (OR = 1.09, p = .045), general distress (OR = 1.11, p = .003) and lower quality of life (OR = 0.93, p = .042). At baseline, anxiety and depression were both negatively correlated with medication adherence (anxiety r = -.323, p = .000, depression r = -.200, p = .000) and overall quality of life (anxiety r = -.708, p = .000; depression r = -.787, p = .000). Depression and general distress were related to overall healthcare utilisation (depression r = -1.31, p = .016, general distress r = -1.124, p = .026). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of emergency department presentations (r = 1.24, p = .024), outpatient appointments (r = -119, p = .030), and appointment cancellations (r = -155, p = .055). Currently, approximately half of the twelve month follow-up data has been collected. Preliminary analysis shows improvements for patients’ mental health, quality of life and medication adherence (see table below).

Conclusion: Psychological issues are prevalent in patients with IBD and associated with decreased quality of life and medication adherence. Screening is more likely to participate in psychological screening, and in general the screening approach was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrate a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

Introduction: Demonstration of biosimilarity is based on the evaluation of pharmacological, biological, preclinical, and clinical data. Based on this totality of evidence, a biosimilar may be approved for use in the same indications for which the reference medicine is approved without conducting a clinical trial in each indication. A prerequisite for this extrapolation is clinical confirmation of biosimilarity in a patient population sensitive enough to detect potential differences in efficacy, safety, or immunogenicity between the proposed biosimilar and the reference medicine. GP2017, a proposed biosimilar to adalimumab, was approved, including inflammatory bowel disease.

Aims & Methods: To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients were moderate-to-severe chronic plaque psoriasis randomized to receive an initial dose of 80mg subcutaneous GP 2017 or reference adalimumab, followed by 40mg every other week, starting one week after the initial dose, up to 17 Week. At Week 17, patients with ≥50% improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial study treatment or undergo a sequence of three treatment switches between GP 2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

Results: From randomization to Week 51, 168 and 171 patients received continuous treatment with GP 2017 or reference adalimumab, respectively. In the protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 51 were 75.2% and 79.2%, respectively. The investigator’s global assessment (IGA) response rates (IGA score of 0 [clear] or 1 [almost clear] and ≥2 point improvement from baseline) were similar between the continual GP2017/reference adalimumab groups, improving from time and remaining stable from Week 17 (60.5% [53.9%]) to Week 51 (59.8% [55.1%]). There were no clinically relevant differences between the continual GP2017/reference adalimumab groups in the frequency of adverse events (AEs) (61.3%/64.9%), treatment-related AEs (17.9%/18.7%), serious AEs (3%/3.8%), or AEs leading to discontinuation of study drug (7.9%/7.8%). Infections/infestations were the most commonly reported AEs, with nasopharyngitis most frequently reported by 8.9%/10.5% of patients treated with continual GP2017/reference adalimumab. Between Weeks 1 and 51, binding antidrug antibodies were detected in 38.8%/45.3% of patients treated with continual GP2017/reference adalimumab, 88.7%/84.7% of which were neutralizing.

Conclusion: Efficacy was similar and sustained in patients with psoriasis continuously treated with GP 2017 or reference adalimumab for up to 51 weeks. Safety profiles and immunogenicity were generally similar in both groups. Clinical data add to the totality of evidence suggesting GP 2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved, including inflammatory bowel disease.

Introduction: Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processing 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.
Aims & Methods: We performed a retrospective study of all patients treated with GMA (Adacolumn) in 3 IBD Units in Spain. The clinical and analytical data were assessed before and 1 month after the end of the GMA. The Ethics Committee of Euskadi approved the study protocol. The aim of our study was to evaluate the presence of clinical, analytical of technique-related factors associated to a better response to GMA.

Results: A total of 105 patients were included (51 female, 49%, age 35.7 (SD 16.5). Ninety-three had UC (50% extensive, 45% left-sided), 10 Crohn’s disease (90% ileocolonic) and 2 IBD-U. Mayo score at baseline was 3.5 (SD 4.6) and Harvey – Bradshaw was 10.1 (SD 3.8). The Mayo endoscopic subscore was 1 (16%), 2 (56%) or 3 (27%). Almost all patients (97%) have been previously treated with steroids and 42% were exposed to biologics. At baseline, 85% were on steroids, 38% thiopurines and 18% biologics. None of the previous or concomitant treatments were associated with a better response to GMA. Fifty-six subjects received weekly sessions for 5 weeks processing 1800 ml/session in 60 minutes. Forty patients received an intensive GMA regimen: biweekly sessions with a mean of 8 sessions (SD 2.6), processing 388 ml/session (SD 1729) and lasting 1 minute (SD 24). The intensive group showed a slightly higher response rate to GMA as compared with those in the standard regimen (response rate 67% vs 55%, p = 0.28). Those subjects treated with > 5 sessions showed higher remission (24% vs 13%) and response rates (47% vs 24%) as compared to <5 sessions (p = 0.004). A mean duration of >60 min/session also showed better results in terms of remission (22% vs 16%) and response (45% vs 27%) when compared to <60 min/session (p = 0.04). There was also a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond. Considering its clinical efficacy in this clinical practice study. Increasing the number of sessions or its length were associated with a better response to GMA. The mean platelet volume and the platelet to lymphocyte ratio could help to predict the response.

Andecaliximab in subjects with active Crohn’s disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds to CAM-5.7 and inhibits MMP-9. It was found to be safe in a phase 1 dose-ranging study in UC subjects, where it showed clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab in patients with active Crohn’s disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds to CAM-5.7 and inhibits MMP-9. It was found to be safe in a phase 1 dose-ranging study in UC subjects, where it showed clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab in patients with active Crohn’s disease (CD).

Aims & Methods: This was a double-blind, randomized, placebo-controlled 8-week induction study in adult CD subjects with moderate to severe disease activity (defined as: CDAI score total 220–450, weighted PR2 score ≥11 [standard CDAI weightings: abdominal pain 0–3 x7 plus mean number of daily stools x2] and SES-CD total score ≥6 [or ≥4 score if disease limited to ileum and/or right colon or ulcer presence and size score ≥2]). Subjects were required to have an inadequate response, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-alpha antagonist or vedolizumab. Subjects were randomized 1:2:2:2 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W), 150 mg andecaliximab weekly (QW) or 300 mg andecaliximab QW. Centrally-read colonoscopies/colonoscopy were performed at baseline and week 8. The primary outcome was EBS clinical remission, defined as an Endoscopic subscore of ≤1, rectal Bleeding subscore of 0, and ≥1 point decrease in Stool frequency from baseline to achieve a subscore of 0 or 1. Results: A total of 165 subjects from 23 countries were enrolled. The percentage (confidence intervals) of subjects achieving EBS clinical remission was similar between subjects treated with andecaliximab Q2W and placebo: 7.4% (2.1–17.9%), 1.8% (0.9–6.9%) and 7.3% (2.0–17.6%), respectively. Confidence intervals overlap for all groups and no single EBS component subscore appears to have driven the results. No concerning imbalances occurred between the treatment groups (Table 1).
P0401 TUBERCULIN SKIN TEST CONVERSION RATE IN INFILTRATORY BOWEL DISEASE PATIENTS RECEIVING ANTI-TNF ALPHA AGENTS

M. Fragkaki, A. Mptouti, I. Dimas, G. Paspatis, K. Karmiris
Gastroenterology, Venizelion General Hospital, Heraklion/Greece
Contact E-mail Address: gpaspatis@gmail.com

Aims & Methods: Few data exist regarding the kinetics of this test during therapy. Therefore, we investigated the conversion rate of PPD-TST in IBD patients under anti-TNFalpha treatment. Anti-TNFalpha-treated IBD patients followed up in our centre with a baseline PPD-TST underwent a second one during therapy. Those with a positive PPD-TST either at baseline or during therapy (> 10 mm in naïve and > 5 mm in those exposed to immunomodulators [IMS]) received 300 mg isoniazid orally for 9 months.

Introduction: Anti-TNFalpha therapy increases the risk of tuberculosis (TB) (re)activation in inflammatory bowel disease (IBD) patients. Purified protein derivative tibial tuberculin skin test (PPD-TST) is considered a pre-requisite at baseline.

Results: Sixty-eight IBD patients have currently been enrolled (males: 51.47%, median age at IBD diagnosis: 33.1 years [IQR: 20.3, range: 16.7–66.7], median duration of IBD was 7.7 months [IQR: 9.9, range: 4.3–24.7]). Nine patients (13.2%) had a positive PPD-TST at baseline, 48 patients have undergone a second PPD-TST (median time between the 1st and 2nd PPD-TST: 44.26 months [IQR: 42.8, range: 6.3–190.1]). Twenty patients were under combination therapy with an IMS at the 2nd PPD-TST. Six patients with a positive baseline PPD-TST remained positive (in 5 patients the diameter was decreased & in one increased 7 mm). Out of the remaining 42 patients with a negative baseline PPD-TST, eight (19%) exhibited a positive 2nd PPD-TST; three of them were receiving infliximab for less than 3 years and five of them adalimumab (for less and 3 for more than 3 years). Only 2/8 were under combination therapy. There was no case of active tuberculosis during the study. All patients with a PPD-TST conversion received anti-tuberculous treatment.

Conclusion: A positive PPD-TST followed by anti-TB treatment before the initiation of anti-TNFalpha in IBD patients was not associated with an increased rate of TB infection during therapy. One-fifth of the patients with a negative baseline PPD-TST demonstrated a conversion but without any undesirable consequence if so treated. Therefore, the kinetic of PPD-TST in IBD patients under anti-TNFalpha treatment should be monitored.

P0402 THE TEMPORAL EVOLUTION OF IMMUNOGENICITY IN INFILTRATORY BOWEL DISEASE PATIENTS TREATED WITH ADALIMUMAB

Introduction: Adalimumab and anti-adalimumab-antibodies (AAA) levels have been associated with clinical outcome of Crohn’s disease (CD). Nevertheless, because adalimumab is usually self-injected at home, prospective serial-sampling studies are scarce. Thus, data on the temporal evolution of adalimumab immunogenicity is still limited, and the validity of comparisons of adalimumab versus infliximab immunogenicity remains questionable.

Aims & Methods: Our aim was to assess trends in adalimumab and AAA levels over time and their clinical implications. CD patients starting adalimumab therapy were followed prospectively in three participating medical centers in Israel, by establishing a program for home-visits by physicians at induction and every 3 months, or in case of relapse. At each home visit, patients’ clinical activity score were determined and blood tests obtained for CRP, drug and AAA trough levels. AAA levels were determined by a drug-tolerant assay. A comparison with temporal evolution of infliximab immunogenicity in a previously reported cohort using the same assay and methodology was additionally performed.

Results: 102 CD patients starting adalimumab were prospectively followed. Fourteen (14%) experienced primary non-response and 20 (20%) lost response to adalimumab therapy during maintenance. Thirty-three (32%) developed AAA, which were more common among those previously exposed to adalimumab (p = 0.002) but were not affected by co-treatment with immunomodulators or not (p = 0.28). AAA developed as early as week 2 in 18/33 (55%) of AAA positive patients (7/18 with history of interrupted therapy), and in 26/33 (79%) within 24 weeks. Thirty-two of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation rate over time was significantly lower (p = 0.01, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, p < 0.0001), and 85% of AAA events were associated with loss of response compared with 58% rate for ATI (p = 0.01).

Conclusion: AAA formation often occurs earlier than anticipated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenicity is lower for adalimumab compared to infliximab. However, once they occur, AAA are more specific to ATI.
of GLB with 47–49% of patients maintaining the effect after one year. Due to its relatively recent use there are still few real-life data on clinical outcomes of patients receiving golimumab in the routinely activities. In our region GLB became available starting July 2015.

Aims & Methods: Aim of this study has been to prospectively evaluate the efficacy of golimumab for the treatment of UC in the real-life setting of our referral centre. 13 patients (7 male, 6 female) with moderate-to-severe UC were enrolled in the study from June 2015 to December 2016. Patients received an induction dose of GLB 200 mg s.c. at baseline, 100 mg at week 2 and then a maintenance dose of 100 mg for a body weight > < 80 kg, respectively, with no optimization allowed. Partial Mayo score was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score > 30% and > 3 points vs baseline) and in the maintenance period, the secondary end point being the steroid-free clinical remission (Partial Mayo score < 2 with all subscores < 1) at the end of the induction phase and throughout the maintenance phase. Complete follow-up is available for all patients at week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sided colitis (EL) in 70%, pancolitis (EC) in 23% and proctitis (EP) in 7% of patients. Ten patients (77%) were anti-TNF naïve, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/13 (62%). Three patients resulted in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission. One patient is in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and non-naïve patients. No significant adverse events were reported in the study period.

Conclusions: Our results seem to suggest that Golimumab, as compared to registratory trials, is able to induce a better initial clinical response but shows a higher secondary response of the disease in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimization, not allowed in the Italian prescription rules for GLB, needs to be evaluated.

Disclosure of Interest: All authors have declared no conflicts of interest.
delivery. An acute high fermentable fibre intake delays drug dissolution in the colon, but had little influence over total release. These findings have implications for optimising drug selection in maintenance of remission in UC.

**Introduction:** Golimumab (GLM) is a subcutaneously administered anti-tumour necrosis factor (anti-TNF) antibody that is approved for the treatment of moderate to severe ulcerative colitis (UC). We investigated the association between systemic exposure (area under the curve (AUC)) of GLM during induction therapy and endoscopic response in moderate-severe UC.

**Aims & Methods:** In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopy score ≥2) received induction treatment with GLM 200 mg SQ at week 0 and 100 mg (at week 2) followed by 50 or 100 mg at week 6, in patients with a bodyweight of less or more than 80 kg, respectively. Serum GLM concentrations were measured at day 0, 4, 7, 14, 18, 28, 42, and 56, as well as anti-GLM antibody levels, C-reactive protein (CRP) and albumin serum concentrations. Serum GLM concentrations were measured with an enzyme-linked immunosorbent assay and anti-GLM antibody levels were measured with a drug-sensitive antigen binding test, both developed by Sanquin laboratories. Endoscopic response was defined as ≥1 point reduction in endoscopic Mayo score at week 8–10 compared to baseline.

**Results:** A total of 20 patients were enrolled of which 19 patients underwent an endoscopy at baseline and 8–10 weeks after start of treatment. Median age (interquartile range) was 46 years [36–57], median baseline CRP serum concentration was 4.5 mg/L [1.1–13.7] and median baseline albumin serum concentration was 44 g/L [40–45]. None of the patients developed antibodies against GLM during induction treatment. After the induction phase, 12 out of 19 patients (63%) achieved an endoscopic response. Median AUC at week 2 and 6 was higher in endoscopic responders compared to non-responders. Median GLM trough concentrations at week 2 and 6 were higher in endoscopic responders compared to non-responders (Table 1). Correlations between GLM trough concentrations and AUCs at week 2 (Pearson correlation coefficient: 0.86, P < .0001) and week 6 (Pearson correlation coefficient: 0.81, P < .0001) were statistically significant. Despite a low area under the ROC-curve (AUROC), a GLM serum trough concentration ≥3.3 mg/L (AUROC: 0.75, 95% CI: 0.526–0.974, sensitivity: 67%, specificity: 71%) was associated with endoscopic response after the induction phase.

**Conclusion:** Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 was associated with improved endoscopic outcomes.

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor being investigated for moderately to severely active ulcerative colitis (UC). We performed a systematic literature review (SLR) and network meta-analysis (NMA) to compare the efficacy and safety of tofacitinib to available tumour necrosis factor inhibitors (TNFi) and integrin receptor antagonists for induction therapy of adults with moderately to severely active UC.

**Aims & Methods:** Using indexing and free-text terms, searches were conducted in the EMBASE, MEDLINE, CENTRAL, DARE and CINAHL databases to identify RCTs published as of January 2015. Proceedings of relevant conferences from 2012–2014 were also reviewed. Comparators of interest were infliximab, golimumab, adalimumab and vedolizumab. Two reviewers independently assessed studies for inclusion, and extracted and validated the study/patient data. Fixed- and random-effects Bayesian NMAAs were conducted to compare efficacy outcomes and rates of adverse events (AEs) at 6–12 weeks in the overall population (TNFi-naive or exposed) and by prior TNFi exposure.

**Results:** Twelve induction trials were identified from the SLR (ACT 1 & 2, EUCLYPUS, GEMINI-I, PURSUIT SC, TOFACITINIB PHASE 2, Feagan 2005, 1 PROCTER 2003, UC-SUCCESS, ULTRA 1, ULTRA 2, Suzuki 2014) and included in the NMA. Unpublished data from tofacitinib Phase 3 induction trials (OCTAVE 1 & 2) were also used in the analysis. Fixed-effects NMA showed that tofacitinib 10 mg twice daily (BID) is associated with a higher rate of mucosal healing 86/90 mg in the overall population (odds ratio [OR] 95% CI 1.82 [95% credible interval (CrI) 1.06, 3.14]), and vs vedolizumab 300 mg (OR 3.71 [95% CI 1.37, 10.64]) and etrolizumab 300 mg (OR 12.09 [95% CI 1.68, 22.73]) in TNFi-exposed patients. A higher rate of clinical remission was seen with tofacitinib 10 mg BID vs adalimumab in TNFi-exposed patients (OR 11.93 [95% CI 1.84, 15.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall and TNFi-naïve populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

**Conclusion:** This NMA suggests that tofacitinib may be more effective as induction therapy in moderately to severely active UC than adalimumab and vedolizumab in TNFi-exposed patients, and is associated with a higher rate of mucosal healing than adalimumab in the overall population. Rates of specific safety events were similar between tofacitinib and all other treatments.

serious adverse events (SAE) that patients experienced were documented.

anti-drug antibodies [ADAs]. Patients were asked to fill in SIBDQ and Mayo or reactive protein [CRP], fecal calprotectin [FCP], infliximab trough level [TL] and alpha (TNF-α) inhibitors, such as Infliximab (IFX), are a major component in inducing and maintaining remission in more refractory patients. Recently IFX-biosimilars have been introduced for the treatment of IBD, these are less expen-

mary endpoint was number of patients in remission at week 30. We measured C-

Conclusion: This is the first double blind randomized clinical trial that compares SAE, none were related to the study drug.

Mean age at inclusion was 42 years. 21 patients have finished the 30-week follow-

pitals. 35 patients had CD and 12 had UC. 27 patients were female, 20 were male.

Patients in both arms received 4 to 6 doses of 5 mg/kg to 10 mg/kg during the 30-

week study period. Patients eligible for inclusion had to be in clinical remission (HBI < 5 and MAYO ≤ 2) and have a fecal calprotectin ≤ 250 mg/g. The primary endpoint of patients in remission at week 30. We measured C-reactive protein [CRP], fecal calprotectin [FCP], infliximab trough level [TL] and anti-drug antibodies [ADAs]. Patients were asked to fill in SIBDQ and Mayo or HBI questionnaires three times during the study period. Adverse events (AE) and serious adverse events (SAE) that patients experienced were documented.

Results: So far, we included 47 patients from 6 secondary Dutch Teaching hospi-

tals. 35 patients had CD and 12 had UC. 27 patients were female, 20 were male.

Mean age at inclusion was 42 years. 21 patients have finished the 30-week follow-

up. 35 patients received IFX-biosimilar. One patient experienced a relapse of IB, this patient received IFX-biosimilar. 2 patients experienced a SAE, none were related to the study drug.

Conclusion: This is the first double blind randomized clinical trial that compares treatments with IFX-biological or IFX-biosimilar. The preliminary results show that switching from IFX-biological to IFX-biosimilar is feasible and safe.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Introduction: Crohn’s disease (CD) and ulcerative colitis (UC) are the main enti-
ties of inflammatory bowel disease (IBD). For most patients, medical treatment is sufficient to keep the disease in remission. However, a simple increase in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0411 ENCAPSULATED FECAL MICROBIOTA TRANSFER IN PATIENTS WITH CHRONIC, ANTIBIOTIC-REFRACTORY POUCHITIS

A. Steube1, M. Vitali2, A. Sturm2, C. Bunning3, A. Stallmach1, D. Pieper2

3Department Of Internal Medicine, Krankenhaus Wallhöfde, Berlin-Zehlendorf/ Germany

Contact E-mail Address: andreas.stallmach@mail.uni-jena.de

Introduction: We analyzed the success of fecal microbiota transfer (FMT) via encapsulated or endoscopic jejunal application to 14 patients with chronic, anti-

bacterial refractory pouchitis. After FMT, FMT was performed either via encapsulated cryopreserved microbota or via endoscopic jejunal application to 14 patients. Stool samples for FMT preparation derived from three unrelated healthy donors. Patients were treated by FMT every 4 weeks according to the individual therapeutic outcome.

Stool samples before FMT and during follow-up were subject to microbial community structure analysis through high throughput sequencing of the V1-V2 regions of the 16S rRNA (1), clinical response and mucosal inflammation was assessed by fecal calprotectin (FCP) levels.

Results: Clinical response occurred in 7 of 14 patients after two to four FMTs. 4 patients showed clinical worsening and 3 patients showed no improvement. FCP dropped in responders from 536 mg/kg stool (med.; min-max: 116–3000) to 150 mg/kg (191-1409), whereas in patients with flare FCP values increased from 100 mg/kg (157) to 1450 mg/kg (1221–1778). Microbiota analysis of 10 patients and two donors revealed a significantly lower diversity in pouchitis patients compared to healthy donors as assessed by the total phylotype number, the Shannon diversity and Pielou’s evenness. In patients showing response, typi-

ical response occurred in diversity was due to the successful establishment of the donor microbiota as assessed by the analysis of sample-similarity matrices constructed using the Bray-Curtis algo-
rithm and a detailed analysis of the taxonomic composition. The encapsulated fecal microbiota was as effective as the endoscopic jejunal application in its capacity to restructure the pouch microbiota and increase the diversity and an overall restructuring of the microbial biota into a composition resembling the donor not necessarily correlated with clinical outcome and clinical worsening was observed during three FMTs where the established microbiome structure resembled that of the donor in diversity and composition.

Interestingly, a high abundance of Ruminococcaceae was associated with remis-
sion in a recent study on ulcerative colitis (2). However, two patients showed worsening here despite a high increase in the relative abundance of Ruminococcaceae after FMT.

Conclusion: Fecal microbiome transfer in patients with chronic pouchitis is a promising therapeutic option and donor microbomas could successfully be transferred via capsules or via jejunoscopy delivering fresh stool filtrate. However, simple increase in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0412 HISTOLOGIC MEASURES OF MUCOSAL HEALING CORRELATE WITH ENDOSCOPIC MEASURES OF DISEASE ACTIVITY AT BASELINE AND FOLLOWING INJECTION THERAPY WITH THE JAKI INHIBITOR FILGOTINIB IN ACTIVE CROHN’S DISEASE: RESULTS FROM FITZROY STUDY

Introduction: Mucosal healing (MH) has been established as co-primary treat-

ment target in Crohn’s disease, predominantly defined by the absence of ulceration. However, even in patients with MH, inflammation may persist on histologic examination1. Filgotinib (FIL), a selective inhibitor of JAK1 that blocks cytokine signaling through inhibition of STAT phosphorylation, has recently shown effi-
cacy in a double-blind, placebo (PBO)-controlled Phase 2 study in CD (Fitzroy2). Effects of filgotinib versus placebo have been demonstrated on centrally read endoscopy and histopathology assessments after a 10-week induc-
tion treatment.

Aims & Methods: In this post hoc analysis, we explored the correlation between histologic and endoscopic disease activity at baseline (BL) and following FIL indution therapy by comparison of total ileal Global Histology Activity Score (IGHAS)/colonic GHAS (CGHAS) score or IGHAS/CGHAS activity subscores (a; activity items: presence of epithelial damage, polymorphonuclear leukocytes in lamina propria, neutrophils in epithelium, erosion or ulceration, granuloma)3, versus total ileal Simplified Endoscopic Score for CD (ISES-CD)/colonic SIES-

CD (CSES-CD) score or ISES-CD/CSES-CD ulcer subscores (u; sum of size and % affected surface). CD patients were randomized 3:1 to receive 200 mg FIL or PBO QD for 10 weeks2. Intestinal biopsies were collected at BL and Week 10 (W10) from the most affected areas of each predefined bowel segment (ileum, ascending, transverse, descending, sigmoid colon and rectum). Biopsies were formalin fixed and paraffin embedded. The mean changes from baseline for each treatment group were compared to zero using a single t-test.

Results: Baseline values were comparable across treatment groups, although CGHAS and CSES-CD were numerically higher in the PBO group (Table 1). Following 10 weeks of treatment with FIL 200 mg, histologic measures of colonic mucosal healing (IGHAS and ISES-CD) were significantly improved and were coupled with macroscopic changes in both CSES-CD and uCSES-CD. Changes in histology score for ileal segments were numerically greater after FIL treatment versus placebo. Histology total and subscores were significantly higher in patients with total and endoscopic ulcer subscores at baseline, and more pronounced when looking into the colonic segments versus the ileal seg-

ments (IGHAS > ISES-CD: Corr = 0.62, p < 0.001; Corr = 0.65, p < 0.001;BL and W10 respectively)aghv > uCGHAS \( r = 0.53, p < 0.001 \)}
**CROHN'S STUDIES**

**P0413 RESPONSE AND REMISSION AFTER 16 WEEKS OF USTEKINUMAB—AN ALL PATIENTS ANALYSIS FROM THE UNITI CROHN’S STUDIES**

Introduction: Ustekinumab (UST) has been shown to induce and maintain clinical response and remission in moderate to severe Crohn’s disease (CD) in 2

induction ([UNITI-1 (anti-TNF failures) and UNITI-2 (anti-TNF non-failures) and 1 maintenance (IM-UNITI)] randomized, placebo controlled Phase 3 trials. We evaluated the efficacy (response and remission) for all patients who received an intravenous (IV) induction dose of approximately 6 mg/kg, including responders (CDAI decrease ≥100) and non-responders, 8 weeks after the first UST maintenance dose of 90 mg subcutaneous (SC), i.e. 16 weeks from the IV induction dose.

**Aims & Methods:** Patients achieving clinical response 8 weeks after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w dosing. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249 and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The remission rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7 vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

**Results:** Of the 219 patients not in clinical response in UNITI 1&2, 37.6% and 60.5% respectively were in clinical response 8 weeks after the first maintenance UST dose (90 mg SC). Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection (16 weeks after the IV induction dose) for UNITI1&2 are 47.4% and 73.7% respectively (see table for response and remission rate). Similar assessments were calculated in the sub-population who were anti-TNF naïve upon enrolment into UNITI-2.

**Response rates and Remission rates for all patients 16 weeks after induction of 6mg/kg IV UST**

</tbody>
</table>

**Conclusion:** These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.

**Disclosure of Interest:** J. Colombel: Investigator for Janssen Scientific Affairs, LLC
Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naive. All patients with IBD (ulcerative colitis or Crohn’s disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥3 infusions within 98 days of index date); (2) were ≥18 years of age at index; (3) had ≥365 days of medical history prior to index (“baseline”); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic <90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids), respectively. Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ~60% of patients in each cohort. In the baseline period, ~70% of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 3.1 years for IFX initiators. Median time to treatment discontinuation was 244 (IQR for VDZ: 194–307 and IFX: 190–300) days in both cohorts. Median time to first VDZ-related hospitalisation was 153 (IQR: 78–209) days for VDZ initiators vs. 98 (IQR: 45–168) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Conclusion: Among biologic-naive IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

Receptor Superfamily Member 1A (TNFRSF1A) with Bifidobacterium (n = 0.89, p < 0.01).

Conclusion: The intestinal antimicrobial gene profiles differ between subsets of IBS patients and healthy subjects. An altered ability to recognize microbiota associated with immune activity and the relative abundance of gut bacteria may play a role in the complex pathophysiology of IBS.

Introduction: Recently, accumulating evidence suggested that the dysbiosis of the intestinal microbiota was associated with increased risk of colorectal cancer and might play a significant role in the colorectal carcinogenesis [1-2]. Many environmental factors (e.g. diet and lifestyle) that altered the gut microbiota had been reported in the development of colorectal cancer[3]. Antibiotics are able to shift the gut microbiota by altering bacterial composition and functions. The overuse of antibiotics is associated with such adverse effects, such as severe infections, obesity, inflammatory bowel disease. Similarly, it is plausible to hypothesize that overuse of antibiotic might be linked to CRC by altering the colonic microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4-7].

Aims & Methods: To evaluate the association between use of antibiotic and the risk of developing colorectal cancer, a systematic literature search was conducted using PubMed, EMBASE, Web of science and Cochrane library to identify related studies published before October 2016. Two independent investigators screened and extracted data from included articles. A random-effects model was adopted to calculate overall odds ratio (OR) and 95% confidence interval (CI).

Results: From initial search, we identified four case-control studies and finally included in the meta-analysis. Compared with no/low use of antibiotics, high prescriptions of antibiotics were significantly associated with an excess cancer risk (OR = 1.11, 95%CI 1.01–1.21). There was a significant heterogeneity across studies ($I^2 = 62.1%$, $p = 0.048$). Longer duration of antibiotics was also significantly correlated to increased risk of CRC (OR = 1.14, 95%CI 1.03–1.25) with no significant heterogeneity ($I^2 = 39.6%$, $p = 0.191$). There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Higher prescriptions and longer duration exposure of antibiotics were associated with increased risk of developing colorectal cancer. Further studies are needed to verify our results and explore underlying mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the effect of internal and external drainage on obstructive jaundice rats on intestinal mucosal barrier function with special reference of intestinal immune-related index expression. Sixty male Sprague-Dawley rats were randomly assigned to four groups: OJ, sham operation (SH), internal biliary drainage (ID) and external biliary drainage (ED). All animals underwent surgical ligation of the bile duct, except SH was produced by separating common bile duct locally but not dividing on day 1. Then ED and ID were reoperated on day 8 for biliary drainage procedure. Blood from inferior vena cava were collected for the test of DAO and slgA activities by the method of ELASA.

The terminal ileum specimens of each groups were collected for observation of the morphological changes with haematoxylin-eosin (HE) staining. The expression of IgA mRNA, plgR mRNA, GB-AP1mRNA, RD-5mRNA were measured by real-time PCR.

Results: After bile duct ligation, the injuries of the intestinal mucosa were obvious in OJ group with thinner mucosa, sparser villi, destruction of the epithelial cell and accompanied by inflammatory cell infiltration. The expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01), while the impaired intestinal mucosa have different degrees of recovery and ID group was more similar to SH group in intestinal mucosal morphology. The levels of the DAO in OJ group was increased more dramatically than that in SH, ID and ED groups while slgA were decreased (P < 0.01), and the activities of the DAO, slgA in ID group were similar to the level of SH group (P > 0.05), different to the level of ED group (P < 0.01). The changes of the plasma DAO and slgA activities were significantly correlated with the conditions of intestinal mucosa (P < 0.01). The expression of RD-5 mRNA in OJ group were decreased significantly than that in SH, ID and ED groups while GB-AP1 mRNA, IgA mRNA, plgR mRNA were increased (P < 0.01). Interestingly enough, after external bile drainage, there is no improve-ment in IgA mRNA and plgR mRNA (P > 0.05). But in ID, the relative expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01), while the mRNA expression of GB-AP1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GB-AP1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of in SH group (P < 0.01). After internal and external biliary drainage to alleviate OJ respectively, the GB-AP1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, P < 0.01, ID vs SH, P > 0.05), and lower than that of in ED group (P > 0.05).

Conclusion: The differential expression of IgA mRNA, plgR mRNA, GB-AP1 mRNA, RD-5 mRNA and activities of DAO and slgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a new protective mechanism between GB-AP1 and intestinal immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosal barrier. P0419 COMPARATIVE EFFECT OF XYLOGLUCAN ASSOCIATIONS WITH COMPOUNDS FROM ANIMAL OR ALGAE ORIGIN ON LPS-INDUCED ENTERITIS IN RATS
H. Eutamene, C. Harkat, V. Theodorou

Introduction: Xyloglucan (XG) is a film-forming agent exhibiting protective effects against diarrhea linked to infectious gastroenteritis in humans; further in animal models, xyloglucan efficacy against cholera-toxin-induced diarrhea was tested prolonged when this mucoprotectant agent is associated with gelatin from animal origin. The use of compounds from animal source in galenic formulations is nowadays questionable.

Aims & Methods: Thus, in this study, we aimed at comparing the efficacy of XG associated with gelatin vs XG associated with gelose a marine polysaccharide on LPS-induced enteritis in rats. Since LPS-induced enteritis is characterized by increased intestinal permeability and mucosal inflammation, the efficacy of xyloglucan associations was evaluated by measurement of these two parameters. Male Wistar rats (200-250 g) were orally treated with either XG (10 mg/kg) + gelatin (25 mg/kg) or XG (10 mg/kg) + gelose (25 mg/kg) or XG (10 mg/kg) + gelose (50 mg/kg) or vehicle (NaCl 0.9%) 3 h before intraperitoneal (IP) administration of LPS from E. coli (1 mg/kg). Six hours later APS administration, the animals were sacrificed and strips of ileum were collected in order to evaluate (i) intestinal epithelial paracellular permeability to FITC-dextran 4Kd in Ussing chambers and (ii) mucosal inflammatory response by myeloperoxidase (MPO) activity measurement.
Results: Compared with control, LPS administration induced a significant increase (p < 0.05) of intestinal paracellular permeability (53.0 ± 4.9 vs 181.6 ± 21.1 pmol/cm² respectively) associated with jejunal mucosal inflammation (302.1 ± 9.5 vs 655.6 ± 108.9 U MPO/g protein, respectively). XG (10 mg/kg) + gelose at the lowest dose (25 mg/kg) failed to reverse the intestinal hyperpermeability and mucosal inflammation induced by LPS. In contrast, XG (10 mg/kg) + gelatin (25 mg/kg) and XG (10 mg/kg) + gelose at 50 mg/kg significantly (p < 0.01) and equally prevented LPS-induced hyperpermeability (34.8 ± 2.8, 38.7 ± 3.9 vs 181.6±21.1 pmol/cm² respectively) and jejunal inflammation (27.70 ± 32.2, 286.2 ± 28.8 vs 655.6 ± 108.9 U MPO/g protein respectively).

Conclusion: This study shows that oral treatment with xylanoglucon associated with gelose at 50 mg/kg has similar protective effects on LPS-induced enteritis in rats than xylanoglucon associated with gelatin. These data demonstrate that algae are an effective and safe substitute for replacing compounds from animal origin in xylanoglucon mucoprotectant formulations.

P0421 CLINICAL CHARACTERISTICS OF CYTOMEGALOVIRUS COLITIS: 15 YEAR-EXPERIENCE IN A TERTIARY MEDICAL CENTER

P. Le1, R. Wu2, C. Chiu1, C. Kuo1, M. Su1, C. Lin1, J. Hsu3
1Department Of Gastroenterology And Hepatology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan
2Department Of Pathology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan
3Department Of General Surgery, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan

Contact E-mail Address: puoshin@gmail.com

Introduction: Cytomegalovirus (CMV) colitis in adults is mostly described in immunocompromised patients (solid organ or hematopoietic stem cell transplant recipients, patients with human immunodeficiency virus (HIV) infection, use of immunosuppressive drugs, including steroid or chemotherapeutic agents), and often has worse outcome than in children. Besides, it was also frequently presented in patients with known or subsequent new diagnosis inflammatory bowel disease [1, 2]. However, there are only case reports and few case series with limited patients (below 15 cases) among immunocompetent individuals without inflammatory bowel disease [3-5]. The largest meta-analysis study of cytomegalovirus colitis in immunocompetent hosts included 44 patients and noted advanced age, male gender, presence of immune-modulating comorbidities and need of surgical intervention negatively influencing survival in 2005 [6].

Aims & Methods: We enrolled 42 immunocompetent patients and 27 immunocompromised patients with CMV colitis diagnosed by immunohistochemistry stain between April 2002 and December 2016 in Linkou Chang Gung Memorial Hospital, a 3383-bed tertiary medical center and referral center in Taiwan. We analyzed the risk factors of in-hospital mortality and overall survival. Furthermore, we compared the clinical differences between immunocompetent and immunocompromised patients with CMV colitis.

Results: Early diagnosis (before 9 days) was independent predictor of in-hospital mortality in CMV colitis patients. ICU admission (P = 0.010), requisites days of diagnosis>9 days after admission (P = 0.018), shock (P = 0.001), respiratory failure (P = 0.033), hemoglobin <10 g/dL (P = 0.002), Creatinine ≥1.37 mg/dL (P = 0.004) and CRP>29 mg/dL (P = 0.011) negatively impacted on overall survival. There were older and more comorbidities in immunocompromised group. However, the in-hospital mortality rate and overall survival rate was similar to immunocompromised group. Besides, Cystadillicum difficile infection or steroid didn’t affect in-hospital mortality rate and overall survival rate neither. Melenia was first and most common symptom in immunocompetent group, but diarrhea in the other.

P0423 A RANDOMISED CONTROLLED TRIAL OF RIFAXIMIN TO PREVENT RELAPSE OF CLOSTRIDIUM DIFFICILE INFECTION ASSOCIATED DIARRHOEA AFTER RESOLUTION WITH STANDARD THERAPY

A. Montgomery2, R. Spiller1
1NHRI Nottingham Digestive Diseases Biomedical Research Centre, University of Nottingham, Nottingham/United Kingdom
2Nottingham Clinical Trials Unit, University of Nottingham, Nottingham/United Kingdom

Contact E-mail Address: Giles.Major@nottingham.ac.uk

Introduction: Clostridium difficile associated diarrhoea (CDAD) is a common nosocomial infection. The most commonly prescribed treatments, metronidazole and vancomycin, have a primary cure rate of 90% but in 4 cases suffer a relapse in the following months. A disrupted microbiota is thought to increase the risk of relapse. Rifaximin is a non-absorbable antibiotic that suppresses C. difﬁcile proliferation. In a trial of 68 patients Carey et al. found that a course of rifaximin after standard therapy reduced relapse rate though not significantly1.

Aims & Methods: We aimed to further investigate the efﬁcacy of rifaximin to prevent CDAD relapse in a parallel group, randomised, placebo controlled trial in 23 hospitals in England. Population: age ≥ 18 with resolution of CDAD after treatment with metronidazole or vancomycin, defined as cessation of diarrhoea for ≥ 2 days. CDAD diagnosis required evidence of toxin production or pseudomembranes at endoscopy. Exclusion criteria were pregnancy or breast feeding; life expectancy < 4 weeks; unable to take intervention (hypersensitivity or swallowing disorder); > 5 days elapsed since treatment. Randomisation was stratified by hospital using a remote, internet-based system. Participants, clinicians and researchers were blind to allocation. Intervention: Rifaximin 1200 mg daily for two weeks then 600 mg daily for two weeks, in three divided doses. Comparator: identical placebo. Primary Outcome: relapse ≤ 12 weeks after treatment initiation, deﬁned as diarrhoea (≥ 3 tines per 6 or 7 stools per day) for 2 days with evidence of toxin production. Sample Size: The planned sample size was 180 to detect a difference in relapse of 20% (30% placebo, 10% rifaximin) with 80% power, allowing for loss to follow-up of 20%. EudraCT 2012-003205-10; www.clinicaltrials.gov NCT01670149; ISRCTN 65163992

Results: Recruitment occurred December 2012–March 2016. Of 2157 patients screened, 151 were eligible, willing and randomised before funding limits were reached (74 placebo, 77 rifaximin). Primary outcome data were available on 130. Mean age was 71.9 (SD 15.3). 36% were in-patients at start of intervention. 36% had a prior recorded episode of CDAD. 26% were using proton pump inhibitors prior to CDAD diagnosis, with a higher rate of use in the rifaximin group (32% vs. 15.9%) on placebo relapse within 12 weeks compared to 11.6% (p=0.08). A difference between groups of 15.7% (95% CI 28.1% to 0.7%, p=0.04). The risk difference was 0.54 (95% CI 0.28 to 1.05, p=0.07). During 6-month follow-up 9 participants died in each group (12%). Adverse event rates were similar between groups.

Conclusion: CDAD relapse rate was 13.7% lower than on placebo. The conﬁdence interval means that lack of effect remains possible but the estimated effect size is similar to Carey’s trial1 with meta-analysis of the trials showing a statistically signiﬁcant effect. The effect size is similar to that reported for fidaxomicin at 40 days2, or for bezlotoxumab at 3 months3. Age and mortality rate were higher in our trial which may reﬂect greater similarity to the population at risk. Comparative trials of the effectiveness and cost effectiveness of alternative treatment strategies should follow.

All other authors have declared no conﬂicts of interest.

References

Aims & Methods: The aim of this study was to assess in-hospital delay of surgery as a potential risk factor for complications in patients with acute appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections and postoperative morbidity. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152,314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.98-1.17) and 1.09 (95% CI 0.95-1.24), respectively. For a delay of 24 to 48 hours, a significant adjusted odds ratio of 1.43 (95% CI 1.21-1.70) was identified. Pooled unadjusted data showed a decreased risk for complicated appendicitis when appendectomy was delayed for 24 to 48 hours, however statistical uncertainty in this interval increased considerably compared to the first 24 hours. Conclusion: Delaying appendectomy for up to 24 hours after admission did not result in higher rates of complicated appendicitis, surgical site infections or morbidity. When prompt surgery is hampered by logistic or personal reasons, delaying appendectomy up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
notably contributed by elderly patients, of which the incidence has increased by three-fold over the period. Recurrence at 60 days increased from 5.7% in 2006 to 9.1% in 2014 (P<0.001). The increased use of proton-pump inhibitors accounted for 58.8% of the surge.

Conclusion: The incidence of C. difficile infection has increased more than three-fold, and was associated with an increased disease recurrence and use of proton-pump inhibitors. Our results suggest need for further surveillance in Asia which hovers half of the world’s population.

P0428 THE PROPHYLACTIC CLIP APPLICATION BEFORE SNARE POLYPECTOMY BLEEDING IN LARGE PEDUNCULATED POLYPS

J.S. Sohn, S.H. Park, Y. Song, K. Kim

Background: The prophylactic hemoclip can be used to reduce post-polypectomy bleeding in large pedunculated polyps. The aim of the present study was to evaluate the effectiveness of prophylactic clips application before snare polypectomy in large pedunculated polyps.

Materials and Methods: We performed prophylactic clip application before snare polypectomy for large pedunculated polyps (>1 cm in size) in 116 patients. Prophylactic clips were applied in the two groups with or without prophylactic clips application. Immediate PPB was defined as bleeding that continued for over 30 minutes from the polypectomy site and graded from grade 1 to 4, and delayed bleeding was defined as a history of hematochezia from the day of procedure to the day of first visit of outpatient clinic.

Results: Sixty-seven patients were included in the clip group and 49 patients in the control group. Prophylactic clips application reduced immediate PPB (P=0.008). However, delayed bleeding was not different in both groups (4.5% vs. 11.4%, P=0.208). Among delayed bleeds, 15 patients were treated by endoscopic hemostasis. The bleeding was significantly lower in the clip group than in the control group (4.5% vs. 20.0%, P=0.008).

Conclusion: Prophylactic clip application before snare polypectomy is effective in reducing immediate PPB.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0429 DOES CONTINUATION OF WARFARIN BECOME A POST-PROCEDUREAL ALTERNATIVE METHOD TO HEMOClip REPLACEMENT IN COLONIC POLYPECTOMY/ENDOSCOPIC MUCOSAL RESECTION?

I. Saito1, S. Ono1, Y. Takeda2, K. Takemura3, H. Doyama4, Y. Tsuji5, K. Niimi6, S. Kodashima7, N. Yamamichi8, M. Fujishiro9, K. Koike1

3Department Of Gastroenterology, Ishikawa Prefectural Central Hospital, Ishikawa/Japan
4Center For Epidemiology And Preventive Medicine, Graduate School of Medicine, the University of Tokyo, Tokyo/Japan

Introduction: Heparin replacement (HR) during periprocedural periods is described in various guidelines as the recommended method for colorectal polypectomy while discontinuing warfarin. However, the rate of post-colonoscopic polypectomy bleeding in patients undergoing HR has been reported to be as high as 20%. As an alternative method to HR, colonic polypectomy without discontinuation of warfarin may be feasible, however there is still insufficient evidence. The aim of this study was to assess the safety of colonic polypectomy/endoscopic mucosal resection (EMR) without discontinuation of warfarin during periprocedural periods.

Materials and Methods: This is a prospective multicenter single-arm exploratory study in Japanese patients who received warfarin for the purpose of prevention of thrombosis. Patients were prospectively enrolled and underwent colonoscopic polypectomy or EMR without discontinuation of warfarin. Conventional clip closure of the resection site was performed in all cases and oral diet was resumed 2 days after the procedure. The primary outcome was post-polypectomy/EMR bleeding that was confirmed by emergency endoscopy or a decrease in the hemoglobin level of >2 g/dl with hematochezia even if the bleeding site was not identified.

Results: Between January 2015 and November 2016, a total of 30 consecutive patients (M:F; 26:4, 69.9±8.0 years) were enrolled in this study after written informed consent was obtained. A total of 81 lesions (tumor diameter: 5.4±2.9 mm, adenoma 70, others 10, lost lesion 1, number of polypctomy clips 4.9±2.2) were treated by polypectomy/EMR. Four patients experienced post-polypectomy/EMR bleeding (4/30: 13.3%) in 3–11 days after the procedure, although no cases required blood transfusion. In 3 of these bleeding cases, a single responsible site was identified by emergency endoscopy. Therefore, the confirmed rate of post-polypectomy/EMR bleeding based on the number of recurred lesions was 3.9% (3/76), but may range to 9.5% (8/81). There were no other adverse events.

Conclusion: The rate of post-colonoscopic polypectomy/EMR bleeding in patients without discontinuation of warfarin single therapy was comparable to that in patients undergoing HR. Continued warfarin without discontinuation of warfarin is feasible and may reduce the hospitalization associated with HR.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Gastroenterology and Endoscopy Center, Tokyo Women’s Medical University, Tokyo/Japan

Introduction: In patients undergoing colonoscopy/EMR without discontinuation of warfarin, the risk of post-polypectomy bleeding (PPB) is high. Although heparin bridging therapy (HBT) has been described in various guidelines as the recommended method while discontinuing warfarin, its efficacy has not been confirmed. This is a prospective, single-center, single-arm study to assess the safety and efficacy of colonic polypectomy/EMR without discontinuation of warfarin.

Materials and Methods: This is a prospective multicenter single-arm exploratory study in Japanese patients who received warfarin for the purpose of prevention of thrombosis. Patients were prospectively enrolled and underwent colonoscopic polypectomy or EMR without discontinuation of warfarin. Conventional clip closure of the resection site was performed in all cases and oral diet was resumed 2 days after the procedure. The primary outcome was post-polypectomy/EMR bleeding that was confirmed by emergency endoscopy or a decrease in the hemoglobin level of >2 g/dl with hematochezia even if the bleeding site was not identified.

Results: Between January 2015 and November 2016, a total of 30 consecutive patients (M:F; 26:4, 69.9±8.0 years) were enrolled in this study after written informed consent was obtained. A total of 81 lesions (tumor diameter: 5.4±2.9 mm, adenoma 70, others 10, lost lesion 1, number of polypctomy clips 4.9±2.2) were treated by polypectomy/EMR. Four patients experienced post-polypectomy/EMR bleeding (4/30: 13.3%) in 3–11 days after the procedure, although no cases required blood transfusion. In 3 of these bleeding cases, a single responsible site was identified by emergency endoscopy. Therefore, the confirmed rate of post-polypectomy/EMR bleeding based on the number of recurred lesions was 3.9% (3/76), but may range to 9.5% (8/81). There were no other adverse events.

Conclusion: The rate of post-colonoscopic polypectomy/EMR bleeding in patients without discontinuation of warfarin single therapy was comparable to that in patients undergoing HR. Continued warfarin without discontinuation of warfarin is feasible and may reduce the hospitalization associated with HR.

Introduction: Intermittent bleeding from colon diverticulum has a significant clinical impact with some cases experiencing recurrent bleeding episodes for several years. No report has directly evaluated the association between arterio-

Aims & Methods: We sought to assess the degree of arteriosclerosis in cases with diverticulum bleeding as well as the patients’ clinical characteristics. We conducted a retrospective cohort study in a group of 79 consecutive patients with colon diverticulum bleeding (51 men) who underwent both colonoscopy and computed tomography (CT) between August 2007 and March 2014. The mean age of the patient population was 69.5 years (range 29–91 years) and mean (±standard deviation) follow-up time was 6.2 (±2.0) years (range 3.1–9.7 years). Patients were divided into two groups: the recurrent bleeding episode group and the single bleeding episode group. Recurrent bleeding episodes were defined as bleeding intervals of >1 month. Cases that underwent successful therapy during the initial bleeding episode were excluded. We compared Agatston scores (total calcium score) between the two groups of patients to assess the degree of arteriosclerosis. A calcified lesion was defined as an area of at least 2 connected pixels with >120 Hounsfield units (HU) on the unenhanced CT scan. Aortic mural calcified area ⩾ cofactor (1:120–199HU; 2:200–299HU; 3:300–399HU, 4:≥400HU) was determined. The sums of the scores for every calcified speck were calculated across all lesions in a slice from the level of the diaphragm to the aortoiliac bifurcation to obtain the total calcium score. Moreover, the relationship between recurrent bleeding episodes and the patients’ characteristics including age, sex, smoking habit, comorbidity (hypertension, cerebro-cardiovascular disease, diabetes mellitus, hyperlipidaemia, chronic liver disease, chronic kidney disease, and chronic obstructive pulmonary disease), internal medicine (antithrombotic drug, non-steroidal anti-inflammato-

drug, and proton pump inhibitor), shock vital on hospitalization, and transfusion need, was determined.

Results: Overall, 39 (49%) cases had recurrent bleeding episode and 40 (51%) had single episode. The cumulative recurrent bleeding episode rate in the recur-

rent bleeding episode group was 33% and 59% at 1 and 3 years, respectively. Agatston scores in the recurrent bleeding episode group were significantly higher than those in the single bleeding episode group (5902 ± 7187 vs 2912 ± 4687, P = 0.0031). Clinical characteristics associated with recurrent bleeding episodes were cerebro-cardiovascular disease (P = 0.0044), chronic kidney disease (P = 0.031), and antithrombotic drug (P = 0.048) in univariate analysis. Subsequent multivariate analysis determined that cerebro-cardiovascular disease was an independent contributor to recurrent bleeding episode (OR: 5.48; 95% CI: 1.11–24.07).

Conclusion: Arteriosclerosis along with cerebro-cardiovascular disease may be a significant contributing factor for colon diverticulum recurrent bleeding.

P0433 THE COMPARISON OF DIRECT ORAL ANTICOAGULANTS (DOAC) AND WARFARIN FOR ANTICOAGULATION IN THE PATIENTS WITH GASTROINTESTINAL BLEEDING

Gastroenterology, Mitsui Memorial Hospital, Tokyo/Japan

Contact E-mail Address: kenken.kojiken.529@gmail.com

Introduction: Direct oral anticoagulants (DOAC) are now popularly used as anticoagulation for atrial fibrillation and deep vein thrombosis, as well as Warfarin. But, direct comparison of DOAC and warfarin in the patients with gastrointestinal bleeding was little reported.

Aims & Methods: We retrospectively analyzed 18 on DOAC and 60 cases on Warfarin of the patients with gastrointestinal bleeding from January 2011 to March 2017 on the basis of single-center experience in Japan. We analyzed characteristics associated with recurrent bleeding episodes during hospitalization, the duration from bleeding to endoscopy, from endoscopy to discharge and from bleeding to discharge in both group. In DOAC group, each 6 patients took Dabigatran, Rivaroxaban and Apixaban.

Disclosure of Interest: All authors have declared no conflicts of interest.

Concentrated red cell transfusion, n (%) 9 (50.0%) 32 (53.3%) 0.80

Re-bleeding during hospitalization, n (%) 1 (5.6%) 12 (20.0%) 0.11

(continued)
continued

Results: Patient characteristics such as sex, age, anti-platelet therapy, location of bleeding and bleeding after endoscopic procedure had no significant difference in both groups. Upper gastrointestinal bleeding occurred 6 (33.3%) of DOAC group and 1 (1.7%) of Warfarin group, respectively. Prothrombin time (PT-INR) had trended to be transfused at high rate in Warfarin group (16.7% vs 33.3%, p = 0.16). Re-bleeding rate during hospitalization had no significant difference in both group, but tended to be higher in Warfarin group (5.6% vs 20.0%, p = 0.11). The duration from bleeding to endoscopy had no significant difference between both group (0.5 days vs 0.2 days, p = 0.52), but the duration from endoscopy to discharge was significantly longer in Warfarin group (9.0 ± 5.5 days vs 23.0 ± 3.0 days, p = 0.03). Also, the duration from bleeding to discharge was significantly longer in Warfarin group (9.8 ± 5.4 days vs 24.2 ± 3.0 days, p = 0.02). Thrombotic embolism during hospitalization occurred only 1 (1.7%) of Warfarin group.

Conclusion: The duration of hospitalization was significantly shorter in DOAC group of the patients with gastrointestinal bleeding, and the rate of re-bleeding and re-bleeding tended to be lower in DOAC group. This study showed that DOAC may be more superior to Warfarin as anticoagulation for atrial fibrillation and deep vein thrombosis at the quality of life (QOL) in the patients with gastrointestinal bleeding.

Introduction: Colonoscopy is an imperfect tool. Several publications confirm colorectal cancer may manifest after a negative colonoscopy(1–3). The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term(1). Post-colonoscopy colorectal cancer (PCRC) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening(2). Although there is overlap between these two terms, they are not synonymous. PCRC can be thought of as the overarching term. PCRC can be subdivided into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval was recommended, up to 10 years following the colonoscopy).

Aims & Methods: The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers- PCRC/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool(4). An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient representative) were summoned by the World Endoscopy Organisation (WEO); the final statement was recommended, up to 10 years following the colonoscopy.

P0435 INCREASED INCIDENCE OF OVARIAN CANCER FOLLOWING COLORECTAL CANCER: A KOREAN NATIONAL WIDE COHORT STUDY

D.W. Shin1, D.H. Lee1, H.S. Kim1

1Internal Medicine, SNUBH, Seongnam/Korea, Republic of

Contact E-mail Address: delight0618@naver.com

Introduction: In Korea, colorectal cancer is the most common cancer among older aged women over 65 years old. The incidence of colorectal cancer, in particular, is dramatically increasing due to environmental factors such as the westernized eating behaviors. Furthermore, due to advanced medical, the survival rate of those with advanced colon cancer is increasing. An increased risk of malignant ovarian tumors is associated with colorectal cancer has been suggested recently, but adequate studies have not been conducted. The purpose of the study is to determine whether ovarian cancer is more common in the patients diagnosed with colorectal cancer than in the general population. If a woman diagnosed with colorectal cancer indeed has a high incidence of ovarian cancer, a screening test can be performed for high-risk patients.

Aims & Methods: This is a retrospective cohort study using data registered in the National Health Insurance Corporation as a cancer diagnostic code since 2007. In Korea, once cancer is diagnosed, this information is recorded by the National Health Insurance Corporation with a relevant code, and this system provides every patient’s data for medical research purposes. The colorectal cancer group includes patients newly enrolled with the corresponding diagnostic code (ICD-10 code C18, C19, and C20). The 56,682 colorectal cancer patients and 288,119 sex-matched controls were included. The main exposure was the colorectal cancer diagnosis. The main outcomes were used to facilitate the creation of comparison group that is similar. Each cancer patient was matched to five individuals in the unexposed cohort. All data was followed by a new diagnostic code of ovarian cancer (ICD-10 code C56) was given. After adjusting for sex, age, smoking, drinking, exercise and comorbidities (diabetes mellitus, hypertension, and hyperlipidemia), further analysis was performed. Hazard ratios and 95% confidence intervals were calculated via Cox proportional hazards regression models. Statistical analysis will be performed with SPSS version 24.0. When P < 0.05, the result was defined as statistically significant.

Results: Patients with colorectal cancer were followed up for an average of 4.4 years until the occurrence of ovarian cancer. During the follow-up period, 338 out of 56,682 (0.6%) colorectal cancer patients and 258 out of 288,119 (0.9%) people in the general population were diagnosed with ovarian cancer. Ovarian cancer was more common in the colorectal cancer group than the general population Hazard ratio (HR) 7.13, 95% Confidence interval (CI) 5.06–10.05. The above result was conducted only for those who had medical checkup data within one year (14, 190 patients in colorectal cancer group, 71,933 people in the control group). Even though the subjects in this group were adjusted for several factors (age, sex, smoking, drinking, exercise, diabetes, hypertension, and hyperlipidemia), the result was also significant in ovarian cancer patients as a whole for colorectal cancer group [HR 7.12, 95% CI = 5.05–10.04]. Colorectal cancer patients had a higher risk of ovarian cancer across all age groups including patients under the age of 55 years [HR 10.69, 95% CI = 6.26–18.26] and patients older than 55 years [HR 5.17, 95% CI = 3.26–8.19].

Conclusion: In conclusion, data from the National Health Insurance Corporation revealed that the incidence of ovarian cancer in colorectal cancer patients was higher than that of the general population. In woman diagnosed with colorectal cancer, the screening test should be done to monitoring the occurrence of ovarian cancer. Further research is necessary to determine the interactive association between the development of ovarian cancer and colorectal cancer, and large prospective studies are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.
5 (strongly disagree). A modified Delphi process was followed; consensus reached on agreement. In areas continuing disagreement, a recommendation for or against a particular statement required both >50% of participants in favour and <20% preferring the comparator. Failure to meet this resulted in no recommendation. The GRADE system for rating evidence and strength of recommendations was applied to final statements.

**Results:** The final output consists of 21 statements providing guidance on key aspects of PCCRC/PICRC, namely definitions, terminology, qualitative review/alethia attribution and quantitative assessment of cases. A Root-Cause Analysis checklist as well as a PCCRC/PICRC manuscript peer-review checklist were also developed.

**Conclusion:** This is the first consensus aiming to standardise terminology around PCCRC. Each previous study defined PCCRC differently, making its use for both reporting and purposes impossible. This consensus presents a methodology for analysis of causation of PCCRC/PICRC and defines its potential role as a key quality indicator, providing recommendations for future investigators, policy makers, services and patients.

**P9437** Excess Risk of Second Primary Cancers in Young-Onset Colorectal Cancer Survivors

X. He 1, W. Wu 1, L. Sun 1, Y. Ding 1, J. Si 1

1Department Of Gastroenterology, Sir Run Run Shaw Hospital, hangzhou/China

2The First Affiliated Hospital, School Of Medicine, State Key Laboratory for Diagnosis of Primary Colon and Rectal Cancer, hangzhou/China

Contact E-mail Address: hexingkang@zju.edu.cn

**Introduction:** Young-onset colorectal cancer (CRC) is still the third most common malignancies in the US according to Colorectal Cancer Statistics, 2017[1]. During past decades, the incidence and mortality of CRC among individuals aged over 50 years are declining significantly, while the rate of CRC in the young is sharply on the rise (2–3). Excluding rate of young-onset CRC, coupled with increased survival rate, would definitely lead to accumulation of young survivors considerably. There is a growing study reporting the risk of second primary cancers (SPCs) in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC at high risk of SPCs than the general population[4–6]. However, to the best of our knowledge, very little is known regarding the risk and sites of SPCs following prior diagnosis of CRC in the young (aged ≤ 50).

**Aims & Methods:** To address this important gap, we aimed to quantify the relative risk of SPCs after a diagnosis of CRC in the young CRC survivors. We conducted this retrospective study by utilizing the Surveillance, Epidemiology, and End Results (SEER) database and identified primary CRC patients with subsequent cancers between 1993 and 2013. We excluded cases with less than 6-months latency restriction. Standardized incidence ratios (SIR) and absolute excess risk (AER) were calculated to assess the relative risk for SPCs. SIRs for subgroup analysis were further stratified by gender, race, calendar year, latency period, SEER stage, cancer subsite, radiotherapy. All statistical tests were performed by SEER*Stat version 8.3 and a P value <0.05 was considered statistically significant. Our study was approved by the review board of Zhejiang Institute of Gastroenterology, Sir Run Run Shaw Hospital, China.

**Results:** In young CRC patients, there were 44,724 survivors who developed 51,084 SPCs during the follow-up, including 3283 young (young aged ≤ 50) and 41,189 (old > 50) old survivors. The SIR of all sites significantly decreased with increased age. Compared with the general population, SIRs of all solid tumors and hematological disease were significantly increased in the young. There was significant 43% risk of SPCs in young survivors (SIR = 1.43, 95%CI = 1.39–1.48, AER = 33.85) and slight increases in old survivors (SIR = 1.02, 95%CI = 1.01–1.03, AER = 4.20). For young survivors, small intestine (SIR = 8.36, colon (SIR = 3.77), rectum (SIR = 3.57), bile ducts (SIR = 3.70) sites were the most commonly affected, a recommendation for or against a particular statement required both >50% of participating in favour and <20% preferring the comparator. Failure to meet this resulted in no recommendation. The GRADE system for rating evidence and strength of recommendations was applied to final statements.

**Conclusion:** This is the first study to report on the pooled incidence of FIT and gFOBT iCRC in screening setting. The incidence rate of iCRC after negative FOBTs are limited.

**Aims & Methods:** In this systematic review and meta-analysis we compared the incidence of iCRCs following a negative fecal immunochemical test (FIT) or guaiac fecal occult blood test (gFOBT). Second, we assessed if screening-related or patient-related factors are associated with FOBT iCRCs. Ovid Medline, Embase, The Cochrane Library, the Science Citation Index, PubMed publisher and Google scholar were searched up to May, 2016. All studies reporting on the incidence of FIT or gFOBT iCRCs in average CRC screening populations were included, without language restrictions. Main outcome was pooled incidence rate of iCRCs per 100,000 person-years (p-y). FOBT iCRC was according to international standards defined as cancer that developed after a negative FOBT and before the next FOBT was due. Pooled incidence rates were obtained by fitting random effect poisson regression models. The between-study heterogeneity of effect-size was quantified using the I².

**Results:** We identified 5,873 records, of which 413 full-text articles were assessed for eligibility and 30 studies were included in both qualitative and quantitative analyses. Meta-analyses comprised data of 5,252,563 screening participants, in which 14,030 screen-detected CRCs and 5398 FOBT iCRCs were documented. Pooled incidence rates of iCRC following FIT and gFOBT were 20 (95%CI: 14.28; 28; 3; 29) and 39 (95%CI: 26.61; 49) per 100,000 p-y, respectively. The pooled incidence rate ratio of FIT iCRC compared to gFOBT iCRC was 0.50 (95% CI: 0.30-0.84, n = 30 studies). For every FIT iCRC, three CRCs were found with FIT, while for gFOBT the ratio between CRC and gFOBT iCRC detected CRC was 1.13, Table 1. No significant differences were found between the relative risk of FOBT iCRC in the second and third screening round compared to the first, with 1.03 (95% CI: 0.94-1.13) and 1.08 (95% CI: 0.95-1.22), respectively. Incidence rate ratio of FOBT iCRC screening populations was 1.13, Table 1. For males relative to females and 5.0 (95% CI: 1.2-2.1) for screenees aged ≥ 60 relative to <60 years.

**Table 1:** Baseline data of 30 studies included in qualitative meta-analyses displayed by test type

<table>

</tbody>
</table>

**Conclusion:** This is the first study to report on the pooled incidence of FIT and gFOBT iCRC in screening setting. The incidence rate of iCRC after a negative
FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as a screening tool. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screenees about the risk of developing a colorectal carcinoma after a negative FIT.

Introduction: Age and family history of colorectal cancer (CRC) are the strongest risk factors for CRC. Obesity, commonly assessed based on body mass index (BMI), is associated with an increased risk for CRC in men but the association is weaker in women and differs between studies. We investigated which of the following body composition measures: BMI, waist-to-hip ratio (WHR), weight-height-ratio (WHRR), weight-height-hip ratio (WHRH), A Body Shape Index (ABSI) and percent body fat that best predict the development of CRC in men and women.

Aims & Methods: We used data from Malmö Diet and Cancer cohort in Sweden, including 16,840 women and 10,903 men (mean age, 58.1 years at baseline), followed for a median of 19.8 years. We identified cases with CRC until the end of 2014 using national Swedish registers. Hazard ratios (HR) for CRC, colon cancer (CC) and rectal cancer (RC) per one standard deviation increase in each body composition measure respectively were calculated using Cox regression models, stratified by sex and adjusted for age, alcohol consumption, smoking, education and physical activity. Likelihood ratio tests and C-statistics were calculated to identify the anthropometric measure that improves the null model the most.

Results: Incident CRC occurred in 880 individuals (477 women) during follow-up. All body composition measures apart from WHRR significantly predicted CRC in men and waist circumference (WC) was the best predictor based on C-statistics and LR-test (HR per standard deviation [SD] increment, 1.19; 95% CI, 1.08–1.31, LR-test p < .001, C-statistics 0.6278). The association between WC and CRC was only found in men with a BMI above 25. All body composition measures apart from WHRR and percent body fat significantly predicted CC in men, again WC was the best predictor (HR 1.25; 95% CI, 1.11–1.42, LR-test p < .001, C-statistics 0.6444). ABSI was the only measure significantly associated with risk for RC in men (HR, 1.24; 95% CI, 1.05–1.47). In women neither of the measures was significantly associated with an increased risk for CRC, CC nor RC.

Conclusion: In this Swedish population-based cohort study on well-characterized colorectal cancers, both tumor-promoting and tumor-suppressing effect have been reported. The role of Th17 cells in colorectal cancer (CRC) remains controversial and the specific mechanism of how Th17 cells affect the development of CRC remains to be explored.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer (CRC) remains the second most common cancer in women and third in men worldwide, with more than 1.3 million patients diagnosed every year (1–3). Still more than 50% of patients are diagnosed with advanced disease (stage III and IV), which has worse prognosis and survival. There is a need for new biomarkers for early diagnostics, predicting patient’s treatment response and follow-up. Recent data suggest that microRNAs (miRNAs) might be utilized as such biomarkers (4).

Aims & Methods: We focused on specifying differences in expression profile between rectal tumor and adjacent healthy mucosa. Individual miRNA levels were analyzed in relation to patient’s treatment response and post-treatment recurrence, as well as to the presence of 3D-miRNAs with possible role of predictive and prognostic markers in rectal cancer. At first, we screened 20 pairs of rectal tumors and healthy surrounding mucosa for the expression levels of 2555 microRNAs using 3D-Genie TORAY microarray system. We have identified 71 candidate miRNAs with different expression profile in tumor and healthy tissue. These 71 miRNAs were further explored and verified in larger cohort of 101 rectal tumors and 105 colon tumors compared to matched healthy tissues by qPCR (Fluidigm BioMark). Results were analyzed in relation to different clinicopathological characteristics of tumors, to individual patient’s treatment response and overall or disease-free survival.

Results: We confirmed 18 miRNAs to be differently expressed in rectal tumors as compared to healthy mucosa. This expression profile was observed in tumors resected prior to neoadjuvant therapy, but not in those that were neoadjuvantly treated. Only 2 miRNAs were dysregulated irrespectively on neoadjuvant therapy. We have further investigated whether this signature is specific for rectal cancer, or is observed also in colon cancer. We have found that 14 out of 18 miRNAs were indeed commonly dysregulated in whole CRC, and 4 miRNAs were dysregulated in rectal tumor only. In order to identify miRNAs with any association to treatment, we have analyzed miRNA expression profile of rectal tumors in relation to patient’s treatment response and their long-term survival. Thirteen miRNAs were differently expressed between tumors that responded to therapy and those that relapsed.

Conclusion: We have identified miRNA expression patterns specific for rectal cancer, which identified miRNA set in relation to different clinicopathological characteristics of tumors, to individual patient’s treatment response and overall or disease-free survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0442 MUSCARINIC-3 RECEPTOR TARGETED MiRNAS ARE INVOLVED IN BILE ACID-INDUCED PROLIFERATION ON H508 COLON CANCER CELL LINE**

F. Tekin, C. Aktan, N. Oruc, O. Onutemi*.

**Gastroenterology, Ege University Medical School, Izmir/Turkey**

Contact E-mail Address: drtekinfatih@gmail.com

**Introduction:** Studies with the colon cancer cell lines which express muscarinic-3 (M3) receptors showed that taurine conjugates of lithocholic acid, but not other bile acids, bind to M3 receptors, and stimulate an increase in cell proliferation. On the other hand, many microRNAs (miRNAs) are involved in colon carcinogenesis. However, the interaction of bile-acid/M3 receptors and miRNAs and their potential effects on colon carcinogenesis remains to be elucidated.

**Aims & Methods:** For the first time in the literature, we examined the possible role of M3 receptor-targeted miRNAs on two human colon cancer cell lines: H508, which expresses M3 receptors, and SNU-C4, which does not. Cell proliferation for 6 days after sodium taurocholic acid (ST) and atropin (A) treatment was analysed by WST-1 method. Expression of M3 receptor gene at mRNA level was analysed by qPCR, and at protein level by Western Blot method. Apoptotic experiments were analysed by Annexin V assay. MiRNAs which possibly targeted M3 receptors were identified by in silico analyses. The methods were repeated three times, and the average values were calculated.

**Results:** When compared to SNU-C4 cells, M3 receptor gene expression was found to be increased 70-fold on H508 cells. After a 6-day incubation, maximum H508 cell proliferation (300% ) was achieved on 5th day with a dose of 300 µM ST, inhibited by a dose of 1 µM A. In contrast, the SNU-C4 cells showed no significant change in cellular proliferation. Treatment of H508 cells with ST caused a decrease (2.53-fold) of M3 receptor gene expression, however, no change of M3 receptor at protein level was seen. No changes in apoptosis on both colon cancer cell lines were observed. Of 25 M3 receptor-targeted miRNAs, expression levels altered in 9; 6 of them were up-regulated (hsa-miR-129-5p, hsa-miR-30c-5p, hsa-miR-224-5p, hsa-miR-30b-5p, hsa-miR-522-3p, hsa-miR-1246) and 3 of them (hsa-miR-30c-5p, hsa-miR-147b, hsa-miR-855-3p) were down-regulated on H508 cells (p < 0.05).

**Conclusion:** ST interact with M3 receptors which modulate colon cancer cell proliferation on H508 cells. M3 receptor-targeted miRNAs are involved in ST induced proliferation. Whether the use of ursodeoxycholic acid, selective anti-miRNAs, anti-cholinergic agents or other approaches to blocking potential interactions of bile acids/salts with neoplastic colonic epithelium may be a useful adjunct to colon cancer prevention or treatment remains to be determined.

**Introduction:** Dyslipidaemia and statin use have been associated to colorectal cancer (CRC), but prospective studies have shown controversial results. Dyslipidaemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidaemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent. [1–4] It is unknown whether lipids and lipoproteins cause cancer or are intermediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidaemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5–6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidaemia and CRC.

**Aims & Methods:** We aimed at determining whether dyslipidaemia is causally linked to CRC risk and to explore association of statins with CRC. A case-control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiological questionnaire that included lifetime usual regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested on regular use of statins and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

**Results:** The LDL genetic risk score was significantly associated with statin consumption (OR = 1.07, 95%CI 1.05–1.10, p = 4.4e-11). The dyslipidaemia genetic risk score was not significantly associated with CRC for either of the target lipids studied. Cases had the same average alleles as controls in all the lipids traits. Statin use was a borderline significant protective factor for CRC (multivariate OR = 0.83; 95%CI 0.69–1.00, p = 0.049).

**Conclusion:** Using the Mendelian randomization approach, our study does not support the hypothesis that lipid levels are associated with the risk of CRC. This study does not rule out, however, a possible protective effect of statins in CRC by a mechanism unrelated to lipid levels.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Our results support that LINC00152 lncRNA can contribute to CRC development by facilitating cell proliferation through upregulation of cyclin D1.

Introduction:
Colonoscopy surveillance of polyps is based on their size, number and location. Risk of developing AML for individual genetic markers was studied prospectively. High level of methylation on CpG islands (CIMP-H) was also tested using allelic discrimination by real-time PCR and direct DNA sequenciation, respectively. Histone H3 hypermethylation in cell lines expressing mutant KRAS. DNA hypermethylation was determined by the Illumina 880K methylation array and Methyl Light qMSP assays. Histone methylation was determined by H3 H3 Modification Multiplex Assay Kit and Western blot. U-13C5-Glutamine metabolic labelling and analysis of glutamine metabolism via the TCA cycle was determined by liquid chromatography-mass spectrometry analysis. In clinical samples, SLC25A22 mRNA expression was determined by real time-PCR. The correlation with CpG Island Methylator Phenotype (CIMP) status and histone methylation mark (H3K36me2) was evaluated.

Results:
Using three pairs of isogenic cell lines harbouring wild-type and mutant KRAS (DKS8(WT) vs DLD1(mutant); HKE3(WT) vs HCT116(mutant); ICT(WT) vs ICT-KRAS(mutant)), we demonstrated that significant DNA and histone (H3K36me2) hypermethylation and histone H3 acetylation occurred in mutant cell lines. In addition, succinate restored cell growth in SLC25A22 knockout cell lines, suggesting that epigenetic dysregulation was closely associated with tumorigenicity. In human CRC, SLC25A22 expression was positively associated with CIMP (P < 0.0001) and histone H3K36me2 methylation status (P < 0.0001).

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: SLC25A22 promotes the tumorigenicity of KRAS mutant CRC by dubbing and reduced DNA and histone hypermethylation, an effect mediated by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0447 FOLLISTATIN-LIKE PROTEIN 1 SUSTAINS COLON CANCER CELL GROWTH AND SURVIVAL

G. Bevivino1, V. De Simone1, R. Iizzo2, M. Di Giovangiulio1, S. Sedda1, E. Franchini3, A. Rizzo1, P. Rossi2, C. Stolfi2, G. Monteleone1, G. Bevivino1

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival and cell cycle were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control. Western blotting, immunohistochemistry and expression of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cancer cell death was evaluated in cancer cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (CDK2), with no modification of early G1 phase proteins (i.e. cyclin D1). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0448 TP53 MUTATION ACQUIRES HIGHER MALIGNANT POTENTIAL IN HUMAN COLON CANCER CELLS

Introduction: TP53 is commonly mutated in colorectal cancer, TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potentials, the effect of TP53 mutation on malignant potential of colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the function of TP53 mutation in colon cancer cells, by using recently established lentiviral CRISPR Cas9 system.

Aims & Methods: Two types of TP53 mutation were generated in LS174T cells, which are derived from human colon adenocarcinoma with wild-type TP53 (WT-TP53), by using lentiviral CRISPR Cas9 system. The guide RNAs were designed to bind exon3 or exon 10 of TP53, respectively. TP53 mutation in LS174T was confirmed by direct sequencing. The expression of TP53 protein was assessed by immunohistochemistry. Loss of function of TP53 was assessed by Nutlin-resistance and the expression of TP53 target genes. Malignant potentials of TP53-mutated cells were assessed by MTS Assay and cell migration assay for cell proliferation, cancer stemness and cell migration, respectively. Chemo-resistance was also assessed by the treatment with 5-FU and L-OPH.

Results: We first selected LS174T cells with WT-TP53 because TP53 gene has already been mutated in almost colon cancer cell lines. We then successfully established 2 types of TP53 mutation in LS174T cells due to high effectiveness of gene-mutating by lentiviral system. Mutation in exon3 (TP53Ex3) and exon10 (TP53Ex10) of TP53 created the shorter form of TP53 (TP53Ex3: 55a.a., TP53Ex10: 377a.a., respectively) compared to WT-TP53 (393a.a.). Mutant TP53 (TP53Ex10) is strongly expressed in nuclei as often shown in colon cancer region, whereas both WT-TP53 and mutant TP53 (TP53Ex3) are not expressed in LS174T cells. In contrast, both TP53 mutants (TP53Ex3 and TP53Ex10) showed TP53-resistant and the down-regulation of TP53 target genes, suggesting that both mutants induced loss of function of TP53. We then assessed the effect of both TP53 mutants on various malignant potentials, resulting in accelerated cell growth, enhanced invasiveness and the resistance against 5-FU treatment compared to WT-TP53. Moreover, both mutants showed more frequent formation of 3D sphere and more expression of Lgr5 than WT-TP53, suggesting the promotion of cancer stemness by TP53 mutation even after being adenocarcinoma.

Conclusion: For the first time showed the direct effect of TP53 mutation on malignant potential in colon cancer cells. Loss of function of TP53 induced by not only TP53Ex3 but also TP53Ex10, might promote malignant potentials including cancer stemness at the late phase of carcinogenesis. In general, expression of TP53 in cancer regions is represented as TP53 mutation. However, negative staining of TP53 might also be careful for TP53 mutation to estimate malignant potential in colon cancer, since N-terminal mutation of TP53 in colon cancer has already been reported.

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphcine analog with mu- and kappa-opioid receptor affinity – results in down-regulation of acute phase factors (induced by dextran sodium sulfate [DSS]) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intra-peritoneal injection of azoxymethane [AOM] (10 mg/kg) and subsequent addition of DSS (1.5% w/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1 mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the necropsy and clinical score was assessed and the samples were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly increased total number of colon tumors as well as colon thickness and width after 14 weeks of disease induction. Myeloperoxidase activity, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoxylin and eosin staining confirmed anti-tumor activity of P-317 as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group.

Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

P0450 INCREASED HMBGI EXPRESSION CORRELATES WITH HIGHER EXPRESSION OF C-IAP2 AND PERK IN COLORECTAL CANCER

W. Zhang1, M. Xia1, F. An1, Q. Zhan1, W. Tian1

1Gastroenterology, Wuxi People’s Hospital Affiliated to Nanjing Medical University, Wuxi/China

Contact E-mail Address: wenjiazhang1221@163.com

Introduction: Colorectal cancer (CRC) is the third most common type of cancer in the world, and its incidence continues to rise. The probability of recurrence and subsequent death due to colorectal cancer is associated with its stage 1, 2. Because of its insidious onset, the diagnosis of CRC is usually delayed. However, serological markers can be a relatively easier and cheaper alternative to传统的 biomarker of colorectal cancer, HMBGI is one of the most recent ones. Several recent studies have shown that HMBGI expression in colorectal cancer is an independent predictor for overall survival of patients undergoing surgery 1, 2. 3. 4. Studies have shown that HMBGI is over-expressed in various types of cancers, including CRC, and those cases with higher expression of HMBGI are associated with lymphatic metastasis, distant metastasis and poor prognosis 1, 5. Several reports have demonstrated that HMBGI is
secreted by cancer cells may be involved in occurrence of tumor metastasis [6, 7]. In a study by Lo et al. 2010, the authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupffer cells which promoted development of liver [6, 7]. Furthermore, some researchers found that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1 are found in tumor tissues [8, 9]. These adipokines may be useful for diagnosis and treatment of CRC. However, whether HMGB1 has any role in the development of CRC metastasis is not clear. In this study, we investigated the effects of HMGB1 on CRC, and the possible underlying mechanisms were examined. 

Aims & Methods: We investigated the relationship between high-mobility group B1 (HMGB1) and colorectal cancer (CRC) and the probable underlying pathogenic mechanism. In this prospective study, patients with CRC undergoing primary surgery and healthy subjects (control group) were included from July 2013 to December 2015. HMGB1 concentrations were determined using ELISA and HMGB1 mRNA expression was detected by RT-PCR method. Immunohistochemical analysis was performed to determine HMGB1, pERK and c-IAP2 protein expressions in the cancer tissues.

Results: 144 patients with CRC and 50 healthy subjects underwent HMGB1 testing. Resected specimens of 50 patients were used for HMGB1 mRNA and protein expression analysis. Serum HMGB1 levels in CRC patients were higher than that of the control group (8.42 vs. 1.79 μg/L, p < 0.05). Preoperative serum HMGB1 concentrations were significantly higher than the postoperative values (8.42 ± 5.67 vs 1.64 ± 1.89 μg/L, p < 0.05). Serum HMGB1 levels in CRC patients with distant metastasis were significantly higher (13.32 ± 6.12 vs 7.37 ± 5.17 μg/L, p < 0.05). HMGB1 mRNA and protein expression in CRC tissues was significantly higher than in the adjacent normal mucosa. HMGB1 protein expression positively correlated with the lymph node metastasis. There was positive correlation between HMGB1 and c-IAP2 (r = 0.457, P = 0.001), HMGB1 and pERK (r = 0.461, P < 0.05) as well as pERK and c-IAP2 (r = 0.399, P < 0.05).

Conclusion: HMGB1 expression in CRC correlates with distant and lymph nodal metastasis. It may inhibit apoptosis by inducing activation of pERK and cIAP2.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Group I. However, only MPV was significantly higher in Group II compared to group I (8.6±1.1 vs 8.2±1, p < 0.001). The cut-off value of MPV in predicting CRC from patients with normal colonoscopic findings was 9.15 fL with a sensitivity and specificity of 80% and 91% respectively (r = 0.892).

Conclusion: Those features may be used for selecting patients with CRC who may benefit from radiomics analysis. The results suggest that radiomics features may have the potential to improve the accuracy of CRC prediction. However, further studies are needed to confirm these findings.

Introduction: In patients with localized rectal cancer who are candidates for advanced neoadjuvant chemoradiation therapy (nCRT), accurate estimation of the response of the tumour to nCRT is crucial for the clinical decision-making process. Radiomics, a relatively new field, has been gaining interest in recent years for its potential to provide additional clinical information from imaging data. This study aimed to evaluate the utility of radiomics features derived from pre-treatment MRI in predicting clinical response to nCRT in patients with rectal cancer.

Aims & Methods: A total of 32 patients with rectal cancer were included in the study. Pre-treatment MRI scans were obtained for all patients and were analyzed using a radiomics software platform. Radiomics features were extracted from the T2-weighted and diffusion-weighted MRI (DWI) images. These features were then used to train a machine learning model to predict the clinical response to nCRT.

Results: The radiomics model achieved an accuracy of 85% in predicting clinical response to nCRT. The most important features identified by the model included signal intensity, texture, and shape features. The model was able to differentiate patients with clinical complete response (cCR) from those with pathological complete response (pCR).

Conclusion: Radiomics features extracted from pre-treatment MRI may have the potential to improve the accuracy of clinical response prediction to nCRT. However, further validation studies are needed to confirm these findings.

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified in colorectal neoplasms according to their morphology and histology: flat type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat-elevated type (LST-NGF), and non-granular pseudo-depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.

Aims & Methods: The aim of this study was to clarify the clinical features of colorectal LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 5352 endoscopically resected specimens during January 2007 and December 2016 at our institution. A total of 422 LSTs were detected. We analyzed the clinical features (mean age, female ratio, size, location, Incidence of concomitant carcinoma) according to their subtypes.

Results: Of these 422 lesions, a total of 151 (35.8%) were LST-GH, 34 (8.1%) LST-GM, 203 (47.9%) LST-NGF and 24 (5.7%) LST-NGPD. Metastasis in each type was detected in 45.4% (27 out of 59), 11.8% (4 out of 34), 66.7% (75 out of 112), and 4.2% (1 out of 24), respectively. Incidences of concomitant submucosal carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 0% (0 out of 151), 14.7% (5 out of 34), 1.9% (2 out of 209), and 25.0% (7 out of 28), respectively.

Conclusion: Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. This study indicates we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

P0459 RISK OF DETECTION OF GASTROINTESTINAL NEOPLASMS AND DEATH IN SYMPTOMATIC PATIENTS WITH A POSITIVE FECAL IMMUNOCHEMICAL TEST WITHOUT COLORECTAL CANCER
N. Pin, M.J. Iglesias, D. Remedios, P. Vega, J. Cubiella
Servicio De Aparato Digestivo, Complejo Hospitalario de Ourense, Ourense, Ourense/Spain
Contact E-mail Address: noel.pin.vieiro@sergas.es
Introduction: The fecal immunochromical test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.
Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (GITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the ≥20ug hemoglobin/g feces threshold. We performed a descriptive analysis of the outcomes detected during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.
Results: We included 1061 patients without CRC and a complete baseline colonoscopy; 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0±8.9 months with no difference between both groups (p=0.2). There were significant differences regarding age (67.7±12.7 years vs. 64.8±13.5 years, p=0.04) and sex (45.9% vs 52.0% females, p=0.04) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CRC, 6 gastric, 2 small intestine adenocarcinoma, one esophageal, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9-4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.7%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8-2.1). However, the risk of death due to a GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2, 95% CI 1.2-8.9).
Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of SCL.

Introduction: A stent is a surgically placed intervention for colorectal cancer (CRC) with acute colorectal obstruction (ACO). Transanal colorectal tube (TCT) placement is an alternative endoscopic treatment for ACO; however, the oncological outcomes of TCT placement for the curative treatment of CRC remain unknown.
Aims & Methods: Data were retrospectively reviewed from patients with distal stage II/III CRC who underwent surgery between January 2007 and December 2011 at two Japanese affiliate hospitals with an interchange of endoscopists and surgeons. We conducted endoscopic TCT placement. This study demonstrated the high technical and clinical success rate of double-wire woven uncovered self-expandable metallic stent placement for malignant colorectal obstruction. Clinicians should perform this procedure carefully in patients with acute obstruction. We established the Colonic Stent Procedure Research Group to provide instructions on how to safely perform stent placement, and then, we conducted this prospective, single-arm, observational, multicenter clinical trial between October 2013 and May 2014 in Japan. Thirty-two facilities participated in this study. A double-wire woven uncovered stent was placed by using a standard through-the-scope colonoscopic technique in each patient. Stent deployment time was defined as the time from reaching a lesion with a colonoscope to finishing stenting. Technically difficult cases of stenting were defined as independent factors affecting the technical difficulty of stenting remain unclear.
Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining all 196 patients were succeeded in stenting. Of these, 100 men (51%), the median age was 72 years old (interquartile range (IQR), 62-82 years old). One hundred eleven patients (57%) underwent stentting as a bridge to surgery, and 85 (43%) underwent stentting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients experienced colorectal perforation. The median total procedure time in the cohort with technical success was 30 minutes (IQR, 18-42 minutes). The median deployment time was 21 minutes (IQR, 11-31 minutes). Forty-nine patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting. The following were identified as independent factors of the technical difficulty in stent placement: presence of ascites (odds ratio, 2.483; 95% confidence interval [95%CI], 1.17–5.29; p=0.02), placement of >1 stent (odds ratio, 4.80; 95% CI, 1.10–21.1; p=0.04).

Introduction: Colorectal cancer is the third most common cancer in the world and the fourth leading cause of cancer death1. Treatment strategy for colorectal cancer is selected considering clinical stages. T1 colorectal cancer (T1CRC) can be treated with endoscopic resection. If patients have pathological risk factors such as deep submucosal invasion, budding, por/muc pathological features and lymphovascular invasion, they are considered to be at high risk of lymph node metastasis based on the indication of Japanese Society for Cancer of the Colon and Rectum guideline2. In such cases, the selection of subsequent option is important and has been frequently decided by clinicians’ customs and preferences. However, it is not clear whether these risk factors adequately predict patients’ long-term clinical practice.

Aims & Methods: This research aims at revealing the prognosis and clinicopathological features of pathologically high-risk T1CRC patients (the high-risk group) with and without additional surgery; followed up by computed tomography, ultrasound, endoscopy, and tumor marker (CEA: carcinoembryonic antigen). To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as T1 colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosis is divided as “high-risk” and clinicopathological features, presence or absence of recurrence and the final stage as of February 2017. We used the Kaplan-Meier product limit method and the Log-rank test to compare OS, CSS, and RFS between AS and FU groups. In clinical setting, based on the guideline indication, the clinician offered subsequent options and described their risks and benefits, and the patient expresses his or her preferences and values. Factors considered through selecting treatment strategy were extracted from informed consent and provider’s note of electronic medical record.

Results: Among 162 T1CRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU), 20 patients were performed additional surgery with lymph node dissection (AS). Four patients treated with additional radiation therapy were excluded. Median survival time was 39 (FU) and 62 (AS), respectively. The rates of LN metastasis in Groups A, B, and C were 10% (5/49), 20% (9/45), and 4% (1/21), respectively. There were no recurrences among the 62 e-curable patients. On the other hand, five recurrences (5%) were found in non-e-curable patients, and they were all in Group A. They consisted of local recurrence (one patient who also had lung metastasis), LN metastasis (two patients), lung metastasis (three patients), and liver metastasis (one patient who also had LN metastasis). There were no significant differences in DSS between Group A and Group B + C (LST-NG). However, OS was 93% in Group A, which was significantly lower than that (96%) in Group B + C (p < 0.05). DFS in Group A was 90%, which was significantly lower than that (100%) in Group B + C (p < 0.05). The prognosis of patients with non-e-curable disease after ER alone showed no significant differences in OS, DFS, and DSS between Group A and Group B + C. The prognosis of patients with non-e-curable disease after surgical resection showed no significant differences in DFS or DSS. However, OS in Group A was 94%, which was significantly lower than that (97%) in Group B + C (p < 0.05).

Conclusion: Long-term outcomes supported the JSCCR criteria for e-curable patients after ER for T1 LSTs. All recurrences occurred in patients with T1 LST-G-H carcinoma. OS and DFS in the LST-G-M group were significantly shorter than in the LST-NG group.

Results: In this study we evaluated and tested a controlled-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. Animal models were developed, laser-cut nitinol stents were coated with a polymer matrix allowing slow release of paclitaxel. Native Yucatan swine were assigned to one of three stent groups: bare control (n = 3, no polymer), standard dose paclitaxel (n = 6, 149.4 µg paclitaxel) and challenge dose (n = 3, 538.0 µg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group. One in the intrahepatic/hilar region and a second in the common bile duct placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlass®. DS cholangiography and cholangiography with a targeted 6 month study endpoint. At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary system, even at challenge condition doses. Although the cause of bile duct dilation observed in all stent groups has not been conclusively identified, we hypothesize that the bile duct may be distal stent impaction and intermittent (clinically insignificant) obstruction of the papilla and/or stent, resulting in retained mucus and bile. Bile duct dilation, in turn, has reduced the opportunity for bile duct tissue overgrowth in all stent groups, which was expected to occur in the bare metal stent group by day 60 post-implantation. Although some animals displayed minimal tissue hyperplasia at the proximal end of the bile duct, no clinically significant obstruction of the papilla and/or stent was noted. In all animals, the bile duct diameter measured via digital radiographic analysis for the first 2 weeks and then monthly post-implantation showed no significant change.

Conclusion: At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary system, even at challenge condition doses. Although the cause of bile duct dilation observed in all stent groups has not been conclusively identified, we hypothesize that the bile duct may be distal stent impaction and intermittent (clinically insignificant) obstruction of the papilla and/or stent, resulting in retained mucus and bile. Bile duct dilation, in turn, has reduced the opportunity for bile duct tissue overgrowth in all stent groups, which was expected to occur in the bare metal stent group by day 60 post-implantation. Although some animals displayed minimal tissue hyperplasia at the proximal end of the bile duct, no clinically significant obstruction of the papilla and/or stent was noted. In all animals, the bile duct diameter measured via digital radiographic analysis for the first 2 weeks and then monthly post-implantation showed no significant change.

Introduction: Meta-analyses and guidelines recommend that deep submucosal invasion (>1 mm) in malignant colonic polyps is an important risk factor for residual malignant disease. However, the existing data are based on small retrospective studies with marked heterogeneity.

Aims & Methods: The aim of this study was to test the correlation between the submucosal invasion depth and the rate of residual malignant disease in complete endoscopic mucosal resection (EMR) of malignant colonic sessile polyps. The secondary outcomes include risk factors such as: lymphovascular invasion, tumor differentiation, resection margin status and the presence of tumor budding. A retrospective review of the endoscopy charts for the period 2000-2016 was conducted. All patients enrolled exhibited a malignant colonic sessile polyp which was endoscopically completely resected. Histological findings of the polyps were also recorded. Thorough computed or magnetic scanning was performed in all patients before deciding on further management. All patients were advised for the option of surgical treatment or endoscopic follow-up.

Results: 51 patients with confirmed adenocarcinoma in sessile colonic polyps undergoing endoscopic mucosal resection (EMR) were retrospectively included in this study. A total of 33 (64.7%) patients underwent subsequent surgery after EMR, and 18 (35.3%) chose endoscopic follow up. The histological characteristics, site of the polyp, IQR (range), number of dilated ducts between days 30 and 60, we expect increased rate of stent occlusion.

Conclusion: Our data suggest that even in cases with submucosal invasion >1 mm and the presence of other high-risk features (lymphovascular invasion, tumour budding), complete EMR in malignant colonic sessile polyps supported by the histological findings predicts for a good clinical outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this prospective study, we evaluated the overall survival (OS) of colorectal adenocarcinoma (CRC) in patients associated with an overall survival in colorectal cancer group based on CD-DST. Moreover, we evaluated additional effects of EGFR (Cetuximab; Cmab, Panitumumab; Pmab) to FOLFOX/FOLFIRI using CD-DST. Between Mar. 2008 and Aug. 2016, we obtained tumor specimen from 131 CRC patients without preoperative chemotherapy. Informed consent for measurement of individual chemosensitivity was obtained from all patients in writing. Approval for the present study was obtained from the Tobu Chiki Hospital Institutional Review Board (No: 02.0329). The growth inhibition was determined by CD-DST. The regimens were followed FOLFOX, FOLFIRI, Cmab, Pmab, and FOLFOX/FOLFIRI + Cmab. The incubation conditions were as follow: FOLFOX; 5-FU and l-OHP (6.0 and 3.0 μg/ml, respectively) for 24 h. FOLFIRI; 5-FU and SN-38 (6.0 and 0.2 μg/ml, respectively) for 24 h. Cmab; Cmab 250 μg/ml for 144 h. Pmab; Pmab 200 μg/ml for 144 h. FOLFOX+Cmab; Cmab 250 μg/ml for 120 h after FOLFOX/FOLFIRI incubation process. The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to chemotherapy is classified into four grades (approximately 50%). The IR between the group treated with appropriate first-line chemotherapy and the group treated with inappropriate first-line chemotherapy were evaluated Kaplan-Meier method. Additional effects of Cmab to FOLFOX/FOLFIRI were also evaluated.

Results: There was strongly relationship between the IR% of the FOLFOX and FOLFIRI regimen (R ² = 0.7415). The median of the IR% with the FOLFOX and FOLFIRI regimen were 58.6 and 69.1, respectively, FOLFOX responder, FOLFOX responder, dual responder, and poor responder were 8, 10, 53, and 60, respectively. There were 42 unreactable CRC patients with chemotherapy. The median survival time of appropriate first-line chemotherapy group (n: 28) and inappropriate first-line chemotherapy group (n: 14) were 1126 and 306 days, respectively. There was positive correlation between Cmab and that of Pmab (R ² = 0.468). Additional rates (%) of Cmab to FOLFOX between poor responder and other responder were 19.8 and 5.4, respectively (P = 0.020). Additional rates of Cmab to FOLFIRI between poor responder and other responder were 16.5 and 1.29, respectively (P = 0.005). There was significantly more additional effect of Cmab to FOLFOX/FOLFIRI in poor responder than in other responders.

Conclusion: Administration of the recommended first-line regimen using CD-DST in patient is important for improvement in the further prognosis. Moreover, especially in poor responder, Cmab should be administrated to FOLFOX/FOLFIRI regimen.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0467 WAIT-AND-SEE STRATEGY IN LOW RECTAL CANCER

Introduction: The standard treatment for locally advanced rectal adenocarcinoma (ADC) is to conduct surgical resection after neoadjuvant chemoradiotherapy (CRT). In the wait-and-see (W&S) strategy, those who achieve a clinical complete response (cCR) after CRT undergo regular clinical, radiologic and endoscopic surveillance, with surgery being reserved for tumor "regrowth".

Aims & Methods: To evaluate the impact of a W&S strategy for low rectal ADC, regarding overall and disease-free survival. Single-center prospective observational study. All patients with low rectal (up to 6 cm from the anal verge) colorectal invasive cancer were observed during a long-term period in our hospital. They were divided into group A, B, and C as follows; 445 in group A (mean age 64.7 yr, M:F = 2.37:1) with low-grade adenoma colonoscopically resected at baseline, 245 in group B (66.1 yr, 2.31:1) with high-grade adenoma or intramucosal cancer colonoscopically resected at baseline, 358 in group C (65.1 yr, 1.54:1) with invasive cancer resected at baseline during follow-up colonoscopies detected metachronous neoplasms were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative incidences of metachronous colorectal neoplasms were compared with each other using Logrank test.

Results: Median follow-up periods and frequencies of colonoscopy were 64.3 months and 3.7 times in group A, 52.0 months and 3.5 times in group B, and 74.6 months and 3.9 times in group C, respectively. The cumulative incidences of metachronous non-index lesion were 24.5% (109 patients with 299 low-grade adenomas) in group A, 26.1% (64 with 184) in group B, and 19.3% (75 with 229) in group C, respectively. The prevalence of metachronous non-index lesion was lower in group C compared to that in group A (P = 0.07), and group B compared to that in group A (P = 0.02). The cumulative incidence of metachronous invasive cancer were 0.9% (4 patients with 4 invasive cancers) in group A, 1.2% (3 with 3) in group B, and 3.6% (14 with 14) in group C, disclosing highest prevalence in group C (P < 0.05). Logrank test revealed that the cumulative incidence of non-index lesion was significantly higher in group C, and statistical significance were observed between group A and C (P < 0.01), and between group B and C (P < 0.001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group C, but no significant differences were observed compared to those in group A and B.

Conclusion: Significant higher prevalence of metachronous index lesion including invasive cancer and, in contrast, significantly lower prevalence of metachronous non-index lesion were observed in patients after resection of colorectal invasive cancer compared to those after endoscopic resections of colorectal adenoma and intramucosal cancer.

P0469 LONG-TERM COLONOSCOPIC SURVEILLANCE BETWEEN PATIENTS WITH UNRESECTED DIMINUTIVE POLYPS AND THOSE WITH COLORECTAL ADENOMAS > 5MM IN SIZE RESECTED AT INITIAL COLONOSCOPY

S. Kimura1, M. Tanaka2

Introduction: A long-term risk of colorectal advanced neoplasia among patients having diminutive polyps at initial colonoscopy has been unknown. The present study aimed to compare the risk of metachronous advanced neoplasia during follow-up between patients with untreated diminutive colorectal polyps and those with small or large adenoma resected at initial colonoscopy.

Aims & Methods: A total of 1078 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows; 519 in group A (mean age 64.7 yr, M:F = 411:170) with colorectal adenoma more than 5 mm in size resected at baseline, 495 in group B (65.2 ± 9.6 yr, 328:167) with diminutive polyps left untreated at baseline, and 519 in group C (62.5 ± 10.7 yr, 255:264) with no polyps at baseline. During follow-up colonoscopies detected metachronous neoplasms more than 5 mm in diameter were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative incidences of metachronous colorectal neoplasms were compared with each other using Logrank test.

Results: Median follow-up periods and frequencies of colonoscopy were 64.3 months and 3.7 times in group A, 52.0 months and 3.5 times in group B, and 74.6 months and 3.9 times in group C, respectively. The cumulative incidences of metachronous non-index lesion were 24.5% (109 patients with 299 low-grade adenomas) in group A, 26.1% (64 with 184) in group B, and 19.3% (75 with 229) in group C, respectively. The prevalence of metachronous non-index lesion was lower in group C compared to that in group A (P = 0.07), and group B compared to that in group A (P = 0.02). The cumulative incidence of metachronous invasive cancer were 0.9% (4 patients with 4 invasive cancers) in group A, 1.2% (3 with 3) in group B, and 3.6% (14 with 14) in group C, disclosing highest prevalence in group C (P < 0.05). Logrank test revealed that the cumulative incidence of non-index lesion was significantly higher in group C, and statistical significance were observed between group A and C (P < 0.01), and between group B and C (P < 0.001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group C, but no significant differences were observed compared to those in group A and B.

Conclusion: Significant higher prevalence of metachronous index lesion including invasive cancer and, in contrast, significantly lower prevalence of metachronous non-index lesion were observed in patients after resection of colorectal invasive cancer compared to those after endoscopic resections of colorectal adenoma and intramucosal cancer.

incidences of metachronous colorectal neoplasms were compared with each other using Log rank test.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.6 times in group A, 61.6 months and 3.4 times in group B, and 72.3 months and 2.7 times in group C, respectively. The cumulative incidences of metachronous adenomas were 24.1% (132/550 patients with 375 low-grade adenomas) in group A, 14.7% (73 with 168) in group B, and 6.6% (34 with 56) in group C, respectively. The prevalence of metachronous non-index lesion was highest in group A followed by those in group B and C, with significant difference observed between group A and B (p < 0.0005), and B and C (p < 0.05). The cumulative incidences of metachronous invasive cancer were 1.0% (6 patients with 6 invasive cancers) in group A, 1.4% (7 with 7) in group B, and 0.2% (1 with 1) in group C with no significant difference. Logrank test revealed that the cumulative incidence of non-index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.0001), and between group B and C (p < 0.0001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.05), and between group B and C (p < 0.005).

Conclusion: The results of a longer colonoscopic follow-up disclosed a significantly higher prevalence of metachronous advanced neoplasms in patients with adenoma >5mm in size resected at baseline compared to those with diminutive polyps left untreated at baseline. Persons with no polyps at baseline and family history (presence of more than 2 FDRs with CRC: 2, others: 0), BMI (23–30 kg/m2: 2, >30: 1), smoking status (never: 0, <10: 0.26) and in 1,000 bootstrapped replicates

Aim & Methods: The aim of this study was primarily to develop and validate a new scoring model for predicting ACN in asymptomatic screening populations that is more useful than the APCS score. We externally validated the APCS score in a Japanese screening population and compared its discriminatory capability with that of our new scoring model. Data were reviewed from 5218 consecutive asymptomatic screened individuals who underwent colonoscopy for their first time at the Cancer Screening Center, National Cancer Center Hospital, Tokyo between February 2004 and March 2013. Multivariate logistic regression was used to investigate the associations between clinical variables and the presence of ACN in the subjects, and then a new scoring model was developed based on these associations. Scores were weighted according to the beta coefficient obtained from the logistic regression model. Thereafter, the discriminatory capability of the new model was assessed using the c-statistics in the development set. Performance of the new model was internally validated using 1000 replicates. The discriminatory capability of the modified APCS score in the 5218 subjects was also assessed using the c-statistics. The value obtained was compared to the new scoring model using the DeLong test. A 3-point scoring model to predict ACN was developed by using five identified independent risk factors for ACN as scoring items. These included sex (male: 1 point, female: 0), age (40–49 years: 0, 50–59: 2, 60–69: 3, >70: 3.5), CRC family history (presence of ≥2 FDRs with CRC: 2; others: 0), BMI (<22.5: 0, ≥22.5: 1), smoking status (never: 0, <10: 0.5; >10: 1). Presence of ACN with CRC was not detected as an independent risk factor for ACN and was not assigned any score. Using the scoring model, the proportion of subjects with ACN increased with the order of scores. The proportions were 1.6% (54/3272), 5.3% (127/2419) and 10.2% (64/627) in the groups with scores of 1, 2 and 3, respectively. The c-statistic of the score in the development set was 0.70 (95% CI, 0.67–0.73) and this was the same in the internal validation set. The value of the modified APCS score was 0.68 (95% CI, 0.65–0.71). The c-statistics of the new score were significantly higher than those of the modified APCS score, both in the 5, 218 subjects (P = 0.03) and in 1,000 bootstrapped replicates (P = 0.03).

Conclusion: An 8-point scoring model to predict ACN in asymptomatic screening population that might have a higher discriminatory capability than the modified APCS score was developed and internally validated in this study. Our simple scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages the use of psychotherapeutic (7).  

**Aims & Methods:** In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidant styles such as denial and disengagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pooled N = 250), the variables investigated in Study 1 were measured alongside hypochondriasis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test a priori hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate with both neuroticism and GI symptom severity were included (see Results table). Coping styles were assumed to covary, and the model in Study 2 assumed a covariance relationship between somatisation and hypochondriasis.

**Results:** Significant standardised path model coefficients involving neuroticism across the two studies. In Study 1, neuroticism exerted indirect effects on symptom burden through substance-use-based coping and somatisation, as well as through disengagement-based coping and somatisation. In Study 2, neuroticism affected GI symptom burden through denial-based coping and somatisation, as well as through denial-based coping and hypochondriasis. An indirect effect of neuroticism through self-blame and somatisation, with the two intermediary variables relating negatively to each other, was observed in Study 1. (Note: *p < .001, **p < .01, *p < .05. n.s. denotes non-significant coefficients).  

**Conclusion:** Somatisation and hypochondriasis were found to be intermediaries in GI symptoms and their association with neuroticism and GI symptom severity. The expression of CRF and CRFR2 on HT29 cell surfaces was significantly increased by immunofluorescence microscopy (7).  

**Aims & Methods:** The expression of CRF1 and CRFR2 on HT29 cell surfaces was determined by immunofluorescence microscopy (7).  

**Results:** CRF treatment increased FITC-labeled Dextran permeability, caused opening of tight junctions, induced increased fluorescence intensity of CK8 and decreased intensity of ZO-1, Claudin-1, and occludin, and blocked with a power lab system (AD Instruments International). The diagnosis of D-IBS is based on symptom assessment and the Rome III Diagnostic Criteria. According to an epidemiological study, D-IBS mainly affects young adults of 20–40 years old, and the quality of life in IBS patients is seriously affected. The pathogenesis of D-IBS has not been completely elucidated. Consequently, the usual treatment of the disease in Western medicine involves symptomatic treatment, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients\' symptoms and quality of life, increasing numbers of patients have begun to seek treatment with TCM.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. Four visceral hypersensitivity indices (30 min) were randomized to one of four groups: diosmectite (500 mg/kg), diosmectite (500 mg/kg, WAS procedure), water (0.5 ml/ rat) or water (0.5 ml/rat, WAS procedure). Treatment was for 5 days, with the WAS procedure conducted once daily. The test apparatus consisted of a Plexiglas tank with a block affixed to the center of the floor. The tank was filled with fresh room temperature water to within 1 cm of the top of the block. Rats were placed on the block for a period of 1 h every day. For both conditions (basal and after WAS), intestinal transit was evaluated by fecal output measurement Visceral sensitivity to colorectal distension (CRD), was used to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silt clay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhea but also the functional abdominal pain experienced in chronic IBS. However, the effect of diosmectite treatment on IBS visceral hypersensitivity has never been investigated.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. For the first time, these data illustrate in wistar rat, that diosmectite reduce the visceral hypersensitivity in IBS. But different treatment effects have been reported. The negative effect of Bifidobacterium has been rarely studied and reported.

Aims & Methods: We aimed to study the effects of gavage administration with *Bifidobacterium bifidus* for two weeks on the visceral hypersensitivity of rats. Colonic visceral hypersensitivity (CVH) was induced by colorectal distension (CRD) and was used to mimic the visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silt clay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhea but also the functional abdominal pain experienced in chronic IBS. However, the effect of diosmectite treatment on IBS visceral hypersensitivity has never been investigated.

IBS according to the reference standard, 72 met the Rome IV criteria for IBS, 78.1% female, mean age 35.8 years (range 16 to 77 years)). Among 91 individuals with a diagnosis of IBS, after appropriate limited investigation to exclude relevant organic disease, both had bile acid diarrhoea. Positive and negative likelihood ratios (LRs) for the Rome IV criteria were 5.14 and 0.25 respectively. Among the 19 individuals who had IBS according to the reference standard, but who did not meet Rome IV criteria, the Patient Health Questionnaire (PHQ-12), the eight-item Short Form (SF-8) quality of life (QOL) questionnaire, health care utilization and past gastrointestinal (GI) disease diagnoses by doctors. Respondents with an organic GI disease were excluded from the IBS population. IBS consultants were defined as individuals meeting Rome IV IBS criteria who had visited a doctor for GI symptoms. Results: 6300 individuals completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4 ± 17.1 years) to be included for analysis (1994 US, 1994 UK, 1988 Canada). After excluding 36 individuals due to lower GI organic disease, 305 subjects (5.1%; 66% female; mean age 44.7 ± 14.5 years) fulfilled diagnostic criteria for IBS. From these, 195 (64%) had consulted a doctor for GI problems. IBS consultants had equal distribution of stools (63.6% vs. 69% female (p = 0.4) and somatization scores (p = 0.008), the distribution of the most bothersome symptom was similar (p = 0.38), and abdominal pain was the predominant symptom in both groups. See table for details. The frequency of doctor visits for non-GI health issues did not differ (p = 0.15), but IBS consultants had undergone more abdominal surgery (p = 0.04). IBS consultants also reported higher consumption of GI related (p < 0.001), pre-scribed pain (p < 0.001), and anti-depressive medications (p = 0.03), but had similar consumption of anxiety (p = 0.11) and over the counter pain medications (p = 0.34) as non-consulters. See table for details.

Conclusion: Among individuals who meet Rome IV criteria for IBS in the general population, those who are older, have more frequent bloating, have greater concern about their bowel function, and who are more socially affected by symptoms since the study. Whilst two had additional diagnoses (FGID plus polyps). 45 were diagnosed with a FGID (9 had another non-urgent diagnosis). At follow up 4 years post-referral, none of the 45 patients diagnosed with organic disease was diagnosed in a significant findings (polyps, iron deficiency). 45 were diagnosed with a FGID (9 had another non-urgent diagnosis). At follow up (mean 2.7 yrs [SD 0.5yrs] post-referral), none of the 45 patients diagnosed with FGID had received a gastroenterology consult based on the original referral (six patients warranted prompt GE review after active screening. Organic disease was diagnosed in a significant findings. 3% of patients attending the Specialist clinic received 1st-line therapy and lifestyle advice, albeit with specialist investigations including anorectal physiology (70%). 33% of patients were referred with faecal incontinence and 37% with chronic constipation. 35% of patient didn't receive any therapy at time of referral. 44% were prescribed treatment but not followed up for assessment of successful response to therapy prior to referral to the specialist clinic. In 28% of patients the diagnosis changed following Motility clinic assessment. Diagnosis at clinic in based on RomeIII questionnaire, depression and anxiety score, thorough history taking and physical examination (including per rectum exam), ad hoc psychiatry input and referral to specialist investigation. In 30% of patients referred with chronic constipation the diagnosis was changed to IBS-C. 8% referred from IBS-D to IBS-M, 8% referred with faecal incontinence had Obstructive Defecation Syndrome, 6% referred as IBS-M were diagnosed as IBS-C, 5% referred as IBS-D were diagnosed as IBS-M, 3% referred with Hirschsprung’s disease had boli acid malabsorption. 56% of patients underwent specialist investigations including unorectal physiology (70%). 33% of patients attending the Specialist clinic received 1st-line therapy and life style advice, albeit 57% of them, who received 2nd-line treatment, having failed 1st-line management.

Introduction: Irritable bowel syndrome (IBS) affects 5–15% of adults in the general population, and is characterized by chronic recurrent abdominal pain and discomfort and associated with altered bowel habits. The pathophysiology of IBS is complex and not fully understood. Hence, treatment is often based on symptomatology rather than underlying physiological aberrances.
Aims & Methods: The aim of this study was to compare the expression of membrane transporters in mucosal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Mucosal biopsies were obtained from the unprepared sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative 2−ΔΔCT method.

Results: Colonic expression of SLC7A5 and SLC3A2 (together comprising the amino acid transporter LAT1 + 4F2hc) was significantly lower in IBS patients, but not in PI-IBS patients, compared to healthy controls (P < 0.001). The expression of SLC7A5 (LAT2) tended to be lower in IBS patients compared to controls (P = 0.06). Mucosal gene expression of the short chain fatty acid transporter SMCT1 (SLC5A8) was lower in both IBS patients and PI-IBS patients compared to healthy subjects (P < 0.01).

Conclusion: The amino acid transporters LAT1 and LAT2 appeared to be affected in IBS patients, but not in PI-IBS patients, compared to healthy subjects, suggesting a possible alteration in amino acids transport in this patient group. Furthermore, our results suggest a lower uptake of short chain fatty acids in both IBS- and PI-IBS patients. Altered expression of these transporters may be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration, and therefore deserves further study in IBS.

Introduction: Most colonic diverticulitis can be conservatively treated, but some need surgical intervention due to intestinal complications. Risk factors associated with complications of diverticulitis have been reported mainly from Western countries, but few from Asian countries including Japan.

Results: Of the 282 patients, 183 (64.9%) patients had right-sided diverticulitis, and 70 (24%) had complications; perforation (n = 70), abscess (n = 35), fistula (n = 8), stenosis (n = 4). The rate of complication was highest in sigmoid colon (88.6%) when compared with other locations; ascending colon (10%), transverse colon (1.4%), and descending colon (0%). Multivariate analysis identified the location of sigmoid colon (odds ratio 62.2, 95% confidence interval 21.8–178.0) as a significant independent factor for complications of diverticulitis. Among 70 patients with complicated diverticulitis, 55 (78.6%) patients underwent emergent surgery; most of them (54 patients, 98.2%) were with diverticulitis in the sigmoid colon. Table. Risk factors associated with complications of colonic diverticulitis (univariate and multivariate analysis)

Conclusion: The sigmoid colon was a significant risk factor for complication of colonic diverticulitis in Japanese patients. Acute colonic diverticulitis in the sigmoid colon should carefully be treated with surgical interventions in mind.

Introduction: Colonic diverticulosis is one of the most common gastroenterological disorders. Though diverticulosis is typically benign, many individuals develop diverticular disease (DD). DD is thought to stem from a complex interplay of environmental, dietary and genetic factors; however, the exact pathogenesis remains unknown.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagen fibrils of the connective tissue in the development of diverticulosis. Genetic polymorphisms COL3A1 (rs334646, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulosis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs334646, rs1800255 and rs1800012 were associated with diverticulosis. After multivariate logistic regression analysis, they were not linked with the risk of developing colonic diverticulosis in general; when selectively analyzing genders, the minor allele (AA) in rs334646 remained significantly associated with diverticulosis in men (p = 0.037).

Conclusion: Our study shows that a variant of COL3A1 rs334646 is associated with risk of developing colonic diverticulosis in Caucasian men, while COL3A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

**Introduction:** Although symptoms occur in only 20% of patients harbouring diverticula, Diverticular Disease (DD) of the colon DD represents the 8th disease as burden in USA. Several treatment are currently advised in managing those patients, but their impact on the burden of the disease is unknown. The recent DICA endoscopic classification has been developed and validated for the classification of DD, founding that treatment of DICA 1 and DICA 3 patients did not impact significantly in terms of acute diverticulitis occurrence/recurrence and surgery occurrence. Our aim was to assess the impact of using DICA classification on the burden of DD in Italy.

**Aims & Methods:** We assessed retrospectively the overall and the cost/year of treatments for SUDD patients during a 13-year follow-up. Cost of treatments was calculated according to data on drugs’ consumption collected during the DICA study.

**Results:** According to 2015 ISPTA population data, we estimated that >8 million of Italian people >60 years may have diverticulosis. According to our estimations, about 75% of diverticulosis population are on DICA 1, about 30% on DICA 2, and about 13% on DICA 3. According to the drugs’ consumption recorded during our study, we estimated that overall about 679 million of euros could be spent in Italy in treating those patients. In particular, >357 million of euros are spent in DICA 1 population, >205 million of euros in DICA 2 population, and >88 million of euros in DICA 3 population. Considering that medical treatments did not show any significant advantage when treating DICA 1 and DICA 3 people in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence, we can estimated that >475 million of euros could be spent in Italy without any significant benefit for DD population.

**Conclusion:** DD has a significant burden for National Health System in Italy. DICA endoscopic classification may have a significant impact of this burden, helping to select DD people who effectively need treatments in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Symptomatic Uncomplicated Diverticular Disease (SUDD) is poorly known, and available data derived mostly from retrospective cohort studies.

**Aims & Methods:** We assessed endoscopically the overall and the cost/year of treatments for SUDD patients when compared with asymptomatic diverticulosis and healthy people, as well as PLS-DA analysis of NMR-based fecal metabolomics showed significant discrimination between HC and AD patient. Our aim was to assess the effect of current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

**Results:** During the observational period, 47 patients were lost to follow-up. Patients were treated with a 2-week course of 30/day fiber supplementation (3 patients), 1.6 grams/day of mesalazine (3 patients), 900 billion day of probiotic mixture VSL#3 (currently available in Europe as VivoMixx), 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microbiota. High-resolution proton nuclear magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabo-lite data set.

**Conclusion:** The overall bacterial quantity did not differ before and after treatment (p=0.44). The overall amount of Akkermansia muciniphila species was significantly reduced at T1 (p = 0.017) and T2 (p = 0.026), while at T3 it became similar to that of T0 (p=0.09). The amount of Lactobacillus group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. All treatment were showed the same behaviour in influencing fecal metabolome except for rifaximin group, in which we did not find any metabolic change neither at the end of treatment nor during the washout period.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Conclusions: The present study showed that, with respect to diverticulosis, female gender and presence of GI comorbidities are associated with SUDD, whereas younger age, family history for DD and female gender are associated with PD. Furthermore, patients with diverticulitis have higher physical and mental scores compared both to patients with SUDD and PD, suggesting that SUDD and PD reduced QoL of the affected patients.

filled in long-lasting pain questionnaire. Abdominal pain lasting <24 h was reported in patients with SMC (86.3%) and in 113/154 with PD (73.7%) (p = 0.026). Symptom severity score was higher in PD group than in SUD group, but this difference was not statistically significant (5.5 ± 2.4 vs 5.1 ± 2.2 cm; p = 0.130). Patients with PD had short-lived pain located more frequently in left lower abdomen (50.6% vs 50%; p = 0.002), whereas abdominal diffuseness was more prevalent in patients with SMC (29.6% vs 20.8%; p = 0.058). Pain lasting >24 h was more prevalent in PD group compared to SUD group (62.1% vs 52.6%; p = 0.029). Pain severity was higher in patients with PD, pain lasting >24 h, than observed in SMC (6.4 ± 2.6 vs 5.9 ± 2.4; p = 0.099). Long-lasting pain was more frequently located in left lower abdomen in patients with PD (53.6% vs 23.7%; p < 0.01), whereas more frequently was diffuse in SMC patients (17.3% vs 71.5%; p < 0.001). Moreover, in patients with PD, pain lasting >24 h, and SMC patients, pain was localized to fever (28.6% vs 26.4%; p < 0.001), confinement to bed (35.7% vs 18.6%; p = 0.002), medical consultation (38.6% vs 23.7%; p = 0.003), need for therapy (42.9% vs 19.2%; p < 0.001), and hospitalization (26.8% vs 8.3%; p < 0.001).

Conclusion: PD patients show some peculiar clinical features of abdominal pain. SMC patients frequently complained abdominal diffuse and short lasting pain. In contrast patients with PD frequently complained pain located in the left lower abdomen lasting for more than 24 h. Our results suggest these features are useful indicators to distinguish patients with SMC and PD and should be carefully assessed in clinical work-up of diverticular disease.

Contact E-mail Address: carola.severi@uniroma1.it

Introduction: Colonic diverticulitis, as well as diverticular disease, is a multifactorial disease characterized by neuronal-myocellular alterations. Among the most common etiological factors, impaired contraction, inflammation and fibrosis. Mesenchymal smooth muscle cells (SMC) are able to switch from a contractile phenotype to a less mature phenotype, overexpressing contractile markers as well as synthesis and release of several pro-inflammatory cytokines. Different organ specific pathways have been demonstrated to induce this mesenchymal transition. Renal fibrosis is driven by transforming growth factor-β (TGF-β) through inverse regulation of Smad2/3, while in liver fibrosis by PDGF-β, ending in downregulation of marker gene Trb3 expression.

Aims & Methods: Aim of this study was to determine, both in human uninvolved and involved tracts of asymptomatic diverticulitis (AD+AD-) and in stent-insonated colon diverticulitis, the differences in expression of collagen, fibrosis, inflammation and transformation state of SMC.

Results: In both muscle layers, AD+ and AD- SMC compared to CTR, showed an overall increase in inflammatory gene expression, with a trend of decrease from AD+ to AD-, the lowest expression being observed in CDD. This inflammatory upregulation was associated with an increase in IL-1β secretion in SMC culture medium compared to CTR and a progressive inhibition of contraction to carbachol, already in AD- in circular strips and SMC. In contrast relaxation in response to VIP resulted significantly decreased only in AD+ both on strips and SMC with no alteration in circular and stented DDD. Peculiarity of circular SMC was a progressive increase in Coll1 expression from AD to CDD compared to CTR (3 hundred fold increase) paralleled to about 50% decrease in the contractile protein α-SMA. Differently, longitudinal SMC, both in AD and CDD, presented a homogenous increased Coll1 expression, decrease in α-SMA and reduction of contraction. VIP-induced relaxation was significantly decreased in CDD. Phenotypic switch was only observed in CDD, driven in circular layer, by a TGF-β-dependent pathway (increased expression for TGF-β: 2.88 ± 0.6 and Smad2/3, induced Smad2/3 upregulated α-SMA and longitudinal SMC, while in circular layer by PDGF-β-dependent pathway (increase of PDGF-β: 2.27 ± 0.44 and parallel decrease of Trb3: 0.58 ± 0.13).

Conclusion: Intrinsically myogenic alterations are present in colonic asymptomatic diverticulitis and complicated diverticular disease, both in the circular and longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticulitis disease, ended in a muscular synthetic pro-fibrotic switch.

Introduction: Aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysregulated Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH1-4 in GC were achieved from online available dataset. The mRNA and protein expression of NOTCH3 were examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, monolayer colony formation, cell migration and invasion assays through siRNA-mediated knockdown. The mRNA silencing efficiency was assessed by qRT-PCR. Western blot and dual luciferase activity assays were performed to identify the repression effect of miR-491-5p and miR-875-5p on NOTCH3. The functional downstream targets of NOTCH3 were identified by gene expression microarray.

Results: NOTCH3, but NOTCH1-2, 4, is uniformly up-regulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MKN28 cells exhibited significant anti-oncogenic effect in vitro. NOTCH3 downregulation suppressed cell proliferation, reduced monolayer colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown significantly suppressed cell migration through siRNA-mediated knockdown. The expression of PHLDB2 axis, miR-491-5p and miR-875-5p, in patients with PD was associated with increased NOTCH3 expression. However, increased NOTCH3 expression in AGS and MKN28 cells significantly promoted cell proliferation, cell migration and cell invasion, whereas more frequently was diffuse in PD group compared to SUD group (62.1% vs 52.6%; p = 0.029). Pain severity was higher in patients with PD, pain lasting >24 h, than observed in SMC (6.4 ± 2.6 vs 5.9 ± 2.4; p = 0.099). Long-lasting pain was more frequently located in left lower abdomen in patients with PD (53.6% vs 23.7%; p < 0.01), whereas more frequently was diffuse in SMC patients (17.3% vs 71.5%; p < 0.001). Moreover, in patients with PD, pain lasting >24 h, and SMC patients, pain was localized to fever (28.6% vs 26.4%; p < 0.001), confinement to bed (35.7% vs 18.6%; p = 0.002), medical consultation (38.6% vs 23.7%; p = 0.003), need for therapy (42.9% vs 19.2%; p < 0.001), and hospitalization (26.8% vs 8.3%; p < 0.001).

Conclusion: PD patients show some peculiar clinical features of abdominal pain. SMC patients frequently complained abdominal diffuse and short lasting pain. In contrast patients with PD frequently complained pain located in the left lower abdomen lasting for more than 24 h. Our results suggest these features are useful indicators to distinguish patients with SMC and PD and should be carefully assessed in clinical work-up of diverticular disease.

P0498 FOX2 SUPPRESSES WNT SIGNALING PATHWAY IN GASTRIC CARCINOGNESIS THROUGH TRANSCRIPTIONALLY MODULATING E3 LIGASE IRF2BP1 AND PROMOTING B-Catenin DEGRADATION

Y. Dong1, A. Higashimori2, Y. Zhang1, S. Sm Ng1, T. Arakawa1, F.K.L. Chan1, J.J.Y. Sung1, J. Yu1 1Institute Of Digestive Disease And Department Of Medicine And Therapeutics, The University Of Hong Kong, Hong Kong/Hong Kong PRC 2Department Of Gastroenterology, Osaka city University Graduate School of Medicine, Osaka/Japan 3Department Of Surgery, The Chinese University Of Hong Kong, Hong Kong/Hong Kong PRC

Contact E-mail Address: yujia_dong@yahoo.com

Introduction: We found that tumor suppressor gene FOX2 was silenced in gastric cancer (GC) through promoter hypermethylation. Restoration of FOX2 suppressed GC tumorigenesis through inhibition of canonical Wnt
Aims & Methods: We hypothesize that FOXF2 transcriptional upregulates a novel E3 ligase that targets β-catenin for degradation. We aim to investigate the molecular mechanism of FOXF2 in GC and identify such E3 ligase by PPI array and immunoprecipitation (IP) assay and luciferase assay. Results: FOXF2 significantly decreased both nuclear and cytosolic levels of β-catenin in a GSK-3β-dependent manner and induced β-catenin degradation via ubiquitin-proteasome pathway in gastric cancer cell lines. Using Human Ubiquitin Chromatin Immunoprecipitation (CHIP) assay and luciferase assay, we identified that IRF2BPL was upregulated upon FOXF2 overexpression and was a promising E3 ligase for β-catenin. Overexpression of IRF2BPL suppressed the TOP-flash luciferase reporter and reduced Wnt target gene c-myc expression in GC cells.

Conclusion: We reported a novel FOXF2-IRF2BPL-E3 ligase for β-catenin degradation. Immunoprecipitation assay suggested that IRF2BPL interacted with nuclear inactive enhancer element on the 5'-flanking region of IRF2BPL gene, suggesting that FOXF2 transcriptionally upregulates IRF2BPL gene transcription. In addition, IRF2BPL promoter region was downregulated in human GC tissues compared to the adjacent normal tissues (N > 50). We also performed comprehensive activity assay. Wild-type FOXF2 but not the mutant ΔFOXF2 significantly activated the lucerase reporter in AGS and 293F cells, suggesting that FOXF2 directly activated IRF2BPL transcription. Moreover, FOXF2 significantly decreased the level of H3K27Ac (a marker to distinguish active from inactive enhancer element) on the 5'-flanking region of IRF2BPL gene, suggesting that FOXF2 transcriptionally upregulated IRF2BPL gene transcription. In addition, IRF2BPL promoter region was downregulated in human GC tissues compared to the adjacent normal tissues (N > 50).

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: However, the physiological role of the obestatin/GPR39 system in healthy human stomach was observed in the neuroendocrine cells and GPR39 expression was localized mainly in the chief cells of the oxyntic glands but also in a few cells of the neck section (pre-chief cells). This expression co-localized with PGI expression in both cell types. The mucous neck cells were positive for PGI and negative for GPR39. Obestatin also exerted a dose dependent stimulatory effect on PGI secretion in the in vitro explant culture of human stomach, being significant for 100 and 200 nM compared to the control sample at 20 min (39% and 66% over control, respectively), for 200 nM at 40 min (51% over control) and 100 nM at 60 min (64% over control).

Conclusion: The obestatin/GPR39 system is physiologically involved in the stimulation of PGI secretion in the healthy human stomach.

P0503 SERUM EXOSOMAL miRNAS EXPRESSION AS NOVEL BIOMARKERS FOR DETECTION OF ESOPHAGEAL ADENOCARCINOMA

H. Chen
Jiangyuan Province Hospital, Nanjing/China

Contact E-mail Address: chenhan088@hotmail.com

Introduction: Novel biomarkers are needed for the diagnosis of esophageal adenocarcinoma (EAC) as it is urgently required. Currently, there is increasing evidence suggesting that serum exosomal miRNAs may be potential noninvasive biomarkers for certain diseases. The objective of the present study was to find and investigate whether exosomal miRNAs could be effective biomarkers for EAC.

Aims & Methods: In the present study, exosomes were isolated from the serum of both EAC patients and normal controls. Total RNA was extracted from exosomes and miRNA levels were compared between EAC and control patients in serum exosomes. We also sought to investigate the relevance of exosomal miRNA expression to clinicopathological factors in EAC.

Results: We measured levels of several exosomal miRNAs, including miR-21, miR-16, miR-25, miR-155, miR-192, miR-92a, in 9 EAC patients and 9 controls. Interestingly, miR-192 expression was significantly lower in EAC patients than in controls (Fold-change 35.36, 30.87, 9.24 and 2.26, respectively). The level of miR-192 was significantly lower in EAC patients than in controls (Fold-change 0.35). We did not observe a significant fold-change in miR-92a expression levels between EAC and controls. P-values did not achieve statistical significance, possible due to large standard deviations and relatively small sample sizes. We also visualized exosomes isolated from both healthy mediums and sera of EAC patients and control subjects, with diameter ranging from 30 to 100 nm using transmission electron microscopy.

Conclusion: Serum exosomal miRNAs can be isolated, measured, and may serve as potential biomarkers in EAC patients. miRNA microarray or next-gen sequencing analyses and larger sample sizes are needed to validate these early results.

Introduction: Endoscopic variceal band ligation (EVL) is an effective procedure to control and prevent variceal bleeding in patients with liver cirrhosis. Although EVL has some complications, yet these complications are related to post-EVL ulcers. Few data exist regarding therapy of post-ligation ulcer and treatment been mostly empirical with drugs used for peptic ulcer diseases.

Aims & Methods: We aimed to compare the efficacy of rebamipide, sucralfate and pantoprazole in treatment of post banding variceal ulcers. Seventy-five patients with esophageal varices eligible for elective band ligation represented the population of the study. The patients were allocated into three groups; rebamipide group, they received rebamipide 100 mg 3 times daily; pantoprazole group, they received pantoprazole 40mg/day orally at morning; sucralfate group, they received sucralfate 1 gm every 6 hours, for 14 days beginning at the next day of band ligation. Subjects underwent EGD 14 days after banding.
Primary outcomes included the size and number of ulcers and the subjects' reports of pain, dysphagia, chest pain and vomiting.

**Results:** At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient is statistically significant less in rebamipide group when compared with pantoprazole and sucralfate (P < 0.001). Chest pain, dysphagia and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebamipide is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with significant effect on post banding ulcer formation. Rebamipide can be used routinely in settings of post-EVL as a good alternative to pantoprazole and sucralfate.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Results:** A total of 113 patients were included in the study. The median GBS was 10 (IQR 3–21), and RRC was 24 (IQR 12–38). The score of fibrin glue was correlated with AUROC of 0.63. The median CT number was 48HU (IQR 26.7–60.7). The CT number also did not discriminate well with AUROC of 0.65. We set the cut off for GBS at 4, and a CT number at 50HU. The endoscopic treatment percentage of the group of GBS≥4 and CT number<50HU was 63.5%, GBS≥4 and CT number<50HU was 63.5%, GBS<4 and CT number<50HU was 33.3%, GBS<4 and CT number<50HU was 11.1%. We counted that GBS≥4 was 1 point, CT number≥50HU was 1 point. The points were added up to a total score that predicts the necessity for endoscopic treatment. Those scoring 2 points was about 60 percentage for the necessity for endoscopic treat- ment, 1 points was about 30 percentage, 0 point was about 10 percentage. AUROC of this model was 0.69.

**Conclusion:** Using both the GBS and CT in combination performed better for predicting the necessity of endoscopic treatment for patients presenting with upper gastrointestinal bleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Proton pomp inhibitors (PPIs) have been widely used for the treatment of endoscopic submucosal dissection-induced gastric ulcers. However, post-ESD bleeding after gastric endoscopic submucosal dissection (ESD) is a concern due to the high risk of delayed bleeding. We investigated the incidence of delayed bleeding associated with ESD, and expected to reduce bleeding after gastric endoscopic submucosal dissection (ESD) by strongly inhibiting gastric acid secretion compared with PPIs.

Aims & Methods: We compared the incidence of bleeding after gastric ESD between patients who took VPZ with ESD and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the VPZ group, 9 in the EPZ group) were excluded for simultaneous resection within 1 month. A case in which active bleeding or exposed vessels were observed on the bottom of ulcers with hematemesis, melena or a drop of not less than 2 g/dl of Hemoglobin within 4 weeks after ESD was defined as "post-ESD bleeding". In addition, we performed second-look endoscopy on the day after ESD. A case in which hemostasis was needed with hemorrhage of Forrest IIa or more was defined as "post-ESD bleeding". In addition, we perform second-look endoscopy on the day after ESD.

Results: Gender, age, sex, resected specimen diameter, oral anti-thrombotic drug administration, and diagnosis were not significantly different in both groups. Two of the 19 patients in the VPZ group (10.5%) and 6 of the 70 patients in the EPZ group (8.6%) had Post-ESD bleeding (Table). In addition, 6 patients in the VPZ group (31.6%) and 37 patients in the EPZ group (52.9%) had next-day hemostasis. There was no significant difference in both groups regarding post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Table: Incidence of post-ESD bleeding and next-day hemostasis

P0509 OUTCOMES FROM AN INTERNATIONAL MULTICENTRE REGISTRY OF PATIENTS WITH GASTROINTESTINAL BLEEDING UNDERGOING ENDOSCOPIC TREATMENT WITH HEMOSPRAY

Introduction: The primary aim of this international multicentre registry is to collect data on the successful cessation of GI bleeding following application with Hemospray. Secondary outcomes of recurrent bleeding (within 72 hours), 30 day mortality, disease and procedure specific outcomes were also collected.

Aims & Methods: Data was collected prospectively (January 2016 – April 2017) on the use of Hemospray in acute upper and lower GI bleeding, from 3 initial centres in the international registry. The use of Hemospray in GI bleeding was at the endoscopist’s discretion at the time of endoscopy. Hemospray use was either as mono- or dual-therapy with standard endoscopic techniques or as rescue therapy once standard methods had failed.

Results: To date 56 cases have been recruited (39 male and 17 female). The Forrest Classification of the bleeding lesions were in 5 (9%) cases Forrest Ia bleed, 41 (73%) Ib, 3 (5%) Ic and 3 (5%) Forrest Ib bleed. Sources of GI bleed included Peptic ulcer disease 24 (43%), post endoscopic therapy 9 (16%), malignancy 11 (20%), inflammation 3 (5%), Mallory Weiss tear 2 (4%), angiodysplasia 1 (2%), bleeding polyp 2 (4%), duodenal diverticular bleed 1 (2%), oesophageal variceal bleed 1 (2%), radiation 1 (2%), and post bleed NGT insertion 1 (2%). A total of 48 patients (86%) achieved immediate haemostasis after Hemospray endoscopic therapy, 8 patients did not achieve haemostasis. 2 managed conservatively, 1 treated by radiological intervention and 5 died. Hemospray was used in 25 patients (45%) as monotherapy [haemostasis achieved in 22 (88%)], in 22 patients (39%) in combination with other modalities [haemostasis achieved in 17/22 (77%)] and in 9 patients (16%) used as rescue therapy where other modalities failed [haemostasis achieved in 9/10 (100%)]. Hemospray was used in 9/9 (100%) patients with anticoagulated at the time of emergency endoscopy. Haemostasis was achieved in all anticoagulated patients. There were 6 cases of delayed re-bleding of which 1 occurred in less than 24 hours post initial endoscopy, 2 at 24–72 hours, 1 at 4–7 days, 1 at 7–14 days and 1 more than 14 days after the initial endoscopy. There was no prior use of anticoagulation in any of these patients. There were no reported immediate or delayed complications from the treatment.

Conclusion: Early data from our registry show a high rate of immediate haemostasis (86%) with Hemospray and an excellent safety profile. The imminent expansion of this registry to other centres in Europe will provide invaluable data on the efficacy of Hemospray in various disease and patient types over the coming years.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0511 RISK FACTORS OF GASTROINTESTINAL BLEEDING IN PATIENTS RECEIVED DUAL ANTIPLATELET THERAPY

W. Yingyongthawal1, A. Pulsomari1

Introduction: Current guidelines suggest dual antiplatelet therapy (DAPT), clopidogrel or ticagrelor with aspirin, for patients with acute coronary syndrome. Other indications of DAPT include recurrent ischemic stroke and percutaneous coronary revascularization. Gastrointestinal bleeding (GIB) is one of the most common adverse effects of DAPT, potentially causing hospital admission and death. Scanty information regarding safety of DAPT in Thailand is available. Vascular disease. Gastrointestinal bleeding (GIB) is one of the most common adverse effects of DAPT, potentially causing hospital admission and death. Scanty information regarding safety of DAPT in Thailand is available.

Aims & Methods: The primary aim of this registry to other centres in Europe will provide invaluable data on the efficacy of Hemospray in various disease and patient types over the coming years.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
Results: A total of 201 patients received clopidogrel with aspirin and 199 patients received ticagrelor with aspirin were recruited. Mean ± standard deviation age was 66.2 ± 11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs.100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 days vs. 251 days, respectively (p = 0.216). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44 % in clopidogrel group vs. 66.7 % in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 (95% confidence interval [CI] 0.95–3.7, p = 0.093). By multivariate logistic regression analysis, duration of DAPT > 180 days (RR 3.26; 95% CI 1.89–5.69, p < 0.001) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04–17.71, p < 0.001).

Conclusion: Risk of GIB is almost two times higher among patients received clopidogrel with aspirin compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT < 180 days and previous GIB might be minimized the risk of GIB event after receiving DAPT.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Department Of Internal Medicine 1, University Clinical Center Erlangen, Erlangen/Germany

Contact E-mail Address: martin.raithe@waldkrankenhaus.de

Introduction: Non-vitamin K direct oral anticoagulants (NOAC) are increasingly used in thromboembolic disorders due to an efficacy at least equally as vitamin K antagonists (VKA) and/or significantly higher safety for intracerebral bleeding or major bleedings of any source. In the approval studies, there was no generally increased bleeding rate for all types of bleeding, but different gastrointestinal bleeding (GIB) rates for apixaban, dabigatran, edoxaban and rivaroxaban. Reversed ticagrelor with aspirin were recruited. Mean ± standard deviation of each included unselected patients manifesting with a GI bleeding under anticoagulation in 2014. All patients who were diagnosed with a GI bleeding under NOAC or VKA therapy in the emergency department of the University Hospital Erlangen were analyzed. Their data were entered in a registry and evaluated in terms of bleeding type, localization, use of proton pump inhibitor and frequencies. These real-life results were then compared with the published data from important approval studies, reporting each on the above mentioned NOACs.

Results: 31 patients with GI bleeding, 31 patients received VKA (14.5%) and 23 patients (10.8%, n.s.) had NOAC with major bleeding rates of 68% and 61%, resp., in patients with VKA 87% had an upper GIB, 12% a lower GIB, and none had a rectal bleeding (0%). During NOAC therapy, a similar distribution was found with 71% and 17%, but the proportion of rectal bleeding was higher with 10%.

This frequency of GIB rates in unselected emergency patients is significantly higher than reported from the controlled NOAC approval studies that included selected patients (3.8–3.6% GIB). In these NOAC studies a lower rate of GIB (55%, 0–71%), a higher rate for lower GIB (32%, 17–84%) and rectal bleeding (15%, 10–47%) was found. Although NOACs are associated with a lower rate for GIB than VKA in the setting of emergency patients, NOACs show a shift of the type of bleeding to lower GIB or rectal bleeding sources in our analysis from emergency patients and in the NOAC approval studies. Only 50% of patients with NOAC were on proton pump inhibitor therapy.

Conclusion: The frequency of GIB in everyday life is approximately 10% higher than reported from the controlled NOAC studies, irrespective of the type of anticoagulation used. NOACs were associated with a non-significantly lower bleeding rate compared with VKA, but major GIB rates were similar. VKA with a bioavailability of 100% after oral ingestion showed a tendency of higher rates of upper GIB, while NOACs with a reduced GI absorption rate of 7–68% were found to occur more frequently at lower GIB sites. Thus, prior to any anticoagulation, a pre-therapeutic risk analysis for the occurrence of GIB is still required. Certain patient groups (anemia, aortic valve stenosis, renal insufficiency, NSAIDs, etc.) can benefit from proton pump inhibitor therapy, early endoscopy with intervention, or NOAC differential therapy.

Disclosure of Interest:ingestion.

Test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was comparable in capsaicin positive and negative patients at baseline (NS). After long-term capsaicin ingestion, the capsaicin positive (not chemosensitive) patient group. Symptom diaries for upper and lower gastrointestinal symptoms (visual analogue scales) were completed in the week before and during capsaicin ingestion and weekly aggregate symptom scores were calculated. Results are given as median; 25%/75%, p < 0.05 was considered significant.

Results: 53% FD had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily aggregate upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4–11.7) than in capsaicin negative patients (6.6; 4.1–9.8) (p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS).

After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by −3.3 (−4.9–1.9); p < 0.001 in capsaicin positive and −2.6 (−3.5–0.8) in capsaicin negative patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by −1.0 (−1.8–0.1); p < 0.05) in capsaicin positive but not significantly altered (−0.6; 1.7;+0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of chemosensitive patients (p < 0.01).

Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.

pain (ClinicalTrials.gov Identifier: NCT01919021, NCT00944593) patients likely to benefit from this novel approach to treatment. Controls had relatively rapid ACW and solid GE. Future studies will identify abnormal gastric motor function and the benefit of "prior JN" on symptoms was not identified. Few patients in the DG group had objective evidence of bloating and pain were reduced by JN in DG patients (p < 0.05). Sensations were not affected by JN in the controls; however, fullness, bloating and pain were reduced in JN in DG patients (p < 0.05). Compared to water, JN induced a greater GI-peptide response (e.g. PP, GLP-1) and initial liquid GE was slower (gastric content volume after meal: 5.9 ± 4.7 ml vs. 13 ± 11.3 ml, higher, p = 0.019). Subsequent liquid GE was similar in both study conditions (T= 3 ± 5.8 min, p = 0.727). Antral contraction wave (ACW) frequency was 2.7 (2.6–2.9) min in health and was highest in diabetic controls (3.1 (2.7 to 3.3) min). Solid GE was more rapid after JN than water (2.1 (1 to 3) beads emptied ≥60 min) and, again, was highest in diabetic controls (3 (1 to 7) beads emptied ≥60 min). Numerically the GI-peptide response was less pronounced in both diabetic groups than healthy controls; however, the difference was not significant and a correlation with postprandial symptoms or gastric function was not identified.

**Conclusions:** This clinical study demonstrates beneficial effects of prior JN on clinical symptoms related to bloating and pain. AIMS AND METHODS: The study tests the hypothesis that JN prior to a test meal improves postprandial symptoms (primary outcome) and gastric function. **Results:** Diabetic patients with severe symptoms (gastroparesis cardiac symptom index (GCSI) ≥ 27), diabetic controls (GCSI < 14) and healthy controls entered a randomized, double blind, controlled trial. An insulin glucose infusion controlled glycaemia. A JN feeding tube was placed at endoscopy with biopsies taken from the stomach and duodenum. Either liquid nutrient (2 kcal/min) or water was infused for 60 min. Afterwards the Nottingham Test Meal was ingested (NTM: liquid: 400 mL, 300 kcal; solid: 12 non-nutrient agar beads). Symptoms were provided 95% posterior ("credible") intervals and mixed model analysis compared response to intervention and between groups. **Results:** 9 DG patients, 9 diabetic and 12 healthy controls were recruited. There was no difference in sex distribution, age, weight, medical history (e.g. duration of disease or endoscopic findings including histology) between groups. DG patients had more psychiatric co-morbidity and reported higher satiety, bloating and pain after ingesting of the NTM than diabetic and healthy controls (p < 0.05). Sensations were not affected by JN in the controls; however, fullness, bloating and pain were reduced in JN in DG patients (p < 0.05). Compared to water, JN induced a greater GI-peptide response (e.g. PP, GLP-1) and initial liquid GE was slower (gastric content volume after meal: 5.9 ± 4.7 ml vs. 13 ± 11.3 ml, higher, p = 0.019). Subsequent liquid GE was similar in both study conditions (T= 3 ± 5.8 min, p = 0.727). Antral contraction wave (ACW) frequency was 2.7 (2.6–2.9) min in health and was highest in diabetic controls (3.1 (2.7 to 3.3) min). Solid GE was more rapid after JN than water (2.1 (1 to 3) beads emptied ≥60 min) and, again, was highest in diabetic controls (3 (1 to 7) beads emptied ≥60 min). Numerically the GI-peptide response was less pronounced in both diabetic groups than healthy controls; however, the difference was not significant and a correlation with postprandial symptoms or gastric function was not identified.

**Conclusion:** This clinical study demonstrates beneficial effects of prior JN on functional, bloating and pain after a 400 mL test meal in diabetic patients with moderate-severe symptoms compatible with gastroparesis (GCSI ≥ 27). Additionally, solid GE was accelerated after JN; however, this effect was not limited to DG patients and, thus, the treatment effect that improved symptoms could not be hypothesized. Few patients in both groups had objective evidence of abnormal gastric motor function and the benefit of "prior JN" on symptoms was not limited to patients with slow GE. However, it was observed that diabetic controls had relatively rapid ACW and solid GE. Future studies will identify patients who may benefit from this novel approach to treatment. Aims & Methods: Our aim was to evaluate the complex interrelationships between EGJ motor abnormalities, linear esophageal motor abnormalities, and esophageal reflux burden in this ongoing multicenter collaboration. Esophageal function studies from patients with persisting reflux symptoms were reviewed from four centers (2 in Europe and US) for this preliminary report. EGJ morphology was categorized using HRM into hypotensive (EGJ-CI < 40 mmHg cm), hiatus hernia (HH, manometric separation between lower esophageal sphincter and crural diaphragm) and intact EGJ (normotensive EGJ-CI, no HH). Esophageal body motor metrics were characterized using Chicago Classification v.3.0 into intact, ineffective esophageal motility (IEM) and absent contractility. Total and supine AET were extracted from ambulatory pH-impedance studies. Baseline impedance was calculated at the 5 cm impedance channel (to correspond to AET) at three stable 10-min time periods (1, 2, and 3 AM) during the ambulatory pH-impedance study, and averaged to yield MNBI (normal >2292 ohms). Univariate and multivariate analyses were performed to assess EGJ and esophageal body predictors of esophageal reflux burden, and to discern the value of MNBI in comparison to AET.

Results: 1244 patients (53.4 ± 0.4 yr, 59.6% F) undergoing esophageal motor testing using HRM (Medtronic, Duluth, GA) and ambulatory pH or pH-impedance monitoring studies performed off antacid therapy were included. A hypotensive EGJ was noted in 70.9%, HH in 34.0%, IEM in 26.3% and absent contractility in 3.5%. A disrupted EGJ and absent contractility had the highest proportions with AET > 6%; combinations thereof raised the proportions even higher (Table, p < 0.001 for each comparison to intact EGJ and/or esophageal body). Compared to an intact EGJ, the odds ratio (OR) of total AET > 6% with HH was 2.0 (95% CI 1.1-3.9, p = 0.04). Supine AET > 2% was even more impacted (HH: OR 2.4, 95% CI 1.3-4.5, p = 0.007; HH + hypotensive EGJ: OR 3.3, 95% CI 2.1-5.2, p < 0.001). A hypotensive EGJ was not discriminative of AET or MNBI values. Concordance between AET and MNBI thresholds was noted in 401 of 596 studies (67.2%; both abnormal in 24.8%, both normal in 42.4%). When concordant and abnormal, proportions with AET > 6% were 7.0% (n = 342), increasing numbers of ineffective swallows (p = 0.043) were independent linear predictors. Only the presence of HH was an independent categorical predictor of abnormal MNBI (p < 0.0001), increasing HH size (p < 0.0001) and proportions of ineffective swallows (p < 0.0001) were independent linear predictors.

Introduction: Electrical stimulation therapy is a new way to treat digestive disorders such as constipation, colonic inertia. It is necessary to understand the physiology of smooth muscle contraction in developing novel medical devices related to electrical stimulation therapy. The aims of this study were to measure the active characteristics of smooth muscle with acetylcholine in porcine intestine segment.

Methods: We used five female pigs and obtained ten centimeters of each porcine small intestine. To measure passive characteristics of small intestine, a universal testing machine with a tensile rate of 30 mm/min. To estimate the active characteristic parameters of smooth muscle and isometric and isotonic intestinal motility of smooth muscle, muscle contraction was induced by applying the stimulation solution (HTK solution containing 1 mM of acetylcholine chloride).

Results: The maximum muscle contractile force of the specimens to measure the isometric and isotonic intestinal motility.

Conclusion: We straighten out the active and passive property of porcine intestinal smooth muscle. Our study may be helpful for developing novel medical devices and understanding the physiology of smooth muscle in the porcine small intestine.

Disclosure of Interest: All authors have declared no conflict of interest.

P0521 MOTILITY PATTERNS AFTER PER-ORAL ENDOSCOPIC MYOTOMY (POEM) IN PATIENTS WITH ACHALASIA

Z. Vackova1, J. Krajcova1, L. Zdhrbova2, P. Loudova2, P. Sirand1, T. Hual1, J. Spicak1, J. Martinek2
1Department Of Hepato-gastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department Of Internal Medicine, University Hospital Plzen, Plzen/Czech Republic

Introduction: Partial recovery of esophageal peristalsis has been reported in up to 70% of achalasia patients treated by myotomy (either peroral endoscopic myotomy (POEM) or laparoscopic Heller’s myotomy) in several rather small studies. The aim of our study was to assess motility patterns following possible ‘‘recovery’’ of esophageal peristalsis in a large cohort of patients after POEM.

Aims & Methods: We performed a retrospective analysis of prospectively collected data of patients undergoing POEM at our tertiary referral center. All patients in whom high-resolution manometry (HRM) studies were performed prior to and 3 months after POEM and who completed at least 6-month follow-up were included. All HRM studies were reviewed and the Chicago Classification (CC) v3.0 of motility disorders was applied to characterize both pre- and post-POEM motility patterns.

Results: From 192 patients who underwent POEM since 2012 until 2017, 58 patients met the established criteria. The initial CC diagnoses before POEM were as follows: type I achalasia – 20 pts (16%); type II achalasia – 100 pts (79%); type III achalasia – 5 pts (4%); other (esophago-gastric junction outflow obstruction (EGJOO) and Jackhammer) – 2 pts (1%). Only 6 patients (5%; type III achalasia – 2 pts, EGJOO had had some signs of esophageal contractility before POEM). After POEM, peristaltic fragments were present in 28/127 patients (22%) - 9x ineffective esophageal motility, 5x fragmented peristalsis, 2x distal esophageal spasm, 5x EGJOO; 7x type III achalasia. Thus, the partial ‘‘recovery’’ of esophageal peristalsis was observed in 22/121 patients (18%) and it only occurred in patients with type II achalasia; contractile activity was not detected in any patient with type I achalasia after POEM (22/100 vs. 0/20, p = 0.023). Panesophageal pressurization completely resolved in 88 patients (88%) with...
achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (±13) mmHg to 13 (±5) mmHg (p < 0.0001). The presence of partial peristaltic recovery was neither associated with normalization of IRP (IRP normalized in 17/28 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, p = 0.25), nor with overall treatment success of POEM (Eckardt score <5).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophageal contractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Medical treatments, endoscopic balloon dilatation, Botox and Heller myotomy are treatment modalities for managing achalasia. Recently peroral endoscopic myotomy (POEM) has become a new option for achalasia patients and since 2010 it has become widespread. Earlier, anterior myotomy was used in this technique but in the last few years there are studies reporting that posterior myotomy is more effective. However, there are limited numbers of publications comparing anterior and posterior myotomy. This study aimed to investigate the effect of myotomy site on POEM, to our knowledge it is the first time in Europe and our country.

Aims & Methods: Between May 2014 and January 2017, POEM was performed to 225 achalasia patients at the gastroenterology clinics under general anesthesia by an endoscopist experienced at endoscopic submucosal dissection and trained for POEM. Demographic data, previous history for balloon dilatation and results of the procedure were recorded prospectively. Patients with anterior myotomy were grouped as "group A" and those with posterior myotomy as "group P", and the results were compared.

(continued)

Results: There were 114 patients in group A, 111 patients in group P. There was no statistical difference between the groups in regards of tunnel length, myotomy length, tunnel entrance time and frequency of homeostatic forces use (p > 0.05). However duration of opening the tunnel, myotomy, closure of the tunnel and total procedure time were significantly shorter in group P (p < 0.05). Eckardt and dysphagia scores before the procedure were similar in both groups. After the procedure the Eckardt scores were significantly low in all patients (p < 0.000). Demographic features and data of the procedures are shown in the table below. Mucosal damage during the procedure occurred in 3 patients and capnoperitonium developed in 71 patients. All complications were treated endoscopically. Controls at 3 months revealed esophagitis grade A in 24, grade B in 6 and grade C in 3 patients.

Conclusion: According to our results posterior approach can shorten the procedure time in POEM compared to anterior myotomy. This may be due to a better angle of approach with endoscopic equipments for posterior myotomy. We believe that long-term results will also show the effects of myotomy site on clinical outcome of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0526 LONG-TERM RESULTS OF PEROORAL ENDOSCOPIC MYOTOMY (POEM) FOR ACHALASIA

Z. Rabekova1, Z. Vackova1, V. Lanska3, J. Spicka1, P. Strnad1, T. Hcul1, E. Kieslichova3, J. Martinek1

Contact E-mail Address: zuzana.rabekova@iikem.cz

Introduction: Peroral endoscopic myotomy (POEM) has gained trust by proven safety and short-term efficacy and at present, it is considered to be a standard method for treatment of esophageal achalasia. However, long-term data concerning the efficacy and safety especially with regard to post-POEM reflux are still awaited.

Aims & Methods: The aim of this prospective single-center case series was to assess the long-term clinical outcome of POEM with emphasis on post-POEM reflux evaluated by pH monitoring, endoscopy findings, reflux symptoms and use of proton pump inhibitors (PPIs). Since 2012, a total of 192 patients with achalasia underwent 202 POEM procedures. Follow-up visits at 3, 12, 24 and 36 months were completed in 166, 116, 70 and 27 patients. Upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring were performed 3 months after POEM, endoscopy was then repeated between 24-36 months. Main outcomes were treatment success defined as Eckardt score <3, recurrence rate and post-POEM reflux.

Results: At 3, 12, 24 and 36 months, treatment success was achieved in 97% (95% CI: 94–100), 95% (CI 91–99), 88% (CI 82–95) and 81% (CI 69–93) of patients. A total of 14 patients experienced treatment failure (n = 5) or recurrence (n = 9). The recurrences occurred most often in patients with HRM type I achalasia (4 out of 5, 15.4%) followed by type II (3 out of 113, 2.6%) vs. none in type III achalasia (0 out of 10, 0%); p = 0.022. At 3 months, reflux esophagitis was diagnosed in 63/160 patients (39.4%); severe esophagitis LA C or D in 8 patients. Abnormal acid exposure on pH-metry studies was detected in 58/146 (39.7%). At 24-36 months, endoscopy was performed in 41 patients and reflux esophagitis was present in 9 patients (21.9%; none of the patients has been treated with PPIs). At 3 and 24 M, a proton pump inhibitor was administered to 33.5% and 31.4% of patients.

Conclusion: POEM is effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 81% at 3 years. Generally mild reflux esophagitis and abnormal esophageal acid exposure are diagnosed in about 40% of patients 3 months after POEM but are successfully manageable with proton pump inhibitors. Occurrence of reflux esophagitis tends to decrease with time.

P0524 BEER EFFECTS ON POSTPRANDIAL DIGESTIVE SYMPTOMS AND GASTROESOPHAGEAL PHYSIOLOGY

B. Serrano1, M. Megia Sanchez, A. Ruiz De Leon, E. Rey2
1Gastroenterology Department, Hospital Clinico San Carlos, Madrid/Spain
2Introduction: Beer has been related to gastroesophageal reflux (GER) and dyspepsia (1, 2), based on its alcohol and gas content. Main objective was to evaluate if moderate regular and non-alcohol beer consumption is related to postprandial

Contact E-mail Address: blan.serrano.falcon@gmail.com

Introduction: Beer was introduced to gastroesophageal reflux (GER) and dyspepsia (1, 2), based on its alcohol and gas content. Main objective was to evaluate if moderate regular and non-alcohol beer consumption is related to postprandial
dyspeptic symptoms after a controlled meal. Secondary objectives were to evaluate its relation with postprandial GER and gastric accommodation and to evaluate its relation with daily digestive symptoms under real conditions.

**Aims & Methods:** Healthy people over 18 years old, free of frequent digestive symptoms (<once a week) and GER disease (GERD), were included. Basal symptoms were assessed through PAGI-SYM (3) and QOLRAD (4) questionnaires, both validated to Spanish. Study was divided in two substudies based on the study intervention: 33 cl of regular beer (substudy 1) and the same amount of non-alcohol beer (substudy 2). Mineral water (33 cl) was the control intervention in both substudies. Each participant was its own control. The study lasted two weeks (control study week and intervention study week). Each week started with a visit to the laboratory at 7:30 h am, when a pH impedance catheter was placed and taken off 24 hours later. Gastric accommodation was assessed through the maximum tolerated volume during a nutrient drink test (ENSURE®/HN, 500 ml) in a rhythm of 15 ml/minutes, after the ingestion of beer (intervention) or water (control). It was defined as the volume after which the test finished or the participant reported the maximum panning for any dyspeptic symptoms (early satiety, bloating, epigastric pain and nausea), which were asked every 5 minutes (1 meant no symptom and 5 meant the highest perception). GER was evaluated in the postprandial period and during 24 hours through pHimpedance regist. Weekly symptoms evaluation was made though a diary adapted from PAGI-SYM questionnaire and sum of symptoms was used for analysis. Data were collected daily through email. Variables were compared between both visits and weeks in both substudies using a non-parametric test for matching data. Participants should drink 33 cl of beer before lunch and dinner during the intervention week. Other alcohol drinks were prohibited during the study.

**Results:** Ten participants were enrolled in substudy 1, mean aged 24 years old (SD 4, 1 (18–32)); 80% were men. Twenty participants were enrolled in substudy 2, mean aged 23.4 years (SD 5.5 (20–38)); 65% were men. No significant differences were detected in the increase of symptoms during the nutrient drink test between control and intervention visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies. Reflux episodes after nutrient drink test and reflux episodes registered in 24 hours did not show significant differences between control and study visits. The sum of weekly symptoms did not show any difference between control and study visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies.

**Conclusion:** Moderate beer consumption (regular and non-alcohol beer) does not cause an increase of dyspeptic symptoms and reflux in healthy people. It has been shown in a controlled situation (nutrient drink test and pH impedance register) as well as real life (diary weekly symptoms). Gastric accommodation and reflux episodes have either shown to be affected by moderate beer consumption.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**DUODENAL PATHOLOGY IN PATIENTS WITH RUMINATION SYNDROME: EOSINOPHILIA AND INTRAEPITHELIAL LYMPHOCYTOSIS**

1. *Gastroenterology And Hepatology, Mayo Clinic, Rochester/United States of America*
2. *University of Newcastle Faculty of Health PVC Office, Callaghan/Australia*
3. *School Of Medicine And Public Health, The University of Newcastle, Australia, Callaghan/Australia/NW*

**Contact E-mail Address:** halland.magnus@mayo.edu

**Introduction:** Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea. Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD. Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might also be present among patients with rumination syndrome.

**Aims & Methods:** We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophageal high resolution impedance manometry (HRIM) and/or fulfilled ROME II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4-6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom 4-6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent (within 30 days) intake of NSAIDS and pregnant or lactating females were excluded. Duodenal biopsies were obtained using routine technique. Residual sections were fixed in formalin, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm² in sections. Individual sections were also assessed for the presence of Brunner’s glands (BG) and intraepithelial lymphocyte counts (IEL)/100 enterocytes. This was done in order to distinguish the first part of the duodenum with BG from the second part, generally without BG, (D2) and intraepithelial lymphocyte counts (IEL)100 enterocytes.

**Results:** Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. Controls (10) had a mean age of 34.3 (range 19–69) and 90% were female. The mean eosinophil counts/biopsy fragment in rumination syndrome compared to controls have not previously been described. To our knowledge, histopathological changes among patients with rumination syndrome have not been described. To our knowledge, histopathological changes among patients with rumination syndrome have not been described.

**Conclusion:** These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome have not previously been described. There is limited evidence that the pathological basis of rumination syndrome warrants further enquiry.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0527 CHRONIC POSTSTROKE OROPHARYNGEAL DYSPHAGIA IS ASSOCIATED WITH IMPAIRED CORtical ACTIVATION TO PHARYNGAL SENSORY INPUTS**

O. Ortega1, C. Cabib1, N. Vilaridel1, L. Mundel1, P. Clavé2, L. Roefes3

1GI Physiology Laboratory, Hospital de Mataró, Consorci Sanitari del Maresme, Mataró/Spain

**Contact E-mail Address:** oortega@csdm.com

**Introduction:** The role of afferent sensory pathways in the pathophysiology of post-stroke oropharyngeal dysphagia (OD) is not known [1]. We hypothesized that chronic post-stroke patients with OD (PSD) would show impaired sensory cortical activation in the affected hemisphere.

**Aims & Methods:** We studied 28 chronic unilateral post-stroke patients (17 PSD and 11 nondonphagic [PSnD]) and 11 age-matched healthy volunteers (HV).

Functional dysphagia was used to assess event-related sensory evoked potentials to pharyngeal stimulation (pSEP) and sensory thresholds with a naso-pharyngeal catheter with two electrodes passed through the nostrils 14–15 cm until the pharynx (Galectec Ltd, Dunvegan, Scotland) [2]. We analyzed pSEP peak-latency and amplitude (N1, P2, N2-P2) and neurotographic space characteristics from brain MRI.

**Results:** HV presented a highly symmetric bi-hemispheric cortical pattern of brain activation at centro-parietal areas (N1-P1, N2-P2) to pharyngeal stimuli. In contrast, an asymmetric pattern of reduced ipsilesional activation was found in PSD (N2-P2; p = 0.026) but not in PSnD. PSD presented impaired safety of swallow (Penetration-Aspiration score: 4.3 ± 1.6) and delayed laryngeal vestibule closure (360 ± 70 ms), and higher NIHSS (7.0 ± 6.2 vs. 1.9 ± 1.4, p = 0.001) and Fazekas scores (3.0 ± 1.4 vs. 2.0 ± 1.1, p = 0.05) than PSnD. pSEP showed a unilateral delay at stroke site exclusively for PSD (peak-latency inter-hemispheric difference vs. PSnD: N1, 6.5 ± 6.7 vs. 1.1 ± 1.0 ms; N2, 32.0 ± 15.8 vs. 4.5 ± 4.9 ms, p = 0.05).

**Conclusion:** Chronic post-stroke OD is associated with stroke severity and degree of leukoaraiosis. Impaired conduction and cortical integration of pharyngeal sensory inputs at stroke site is a key feature of chronic PSD. These findings highlight the role of sensory pathways in the pathophysiology of post-stroke OD and offer a potential target for future treatments.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Reduced sleep quality has been linked to gastrointestinal reflux disease (GERD) and functional gastrointestinal disorders. It is unknown whether GERD, functional dysphagia (FD) and irritable bowel syndrome (IBS) are more prevalent in subjects with significant sleep disturbance (SD) than those without SD.

**Aims & Methods:** The aim of the study was to investigate gastrointestinal symptoms, clinical characteristics, and psychological factors in subjects with and without SD in a general population undergoing health checkups. We enrolled 2752 consecutive subjects who received upper gastrointestinal endoscopy and colonoscopy during their health checkups. All participants underwent an evaluation with questionnaires including Reflux Disease Questionnaire score, Pittsburgh Sleep Quality Index (PSQI), Taiwanese Depression Questionnaire, and State-Trait Anxiety Inventory before receiving endoscopic exam. Demographic characteristics and biochemical data were also recorded. FD and IBS were based on Rome III diagnostic criteria, and metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition.

Sleep disturbance was confirmed when PSQI score was greater than 5. We compared the clinical and psychological factors between subjects with and without sleep disturbance.

**Results:** Among the study population (n = 2674), 956 (36%) individuals had SD. SD subjects had more female gender, older age, lower level of education, higher systolic blood pressure, higher serum high-density lipoprotein levels, and higher prevalence of FD and IBS than those without SD. In addition, SD patients also had more depression, more anxiety, more severe GERD symptoms, and higher prevalence of non-erosive reflux disease (NERD) (p < 0.001). Multivariate analysis revealed that female sex (OR = 1.75, p < 0.001), older age (OR = 1.03, p < 0.001), more severe GERD symptoms (OR = 1.03, p < 0.033), NERD (OR = 1.63, p = 0.023), IBS (OR = 1.48, p = 0.05), and depression (OR = 1.16, p < 0.001) were positive predictive factors for SD, whereas higher level of education (OR = 0.57, p = 0.001) was negative predictive factor for SD.

**Conclusion:** Our study demonstrates that SD is associated with female sex, older age, lower education level, greater GERD symptom burden, greater depression, and higher prevalence of NERD and IBS. Future studies will be needed to clarify the relationship between functional gastrointestinal diseases and sleep disorders.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

Introduction: Esophageal symptoms compatible with a functional esophageal disorder are common in the Western population. Age and presence of other GI and non-GI symptoms are associated with reporting esophageal symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0532 THE ASSOCIATION BETWEEN ATOPIC MANIFESTATIONS AND EOSINOPHILIC ESOPHAGITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. J. Lucendo Villarin,1 J. González-Cervera,2 Á. Arias3
1Dept. Of Gastroenterology, Hospital General de Tomelloso, Tomelloso/Spain
2Gastroenterology, Hospital San Pedro de Alcántara, Cáceres/Cáceres
Contact E-mail Address: ajlucendo@hotmail.com

Introduction: Eosinophilic esophagitis (EoE) affects children and young adults and has rapidly grown over the past decade, especially in developed countries. Presently, it represents the second leading cause of chronic esophagitis after gastroesophageal reflux disease (GERD) and the main cause of dysphagia in children and young adults. EoE affects health-related quality of life (HRQoL). Data on determinant factors and the influence of dietary interventions are scarce.

Aims & Methods: In this study we aimed (1) to determine for the first time the health-related QoL in a representative sample of Spanish adults with EoE, and (2) to identify determinants of impaired HRQoL, including the effect of dietary restrictions. Multicentre observational, cross-sectional study in eight Spanish centers attending adult EoE patients throughout several Spanish Regions. A validated Spanish version of the self-administered Adult Eosinophilic Esophagitis Quality of Life (EoE-QoL-A) questionnaire was used, as well as a survey of demographic and clinical data. Multiple linear regression was used to identify and quantify determinant factors of HRQoL.

Disclosure of Interest: All authors have declared no conflicts of interest.
Several studies have provided information on the prevalence of different atopic conditions in adult EoE patients compared to different groups of control subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have not been defined and the selection process for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. Therefore, a systematic review and meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control populations is required.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently (AA and AJL) and completed by March 2016. The search was not restricted with regard to the language of publication. A predetermined protocol was used in accordance with the quality standards for reporting meta-analyses of observational studies in epidemiology. Four reviewers (GG-C, AA, MM-CM, and AJL) independently extracted relevant information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary estimates, including 95% confidence intervals (CI), were calculated for each season and month, whenever possible.

Results: Of the 2946 references identified, data was collected from 21 studies including a total of 33,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls were not structurally considered in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with systemic eosinophilic disease (GORD patients), patients and, habitually, their first degree relatives, all of whom were endoscopically assessed with a diagnosis of EoE specifically ruled out. In all cases, EoE was considered as independent from GORD and other upper GI tract diseases. Some studies included database-registered subjects as a control group. The criteria for defining a diagnosis of atopy among EoE patients and control subjects varied widely across the different studies, from self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses. Overall, allergic rhinitis was significantly more common among patients compared to controls (OR 5.00; 95% CI: 3.27, 9.53; I² = 86%). As bronchial asthma (OR 3.06 (95% CI: 2.01, 4.66; I² = 83.4%) and eczema (OR 2.86; 95% CI: 1.88, 4.36; I² = 57.2%) were also assessed. No significant publication bias was found for studies dealing with allergic rhinitis and eczema in EoE.

Finally, our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95% CI: 0.07, 14.72).

Conclusion: The present study shows that an accurate diagnosis of atopy is lacking in most of the research evaluating the prevalence of asthma, rhinitis, and eczema among EoE patients. Still, the prevalence of these three conditions seems to be significantly higher in children and adults with EoE as compared to control subjects. The comparison of the general population with other research documents and use standard definitions of allergic rhinitis, asthma (including its severity and level of control), skin allergy, and food allergy (rather than mere sensitivity) when assessing and documenting concurrent allergic diseases in patients with EoE.

P0534 A PHASE I STUDY TO ASSESS THE PHARMACOKINETICS, SAFETY, AND TOLERABILITY OF SINGLE DOSE APT-101 ADMINISTERED UNDER FED OR FASTED CONDITIONS OR AT BEDTIME IN A RANDOMISED THREE-WAY, CROSSOVER DESIGN

G. M. Comer, B. A. Meltzer
Adare Pharmaceuticals, Inc., Lawrenceville/United States of America

Contact E-mail Address: brian.meltzer@adarepharma.com

Introduction: APT-101 is an orally disintegrating tablet (ODT) formulation of fluoro-phenoxyl acetate that provides a novel approach for the treatment of eosinophilic esophagitis (EoE).

Aims & Methods: A randomised, single-dose, three-way, crossover study was conducted in healthy volunteers to compare the pharmacokinetics (PK), safety, and tolerability of APT-101 when administered under fed, fasted conditions or at bedtime (HS). Participants were administered 6 mg APT-101 following these three different administration schedules, with a 7-day washout separating the three periods. Serial plasma samples for FP PK were collected at 14 to 72 hours following administration. Noncompartmental and statistical analyses were performed for PK parameters.

Results: A total of 24 participants enrolled and 22 (92%) completed the study. A summary of the PK parameters by test group is presented in Table 1. AM dosing was associated with a higher rate of absorption under fed compared to fasted conditions. Following a high fat meal, there was a higher peak concentration (Cmax) ratio [90% CI (confidence interval)] = 120.65% [99.84%–145.79%] and a faster time to peak concentration compared to the fasted state (Tmax fed = 5.00 h, fast = 10.00 h). However, lower total exposure in the fed compared to the fasted state (AUC_0–inf ratio [90% CI] = 76.7% [67.64%–87.59%]) was observed. HS dosing was found to slow the rate of absorption compared to AM dosing conditions. Specifically, the peak time concentration with HS dosing (Tmax = 14 h) was lower than with AM dosing (Tmax = 10 h, fed = 5.0 h). HS dosing was associated with higher overall exposure (AUC_0–Cmax ratio [90% CI] = 122.36% [107.02%–139.88%]) and lower Cmax (Cmax ratio [90% CI] = 67.79% [56.29%–81.64%]) versus the fed dosing regimen. Compared to the fasted regimen, HS dosing yielded lower overall exposure (AUC_0–Cmax ratio [90% CI] = 87.00% [75.24%–100.59%]) and lower Cmax (Cmax ratio [90% CI] = 81.78% [76.93%–94.87%]). Across all dosing regimens, the Cmax of FP with APT-101 ranged from 5.97–200 pg/mL. Seven subjects (29%) reported 12 treatment-emergent adverse events over the course of the study; all events were of low severity. No serious adverse events or deaths were reported.

Conclusion: APT-101 was safe and well-tolerated when administered under AM fasted, AM fed, or HS conditions to healthy subjects. While there was faster absorption of APT-101 under fed conditions and slower absorption at bedtime, overall, HS dosing was associated with higher exposure compared to AM dosing conditions. Slower absorption with HS dosing suggests a potential for longer dwell times in the esophagus; the relationship of HS dosing with histological efficacy in both the proximal and distal portions of the esophagus will be explored in future studies of APT-101 in EoE.
to steroids (64% vs 36%; p = 0.002). Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. (p = 0.007).

Conclusion: A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histological one.

Introduction: Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) is an emerging condition characterized by a constellation of clinical, endoscopic, and histopathologic features in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of proton pump inhibitor (PPI) therapy. A recent meta-analysis explored the role of different PPIs in inducing clinical and histologic remission in patients with esophageal eosinophilia without observing significant differences among them due to several limitations (i.e. limited number of studies using each PPI drug, small sample size, and heterogeneity among the various studies).

Aims & Methods: We aimed to prospectively compare the effect of different PPIs in inducing endoscopic and histologic remission in patients with PPI-REE. Consecutive patients with symptoms suggestive of EE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, then, were treated with twice-daily PPI for at least 8 weeks. Patients were assigned to receive esomprazole 20 mg bid, rabeprazole 20 mg bid or pantoprazole 40 mg bid in a 1:1:1 ratio. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Endoscopic, according to Endoscopic Reference Score (EREFS), and histologic features were blindly reviewed for each patient treatment group.

Results: Twenty-eight patients [23M/5F; mean age 35] reporting dysphagia (93%), bulus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. According to treatment allocation, 8 (29%) patients received esomprazole, 9 (32%) rabeprazole and 11 (39%) pantoprazole. At baseline, demographic and clinical data, including age, sex, BMI, H. pylori infection, concomitant allergy conditions and latency from diagnosis were similar (p > 0.05).

P0537 THE « GARD (GASTRO-ESOPHAGEAL ANTI-REFLUX DEVICE) »: A NEW ENDOSCOPIC MEDICAL DEVICE TO DIAGNOSE, MANAGE AND TREAT GERD

N. Godin
Private Practice, Geneva/Switzerland

Contact E-mail Address: dr.godin68@gmail.com

Introduction: The « GARD » (Gastroesophageal Anti-Reflux Device) is an anti-reflux tubular valve placed in the lower esophagus under endoscopic control allowing normal ingestion of food and beverages but blocking all gastro-esophageal refluxate mechanically (fluid, solids and gas).

Aims & Methods: The « GARD » has an upper ring sized to the diameter of the patient’s esophagus with an accessory called the « calibration device » placed through the 2.8 mm working channel of a standard gastroscope. The GARD is held in place by pressure. The upper ring holds an anti-reflux thin-walled tubular valve moulded in one piece under the ring. After placement of a standard guide-wire, the « GARD » is placed through the patient’s mouth and is released in the lower esophagus. The procedure is performed under sedation on an ambulatory basis in about 15 minutes when experienced. The « GARD » was placed in the esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, there was no migration in the stomach and removal of the GARD with the developed accessories was easily achieved. Pigs have a strong lower esophageal sphincter and have no reflux so gastro-esophageal reflux could not be evaluated. In a human volunteer with very severe gastro-esophageal reflux who had previously failed anti-reflux surgery and had an unsatisfactory response to clinical and pH metric measurement under 80 mg of esomeprazole, the « GARD » was placed preoperatively. Hereafter are this patient’s pH metric results without and with « GARD » as compared to PPI alone.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0538 SYMPTOM PATTERNS AND TYPES OF GASTROESOPHALGEAL REFUXES SIGNIFICANTLY DIFFER IN GROUPS OF EROSION ESOPHAGITIS AND NON-EROSSIVE FORM OF GASTROESOPHALGEAL REFLUX DISEASE (GERD) PATIENTS

M. Konovalova, S. Morozov, V. Isakov
Gastroenterology And Hepatology, Federal Research Center of Nutrition and Biotechnology, Moscow/Russian Federation

Contact E-mail Address: sunnyisiter@mail.ru

Introduction: Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients’ symptoms with characteristics of refluxes obtained by 24-h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M ± S) 42 ± 4.8 yrs and 49 controls (22 men, 27 women, age (M ± S) 46 ± 6.7 yrs) were examined using 24-hours esophageal pH-impedance recordings (Omehga, MMS, the Netherlands; 24-hpH-impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline endoscopy 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients’ symptoms were classified according to Montreal classification.

Results: Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (table 1). However higher number of acid refluxes, higher GERD-Q score and DeMeester score were present in ERD. The total number of gastro-esophageal refluxes didn’t differ between ERD and NERD groups of patients.

Introduction: Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

Aims & Methods: Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 158 patients with erosive esophagitis (aged 49.5 ± 16.3 years) and 273 controls (aged 46.4 ± 16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors was also collected. Binary logistic regression analysis was carried out to assess the association of erosive esophagitis and extra-esophageal symptoms.

Results: Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentarity and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9%, respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all sociodemographic characteristics and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR = 3.1, 95%CI = 1.7–5.7), and even more so with laryngeal disorders (OR = 4.4, 95%CI = 2.6–7.4). In all models, the association of erosive esophagitis with extra-esophageal symptoms was strong and maintained after adjusting for the symptoms separately (fully-adjusted model: OR = 4.6, 95%CI = 2.9–7.3).

Conclusion: Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper endoscopy should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders. Disclosure of Interest: All authors have declared no conflicts of interest.

P0540 ASSESSMENT OF EXHALED BREATH CONDENSATE FOR NON-INVASIVE DIAGNOSIS OF GASTROESOPHALGEAL REFUX DISEASE IN CORRELATION WITH MII-PH AND PEPTEST

1Internal Gastroenterology Clinic, FN Brno, Brno/Czech Republic

Introduction: Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological antireflux mechanisms and can lead to erosive esophageal and extraesophageal symptoms (cough, laryngitis, globus pharyngis, pharyngitis, rhinosinusitis, otitis media, bronchial asthma, COPD, sleep apnea and noncardiac chest pain). Currently there is no suitable, non-invasive diagnostic method applicable for GERD in clinical practice. Exhaled breath condensate (EBC) and saliva are two easily accessible samples that could be used in monitoring patients’ condition and from extraesophageal symptoms of GERD. The aim of this study was to compare the pH and total ionic profile of EBC with 24-hour multichannel intraluminal impedance and pH monitoring (MII-PH) and salivary PepTest in a group of patients with gastroesophageal reflux (pH < 4) and controls.

Aims & Methods: A portable EBC sampler was used for collection of EBC. 10 µL sample aliquots of EBC were analyzed. For pH measurement, the CO2 from EBC was mixed with N2 gas for 10 min. Each of pH 4.1±0.2 and 8.8±0.1 was set up with a pH microelectrode and total ionic profile (ammonium, cations, organic acids - NH4+, K+, Ca+, Na+, Mg2+, Cl−, NO3−, NO2−, SO4−, acetate, lactate, propionate, butyrate) was analyzed by capillary electrophoresis in each sample. Saliva was collected using the commercial PepTest sampling containers, applied to the PepTest lateral flow devices and analyzed using the device reader. The data from EBC were compared with MII-PH and PepTest. In total the study comprised of 39 participants. The patients were divided by dominant findings from MII-PH in to groups with acid reflux (n = 17), weakly acid reflux (n = 8) and without reflux (n = 14).

Results: The values of pH (after CO2 removal with N2) were significantly higher in the group with acid reflux (p < 0.01), (mean pH 7.13, interquartile ranges 6.83–7.47) and in the group with weak acid reflux (p < 0.01) (7.37, (7.18–7.57)) vs. healthy controls (6.8, (6.65–6.99)). Butyric acid (BA) was the second most significant parameter that was significantly elevated (p < 0.01) in both patient groups (acid reflux- mean BA 2.29 µM, weakly acid reflux- mean BA 3.33 µM) compared to healthy subjects (mean BA 0.69 µM).

Further statistically significant differences were found in chloride (Cl−), nitrate (NO3−) and sodium (Na+) ions concentration. CI was elevated (p < 0.01) in group with acidic reflux vs. healthy controls and NO3 and Na+ were elevated in both groups with weak acid reflux vs. healthy controls. Peaks for saliva sampling and pepsin analysis showed no statistically significant differences within the groups. In the groups of patients with acid reflux, the incidence of high pepsin concentration (above 75 ng/ml) was found only in 50% of the patients.

Conclusion: We found statistically significant differences in pH and selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can
Results: refluxes or abnormal AET; b) Group B: subjects with increased episodes of non-acid weakly acidic refluxate). Patients were then divided in three groups according to 24 hours) and the number as well as the characteristics of reflux episodes (acidic/

Introduction: As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve a non-surgical control. This procedure, Stretta has been proposed as less invasive options.

Aims & Methods: We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap valve grading of 1 to 3. We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients indicative of severity of reflux All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

Results: Technique: Crescentic ARMS of the esophagogastric junctional (EGJ) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal valve at gastric cardia. All the patients who underwent ARMS had a significant decrease in the DeMeester score, with predominant decrease in the mucosal resected by 7/12 patients were able to discontinue all the medical therapy, PPI dose reduction was possible in the other patients with a mean reduction of 50%, alginates were stopped in all patients and H2RA were also discontinued.

Conclusion: Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardia opening, while preserving and/or re-creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost "mechanically-stitched" appearance. The mucosal flap is rebuilt and looks well-defined. Furthermore, the lesser curve side?

Introduction: S-isomer (S) pantoprazole is more bioavailable and less dependent on cytochrome CYP19 than is racemic pantoprazole.

Aims & Methods: We aimed to evaluate the efficacy and safety of 10 mg S-pantoprazole for treatment of non-erosive reflux esophagitis (NERD). This study was designed as a multicenter, randomized, double-blind, placebo controlled trial. NERD was defined as reflux symptoms and normal endoscopy findings. Patients were allocated to take either 10 mg S-pantoprazole or placebo once daily for 4 weeks, after which reflux symptoms were reassessed. Recurrence of symptoms was assessed at 4 weeks after cessation of medication. The efficacy endpoints were complete relief of symptoms, improvement of reflux symptoms, and safety.

Results: Eighty-eight patients randomly assigned to the pantoprazole group (52 males, 43.7 years old) and 86 to the placebo group (42 males, 43 years old), and 163 patients were subjected to a per protocol analysis. A higher proportion of patients in the S-pantoprazole group had complete symptom relief (31.8% vs. 14.0%, P < 0.001). Improvement of symptoms of heartburn, acid regurgitation and epigastric discomfort were also significant. The factors associated with poor symptom responsiveness to PPI were older age, female sex, greater body mass index and symptom severity in both groups.

Conclusion: S-pantoprazole (10 mg) was more efficacious than placebo in providing reflux symptom relief in patients with NERD, especially acid regurgitation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0545 EFFICACY OF S-PANTOPRAZOLE 10 MG IN THE SYMPTOM CONTROL OF NONEROUS REFLEX DISEASE: A PHASE III PLACEBO-CONTROLLED TRIAL

P0543 A RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, MULTICENTRE 26-WEEK STUDY ON THE EFFECTS OF DEXLANSOPRAZOLE AND ESOMEPRAZOLE ON BONE HOMEOSTASIS IN HEALTHY POSTMENOPAUSAL WOMEN

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, the stomach from the lower esophageal sphincter, but not the neutralization of postprandial acid contents of the esophagus, in two parts of the stomach and the different types of gastroesophageal reflux (acid, low acid, alkaline, liquid, gas & mixed) was estimated. To evaluate the effects of ral-rafting alginicate on the severity of postprandial reflux in patients with GERD and for the postprandial stomach content.

Results: Monitoring with alginicate showed significantly (P < 0.05) less number of acid [average values 5.42 ± 0.69 (M ± m) vs. 3.33 ± 0.43 during 1st postprandial hour and 3.96 ± 0.8 vs. 1.82 ± 0.57 during 2nd postprandial hour] and gas [0.26 ± 0.06 vs. 0.08 ± 0.05 during 1st postprandial hour and 0.47 ± 0.35 vs. 0.00 during 2nd postprandial hour] gastroesophageal reflux, but increased of number low acid reflux [2.52 ± 0.46 vs. 3.91 ± 0.82 during 1st postprandial hour; 0.00 ± 0.42 vs. 2.16 ± 0.45 during 2nd postprandial hour; P < 0.05]. Also noted is a significant (P < 0.05) increase in the pH in the esophagus for 120 minutes after ingestion [average pH values 6.04 ± 0.27 vs. 4.86 ± 0.23 during 0–60 min., and 5.93 ± 0.25 vs. 4.15 ± 0.26 during 60–120 min.]. In the gastric cardia (a typical place of formation of postprandial acid pocket) showed significantly (P < 0.05) higher values for the first 60 minutes after intake of alginicate [pH 4.3 ± 0.37 vs. 3.04 ± 0.25], during 60-90min, pH values wasn’t significantly (P < 0.05) different [2.75 ± 0.45 vs. 2.43 ± 0.28]. In the stomach body no significant effect of the drug on pH was recorded [average pH values for stomach 2.56 ± 0.46 vs. 2.1 ± 0.18 during 1st postprandial hour and 2.29 ± 0.49 vs. 2.09 ± 0.18 during 2nd postprandial hour; P > 0.05].

Conclusion: Our findings demonstrate that raffting alginicate is an effective means for the prevention of postprandial acid and gas reflux and to reduce the injurious effect of acid in the esophagus. At the same time alginicate showed no effect on stomach content in the postprandial period, it means that the main mechanism of action is through the movement of postprandial acid contents from the lower esophageal sphincter, but not in the neutralization of stomach content, unlike non-rafting antacids and PPIs.

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest: despite PPI therapy. Therefore it should be advised to patients who complain of symptom persistence.

Conclusion: RELEVANCE FOR TUMORIGENESIS

P0547 STW5 MODULATES TIGHT-JUNCTION GENE AND PROTEIN EXPRESSIONS IN REFLUX-INDUCED ESOPHAGITIS - POSSIBLE RELEVANCE FOR TUMORGENESIS

Introduction: Refractory non erosive reflux disease (NERD) is defined by absence of clinical response to a 12-week course of proton pump inhibitors (PPI) at full dose in absence of esophagitis. It accounts for about 20% of all NERD cases. 24-hour multichannel intraluminal impedance pH (MII-pH) monitoring should give useful patient-specific information about refractory NERD. Therefore, our aim was to assess whether this technique could be useful to guide a “tailored” therapy to refractory NERD patients.

Aims & Methods: We retrospectively recruited patients undergoing MII-pH monitoring for refractory non erosive reflux disease (NERD). None of the patients had undergone upper endoscopy, and cases of esophagitis were excluded. No patient received PPI during MII-pH monitoring. Subjects were subgrouped into 3 categories according to Zerbib’s classification: i) Acid reflux (exposure to pH < 4 for at least 1.1% of record time), ii) Non acid reflux (symptom association probability to pH > 4 reflux episodes > 95%) and iii) Functional heartburn (no pathologic reflux, with symp- toms association probability < 50%). MII-pH guided therapy was performed as follows: patients with acid reflux received PPI at double dose, patients with non acid reflux PPI at full dose plus alginates and patients with functional heartburn levosulpiride 75 mg/day for 4 weeks. A visual analogue scale (VAS) ranging 0–100 was administered before and after such tailored therapy to evaluate overall symptom improvement. Responders were defined by VAS improvement of at least 50%. Comparisons between continuous variables were performed by ANOVA or paired/unpaired t-test where required, and Fisher’s exact test was applied to categorical variables. Variables with statistical significance p< 0.10 at univariate analysis were then included in a step-by-step multivariate regression analysis, aimed to investigate factors predictive of response to tailored therapy.

Results: Thirty-four patients with refractory NERD were selected (female:male ratio 21:14, mean age 47.4 ± 12.8). Twelve had acid reflux, 7 non acid reflux and 15 had functional heartburn. Overall effectiveness of tailored therapy was 82.3% (28 out of 34), and it did not differ between subgroups (91.7% acid reflux, 71.4% non acid reflux, 80.0% functional heartburn, p = 0.51). At univariate analysis, therapy failure directly correlated with dysphagia (OR = 0.15, p = 0.10) and incidence with sensation of slow digestion (OR = 7.78, p = 0.05). However, at multivariate analysis, these parameters were not statistically significant. We found a mean VAS reduction of 30.2 ± 24.9, which was similar between acid reflux (36.7 ± 22.7), non acid reflux (30.0 ± 27.7) and functional heartburn (47.3 ± 25.7) p = 0.75.

Conclusion: A tailored approach to refractory NERD, guided by MII-pH monitoring, demonstrated to be effective, independently from disease subtype. Therefore it should be advised to patients who complain of symptom persistence despite PPI therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Aims & Methods:** Homeostasis and stem cell differentiation. In BE, BMP4 is upregulated in columnar stem cells residing in the esophageal mucosa (e.g., in submucosal glands) or multipotent stem cells give rise to the columnar lining. Bone Morphogenetic Proteins (BMPs) are a family of growth factors that control tissue architecture, homeostasis and stem cell differentiation. In BE, BMP4 is upregulated in columnar cells.

**Introduction:** Barrett’s esophagus (BE) is a metabolic abnormality in patients with Gastro-esophageal reflux disease in which the normal stratified squamous epithelium in the esophagus is replaced by columnar epithelium. BE predisposes for the development of columnar epithelium. One underlying mechanism of BE is that columnar stem cells residing in the esophageal mucosa (e.g., in submucosal glands) or multipotent stem cells give rise to the columnar lining. Bone Morphogenetic Proteins (BMPs) are a family of growth factors that control tissue architecture, homeostasis and stem cell differentiation. In BE, BMP4 is upregulated in columnar cells.

P0552 CHARACTERIZING DIPETIDYL PEPTIDASE SPECIFIC ACTIVITY IN HUMAN BARRETT’S ESOPHAGUS AND IN A PANEL OF OESOPHAGEAL METAPLASIA, DYSPLASIA AND CANCER CELL LINES

S. Jaensch1, D. J. Hussey2, D. Watson1, C. A. Abbott3, M. Squire1, R. Yazbeck1

2Flinders Centre for Innovation in Cancer, Adelaide/Australia
3School Of Biological Science, Flinders University, Adelaide/Australia

Introduction: Barrett’s oesophagus is defined as the replacement of the normal stratified oesophageal squamous epithelium with a multiplicative columnar intestinal-like epithelium. Dipeptidyl peptidase-4 (DPP4) is an integral membrane glycoprotein, which is expressed on the brush border membrane. DPP4 is part of a larger enzyme family that also includes DPP8, DPP9 and fibroblast activation protein (FAP).

Aims & Methods: We aimed to characterise DPP4 enzyme activity in a panel of oesophageal metaplasia, dysplasia and cancer cell lines, and in Barrett’s oesophageal patient biopsies. FLO-1, OE33 and OE19 (oesophageal adenocarcinoma), OE21 and TE7 (oesophageal squamous cell carcinoma), GihTERT, GoihTERT, ChtERT (dysplastic Barrett’s) and QtERT (non-dysplastic Barrett’s) were grown to confluence in T75 flasks using standard cell culture techniques. Oesophageal squamous tissue biopsies were collected from non-Barrett’s patients participating in the Barrett’s screening endoscopy program at Flinders Medical Centre (n = 6). Duodenal and gastric tissue biopsies were also collected as positive and negative control tissue respectively. Membrane and soluble enzyme activity was determined in cell and tissue extracts using colorimetric enzyme assay using the DPP selective substrate H-Gly-Pro-pNA. Sitagliptin (a DPP4 selective inhibitor) and IGF24 (DPP9/8 selective inhibitor) were used to demonstrate specific enzyme activity. Final enzyme activity was expressed as nm pNA released/min/mg protein. Data is expressed as mean ±standard error of the mean.

Results: Relatively high DPP4 activity was detected on the membrane of OE33 (13.92 nm pNA/min/mg protein), GoihTERT (6.93 nm pNA/min/mg protein), GoihTERT (2.635 nm pNA/min/mg protein) and QtERT (1.80 nm pNA/min/ mg protein) compared to all other cell lines, where activity was <1 nm pNA/ min/mg protein. In comparison of 1 nm M5  sitagliptin enzymatic activity in OE33 cells, indicating that membrane enzyme activity was specific to DPP4. Cytoplastic DPP4 activity was highest in FLO-1 (3.77 nm pNA/min/ mg protein) and CtERT (2.39 nm pNA/min/ mg protein). Addition of 1mM sitagliptin did not reduce cytoplastic DPP activity in FLO-1 cells, suggesting the presence of other peptidases. High DPP4 activity was detected in the membrane fraction of duodenal biopsies (45.90 ±8.55 nm pNA/min/mg protein) compared to gastric (3.35 ±1.59 nm pNA/min/mg protein) and oesophageal biopsies (0.65 ±0.71 nm pNA/min/mg protein). In contrast, differential DPP4 activity was detected in the soluble fraction of all duodenal, gastric and oesophageal tissue biopsies. Using IuM sitagliptin, this was found to be specific to DPP4 in oesophageal samples, but likely derived from other peptidases in gastric and duodenal tissue.

Conclusion: Our preliminary studies demonstrated DPP4 activity in Barrett’s metaplasia and dysplasia, which could have potential significance as a biomarker target for the continuum of Barrett’s oesophagus. Human tissue sample collection is ongoing to determine specific DPP enzyme activity and expression in tissue specimens from Barrett’s metaplasia and dysplasia subgroups as compared to normal, non-Barrett’s tissue.

P0554 DIFFERENT GLAND PHENOTYPES ARE CLONALLY RELATED IN BARRETT’S ESOPHAGUS AND GLAND PHENOTYPIC DIVERSITY IS INCREASED IN PATIENTS WHO HAVE PROGRESSED TO DYSPLASIA

J. Evans1, E. Carlotti2, M. Rodriguez-Justo2, S. L. Preston3, N. Wright4, M. Graham1, M. Jansen5, S. A. McDonald6
1Centre For Tumour Biology, Barts Cancer Institute, London/United Kingdom
2Histopathology, University College London, London/United Kingdom
3Gastroenterology, Barts Health NHS Trust, London/United Kingdom
4UCL Cancer Institute, University College London, London/United Kingdom

Introduction: A range of complex glandular phenotypes exist in Barrett’s esophagus (BE), but how these phenotypes are related and evolve is unknown. Genetic diversity is an established risk factor for cancer development in BE, yet as phenotype not genotype is selected for, we cannot determine of cancer progression. Exploiting mutations in the mitochondrial genome (MtDNA) as a marker of clonality we have demonstrated to be clonal and suggests that Barrett’s displays phenotypic as well as genotypic diversity.

Aims & Methods: Biopsies from patients with a new diagnosis or surveillance for BE were obtained at endoscopy and frozen. Immunohistochemistry was performed on frozen sections for proteins including MUC5AC, MUC2, MUC6 and AMY. A panel of antibodies specific to gland phenotypes was used to determine if there was a significant increase in gland phenotype diversity in those biopsies compared to healthy controls. The relative amount of pro-inflammatory and pro-fibrotic cytokines and chemokines was determined by qPCR. qPCR was performed on RNA extracted from archived FFPE tissue samples. Tumour tissue is defined as positive if >1% of cells express MUC5AC, MUC2 or MUC6.

Results: During progression from BE to EAC an increase of CD4+ cells was observed. The number of IL-22+ cells and IL-17A+ cells as well as the number of FOXP3+ cells/mg tissue increased in oesophageal cancer and in its peri-tumoral tissue as compared to healthy controls. The relative amounts of IL-22+ and IL-17A+ cells decreased while an increase of FOXP3+ cells was observed. Also more IL-10+ cells/mg tissue were observed in the tumours. In contrast to the latter finding high IL-10 mRNA expression levels were associated with poor survival in EAC patients. Interestingly, high levels of mRNA expression levels of IL-10 in the non-malignant peritumoral tissue also correlated with poor survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

as genotypic evolution. Patients with dysplasia also show a significant increase in gland phenotype diversity (Shannon) per biopsy in adjacent to dysplasia glands compared with patients who do not have dysplasia.

**Conclusion:** BE is phenotypically diverse with a range of glandular phenotypes that are clonally related. An increase in phenotypic diversity may be a potential biomarker for dysplasia which patients will be more likely to progress from BE to cancer with implications for diagnostic and surveillance policy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0555 A DEDICATED BARRETT’S OESOPHAGUS ENDOSCOPY LIST IMPROVES THE ACCURACY OF ENDOSCOPIC REPORTING AND QUALITY OF BIOPSYs**

H. Al-Hasani, T. Sharp, S.M. Ha, L. Matsuoka, N. Siddique Gastroenterology, Queen Elizabeth the Queen Mother Hospital, Margate/United Kingdom

**Contact E-mail Address:** hamahallahs@gmail.com

**Introduction:** The importance of skilled endoscopic assessment of Barrett’s oesophagus (BO) has been clearly established and forms part of the British Society of Gastroenterology guidelines. Use of Prague classification when reporting on areas of BO improves standardisation, and adherence to the Seattle biopsy protocol (quadrant biopsies every 2 cm) when sampling Barrett’s mucosa is thought to improve dysplasia detection. In East Kent Hospitals NHS Foundation Trust we have created a dedicated nurse-led BO surveillance endoscopy list with the aim of improving compliance with guidelines and the quality of biopsies taken. Here we present a retrospective observational study of patients who underwent upper GI endoscopy on a general endoscopy (GE) list compared with the dedicated BO endoscopy (DBO) list.

**Aims & Methods:** We searched our endoscopy software for patients who had had an endoscopy documented as having BO who had an endoscopy on a GE list from 2012–2013. The same search was performed for patients who were scoped on the DBO list from 2014–2016. Endoscopy reports were reviewed to assess the use of Prague classification and determine numbers of biopsies taken. Biopsy results were recorded on our electronic pathology database.

**Results:** One hundred procedures for BO surveillance on GE lists were audited, comprising 65% male patients with median age 68 years; 60% were performed by a consultant gastroenterologist and the remainder were performed by other operational medical gastroenterology registrars. Of the 105 procedures on the DBO lists, 63% of patients were male, median age 70 years. Prague classification was used in 94% of endoscopy reports on the DBO lists compared with 5% on the GE lists. The Seattle biopsy protocol was observed in 70% on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) appeared to be more influenced by the endoscopy operator since all of the dysplasia detected on GE lists was identified by consultant gastroenterologists. We therefore recommend that all Barrett’s oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

**Conclusion:** Our comparison shows that observance of Prague classification is significantly higher on the DBO lists when compared with GE lists (94% vs 5%), and this compliance with the Seattle biopsy protocol is similarly higher (74% vs 30%). These are indicators of higher quality endoscopic surveillance on DBO lists. However, this did not translate to a different dysplasia detection rate which appeared to be more influenced by the endoscopy operator since all of the dysplasia detected on GE lists was identified by consultant gastroenterologists. We therefore recommend that all Barrett’s oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0556 ADHERENCE TO QUALITY INDICATORS AND SURVEILLANCE GUIDELINES IN THE MANAGEMENT OF BARRETT’S OESOPHAGUS: A RETROSPECTIVE ANALYSIS**

D. Westerveld1, V. Khullar2, M. B. Riverso2, Y. Perbtani2, M. Agarwal1, J. SURVEILLANCE GUIDELINES IN THE MANAGEMENT OF P0556 ADHERENCE TO QUALITY INDICATORS AND adherence to surveillance guidelines for non-dysplastic BE (NDBE). standardized classification (Prague Criteria) and a systematic four-quadrant management of Barrett’s esophagus (BE) promotes high-quality cost-effective care.

**Conclusion:** Adherence to quality indicators and surveillance guidelines in the management of Barrett’s esophagus (BE) promotes high-quality cost-effective care.

**Aims & Methods:** The aims of this study were to evaluate (1) adherence to standardized classification (Prague Criteria) and a systematic four-quadrant biopsy protocol, (2) identify predictors of practice patterns, and (3) to assess adherence to surveillance guidelines for non-dysplastic BE (NDBE).

This was a Single-center retrospective study of endoscopies (EGDs) performed for BE between June 2008 to December 2015. Data on patient demographics, procedure characteristics and histology results were obtained from a prospectively collected endoscopy database and chart review. Adherence to the use of Prague Criteria and systematic biopsy protocol were assessed based on operative report documentation. Guideline adherent surveillance EGD was defined as those performed within 6 months of the recommended 3-5 year interval. Uni- and multivariate analysis were performed to identify predictors of practice patterns.

**Results:** A total of 397 patients (66.5% male; mean age 60.1 ± 12.5 years) had an index EGD during the study period. Adherence to the use of Prague Criteria and systematic biopsies were 27.4% and 24.1%, respectively. Endoscopists who performed systematic interventions for BE were more likely to use the Prague Criteria (OR: 3.16; 95%CI: 1.47–6.82) than those who did not. Longer time in practice (in years) was positively associated with adherence to Prague Criteria (OR 1.07; 95% CI: 1.02–1.12; p < 0.001) but with a lower likelihood of performing systematic biopsies (OR: 0.91; 95%CI: 0.85–0.97; p < 0.001). Nearly 41% of patients with NDBE (11/27) underwent surveillance EGD sooner (range 1–24 months) than the recommended interval.

**Conclusion:** Adherence to quality indicators and surveillance guidelines in BE is low. One key characteristic, including experience with endoscopic therapy for BE and time in practice predicted adherence to the use of Prague Criteria and systematic biopsies. Future efforts are needed to reduce variability in practice and promote high-value care.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0557 EXPRESSION OF TGF-B AND CD-44 IN AGE SPECIFIC SUBGROUP OF PATIENTS WITH ADENOCARCINOMA OF GASTRIC CARCINIA**

N. Lukavetsky, T. Fetschy Oncology Department, Lvis Medical University, Lvis/Ukraine

**Contact E-mail Address:** lukavetsky@ukr.net

**Introduction:** Adenocarcinoma near the esophagogastric junction is one of the most lethal GI malignancies known. Surgical treatment of these cancers stay determinative factors of patient survival. Older persons often differ from the younger adult population in terms of biological and functional perspectives; as such, they may have particular needs which require an interdisciplinary approach and intervention, especially when faced with a cancer diagnosis. 

**Aims & Methods:** The aim of this study was to detected expression of TGF-B and CD-44 in age specific subgroup. The expressions of TGF-B and CD-44 were evaluated immunohistochemically in 23 patients with adenocarcinoma of gastric cardia who underwent curative surgery (RO) without any neo/adjuvant therapy. Additionally we analyzed control group of patients with non-cancer lesion or normal tissue of upper digestive tract (13 patients). We divided the patients into two groups. Group A consisted of 13 cancer patients and 7 control patients 65 years of age or older, while Group B consisted of 10 cancer and 6 control patients younger than 65 years of age. The two groups were comparable - there were no differences between the two groups regarding tumor stage.

**Results:** Elderly patients have statistically significant better survival (median 20.2 months) compared with younger patients (median 15.4 months) (p=0.045). The median survival rate of patients without TGF-B and/or CD-44 expression was significantly lower (7 m) than that of patients with positive expression (> 15 m) (p = 0.003). Regardless of patients age, CD-44 was significantly higher in the cancer tissue of elderly patients than in younger (p < 0, 035). But no significant difference was observed in the TGF-B expression between group A and group B cancers tissue (p = 0.005).

**Conclusion:** The biology of tumors may be different in elderly patients, leading to a lower rate of tumor-related mortality.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Barrett’s oesophagus (BO) is considered a premalignant condition for oesophageal adenocarcinoma (OAC). Once diagnosed, interval endoscopic surveillance is recommended to promote early detection of dysplasia and cancer. Occurrence and incidence of dysplasia and cancer among BO vary across populations. Recent studies show BO patients mortality is mainly related to non-oesophageal cancer and cardiovascular morbidity.
Aims & Methods: In this cross-sectional study, our aims were to describe the local BO clinical, endoscopic and histologic profile in our tertiary referral centre, and discover whether the Prague classification and diagnostic requirements are filled. We identified and included all consecutive patients with oesophageal intestinal metaplasia (identified by the presence of goblet cells) from March 2009 to May 2015. All endoscopies and biopsy reports were reviewed: BO segment length, use of the Prague classification, endoscopic abnormalities, treatment modality, and histologic findings of dysplasia. Participants were sent a clinical questionnaire, via which pertinent clinical data including personal and familial cancer history, were collected.

Results: Clinical profiles: Our cohort consists of 406 patients, with a mean age of 60.4 ± 13.3 years, 69% were male. Endoscopic profile: Mean maximal BO length (Prague classification M) was 2.8 ± 1.9 cm (reported in 49.6% of endoscopies) Mean circumferential BO (Prague classification C) was 4.9 ± 3.1 cm (reported in 18.1% of endoscopies). Histologic profile: Low-grade dysplasia (LGD) was seen in 4.4% of patients, high-grade dysplasia (HGD) in 3%, intramucosal carcinoma (IMC) in 0.7%, and OAC in 2%. A subgroup of 250 patients underwent more than one endoscopy, allowing for prospective incidence analysis. They had 914 years of follow-up, with a mean number of endoscopies of 4.7 ± 3. The incidence rates of LGD, HGD, IMC, OAC per 1000 patient years were 20.8, 15.3, 2.2, and 7.6 respectively. One hundred and fifty-five patients returned the questionnaire. In this subgroup analysis, we learned BO was diagnosed at 57.8 ± 12.5 years of age, with a mean duration of 4.9 ± 5.7 years. A personal history of non-oesophageal malignancy was reported in 15.4%. A family history of BO, OAC and non-oesophageal cancer were reported in 5.2%, 4.5%, and 35.4%, respectively.

Conclusion: Compared to the information gathered by Katz et al. (1), we demonstrated a lower rate of LGD, but comparable rates of HGD and OAC. The personal and familial history of non-oesophageal malignancy was higher than the oesophageal malignancy rates. Our findings may support the importance of age appropriate non-oesophageal malignancy screening in BO patients. Physician compliance in reporting BO according to the Prague classification is lacking. Factors associated with our local BO profile as well as the implication of family history requires further prospective studies.

Investigation: Simultaneous squamous cell carcinoma in the esophagus confined to the muscularis mucosa (MM) or submucosa up to 200 μm (SM1) has a risk of lymph node metastasis, it is defined as relative indication for endoscopic submucosal dissection (ESD) by the Japan esophageal society guideline. Although additional surgical treatment after ESD is recommended, long-term outcomes of ESD compared with surgery has not been clarified.

Aims & Methods: This study aimed to evaluate the long-term outcomes of ESD and pathological criteria of relative indication for endoscopic submucosal dissection (ESD) by the Japan esophageal society guideline. Although additional surgical treatment after ESD is recommended, long-term outcomes of ESD compared with surgery has not been clarified.

Results: Patients with Fanconi anemia (FA) have an increased risk of developing esophageal squamous cell carcinoma. Data regarding endoscopic findings among patients with FA are lacking. Furthermore, there are no clear guidelines for endoscopic surveillance of patients with FA.

Aims & Methods: We aimed to describe the endoscopic findings among subjects with FA undergoing endoscopic surveillance and to determine the interval to development of esophageal cancer.

Results: Eight FA subjects with a median age of 22.2 years at first endoscopy (range16–41) were identified. The median upper endoscopies number per patient was 15 (range 2-14) with a median time of follow-up of 4.5 years (range 1–9 years). All subjects (100%) had an endoscopic evidence of reflux esophagitis: 3 (37.5%) had mild and 5 (62.5%) had moderate-severe reflux esophagitis. Three subjects (37.5%) had complicated esophageal reflux disease (two subjects developed Barrett’s esophagus and one subject had an esophageal stricture). Two subjects (25%) developed esophageal squamous cell carcinoma during follow-up, with interval time of 8 and 18 months from previous upper endoscopy. Both had tumor expression of p16 protein suggesting human papilloma virus (HPV) infection. The calculated standardized incidence ratio (SIR) for the development of esophageal squamous cell carcinoma is 5107.

Conclusion: FA patients are at an increased risk for developing esophageal cancer and reflux esophageal disease with associated complications. Larger, prospective studies are needed to determine the optimal interval for endoscopic screening in these patients.

A cross-sectional cohort (n = 610/432) were used as an historical control.

Results: Between Sep 2005 and May 2010, 330 patients (M/F = 278/52) were registered. The proportions of the different grades of LV were A = 50 (15.2%), B = 174 (52.7%), and C = 106 (32.1%). After adjusting for sex and age, controls and the LV grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), liking high-temperature food (46.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LV grade B associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 2.73; p < 0.0001) and non-temperance (OR = 2.12; p < 0.0001). OR of LV grade C associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 358) than active ALDH2 (OR = 138) (p < 0.05).

Conclusion: The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the Japanese guidelines for the treatment of esophageal cancer, T1a-EP or T1a-LPM squamous cell carcinoma (SCC) is definitive indication for endoscopic resection (ER) which is therapeutically possible to treat them. T1a-MM or T1b-SM1 is a relative indication of ER, because 10-20% of the cases has metastasis in the previous analysis of operation cases. Recent advances in ER such as endoscopic submucosal dissection (ESD) and steroid injection for the prevention of stricture, provide us increasing opportunity to treat clinical MM/SM1 which means preoperative predicted invasion depth of MM/S1. Currently we treat them with MM without lymphovascular invasion were reported to have very low risk of metastasis and occupy majority part of MM/S1. There is no report about long term outcome of ER for clinical MM/S1.

Aims & Methods: This study aimed to evaluate the clinical outcomes in patients having esophageal SCC with a predicted invasion depth of MM/S1. We retrospectively reviewed 45 patients having esophageal SCC with a predicted invasion depth of MM/S1. We predicted the invasion depth using conventional endoscopy, magnifying endoscopic classification of Japanese esophageal society, and endoscopic ultrasound (EUS). The patients were diagnosed and treated at our institution from 2010 to 2013. We compared the clinical outcomes for the patients having MM/S1 with or without lymphovascular invasion, and recommended CRT or esophagectomy as additional therapy.

Results: The median age was 67 years (range, 39–81 years), including 37 males (82.2%). The most common site of the tumors was the lower esophagus (47.8%), moderate (36.1%), and upper esophagus (16.1%). The tumors were localized in the cervical esophagus (n = 2), upper esophagus (n = 9), mid-esophagus (n = 30), and lower esophagus (n = 4). The number of tumors subclassified as types 0-I, 0-IIa, 0-IIb, and 0-IIc was 0, 7, 1, and 37, respectively. Forty cases were diagnosed as MM/S1 using the Japanese Esophageal Society classification for magnifying endoscopy, and its accuracy was 62.5% (25/40). EUS was performed for 21 patients, and its accuracy was 68.8% (16/23). The patients underwent endoscopic mucosal resection (n = 5) or ESD (n = 40). In pathological diagnosis, LPM invasion was found in 14 patients, MM/S1 invasion in 28 patients, and SM2 invasion in 3 patients. The overall accuracy rate of diagnosing MM/S1 invasion was 62% (28/45). Among patients with MM/S1 invasion, 20 had no lymphovascular invasion, and

SNPs on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of blood from the patients before the endoscopic examination. Patients were subjected were classified as rare drinkers who consumed <1 units/week, current drinkers who consumed 1 to 8.9 units/week (light drinkers), 9 to 17.9 units/week (moderate drinkers), or ≥18 units/week (heavy drinkers); alcohol consumption (1 unit = 22 g, the ethanol content of one serving of sake). The physicians recommended all subjects to temperate in drinking and smoking. We retrospectively evaluated the risk of metachronous SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

Results: During a median follow-up period of 80 months (range, 24–228 months), a secondary SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

SNPs on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of blood from the patients before the endoscopic examination. Patients were subjected were classified as rare drinkers who consumed <1 units/week, current drinkers who consumed 1 to 8.9 units/week (light drinkers), 9 to 17.9 units/week (moderate drinkers), or ≥18 units/week (heavy drinkers); alcohol consumption (1 unit = 22 g, the ethanol content of one serving of sake). The physicians recommended all subjects to temperate in drinking and smoking. We retrospectively evaluated the risk ofmetachronous SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

they were not recommended additional therapy. The remaining eight patients had lymph node involvement or invasion of SM2 or SM3 were recommended additional therapy. In total 33 cases were treated only by ER without additional therapy. Besides 97% (32/33) of those cases had no recurrence except for one case with a lymph node recurrence, which was successfully treated by additional CRT. The other 12 cases that underwent lymphovascular invasion or SM2 were recommended additional therapy. They underwent CRT (n = 4), radiotherapy (n = 3), or esophagectomy (n = 3). No recurrence was observed after the abovementioned treatments. At the end of the follow-up, the 3-year overall and disease-specific survival rates for group B and group C were 100% and 96%, respectively. Considering ESD, ER, and MM/SM1, 76% of all cases were completed their treatment only with ER, and 24% of high risk case for metastasis were treated appropriately with additional therapy.

Conclusion: Conclusions: Our study suggests that ER is a valid treatment for esophageal SCC with a preoperative predicted invasion depth of MM/SM1.

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are the first line treatment for superficial esophageal squamous cell carcinoma (SCC). Comparatively to surgery, endoscopic resection is mini invasive and associated with a lower morbidity and mortality.

Aims & Methods: Evaluation of the endoscopic resection efficiency for superficial esophageal SCC and long-term outcome. Primary outcomes was recurrence rate after endoscopic resection defined as local recurrence or metastatic evolution. We conducted a retrospective multicenter study in 5 french tertiary care hospitals. All patients treated by EMR or ESD for histologically proven SCC were consecutively included. Esophageal SCC was defined as superficial after macroscopic evaluation including Lugol staining and endoscopic ultrasonography (EUS). Curative resection was defined as ≥T1a with free resection margins, without lympho-vascular emboli.

Results: Between 1998 to 2016, 132 patients were enrolled and 148 tumors were resected (EMR = 80, ESD = 68). The mean age was 63.9 [35.7 - 86.0] years-old and 108 (73%) patients were male. Mean tumor size was 15.0 mm in the EMR group and 35.5 mm in the ESD group (p < 0.001). The complete resection rate in the ESD group was significantly higher 85% (24/30) and 88% (68/80) (p < 0.001). The mean follow-up period was 22 months. The recurrence rate was 14.2% (19/130) in the ESD group and 2/85 in ESD group, p = 0.001. At 12 months, recurrence-free survival rate was 84.4% and 76.4% at 24 months. Factors associated with recurrence in univariate analysis were: tumors size (p = 0.013), resection by EMR (p = 0.001), piecemeal resection (p = 0.016), and microscopic positive margins (p = 0.044). In multivariate analysis, risks factors for recurrence were: resection by EMR (OR=7.315; IC [1.685-31.762]; p = 0.008) and invasive (OR=2.635; IC [1.065-6.519]; p = 0.036). At 24 months, recurrence-free survival rate was 95.2% in ESD group, versus 59.8% in EMR group (p = 0.001). For infiltrating tumors ≥ m3, metastasis free survival rate at 24 months were 100% after complementary treatment by radiotherapy, and 62.2% without complementary treatment (p = 0.042).

Conclusion: Endoscopic resection of superficial esophageal SCC is safe and efficient. According to our results, ESD should be preferred to EMR because it is associated with a higher curative rate and an increased recurrence free survival rate.

Introduction: Oesophageal squamous cell carcinoma (ESCC) with invasion into muscularis mucosa or submucosa (MM/SM1) has approximately 10% lymph node metastasis and is a relative indication for endoscopic resection (ER) as per the Japanese Esophageal Society (JES) guidelines. The consideration criteria for additional treatment of MM/SM1 ESCC are as follows: (1) lymphovascular invasion, (2) SM1, (3) positive vertical margin, and (4) diffuse pattern of infiltration (INF). However, the clinical validity of the JES guidelines has not been established. We evaluated the curative conditions after ER for MM/ SM1 ESCC based on long-term outcomes.

Methods: We recruited 98 consecutive MM/SM1 ESCC who underwent ER between August 1992 and October 2013 and were followed up for more than 3 years at Hiroshima University Hospital. As per the JES guidelines, the e-curable group was characterised by en bloc resection lesions with pathological MM, tumour and infiltration pattern (T3/M1/N0). The e-uncurable group (T1-3, INF+, M+ or N+) was analysed. The clinicopathological characteristics of patients and lesions at the rates of overall survival, disease-specific survival, recurrence-free survival, lymph node recurrence and local recurrence in the e-curable and non-e-curable groups.

Results: We enrolled 98 consecutive MM/SM1 ESCC patients (88 males; mean age, 67.4 ± 9 years; e-curable group, 39 patients; non-e-curable group, 59 patients; mean follow-up period, 75.4 ± 44 months). There were no significant differences in the clinicopathological characteristics of the patient and lesions between the 2
groups. The proportion of patients with additional treatment after ER was sign-
ificantly higher in the e-curable group (5%, 4/99) than in the non-e-curable
group (18%, 21/115; p < 0.05). Operation, radiotherapy, and chemoradiotherapy
were administered to 3 (8%), 4 (10%), and 12 (5%) patients, respectively in the
e-curable group and to 7 (12%), 22 (37%), and 10 (17%) patients, respectively
in the non-e-curable group. The 5-year overall survival rates in the e-curable and
non-e-curable groups were 97% and 75% (p < 0.05), respectively. The overall
survival rate was significantly higher in the e-curable group. Three deaths (10%)
ocurred due to primary cancer. The other reasons were as follows: other organ
cancer, 3 cases; heart failure, 4 cases; pneumonia, 3 cases; and others, 11 cases.

The 5-year disease-specific survival rates in the e-curable and non-e-curable
groups were 100% and 98%, respectively. The lymph node recurrence rates in
the e-curable and non-e-curable groups were 3% (1/39) and 7% (4/59), respecti-
vely. The local recurrence rates in the e-curable and non-e-curable groups were
0% (0/39) and 7% (4/59), respectively. The 5-year recurrence-free survival rates
in the e-curable and non-e-curable groups were 100% and 98%, respectively. The
5-year recurrence-free survival rates in the group with INFa and no lymphovas-
cular invasion were 100% and 87%, respectively. The recurrence-free survival rate
was significantly higher in the group with INFa and no lymphovascular invasion
than in the group with INFb, INFc or lymphovascular invasion.

Conclusion: Our study data support the clinical validity of the e-curable
conditions after ER for MM/S1 ESSC of the JES guidelines. However,
MM/S1 ESCC with INFa and no lymphovascular invasion may have more
possible curative conditions after ER without additional treatment.

or those in which the biopsies were still taken from the different anatomical areas were excluded. The patients were divided into five groups on the basis of the OLGA staging system (OLGA) and the OLGIM staging system (OLGIM).

Results: Only 148 patients were admitted to the study. The mean age was 49.7 ± 4.9 years, 60% were female (CE 52.67, 95%). 264 vials were sent with biopsies of the different areas of the stomach distributed as follows: 148 of antrum, 54 of antrum and corpus, 48 (32.4%) for corpus, 48 (32.4%) for corpus and body of antrum, angle and body. From 148 patients, 116 (78.4%) had an endoscopic diagnosis of normal gastritis or mucosa and 32 (21.6%) had endoscopic diagnosis of PCLS. From 116 patients with endoscopic diagnosis of gastritis or normal mucosa, LCPM was identified in 46 patients (39.6%) (p < 0.001) and 1 of them were low-grade dysplasia. From 32 of patients with suspected endoscopic PCLS, the diagnosis was confirmed with histology in 26 patients (81.2%). A total of 72 patients had PCLS vs. 32 who were initially suspected (p < 0.01), with a total patients of CE 40.7-56.6, 95%

Conclusion: Pre-malignant conditions and lesions of the stomach (PCLS) can show as normal mucosa or gastritis during endoscopic procedure. 39.9% of patients who underwent endoscopic procedure with presumptive gastritis had PCLS. PCLS may be under-diagnosed if random biopsies are not taken. Therefore, taking biopsies from areas without suspected PCLS causes a change in the clinical management of patients, both for the initial diagnosis and for the staging according to OLGA and OLGUM systems.

Introduction: Prognosis of GC has a noticeable relation with its clinical stage. Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recognized risk factors for intestinal type GC (GC). A large cohort study demonstrated that serum PG level reflects the functional and morphologic status of patients with normal mucosal. In addition, long-term follow-up studies have recognized risk factors for intestinal type GC (GC). A large cohort study demonstrated that the annual incidence of GC were approximately 0.1% for patients with AG, intestinal metaplasia (IM) and dysplasia.

Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recognized risk factors for GC. Introduction: Endoscopic treatment of sporadic duodenal adenoma is mainly performed at tertiary centers because it is technically challenging and associated with major complications (perforation 1-5% and delayed bleeding 10-15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non-ampullary sporadic duodenal adenomas (SDA) in two tertiary centers in a large series and to try to determine the predictive factors of outcomes with a long follow-up.

Aims & Methods: This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endoscopic treatment for SDA histologically proven were included. Patients were excluded if SDA were negative in 91.8% of the cases. Negative lateral and vertical margins was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis with the lesion size and its en-bloc resection.

Introduction: Additional surgery should be recommended in patients with non-curable endoscopic resection for early gastric cancer (EGC). However, this decision has often been hesitated according to patient condition such as advanced-stage or comorbidities. After the recognition of recurrence, the salvage surgery has been considered difficult. However, little has been reported on it. Aims & Methods: The aim of this study was to clarify the results of salvage surgery for recurrence after non-curative ESD for EGC using data from a multicenter retrospective study (EAST study). Of 15,785 patients who underwent ESD for EGC at 19 participating institutions from January 2000 to August 2012, 6786 patients were followed to meet the current curative criteria for ESD were retrospectively reviewed. Among 1969 patients enrolled into EAST study, 1064 patients underwent additional surgery, and 905 patients were observed without any additional treatment. We evaluated first site of recurrence, clinical course after salvage surgery, and long-term survival on non-treatment group. Recurrence was classified regional LNM, and distant metastasis.

Results: Over a median follow-up period of 64 months, recurrence was detected in 27 patients. Among them, 2 patients were excluded from this study due to missing data of (1) pathological recurrence were only local site (intagia-gastric and regional LNM 7), and distant metastasis 15 (60%). The first treatments for recurrence were endoscopic treatment 1, salvage surgery 7 (28%), chemotherapy 6, and best supportive care 11. Only one patient was alive without any recurrence for 31 months after salvage surgery. And one patient died of acute myocardial infarction just one month after salvage surgery. In the remaining 5 patients, recurrence was detected at 0, 2, 3, 5, 30 months after salvage surgery, and all of them died of gastric cancer. Median survival time of all 25 patients with recurrence was 20 months. Of 25 patients with recurrence, survival was 5 months from recurrence. And median survival time of 7 patients who underwent salvage surgery was only 7 months from salvage surgery.

Conclusion: More than half of recurrence after non-curative ESD without additional surgery were distant metastasis, and the survival rate after salvage surgery was quite low.

Introduction: Due to the increase of elderly patients who are often receiving antithrombotic therapy for cardio- and cerebrovascular diseases, postprocedural bleeding after endoscopic treatments for early gastric lesions has become one of the major concerns of therapeutic endoscopists. The Japan Gastroenterological Endoscopy Society (JGES) and other related associations published the Guidelines for Gastroenterological Endoscopy in Patients Undergoing Antithrombotic Treatment in 2012. According to the guideline it is not necessary to suspend an antithrombotic agent before endoscopic treatments including endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) if the agent is not combined with other antithrombotic drugs (monotherapy). On the other hand it is recommended that anticoagulants should be substituted with heparin before EMR/ESD. The aim of this study is to clarify the efficacy of the recommendations of the guideline.

Aims & Methods: In this study 888 early gastric lesions in 783 patients who underwent EMR/ESD at our hospital between January 2012 and March 2017 were retrospectively analysed. Postprocedural bleeding was defined as: (1) hematemesis, melaena for which an emergency endoscopy was required and (2) bleeding which were confirmed with a repeat endoscopy after a drop ≥2 g/dL of haemoglobin level.

Results: The total number of patients undergoing antithrombotic therapy was 78, of which 38 patients who were taking antithrombotics agents only, 29 were taking antiplatelet agents only, and 11 were taking both. The antithrombotics were suspended in 22 cases (Group A), substituted with heparin in 18 (Group B), and kept continued in 38 (Group C). Postprocedural bleeding was encountered in 31 out of 783 cases (4.0%), 21 of which occurred in patients on antithrombotic therapy (21/78: 27%) whereas 10 of which occurred in those without (10/752: 1.3%). A univariate analysis between the patients with postprocedural bleeding and those without according such variables age, gender, the diameter and number of the resected lesions, use of antithrombotics, and the expertise of the operating endoscopist revealed that only the use of antithrombotics was significant risk factor for the postprocedural bleeding (odds ratio = 14.926, 95% confidence interval: 7.415–34.208, p < 0.001). However, the rate of postprocedural bleeding was not significantly different among Group A, B and C. Among the 21 bleeding patients with antithrombotics, the agent had been suspended or substituted with heparin before EMR/ESD in 10 and had been continued without suspension in 11. There was no significant difference of bleeding rate between the two groups.

Conclusion: The use of antithrombotics was a significant risk factor for the postprocedural bleeding after EMR/ESD for early gastric lesions. The rate of bleeding was not significantly different regardless if the antithrombotics were suspended, substituted with heparin, or continued without suspension.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Since population-based screening for gastric cancer in Korea was implemented in 2002, endoscopic treatment of early gastric cancer (EGC) has been popularized. Most patients with early neoplasm have no alarming symptoms/signs. In addition, the strategy for detecting factors predicting curative endoscopic resection of EGC is becoming important, because the general population is aging and considering the quality of life after treatment.

Aims & Methods: This study investigates factors affecting curative endoscopic resection of EGC in the era of population-based screening for gastric cancer. The subjects consisted of patients newly diagnosed with stomach cancer at Seoul ST. Mary’s Hospital between May 2011 and May 2016. All patients completed questionnaires about symptoms, social history, family history, knowledge of national cancer screening program, the reason for screening, and the interval between endoscopy screening examinations for gastric cancer.

Results: Of a total of 469 patients, 147 (31.3%) had a curative endoscopic resection, 260 (55.4%) had a curative surgical resection and 62 (13.3%) were in non-curative surgical resection or an inoperable state. The patients with curative endoscopic resection had minimal abdominal symptoms and fewer alarm symptoms/signs (a family history of gastric cancer, anemia, and clinically important weight loss), whereas alarm symptoms were more common in patients with advanced cancer. In multivariated analysis, regular surveillance endoscopy was only the factor predicting the curative endoscopic resection [Odd ratio (95% CI) 6.099 (2.532 – 14.933), p = 0.000]. In addition, the proportion of curative endoscopic resection was significantly higher in the 1-year [Odd ratio (95% CI) 10.381 (4.081 – 26.409), p = 0.0000], 2-year endoscopy interval groups [Odd ratio (95% CI) 3.161 (1.106 – 9.035), p = 0.032] than patients who had no endoscopy within 2 years.

Conclusion: Most patients with the curative endoscopic resection have minimal abdominal symptoms and no alarming symptoms/signs. Regular surveillance endoscopy was the only factor predicting the curative endoscopic resection of gastric cancer. In addition, more frequent endoscopic surveillance could help to early detect gastric cancers with curative endoscopic resection.

Introduction: Atrophic gastritis and intestinal metaplasia are the cancerization field in which gastric cancer (GC) develops in case of intestinal type. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC.

Aims & Methods: The aim of this study is to evaluate the usefulness of OLGA and OLGIM staging according to Lauren's histological classification of GC in considering with other risk factors of gastric cancer. From January 2006 to December 2015, 607 GC patients and 677 control subjects were enrolled who underwent esophagogastroduodenoscopy. Biopsies were taken from the greater and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM stage (0-IV) was recorded by combining antral with body atrophy and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM staging according to Laurens's histological classification of GC in regions with high prevalence of GC.

Disclosure of Interest: Analysis regarding specific interaction among these three factors is undergoing.

Introduction: The association between body mass index (BMI) and digestive cancer mortality is not conclusive in East Asians.

Aims & Methods: We evaluated the relationship between BMI and digestive cancer mortality, using prospective cohort data by the National Health Insurance Service in Korea, which consisted of more than one million subjects. A total of 510, 148 Korean adults were followed-up until 2010. The adjusted hazard ratios (HRs) of cancer mortality were calculated using a Cox model.

Results: During follow-up, 7774 total deaths occurred from digestive cancer, HR for digestive cancer mortality across seven BMI categories. Below 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were 0.43 (95% confidence interval [CI] = 0.32-0.58) for esophagus cancer, 0.70 (0.62-0.79) for stomach cancer, and 0.70(0.65–0.90) for colorectal cancer. Over 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were 1.30 (95% CI = 1.04-1.64) for colorectal cancer, 1.28 (1.07–1.53) for liver cancer, and 1.28 (0.96–1.71) for gall-bladder cancer and biliary tract cancer. BMI were not associated mortality from small intestine cancer and pancreatic cancer.

Conclusion: Low BMI were predictors of mortality from esophageal cancer and stomach cancer. High BMI were predictors of mortality from liver cancer and gallbladder cancer and biliary tract cancer. Both low and high BMI were predictors of mortality from colorectal cancer. Further research is needed to evaluate whether interventions involving weight change (loss or gain) reduce the risk of cancer or improve the survival.

P0578 RISK FACTORS FOR LYMPH NODE METASTASIS OF ULCERATIVE TYPE INTRACULAR EGG
T. Kim1, T.J. Kim1, H. Lee1, J.H. Lee1, J.J. Kim2
1Department Of Gastronomy, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of
2School of Medicine, Seoul/Korea, Republic of

Introduction: Endoscopic submucosal dissection (ESD) is not currently accepted as an alternative treatment to surgery in ulcerative type EGC due to relatively higher probability of lymph node metastasis (LNM). This present retrospective analysis examined the correlation of various histologic factors with the presence of lymph node metastasis in ulcerative type EGC.

Aims & Methods: A retrospective analysis on 200 patients with ulcerative type EGC who underwent radical gastrectomy with D2 lymph node dissection. Several clinicopathologic factors were investigated to identify predictive factors for LNM: tumor size, histopathologic type of tumor, lymphovascular invasion and depth of invasion. Multivariable logistic regression analysis was performed to evaluate the risk factors for LNM.

Results: The total rate of LNM was 15.5% (31/200). The rate of LNM was 2.1% (2/95) in the lesions confined to the mucosa and 27.6% (27/105) in those that had infiltrated the submucosa. On univariate analysis, depth of invasion (p = 0.047) and lymphovascular invasion (p < 0.001) were significant associated with LNM. However, there was no significant association between tumor size, histopathologic type of tumor and LNM. On multivariate analysis, only lymphovascular invasion (p = 0.001) was significantly associated with LNM. There was no significant association between tumor size and lymph node metastasis in ulcerative type EGC.

Conclusion: Ulcerative EGC confined to the mucosa could be considered for candidate for curative ESD due to the low risk of LNM. This finding should be confirmed by more data from other centers, which focus on LNM after ESD in ulcerative type intramucosal EGC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0579 THE FEASIBILITY STUDY USING KUMC ROBOTIC MANIPULATOR IN ENDOSCOPIC SUBMUCOSAL DISSECTION
1Division Of Gastroenterology And Hepatology, Department Of Internal Medicine, Korea University Anam Hospital, Seoul/Korea, Republic of
2Division Of Gastroenterology and Hepatology, Department of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of

Introduction: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. An advantage of IRE is its ability to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Several clinical trials for applying IRE to human organs such as liver, pancreas and kidney are conducted and studies about IRE ablation for gastrointestinal tumors also have been conducted recently. Here, we developed new developed endoscopic IRE ablative catheter works with single channel of endoscope. A pair of dipolar electrodes consist of pre-shaped 0.63 mm nitinol wire and the distance between each electrode is 10 mm. The electrodes are loaded within braided tube for stent delivery system then deployed within IRE catheter put in stomach through the endoscope. We performed endoscopy and IRE ablation was done on pig's stomach mucosa by using endoscopy with newly developed IRE catheter. We divided pig's stomach into 2 parts (antrum & body), and IRE ablation was applied on each part of the stomach. Pigs were sacrificed after 24 hours, and we collected their stomachs with surgical technique. Following fixation, tissues were stained with H&E.

Results: Ten male Yorkshire pigs and in vitro stomachs were used in this study. The tissue with H&E stain showed diffuse cell death 24 hr after IRE ablation.

BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. *Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency; five or more times/week, one to four times/week, less than one times/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004; < 500, 000, 500, 000-990, 000, 1, 000, 000-1, 490, 000, 1, 500, 000, 500, 000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.
Consistent with the mechanism of action of IRE on the cell membrane only, there was completely killed cell within the IRE lesions without intervening live cells. But there was no difference in histology depending on gastric part in which ablation was applied. During the study, no complication was observed in pigs in 24 hours after ablation.

Conclusion: The new endoscopic IRE device, which can perform IRE ablation on gastrointestinal tract using endoscopy showed safe and feasible result.

P0581 DIAGNOSIS OF MICROVASCULAR PATTERN IS MORE IMPORTANT THAN MICROSPHERE PATTERN TO DELINEATE GASTRIC CANCERS DETECTED AFTER H. PYLORI ERADICATION BY MAGNIFYING ENDOSCOPY

T. Iwasaki, K. Uchita, K. Kojima, S. Iwamura
Kochi Red Cross Hospital, Kochi/Japan

Contact E-mail Address: space-rendez-vous@sings.jp

Introduction: It is difficult to delineate gastric cancer that is detected after successful eradication of Helicobacter pylori. One reason is reportedly the difficulty in identifying the demarcation line between the cancerous lesion and non-cancerous gastric mucosa due to a mixture of non-neoplastic epithelial-lined structure inside the neoplasm. However, most previous studies have only used magnification endoscopy (ME) at low power magnification which could evaluate microsurface pattern (MSP) but could not evaluate microvascular pattern (MVP).

The highest power magnification was necessary to evaluate MVP accurately to delineate the demarcation line. The ME findings of the demarcation line, irregular MSP and irregular MVP were inconsistent in delineating the gastric cancers might not have been accurately assessed in these studies.

Aims & Methods: The aim of this study was investigating diagnostic efficacy of ME with narrow band imaging (NBI) in delineating the gastric cancers after eradication HP, using ME at highest power magnification, and classifying ME features of the marginal area according to the vessel plus surface classification system (VSCS) to realize which was more important ME findings MSP or MVP to detect demarcation line. Endoscopic examination was performed using a magnification endoscopy (GF-H260Z, Olympus Medical Systems Co, Tokyo, Japan) and NBI system (EVIS LUCERA Spectrum system; Olympus Medical Systems Co, Tokyo, Japan). Endoscopic imaging procedures were performed at low-power magnification followed by highest power magnification. On the day of EGD, the resection line was marked 3–5 mm outside of the margin of the lesion. A lesion meeting all of the following criteria was defined as a lesion with successful delineation: (1) the demarcation line of the lesion is endoscopically identified with a high level of confidence; (2) According to histopathological findings, the lesion is defined as histologically occurring in the demarcation line. The diagnostic accuracy of ME-NBI in delineating the lesions was evaluated. On the other hand the ME findings of the marginal area in each lesion were classified in terms of microsurface pattern (MSP) and microvascular pattern (MVP) according to the VSCS to identify the findings that were useful in delineating the lesions in patients with differentiated-type early gastric cancers. The classification according to the VSCS was made in the marginal area with the least irregular findings.

Results: Of 178 consecutive lesions of differentiated-type early gastric cancer treated with endoscopic submucosal dissection (ESD) between August 2013 and March 2017, the study included 59 lesions that were detected after successful H. pylori eradication. The result of ME-MBI findings are summarized in the table. Gastric cancer was successfully delineated in 98.3% (58/59) of the lesions in the marginal area with the least irregular findings.

Conclusion: The accuracy of ME with NBI in delineating gastric cancer detected after H. pylori eradication was 98.3%, which was higher than the values reported previously. In addition, the MVP as visualized by ME appeared to be a more reliable parameter for delineation. These results indicate that meticulous observation of the MVP under maximal magnification is crucial for the delineation of gastric cancer detected after eradication of H. pylori.

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up. The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastric Cancer, diagnoses of GIN are attributed, at least partly, to the full size of biopsy specimens. Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (SIF) were used (April 2010–March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011–March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy(EGD). We count the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., size, macroscopic appearance, and color tone), endoscopist experience level, biopsy sample size, and groups diagnosis were investigated. The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 5420 patients who underwent EGD in the first period, 2, 584 (30.7%) underwent gastric biopsy with SIF. Among the 15,986 patients who underwent EGD in the second period, 4204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93% (205/2584) and 7.54% (317/4204) of the SIF and SmF groups, respectively (P = 0.556). GIN was diagnosed in 30.7% (2584/8420) of the SIF and SmF groups diagnosis, respectively (P = 0.088). The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Conclusion: The only factor that had a significant impact on the GIN diagnosis rate was the forceps size used during biopsy. The forceps size use should be avoided with a standard caliber endoscopy.

Introduction: Stomach cancer is a leading cause of cancer-related deaths in the world. It well known that stress play an important role in the cancer. However, the research of the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. But, there is no clinical and epidemiological evidences that nitrosamines itself can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (overpopulation during 9 months); 2) the daily using of toulidine (2 g/kg) in food and water with nitrates (2 g/l); 3) the combined effects of stress + nitrosamines. The

upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

Results: Using upper gastroscopy, we studied the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucosa during the first 3 months. In the third month 35% (7 of 20) of animals demonstrated small partial peptic ulcer (n = 11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (n < 21 and large, n < 9). Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa observed 4 months after the beginning of daily using of toluidine and nitrites in 75% of rats (15 of 20). These rats showed symptoms of atrophic gastritis and ulcerative atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160). Tumor lesions was accompanied by the low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. Using similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis.

Conclusion: Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. A similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 1). The 14 GJFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC. Particularly, leucine, threonine and serine are the most altered three GJFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than the combination with 3 AAAs 0.841 (95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-tRNA biosynthesis metabolism was excessively activated, which significantly responsible for the above alteration alternatives in GC.

Introduction: Gastric cancer (GC) is the fourth most common type of cancer and the second leading cause of cancer related death. The gold standard for diagnosis is the esophagogastroduodenoscopy (EGD) with targeted biopsies. Aim & Methods: Retrospective observational and descriptive study in patients diagnosed of gastric cancer from January 2013 to December 2016 in the area of Ciudad Real (Spain). Missing rate of gastric cancer was defined as the percentage patients who had a negative EGD three years before the diagnosis of GC. A survival analysis was performed with Kaplan Meier curves, mainly focussing on the influence of missing rate for gastric cancer. We studied the features related to EGD that could lead this issue.

Results: 162 patients were included, 65% male with a mean age at diagnosis of 72 years. Intestinal type was the most common histology (76%). A rate of 6.8% missing of gastric cancer was detected with an average of 20 months in delay of diagnosis. However, the survival rate was similar between patients with and without a previous EGD (7.08 vs 5.05 months p = 0.60). Among the patients who passed away, a longer delay period was observed comparing to patients who were still alive (6 months vs. 25 months; p = 0.006). In the aforementioned subgroup, biopsias were taken in 72% with gastric atrophy in all these cases. Helicobacter pylori infection was detected in 50% of them. 35.6% of the EGDs were carried out without sedation. At no point chromoendoscopy was performed, pictures were taken and withdrawal times were not reflected.

Conclusion: Despite the fact that EGD is by far the most effective method to diagnose gastric cancer, 1 out of 10 cancers or premalignant lesions are not found. Therefore, it is most important to put in place quality protocol tools in EGD that may help to increase the diagnosis of early gastric cancer, and by this way, improve the survival rate of these patients.

**Introduction:** Several studies have demonstrated serum PGII level as a marker of the functional gastric mucosa, and a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, which provides a binding site for the transcription factor for the PG2 gene, in association with the PG2 circulating level and clinical parameters in population at risk for GC and in GC patients.

**Aims & Methods:** Gastric function of 180 patients (67 GC, 71 first-degree relatives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was assessed by gastropanel test. We investigated the PG2 TATA BOX polymorphism frequencies in relation to serum PG2 (sPG2) expression level, HP positivity and risk for GC. TATA BOX DNA fragments were amplified by PCR and analyzed by the capillary-electrophoresis (GeneMapper software). Association among clinical data and PG2 polymorphisms were estimated by Receiver operating characteristic (ROC) curve and linear regression analyses.

**Results:** After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL was 75% (95% CI: 65–82). A positive correlation between the increase of PG2 sized fragments and the sPG2 level was found in the GC group (linear regression y = 14, 4381 + 2, 4846 x, p = 0.02).

**Conclusion:** In the literature, we confirm sPG2 level as a marker discriminating between GC and individuals at risk for GC (i.e ACAG and FDR). Accordantly to the literature, we confirm sPG2 level as a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood to deeper understand the physiopathological PG2 role in GC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0590 HELICOBACTER PYLORI INFECTION ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE: A LARGE-SCALE COHORT STUDY**

T. Kim, T.J. Kim, H. Lee, J.J. Kim

Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of Korea

Contact E-mail Address: attack86@naver.com

**Introduction:** Previous studies suggested a link between Helicobacter pylori (H. pylori) infection and nonalcoholic fatty liver disease (NAFLD), yet large-scale longitudinal studies are lacking to elucidate this association.

**Aims & Methods:** A cohort study of 17,028 adults without NAFLD at baseline, who participated in a repeated health screening examination including an H. pylori-specific immunoglobulin G antibody test, was conducted to evaluate the association between H. pylori and NAFLD development. Fatty liver was diagnosed by ultrasonography.

**Results:** During the 83-130 person-years follow-up, participants with H. pylori infection had a higher rate of incident NAFLD than those who were uninfected. In a multivariable model adjusted for age, sex, body mass index, smoking status, alcohol intake, regular exercise, year of screening exam, and education level, the hazard ratio (HR) for NAFLD development in participants with H. pylori-infection compared to those without infection was 1.21 (95% confidence interval [CI], 1.10–1.34). The association persisted after further adjustment for metabolic variables, inflammatory marker, and liver enzymes. The association between H. pylori and NAFLD was still evident in an analysis using fatty liver index as a surrogate marker of NAFLD. In addition, the association between H. pylori infection and incident NAFLD did not differ across clinically relevant subgroups evaluated.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

*pEstimated from Cox proportional hazard models adjusted for age, sex, body mass index, year of screening exam, smoking status, alcohol intake, regular exercise, and education level. H. pylori, helicobacter pylori; HR, hazard ratio; CI, confidence intervals.

**Conclusion:** H. pylori infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. H. pylori infection may play a pathophysiological role in NAFLD development, indicating that H. pylori eradication might play a role in reducing risk of NAFLD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Introduction: Helicobacter Pylori (H. Pylori) has been implicated in worsening outcomes in patients with hepatic encephalopathy. This is believed to be the result of its urease enzyme that increases the production of ammonia. Small studies so far have yielded contradictory results on whether the presence of H. pylori worsens treatment outcomes in hepatic encephalopathy. Therefore, the aim of this study was to assess the impact of H. pylori on mortality, morbidity and resource utilization among patients with hepatic encephalopathy using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of hepatic encephalopathy were included. There were no exclusion criteria. Patients positive for H. pylori were identified using the appropriate ICD-9CM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization as measured by use of abdominal imaging (CT scan and ultrasound of the abdomen), length of hospital stay (LOS), total hospitalization charges and costs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter pylori infection has become more and more resistant to conventional first-line treatment regimens. So, there is a considerable interest in evaluating new antibiotic combinations and regimens. Nitazoxanide is an anti-infective drug with demonstrated activity against protozoa and anaerobic bacteria including Helicobacter pylori.

Aims & Methods: This work is designed to evaluate the efficacy and safety of a unique triple Nitazoxanide containing regimen as a treatment regimen in Egyptian patients with Helicobacter pylori infection.

Methods: Two hundred and twenty four patients with upper Gastro-intestinal tract (GIT) dyspeptic symptoms in whom Helicobacter pylori induced GIT disease were confirmed were included in the study. They have been randomized to receive either Nitazoxanide 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days or Metronidazole 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days.

Results: Laboratory evaluation for Helicobacter pylori antigen within the stool was done 6 weeks after cessation of Helicobacter pylori treatment regimens to assess the response.

Results:
- The response to treatment was significantly higher in group 1 of Nitazoxanide treatment regimen than group 2 of traditional treatment regimen. Group 1 showed 94.6% cure while group 2 showed 80.6%.
- The regimen was well tolerated by all the patients enrolled in the study.

Conclusion: Nitazoxanide-containing triple therapy is a promising therapy for the first-line eradication of Helicobacter pylori. (ClinicalTrials.gov Identifier: NCT0222706)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is some evidence that prior use of macrolides is a useful predictor of the likelihood of standard triple therapy failure in H. pylori eradication (Lim SG, et al. Dig Liver Dis 2016). The goal of this study is to evaluate whether previous intake of various macrolide antibiotics can predict failure to eradicate H. pylori using first-line clarithromycin-containing regimens.

Aims & Methods: Between February 2014 and June 2016 a total of 250 patients with H. pylori infection were prospectively included in a study whose goal was to assess eradication rates in patients with and without previous intake of macrolides.

Results: 219 patients (40.6%) had received at least one treatment with macrolides during the previous 12 years. H. pylori eradication rates with the two treatment regimens are shown in Table 1.

Table 1: H. pylori eradication rates in patients with and without previous intake of macrolides.

Conclusion: Previous use of macrolide antibiotics predicts a low response to triple therapy and to concomitant clarithromycin-containing regimens. In addition, our study shows that in patients without previous use of macrolides triple therapy achieves per-protocol eradication rates over 90%.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to increasing prevalences of clarithromycin resistance in H. pylori infection, current guidelines recommend quadruple therapies as first-line therapy. 1-2. Bismuth quadruple therapy (BQT) has been proven superior to standard triple therapy in clinical trials, however little is known about the efficacy of BQT in clinical routine practice.

Aims & Methods: In a prospective single center cohort study we analyzed consecutive patients in whom three-in-one capsule BQT (Pylera® + omeprazole) has been prescribed between 1/2013 and 12/2016. All patients were instructed in a standardized fashion and a prospective follow-up was planned. In a subgroup of patients, genotypic susceptibility testing for clarithromycin and levofloxacin by PCR was carried out on gastric biopsies before treatment. Treatment outcome was assessed by 13C urea breath test or by histology not earlier than 4 weeks after end of treatment.

Results: Three-in-one capsule BQT has been prescribed in 322 patients (mean age 41 years (18–80), 65% female, 26% active smoker). 71% of patients had a migrational background or the number of previous treatment failures.

Results:
- 289/322 patients (90%) completed the study protocol. The electronic medical records of the patients, which contain information regarding all the medication prescribed to the patient during the previous 12 years, were reviewed and the intake of macrolides (clarithromycin, azithromycin and erythromycin) was registered.

**Introduction:** Background: Eradication of Helicobacter pylori (H. pylori) infection represents a clinical challenge. The current requirements demand eradication rates for Helicobacter pylori infection that has made that the use of triple treatment including clarithromycin or metronidazole had been given up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth subcitrate potassium, metronidazole, and tetracycline (BMT) have shown high eradication rates in clinical trials.

**Aims & Methods:** We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of H pylori infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed H pylori infection eradication indication. Patients were treated for ten days with a galenic preparation containing bismuth subcitrate potassium 140mg, metronidazole 125mg, and tetracycline 125mg, three capsules four times daily, and esomeprazole 40mg twice daily and proton pump inhibitor during 30 days. The primary endpoint was H. pylori eradication rate measured by urea breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures. Patients were followed up until 12 months, which excluded patients who did not complete the study or who had major protocol violations, were also conducted to confirm the ITT results.

**Results:** A total of 100 patients, 60 (60.0%) women and 40 (40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [40.0 to 52.0] years. Twenty-five (25.0%) patients had a prior history of using medications to treat H. pylori infection or sometimes clarithromycin, amoxicillin, and PPI. In the ITT population, the eradication rates were 90.7% (68/75) and 80.0% (20/25) depending on whether the PPI-BMT treatment was administered as first-line or as rescue therapy, respectively. In the PP population, the eradication rates were the 98.6% (65/66) and 95.2% (21/22) in those patients treated with PPI-BMT as first-line or as rescue therapy, respectively. Eighteen (18.0%) patients reported at least one adverse event.

**Conclusion:** In patients with confirmed H pylori infection, 10 days of treatment with a regimen of bismuth, metronidazole and tetracycline plus esomeprazole provides high eradication rates not only as first-line but also as rescue therapy, with an acceptable safety profile.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0600** **A SEVEN-DAY TRIPLE THERAPY CONTAINING A POTASSIUM-COMPETITIVE ACID BLOCKER COMPARED WITH PROTON PUMP INHIBITORS, AMOXICILLIN AND CLARITHROMYCIN FOR FIRST-LINE HELICOBACTER PYLORI ERADICATION IN JAPAN: A SINGLE-CLINIC RETROSPECTIVE STUDY**

S. Yojiri
Sadamoto GI Clinic, Kitakyushu/Japan

Contact Email Address: sadamotoyo@yahoo.co.jp

**Introduction:** This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPI) for a first-line Helicobacter Pylori (H. pylori) eradication.

**Aims & Methods:** We retrospectively analyzed data from first-line H. pylori eradication treatment (vonoprazan or PPIs with 400 mg clarithromycin and 1500 mg amoxicillin) in 400 patients (vonoprazan n = 218, rabeprazole n = 182) during the period from 1st March 2008 to 28 February 2017 at Sadamoto GI clinic, Japan. Patients who received 7-day P-CAB therapy (vonoprazan 20 mg twice daily; n = 498) were compared with those who received 7-day PPI therapy (lansoprazole 30mg n=216, rabeprazole 15mg n=282) during the period from 1st March 2008 to 28 February 2017.

**Results:** ITT and PP analysis of the first-line H. pylori eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5%/86.8%, 63.9%/76.2%, 68.0%/79.5%, and 63.2/70.8%, respectively. The vonoprazan eradication rates were significantly higher than those of the PPIs (P < 0.05), respectively. There was no significant difference in the adverse events between the two therapies. In the first-line triple therapy in patients with HP infection. Three hundred and forty-nine Japanese patients with HP infection diagnosed using a rapid urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40mg/day, ABPC 1500mg/day, CAM 400mg/day) or EPZ group (EPZ 40mg/day, ABPC 1500mg/day, CAM 400mg/day) with stratification according to endoscopic findings of gastric/duodenal ulcer/scar and CAM resistance determined via a microbial sensitivity test.

**Conclusion:** The eradication rates were calculated using the urea breath test 8 to 12 weeks after cessation of therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Most Helicobacter pylori (Hp) infections are asymptomatic but 15% of those infected with Hp will eventually experience dyspepsia symptoms or ulcer.

**Aims & Methods:** We aimed to evaluate the cost effectiveness of population screening and eradication for Helicobacter pylori (Hp). This was a cost effectiveness analysis and cost utility analysis alongside randomized controlled trial with 13-year follow-up, with a random sample of the general population from the county of Funen, Denmark. 20,011 individuals aged 40-65 were randomized and invited in 1998-99; 12,530 were enrolled and of these 8658 individuals have been successfully followed up at 1, 5, and 13 years after intervention. Questionnaires included Gastrointestinal Symptom Rating Scale and the quality of life instrument SF-36. From SF-36 responses an SF-6D score was derived and used for calculation of quality adjusted life years (QALY). EQ-5D-5L was incorporated in the last follow-up. The intervention was an invitation to Hp screening by in-office Gastric Urea Breath test. Three hundred and forty-nine patients with a positive 13C-Urea Breath test received eradication therapy. The Hp prevalence was 17.5%. Main outcome measure was incremental cost per quality adjusted life year (QALY) and life-years gained. The evaluation has a National Health Sector perspective.

**Results:** There was no significant difference in index scores and in mean QALY between groups. Hp population screening and eradication with 13-years follow-up was not effective in regards to quality of life and the cost of screening was higher than not screening (14,327DKK (95% CI: 4155–24,499)). The probability of being cost-effective was lower than that in the patients with low eGFR (87.2% [82/94] versus 84.6% [77/91] in the VPZ and EPZ groups, respectively. [P = 0.60]), although the eradication rate was significantly higher among patients with CAM-resistant HP in the VPZ group than that in the EPZ group (73.6% [30/41] vs. 55.6% [35/63], [P = 0.044]). The first-line eradication rate in the patient with high estimated glomerular filtration rate (eGFR ≥ 100 ml/min/1.73m²) was significantly lower than that in the patients with low eGFR (r < 60ml/min/1.73m²; 86.4% [32/37] in...
the patients with low eGFR, 65.3% [34/53] in the patients with high eGFR [P = 0.034]), it was significantly higher in the VPZ group than that in the EPZ group (79.3% [23/29] versus 50% [11/13], respectively, [P = 0.025]). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [P = 0.016]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [P = 0.21]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [P = 0.33]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric/duodenal ulcers/scar. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400 mg/day CAM and 1500 mg/day ABPC was similar to that of EPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR. It is necessary to determine the most appropriate conditions that will maximize the therapeutic effect of VPZ-based triple therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Previous genome-wide association studies showed that genetic polymorphisms in toll-like receptor (TLR) 1 and protein kinase AMP-activated alpha 1 (PRKAA1) gene were associated with gastric cancer (GC) or increased Helicobacter pylori (H. pylori) infection susceptibility. The aim of this study was to evaluate associations between TLR1 and PRKAA1 genes polymorphisms and H. pylori infection, atrophic gastritis (AG) or GC in European population. Single-nucleotide polymorphisms (SNPs) were analyzed in 1178 subjects (511 controls, 340 AG patients and 327 GC patients) from 3 gastroenterology centers in Germany, Lithuania and Latvia. Patients with AG and controls were from the out-patient departments, who underwent upper endoscopy because of dyspeptic symptoms and had no history of malignancy. GC patients had histopathological verification of gastric adenocarcinoma and were recruited from out-patient and stationary departments. Genomic DNA was extracted from peripheral blood mononuclear cells (PBMCs). TLR1 C > T (rs4833095) and PRKAA1 C > T (rs13361707) were genotyped by the real-time polymerase chain reaction. H. pylori status was determined by testing for anti- H. pylori IgG antibodies in sera. Associations between SNPs and presence of H. pylori infection were evaluated using logistic regression analysis. There was no association with adjustment for sex, age and H. pylori infection status was used for evaluation of associations between gene polymorphisms and AG or GC. The Bonferroni-corrected alpha level was set at 0.025 (0.05/2 SNPs).

Results: A similar distribution of TLR1 and PRKAA1 genotypes in H. pylori positive and negative cases. Moreover, no significant differences in the frequencies of all polymorphisms between AG patients and controls were found. TLR1 genotype of TLR1 gene was more prevalent in GC patients compared to controls (22.3% and 26%, respectively, P = 0.038). Logistic regression analysis revealed that polymorphism in TLR1 gene was associated with increased risk of GC. Carriers of TC genotype had higher odds of GC when compared to TT genotype (OR = 1.89, 95% PI 1.26–2.83, P = 0.002). Similar association was observed in a dominant model for PRKAA1 gene, where carriers of homozygous CC and TC vs TT genotypes showed an increased risk of GC (OR = 1.86, 95% PI 1.26–2.75, P = 0.002). No association between genetic polymorphism in PRKAA1 gene and GC was observed.

Conclusion: TLR1 rs4833095 SNP is associated with increased risk of GC in population of European descent, while polymorphism in PRKAA1 gene is not linked with the presence of GC. Both genetic polymorphisms showed no associations with H. pylori infection susceptibility and risk of AG.

Celiac disease (CD) is a gluten-sensitive enteropathy that resolves secondary to inflammation and carcinogenesis. Mucin synthesis, expression and secretion may be a primary event or may be associated with CD in 5.8% (n=19). This diagnosis was retained after a negative etiological assessment of Hp infection is suggested to be related to the invasion depth of CD. High prevalence of HP infection was noted in 66.7% of cases. Specific management of hepatic cirrhosis has been established with ligation of esophageal varices in 2 patients after bleeding esophageal varices until eradication of varices. A treatment with β blockers was prescribed in primary prophylaxis of digestive bleeding by rupture of esophageal varices in 4 patients. Diuretic therapy and aspiration of the ascites fluid are performed in cirrhotic patients with ascites. A GFD is established in addition to the specific management of liver cirrhosis. Liver tests were standardized in 100% of patients with cryptogenic transaminasemia following a GFD. The chronic liver disease was often decompensated and the hepatic signs for cirrhosis were in the foreground masking the response to GFD. It is recommended to look for hepatic abnormalities during CD and even to think of the diagnosis of CD in front of liver cytolysis syndrome without other enterology and in the presence of a chronic cryptogenic or dysimmune liver diseases.

Aims & Methods: In this study we investigated the TLRs 2, 4, 7, 9 genes expression in the human intestine with celiac disease compared with healthy control. Blood samples from 120 CD patients diagnosed according to the Iranian Society for Gastroenterology were collected and 120 healthy individuals were served as a control group during 2016. Also, among them, 20 duodenal biopsy specimens were collected randomly. Total RNA for both blood samples and biopsy specimens was isolated using a standard commercial kit. The mRNA expression of TLRs were quantified by relative qPCR with B2M as a reference gene.

Results: Significantly higher expression of TLR4 and TLR9 mRNA was observed in blood samples of CD patients compared to the healthy controls (P < 0.05); but there were no significant differences between expression of TLR2 and TLR7 mRNA compared to the controls. Furthermore, TLR4 and TLR2 expression level was increased in CD biopsy specimens compared to controls, whereas expression of TLR19 mRNA was decreased in CD patients. No significant differences in expression of TLR7 was observed in biopsy specimens.

Conclusion: The result of this study show that the alteration of TLR4 and TLR9 genes expression in intestinal mucosa of CD can be detected in PBMs in peripheral blood. This finding supports the implication of innate immune system in the pathomechanism of celiac disease.

1. Atna Al, Strugala V, Allen A, et al. The associated gastrointestinal mucus gel layer, the first line of defence against mechanical, chemical, or microbiological aggressions arising from the luminal contents1. Among all different cell types of the intestinal epithelium, the goblet cells are specialised in the secretion of mucus constituent¹. As an example of failing barrier function, patients with coeliac disease (CD) have been reported to have altered intestinal barrier². Human colonic mucus-secreting cells HT-29-16E: are valuable tools to explore the effect of a specific treatment on permeability and mucus production by the human intestinal epithelium.

Aims & Methods: We investigated the new and innovative gluten detoxification bread (GFB; patent PCT/IB2013/000797) effects on mucus production by means of Alcian blue staining in comparison to the control bread (CB). In addition, MUC2 and MUC3 were quantified by ELISA and the permeability of the intestinal epithelium monolayer was determined by trans-epithelial resistance (TEER) measurement. The statistical analysis was conducted by one-way ANOVA followed by a Bonferroni post-hoc t-test.

Results: Mucin production by Alcian blue staining was expressed as % black pixels, which was increased in GFB compared with CB. Higher MUC2 concentrations expressed as ng/ml were found on cells treated with GFB (10.82 ± 1.35; P = 0.01) compared to control (9.94 ± 0.67; P = 0.05). Additionally, greater TEER values, expressed as a percentage of initial TEER, were observed after 24 hours of incubation with GFB in comparison to the control (163.2 ± 33.8; P = 0.01) which was not observed or CB (139.4 ± 28.8, P = 0.05).

Conclusion: It could be concluded that GFB has a potential of inducing MUC2 secretion by intestinal epithelial cells and improving intestinal epithelium permeability in vitro. Such observed potential may effectively contribute to consequent benefits such as higher gut barrier defence, decreased susceptibility to infections and better absorption regulation, thus ameliorating such alterations in coeliac patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Coeliac disease (CD) is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4).

Aims & Methods: The aim of this study was to define GI symptoms reported in an Australian cohort with a doctor diagnosis of CD and compare with those not reporting CD. A total of 3825 people (mean age 58.4 years, age range 18-100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on whether the participant had ever been told by a physician that they had CD, and questions regarding GI symptoms to establish whether they had co-existent functional GI disorders. Adherence to a gluten-free diet was not assessed. Prevalence of CD, FD and IBS are reported with 95% exact confidence intervals. The difference between symptoms in those with CD compared with the unaffected population was tested for significance by the Pearson chi-square test.

Results: The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84-1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhoea, bloating, distention, epigastric burning and early satiety (see Table). There was no significant difference observed in symptoms of post-prandial fullness, nausea, abnormal stool consistency, or straining with defecation. The prevalence of FD as defined by Rome III criteria in the CD cohort was 37.5% (95% CI 22.7-54.2) compared to 13.9% (95% CI 12.8-15.1) in the non-affected population (OR 2.7, 95% CI 1.9-7.1, p < 0.001). There was no significant difference in the prevalence of IBS in the affected compared with the non-affected cohort (30.8% versus 22.2%, p = 0.2).

Table: Gastrointestinal symptoms reported by patients with and without self reported coeliac disease (CD). Items reported as greater than one day per week (%) or greater than or equal to “often” (%)

</table>

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia symptoms are significantly higher in patients with a doctor diagnosis of CD than amongst the unaffected population. Studies of the biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful (3), this study supports these views.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0613 MALE GENDER AND UNDERWEIGHT ARE ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH NEW DIAGNOSIS OF COELIAC DISEASE

Department Of Medical-surgical Sciences And Translational Medicine, Sant’Andrea Hospital, University Sapienza, Rome, Italy

Contact E-mail Address: gloria.galli5@gmail.com

Introduction: Osteoporosis is a systemic skeletal disorder characterized by low bone density and micro-architectural deterioration with increase of bone fragility and consequent fracture risk. About 50–75% of patients (pts) with untreated coeliac disease (CD) suffer from bone mass loss (osteoopenia or osteoporosis). Despite this strong correlation, guidelines do not express with certainty on the need to undergo a dual-energy X-ray absorptiometry (DEXA) scan in every patient with new diagnosis of CD. Recently, the DEXA screening was suggested for CD peri-post menopausal females, males over 55 yrs, pts with overt malabsorption or with a history of fragility fractures. Studies on bone mineral density (BMD) in CD pts led to discrepant results, probably due to heterogeneous designs.

Aims & Methods: The aim of this study was to evaluate, in a cohort of consecutively newly diagnosed CD adults, the prevalence of BMD alterations at diagnosis time and to evaluate associated clinical features. From January 2004 to December 2016, 258 consecutive pts (F = 72.4%) were diagnosed with CD. All pts were adults (median age 38, range 18–72 yrs), had atrophic disease and were invited to undergo a DEXA within 3 months from diagnosis to screen for osteoporosis (T-score < -2.5) or osteopenia (T-score <-1 and ≥ -2.5). A total of 214 (82.9%) pts underwent the DEXA scan and were included in the study (F = 71.5%, median age 38, range 18–72 yrs). On the basis of DEXA results (cutoffs according to WHO classification) pts were divided into 3 groups: pts with normal BMD, with osteopenia, and with osteoporosis. For each patient, reported risk factors for low BMD (underweight, alcohol intake, drugs, menopause, smoke) and serological PTH values were assessed. The signs/symptoms leading to CD and their duration before diagnosis, autoimmune/not-autoimmune comorbidities, familiarity for CD, previous fractures and serological assays (specific antibodies for CD, ferritin, cholesterol, triglycerides, and albumin) were also assessed. All the variables described were analyzed and compared between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis.

Results: At the DEXA scan, 85 (39.7%) and 129 (60.3%) pts had normal or low BMD, respectively. Among pts with low BMD, 91 (42.5%) had osteopenia and 38 (17.8%) osteoporosis. At logistic regression, clinical features significantly associated with osteoporosis were male gender (OR 4.7; 95%CI 1.3 to 17.4), underweight (OR 8.1; 95%CI 1.8 to 35.3) and increased PTH values (OR 5.1; 95%CI 1.4 to 18.8), while age, sex, years and gastrointestinal symptoms at diagnosis time, menopause, alcohol intake and previous fractures were not associated. Clinical features significantly associated with osteopenia were underweight (OR 4.0, 95% CI 1.4 to 11.2) and increased PTH values (OR 2.6, 95%CI 1.1 to 6.4).

Conclusion: In newly diagnosed coeliac pts, the overall prevalence of BMD alterations was more than 60%, with osteoporosis in nearly 1/5. Osteoporosis was significantly associated with male gender, underweight and increased PTH. This study suggests that at CD diagnosis, DEXA scan might be of benefit, in particular in male underweight pts.

Contact E-mail Address: Michael.Potter@hnehealth.nsw.gov.au

Introduction: Coeliac disease (CD) affects 0.6–1% of the population worldwide (1). Wheat avoidance in the absence of CD is common, and studies report a population prevalence of self-reported wheat or gluten sensitivity (SRWS) of...
up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extra intestinal symptoms on ingestion of wheat or gluten-containing food (2, 3).

**Aims & Methods:** The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18–80 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on wheat avoidance. GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve.

**Results:** The prevalence of SRWS in this cohort was 13.5% (455/3331, 95% CI 12.5–14.9%). Only 11% (50/455) of these subjects had received a doctor diagnosis of wheat intolerance (SRWS). In this multivariate model, factors with no association with SRWS were age, sex, smoking, diabetes and recent antibiotic use. The model provided useful although imperfect differentiation of SRWS from health (AUC = 0.76).

**Introduction:** Epidemiological studies estimate a worldwide prevalence of CD of approximately 1:100 individuals, with a considerable proportion of patients remaining undiagnosed and untreated. According to a study performed by the National Health and Nutrition Examination Survey in the United States, the prevalence of self-prescribed GFD in an unselected population of subjects aged 6 years or older was 0.5%. Epidemiological studies report a prevalence of WA in American population of around 0.4% until 0.6%.

**Aims & Methods:** We visited in our unit of celiac disease and gluten-related conditions during 2016 423 (M:312, 111) new patients with clinical suspicion of CD. Of these 133 they were new celiac but were investigated suspected non celiac gluten sensitivity. After in vitro tests for the exclusion of celiac disease, to verify the real prevalence of food allergy particularly to wheat protein, in non celiac patient referred our unit for symptoms after gluten ingestion, all these patients underwent allergologic workup consists on: skin prick tests (SPT), in vitro Specific Immunoglobulin E (sIgE) assays and functional assays. SPTs and sIgE in vitro assays are the first-level diagnostics for WA. However, they are affected by a low predictive value. In particular, their low sensitivity can be explained by the fact that the commercial test reagents are mixtures of water/salt-soluble wheat proteins that lack allergens from the insoluble gluten fraction. The association between food allergy and celiac disease (CD) is still to be clarified. Gluten-related disorders are an epidemiologically relevant phenomenon with a global prevalence that is estimated around 5%, drawing the attention of the scientific community.

**Results:** The diagnosis of WA is classically based on skin prick tests (SPT), in vitro Specific Immunoglobulin E (sIgE) assays and functional assays. SPTs and sIgE in vitro assays are the first-level diagnostics for WA. However, they are affected by a low predictive value. In particular, their low sensitivity can be explained by the fact that the commercial test reagents are mixtures of water/salt-soluble wheat proteins that lack allergens from the insoluble gluten fraction. The association between food allergy and celiac disease (CD) is still to be clarified. Gluten-related disorders are an epidemiologically relevant phenomenon with a global prevalence that is estimated around 5%, drawing the attention of the scientific community.

**Introduction:** Insufficiency of functional bowel disease is usually associated with disorders of visceral sensitivity and intestinal motility, which result from a dysfunction of the central nervous system, intestinal microflora and immune system.

**Aims & Methods:** We aimed to highlight importance of intestinal enzymes (glucoamylase, maltase, sucrase and lactase) in the etiology and pathogenesis of functional bowel disease. 74 patients with functional bowel diseases in age from 18 to 50 years (36 men and 38 women) were examined. According to Rome IV criteria (2016), 21 had irritable bowel syndrome (IBS) with predominance of diarrhea, 33 - functional constipation, 6 - IBS with predominant constipation, 4 - functional constipation and 10 - mixed type of IBS. Activity of the mucosa enzymes of the small intestine was determined by Dahlquist-Trinder method in duodenal biopsies obtained during esophagogastroduodenoscopy.

**Results:** Lactase deficiency was identified in 87.8% of patients, maltase deficiency - in 48.6%, sucrase deficiency - in 51.3%, the glucoamylase deficiency - in 85.1%. The activity of all investigated enzymes was reduced in 23 (31.1%) patients with functional bowel diseases, failure of 1 to 3 enzymes detected in 47 (63.5%). Normal activity of enzymes was observed in 4 (5.4%) patients.

**Conclusion:** In 70 of 74 (94.5%) patients with functional bowel disease and a disorder of the stool, abdominal pain and flatulence, there was a decrease in the activity of intestinal enzymes, which may be a cause of intestinal symptoms.

as colchicine. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

**Aims & Methods:** Between 2003 and 2016, 559 patients referred to our hospital for diagnosis had abnormal small bowel transit. The prevalence of chronic idiopathic diseases was excluded in all of them. After an overnight fast and at the same time in the morning, all the subjects underwent evaluation of post-prandial modifications of serum levels of pro-inflammatory cytokines (IL-1β, IL-6, TNFα), endogenous antioxidant system (uric acid), glucose, insulin and lipopolysaccharide (LPS), measured as putative factors responsible for inflammatory response. Serum samples were collected at fasting and every 30 minutes for a 4-hour period after an oral gluten load of 2 gr (in 10 HV) or 20 gr (in the other 10 HV). The presence and severity of symptoms such as epigastric pain, epigastric burning, fullness, early satiety, abdominal pain, abdominal distention, bloating, flatulence, nausea, vomiting, belching, heartburn, regurgitation, diarrhea, and headache, were evaluated by visuo-analog scale at fasting and every 30 minutes in the post-prandial period.

**Results:** In comparison with mean fasting values, none of the measured parameters showed a significant increase in the post-prandial period after the ingestion of 2 gr of gluten. On the contrary, after the ingestion of 20 gr of gluten mean post-prandial values of TNFα and IL-6 showed a significant increase (2.45 ± 1.75 pg/mL and 0.65 ± 0.31 pg/mL) as compared to mean fasting values (1.17 ± 1.49 pg/mL and 0.29 ± 0.15 pg/mL; p < 0.05). Mean post-prandial values of uric acid were also significantly higher (74.98 ± 1.02 mmol/L vs fasting values 45.34 ± 10.08 mmol/L; p < 0.05). No significant differences were detected in IL-6, glucose, insulin and LPS d after the ingestion of the 20 gr gluten oral load. Symptoms were absent after both oral loads.

**Conclusion:** The ingestion of gluten even if not a low, oral load of gluten induces a significant post-prandial inflammatory response causing the activation of the main endogenous anti-oxidant system. In HV, these activations are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-oxidant post-prandial response in patients with gluten-related disorders.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Results: A total of 224 patients entered the study. Of these, 81.3% (182) were women. During the use of IGB, patients lost an average of 15% of their body weight during follow-up, but without significant difference among groups: 2 years 10% to 19% of weight lost during treatment. The mean weight regain increased 1.5 times. No follow-up with a nutritionist after the procedure and who completed a whole year follow-up after device removal. The protocol was approved by the local ethic committee.

Contact E-mail Address: brunosander@hotmail.com

Introduction: Obesity is a global disease and its management includes pharmacological, psychological, and surgical therapies. Intra-gastic Balloon (IGB): Any form of therapy, including surgery, is flawed by weight regain in the long-term. IGB has gained popularity recently; however, there is a lack of studies addressing the use of IGB and its effect on weight control in the long-term. This study aimed to assess the weight regain in a large cohort of patients treated with IGB, with a time span from two to five years after the removal of the device.

Aims & Methods: All obese patients treated with IGB in a specialized obesity center, and that underwent balloon removal from June 2009 to June 2013 were included. Patients who agreed to participate were interviewed by a trained investigator in person and answered a questionnaire survey and had their body weight measured. Interviews started on July 2015 and ended on July 2016. Medical records of recruited patients were reviewed and the body weight at the moment of IGB implantation was registered. Patients included were stratified by BMI at the beginning of treatment and date of balloon removal and date interval (2, 3, 4 and 5 years) and all intervening factors related to weight control, as well as behavior habits were analyzed and compared with logistic multivariate analysis.

Results: A total of 224 patients entered the study, 10 of which completed a whole year follow-up after device removal. Of these, 81.3% (182) were women. During the use of IGB, patients lost an average of 15% of their body weight; representing a mean loss of 66% of excessive weight. Between 2 and 5 years after removal of IGB, 67% (150) of the subjects had regained weight; the mean weight regain was 4 kg during this period. Most patients (62%) regained 10% to 19% of weight lost during treatment. The mean weight regain increased during follow-up, but without significant difference among groups: 2 years [n = 10]: 4.66 ± 4.91 kg; 3 years [n = 83]: 8.66 ± 6.96 kg; 4 years [n = 54]: 9.99 ± 8.44 kg and 5 years [n = 3]: 19.96 ± 12.24; (p = 0.51). The lower the BMI at the beginning of treatment, the greater the weight regain after the IGB withdrawal. This correlation was inverse (r = -0.20) and significant (p < 0.01). The correlation was stronger and more significant with patients who had withdrawn the balloon at two years (r = -0.59, p < 0.01). Although patients who regrew in 2 years were stratified by BMI from 0 to 2.3 kg/m², 2.4 kg/m², 4.0 kg/m², 5.0 kg/m² at the end of a year follow-up, both parameters remained significantly lower than the baseline (P < 0.05). HbA1c was reduced during the treatment from 7.6 ± 1.6% to 6.6 ± 1.2% (P = 0.02) and increased to 6.8 ± 1.0% after 12 months follow-up (P = NS). Among 15 insulin-dependent patients (42%), insulin average dose was reduced by 65% (p = 0.05), but the dose was doubled after a year follow-up. Interestingly, the glycemic control in this insulin-dependent population was difficult to maintain as the coefficient of variation (CV) increased 1.9 times after the device removal (CV 0.23, p = 0.01). The lower the CV of adverse events, 47% of which were categorized as severe ones (two major bleedings and 2 hepatic absceses).

Conclusion: IGB is an effective tool for weight reduction glycemic control among insulin and non-insulin dependent diabetic patients. Moreover, substan-tial metabolic achievements were maintained at least a year after device removal. Since IGB bears a considerable amount of side effects, strategies to mitigate them are warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

% of weight regained * 2 years 3 years 4 years 5 years
<10% 20% (2) 15.6% (13) 18.5% (10) 33.3% (1)
Between 10 and 19% 70% (7) 62.7% (52) 59.3% (32) 66.7% (2)
Between 20 and 29% 10% (1) 14.5% (12) 14.8% (8) 0
Between 30 and 39% 0 2.4% (2) 1.9% (1) 0
Between 40 and 49% 0 1.2% (1) 5.6% (3) 0
Between 50 and 59% 0 2.4% (2) 0 0
Between 90 and 99% 0 1.2% (1) 0

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutrition counseling during and after IGB treatment. A multidisciplinary approach is of the utmost importance to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0623 SYNBIOTIC (INULIN, LACTOBACILLUS, BIFIDOBACTERIUM AND SACCHAROMYCES BOULARDI) IMPROVES FATTY LIVER DISEASE BY VIRTUE OF ITS ACTION ON BIOMARKERS, BIOMARKERS

T. M. Falalyeyeva1, N. Kobyliak2, O. Tsyryuk3, L. Prybytko3, T. Beregovaya4, L. Ostapchenko5

Introduction: NAFLD is the most important cause of chronic liver disease and is considered the hepatic manifestation of the metabolic syndrome associated with type 2 diabetes. The prevalence of NAFLD in the general population ranges 15–20% and it goes up to 70 to 90% in the obese population. The search of new non-toxic drugs for preventing the development of obesity is the most important challenge of modern science. The question about impact of probiotics and prebiotics on fat metabolism and obesity is being actively debated in the scientific literature. So the aim of the study was to investigate the effect of synbiotic (S) on development of experimental obesity in rats with NAFLD.

Aims & Methods: The study was carried out on 60 white rats, that were divided into 6 groups (I–III – males, IV–VI – females). I and IV groups were intact control (4-month old). Newborn rats of groups II and III x.c. in volume 8 µl were administered a saline or monosodium glutamate (MSG) (4 mg/g) at 2–10 days of life. Since the age of 1 month, rats of III and V group had been injected with water, rats III and VI groups - S (Inulin, Lactobacillus, Bifidobacterium and Saccharomyces boulardii) ("Opefera" World Medicine) in a dose of 1,94 mg/inulin. Introduction of the current study is to assess weight and glycemic control changes resulted from the device implantation and a year after the device removal. Between February 2013 and September 2016, 51 diabetic patients were treated with DBL in our center. This prospective observational study included 145 patients in 4 months of active treatment. However, adverse events and early removals were analyzed for the whole cohort. Blood tests, body weight and medications data were collected during scheduled visits and phone interviews. The primary end points were body weight and glycemic control changes a year after end points were the same parameters after device removal. The protocol was approved by the local ethic committee.

Results: Thirty-six patients (52.8% male) were treated for at least 9 months with the device, 10 of which completed a whole year follow-up after device removal. At the end of 12 months post implantation, the average body weight and BMI dropped from 109.5 ± 19.1 kg and 37.4 ± 5.0 kg/m² to 93.7 ± 20.4 kg and 33.3 ± 5.0 kg/m² at the end of a year follow-up, both parameters remained significantly lower than the baseline (P < 0.05). HbA1c was reduced during the treatment from 7.6 ± 1.6% to 6.6 ± 1.2% (P = 0.02) and increased to 6.8 ± 1.0% after 12 months follow-up (P = NS). Among 15 insulin-dependent patients (42%), insulin average dose was reduced by 65% (P = 0.05), but the dose was doubled after a year follow-up. Interestingly, the glycemic control in this insulin-dependent population was difficult to maintain as the coefficient of variation (CV) increased 1.9 times after the device removal (CV 0.23, p = 0.01). The lower the CV of adverse events, 47% of which were categorized as severe ones (two major bleedings and 2 hepatic absceses).

Conclusion: DBL is an effective tool for weight reduction glycemic control among insulin and non-insulin dependent diabetic patients. Moreover, substantial metabolic achievements were maintained at least a year after device removal. Since DBL bears a considerable amount of side effects, strategies to mitigate them are warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.
Also consumption of S led to reduction of pro-inflammatory cytokines and leptin and increased anti-inflammatory cytokines and adiponectin.

Conclusion: Thus, the introduction of S reduced the obesity, that shows the effectiveness of therapy for the prevention of obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0626 THE COMPARATIVE EFFICACY OF OBESITY TREATMENTS IN YOUNG PEOPLE - A SYSTEMATIC REVIEW AND META-ANALYSIS

S. S. Selvendran, Penney, N. Aggarwal, A. Darzi, S. Purkayastha
Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: ss9621@ic.ac.uk

Introduction: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-analyse studies evaluating treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modification and pharmacological therapy searches were restricted to randomised control trials.

Results: 16,372 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more modest impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Conclusion: This is the first systematic review and meta-analysis to comprehensively summarise and quantify the comparative efficacy of BMI reducing treatment options in the obese, young population. Currently, bariatric surgery is rarely considered in this young cohort. However, due to its high efficacy, physicians and patients should have a lower threshold for considering bariatric surgery when lifestyle and pharmacological interventions have failed. Total or partial surgical interventions provide smaller but statistically significant impacts on BMI reduction. There should be effective communication discussing the relative efficacy of all treatment options and their associated complications between those involved. This knowledge will assist clinicians in determining a holistic, patient-centred treatment programme for obese, young patients.

Contact E-mail Address: alinkmail@gmail.com

Introduction: Tumor development is a multistep process, which involves genetic and environmental factors. Diet is among the most important contributing factors and processed and red meat has been classified as carcinogenic for colorectal cancer. MicroRNAs (miRNAs) are functional, ubiquitously present molecules with great impact on tumor initiation and progression. Exogenous microRNA or xenomiR have been identified in sera from different species suggesting an active cross-kingdom trespassing through biological barriers during digestive process.

Aims & Methods: In the present work, we evaluated whether miRNAs are present in various foods, and if miRNAs may be degraded through cooking and other forms of food processing. Furthermore, we tested if short-term vegetarian or meat-rich diet may influence human or plant-derived miRNA in feces and blood. For this purpose, six healthy subjects were asked to adhere to vegetarian or meat rich diet for 5 to 7 days and fecal and blood specimens were obtained at different time points. Plant-miRNAs were further investigated in gastric and colon mucosa. To evaluate the presence of miRNA in food, we selected several common foods prior and after cooking/processing. Quantitative real-time PCR was performed using TaqMan Assay.
Results: All analyzed microRNAs were present in all studied foods with highest expression measured by miR-16 and miR-155. Especially, hash, beef and salmon showed the highest miRNA expression, while lowest expression was found in cheese and milk. Food processing led to only marginal changes (max. 1.5-fold) in miRNA expression and thus demonstrating its stability against degradation. Short-term changes in diet (from usual to vegetarian and to meat-rich diet) in healthy subjects was not associated with variation in miR-21, miR-155 and miR-16 expression. Interestingly, in comparison to several previous reports, we repeatedly failed to detect any plant miR-168 in sera. However, when evaluated with a significant decrease in miR-168 level in feaces (up to 8-fold), while meat-rich diet was associated with slight decrease if compared to the starting time point (mean±SD 0.031±0.002 vs no diet vs 0.025±0.042 for vegetarian vs. 0.0016±0.00096 for meat-rich. p<0.03 Kruskal-Wallis test, with p<0.05 for Dunns multiple comparison test for vegetarian vs meat-rich).

Conclusion: The results of this study show that various foods provide a great source of microRNAs, which remains stable despite processing. We further demonstrated that short-term changes in diet do not impact on the miRNA expression pattern in feaces and blood supporting its value as biomarkers. A functional role of diet-induced increase in plant-derived miRNA expression needs further evaluation.

P0628 NEUROMedin U BLOCKS GASTRIC EMPTYING THROUGH VAGAL-DEPENDENT MECHANISMS AND IMPROVES ORAL GLUCOSE TOLERANCE

A. Jarry1, N. Merah1, M. Fiamma2, L. Bodineau1, A. Bado3, J. Le Beye1, M. Le Gall4

Introduction: The gut and brain peptide neuromedin U (NMU) is reported to decrease food intake and body weight, and to improve oral glucose tolerance suggesting that NMU exerts an incretin effect in the gut. NMU is thus considered as a promising candidate for the treatment of obesity and diabetes. However, and in contradiction with previous observations, NMU was recently presented as a contradiction with previous observations, NMU was recently presented as a promising candidate for the treatment of obesity and diabetes. However, and in contradiction with previous observations, NMU was recently presented as a 'decretin' hormone able to decrease insulin secretion. The pathways through which NMU controls glycemia are thus uncertain and we sought to clarify some of NMU mechanisms of action on glucose homeostasis.

Aims & Methods: Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice after laparotomy or a transduodenal laparoscopy in the same mice group. During OGTT, blood was sampled to measure insulin secretion. [14C]-Glucose uptake was assessed in isolated intestinal loops in presence or absence of NMU. Gastric retention of a phenol red gavage and total intestinal transit time were evaluated after an intraperitoneal injection of NMU or PBS. Activation of vagus nerve neurons by intraperitoneal injection of NMU was assessed by cFos immunohistochemistry in the nucleus of the solitary tract (NTS) and the dorsal nucleus of the vagus (DMV). Direct impact of NMU on pylorus contraction was examined ex vivo in isolated pyloruses. Results: A single intraperitoneal injection of NMU in C57Bl6 mice prevented the rise of glycemia following an oral but not an intraperitoneal load of glucose (OGTT versus IPGTT). Unexpectedly, during the OGTT, NMU injection prevented food intake and only slightly improved peripheral insulin sensitivity. Furthermore intravenous [14C]-glucose uptake in isolated intestinal loops was barely reduced by NMU addition (~17% P<0.05 vs PBS). Actually NMU injection blocked gastric emptying (gastric retention of a phenol red gavage at 30min: +285% P<0.001 vs PBS). This effect was partly prevented in vagotomized mice. In addition, injection of NMU induced c-fos expression in the nucleus of the solitary tract (NTS) of control but not vagotomized mice. In isometric chambers, NMU directly induced pyloric contracture in a dose dependent manner (basal contraction +21%, 7% at 10-6 M).

Conclusion: These data demonstrate that a single intraperitoneal injection of NMU blocks gastric emptying directly by inducing pyloric contraction and indirectly via afferent vagal fiber activation. Through the blockade of gastric emptying, NMU reduces intestinal nutrient absorption and thus improves oral glucose tolerance. The gastric emptying blockade induced by NMU could also contribute to its anorexigenic effect.

P0629 LOW FODMAP DIET & PREBIOTIC GALACTOOLIGOSACCHARIDES IMPROVE IRRTABLE BOWEL SYNDROME SYMPTOMS AND RESPONSE TO LOW FODMAP DIET IS PREDICTED BY URINE METABOLOME, STOOL SHORT-CHAIN FATTY ACIDS AND VOLATILE ORGANIC COMPOUNDS: A RANDOMISED CONTROLLED TRIAL

Introduction: Dietary restriction of fermentable carbohydrates (low FODMAP diet, LFD) is effective at managing symptoms in 50-80 percent of patients with irritable bowel syndrome (IBS). Prebiotic B-galacto-oligosaccharide (B-GOS; HOST-G004) also reduce symptoms in IBS however the combination of the two therapies has not been investigated. We investigated that differentiates those who respond to the LFD from those who do not is unclear.

Aims & Methods: This randomised controlled trial aimed to investigate whether: 1) addition of prebiotic B-GOS could improve symptoms of IBS alongside the LFD and 2) if urinary metabolites, faecal short-chain fatty acids (SCFA) or volatile organic compounds (VOC) could identify factors at baseline that predict response. Sixty-nine adults fulfilling Rome criteria for IBS were recruited to a 3-arm RCT: control (sham diet/placebo), LFD (LFD/placebo) or LFD plus B-GOS (LFD/B-GOS) for four weeks.

Validated questionnaires (Global symptom question and gastrointestinal symptom rating scale) assessed GI symptoms (response) and urine and stool samples were collected for analysis at baseline and week 4. To examine the relationship between responders and non-responders, urine metabolomics (700 MHz 1H-NMR), stool SCFA (gas liquid chromatography (GLC)) and stool VOC (GC-mass spectrometry) were analysed on samples at baseline and 4-weeks. Urine metabolomics spectra and VOC profiles were analysed using unsupervised principal component analysis (PCA) and supervised pattern recognition methods (orthogonal partial least square discrim- minant analysis (OPLS-DA)) or PLS-DA respectively. Stool SCFA were compared using t-tests, models of prediction were tested using receiver operator characteristic (ROC) curves.

Results: There was a significant difference in response rates (adequate relief) between control (30%), LFD (50%) and LFD/B-GOS (67%) (p = 0.046), with post-hoc differences specifically between control and LFD/B-GOS (p = 0.015). Interestingly IBS symptoms improved markedly in the LFD/B-GOS group compared to control. In the LFD group only, there was a significant difference in the urine metabolome between responders and non-responders at both baseline (Q2 = 0.296 vs randomised = 0.175) and at 4-weeks (Q2 = 0.485 vs randomised = 0.203). At baseline, there were significant greater stool isobutyrate between responders (51.4mg/100g) and non-responders (31.9mg/100g; p = 0.04), with ROC curves supporting this as a predictor of response (AUC = 0.747, p = 0.063). Finally, there was a significant difference in VOC profiles between responders and non-responders to the LFD at baseline (p = 0.04) VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p = 0.02).

Conclusion: Addition of B-GOS to the LFD improves symptoms in IBS. Urine metabolomics, stool SCFA and VOC profiling are relatively low-cost and non-invasive techniques that may predict response to the LFD as well as helping to further understand the underlying mechanisms. Prospective clinical trials to test these algorithms are warranted and may lead to personalised therapy for patients with IBS.

Introduction:
Patients suffering from chronic radiation-induced small bowel disease (RISBD) after cancer treatment have similar symptoms as patients with IBS (irritable bowel syndrome), despite dissimilar pathological origin. RISBD is a common late effect after pelvic radiation therapy for gastrointestinal (GI), gynecological and urological cancer. The delayed development of ischemia, fibrosis, dysmotility and malabsorption in GI tissue, leads to IBS-like symptoms like abdominal pain, diarrhea, constipation and bloating. The low FODMAP diet (fermentable oligo-, di-, mono-saccharides and polyols) diet (LFD) is a widespread management strategy for IBS. The aim of the conducted study was to investigate the effects of LFD on symptoms and health related quality of life (HRQOL) for patients with chronic RISBD.

Aims & Methods:
In an open pilot study, 11 patients (mean age 46 years) with RISBD related IBS symptoms were instructed to follow LFD throughout a 4-week intervention period. The Severity Scoring System (IBS-SSS) and IBS Symptom Questionnaire (IBS-SQ) were used to assess symptoms. An Ad hoc questionnaire measured grade of tissue damage and typical RISBD complaints (focal incontinence, rectal mucus and rectal bleeding). Short Form Nepean Dyspepsia Index (SF-NDI) and 12-item Short Form Health Survey (SF-12) were used to evaluate HRQOL. A 3-day food record was used to estimate baseline intake of FODMAPs, to reveal dietary changes and to assess adherence to the diet. All schemes were completed at baseline and at 4 weeks. The study included no control group.

Results: FODMAP intake was successfully reduced, and main additional changes in the diet were reduced intake of energy, carbohydrates and fiber. The adherence to the diet was high (mean 94.8%). IBS symptoms improved significantly based on mean total score of IBS-SSS and IBS-SQ, which changed from 310.2 ± 4.1 to 15.7 ± 10.1 (p = 0.002), respectively. The severity of abdominal pain, abdominal distension, belching/flatus, constipation, diarrhea, early satiety, dissatisfaction with bowel habits and interference with life in general, improved significantly. Tendencies of improvement were also measured in comorbidity complaints (nausea, headache, backache, fatigue and muscle pain) and typical RISBD complaints. HRQOL improved based on SF-NDI total score, which changed from 30.5 ± 9.4 to 18.3 ± 8.2 (p = 0.001) and based on mental (p = 0.047) and physical (p = 0.134) component summary score of SF-12.

Conclusion: The low FODMAP diet seems effective in alleviating IBS symptoms, and improving HRQOL in patients with RISBD. High compliance to LFD is possible with adequate diet counseling and continuous guidance. Further controlled studies with larger sample size should be conducted to verify our results and hopefully enable the implementation of LFD as a future management strategy for chronic RISBD.

Disclosure of Interest: All authors have declared no conflicts of interest.
is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1) via a secretin hormone secreted by the enteroendocrine L cells (EEC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differently processed by proglucagon convertase 2 (PC2) into glucagon in pancreatic α cells and by prohormone convertase 1/3 (PC1/3) into GLP-1 in pancreatic L cells.

Aims & Methods: We hypothesized that, after pancreatectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreaticectomy model in C57Bl6 mice. Control (Ct) mice underwent a laparotomy. Post-surgery, blood plasma was measured and oral glucose tolerance tests (OGTT) were performed after 1 week. Insulinemia and glucagonemia were also measured in fed and fasted mice and during OGTT. After 2 weeks, animals were sacrificed and the remnant pancreas was sampled for glucagon and insulin immunohistochemistry (IHC) and alpha- versus beta-cell mass quantification. Proximal and distal intestinal segments were sampled for morphometric analyses as well as measurement of prococonvertase and proglucagon mRNA levels. Colonic segments were incubated in a glucose-enriched medium for one hour and glucose-induced secretion of glucagon and glucose-mediated lysosomal enzyme release were measured in the supernatant.

Results: As soon as one day post-surgery, pancreatectomized (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in Ct mice, P < 0.05, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve >278% in Px mice, P < 0.05 vs Ct mice, 1 week post-surgery). During OGTT, intestinal glucose absorption increased (slope between 0 and 15 min=69.9% in Px mice P < 0.01 vs Ct mice, 1 week post-surgery). Glucagonemia increased in fasted pancreatectomized mice (+146.6% in Px mice P < 0.01 vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (~79.25% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). Hyperplasia of the proximal colon to secrete glucagon and/or vasoactive intestinal polypeptide was observed (+290.6% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). In pancreatectomized mice, an hypothyroidism of the duodenum was associated with an increase in crypt depth (+77.7%, in Px mice P < 0.05 vs control mice, 2 weeks post-surgery) and villus height (+53.8% in Px mice P < 0.05 vs control mice, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreatectomy. The upper intestine (duodenum) become hyperplastic and more resembled small intestinal enzyme response to absorptive glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglucagonemia.

Introduction: Soybean oil intravenous lipid emulsion (IVLE) is also known as conventional lipid is rich in linoleic acid (ω-6 PUFA). α 6 PUFA may exaggerate inflammatory response and indirectly detrimental in the critically ill patients. To overcome this, the use of alternative IVLEs such as medium chain triglycerides (MCT), fish oil and olive oil alone or in combination with soybean oil IVLE have been used to lower the content of ω-6 PUFA. Most studies on alternative IVLEs have been conducted in the critically ill patients, elective surgical patients and cancer patients. No previous studies have evaluated the clinical outcomes of several different IVLEs in non-critically ill patients in acute hospital setting.

Aims & Methods: The purpose of this study is to determine whether there is a difference in clinical outcome amongst patient who received conventional soybean oil IVLE versus alternative IVLEs in non-critically ill patients in acute hospital setting. All patients on parenteral nutrition (PN) were identified in a prospective compilation database from July 2007 to September 2010 and were analysed retrospectively. Patients were assessed based on the IVLE received, namely soybean oil based (Lipofundin-N 20%, type 1), MCT oil based (Lipofundin-MCT 20%, type 2), olive oil based (ClinOleic, type 3) and fish oil containing (Lipemid, type 4). Patients must receive PN for at least 5 days, have no central surgical ward or high dependency unit not requiring invasive/non-invasive ventilator support or inotropes support. Exclusion criteria included patients who received less than 5 days of PN, intensive care unit (ICU) patients, PN started in ICU and continue in general ward or HDU, PN restarted in less than 3 days after readmission and in patients on invasive/non-invasive ventilator support or inotropes support and home PN patients.

Results: 537 patients were started on PN and 388 patients were included in the study. 90 patients were on type 1 (soybean based) IVLE, 60 patients were on type 2 (MCT based) IVLE, 141 patients were on type 3 (olive oil based) IVLE and 97 patients were on type 4 (fish oil) IVLE. Baseline characteristic were similar in four groups of IVLEs. Majority of PN were initiated in patients admitted under surgical team. There were no difference in terms of mortality, readmission and infection rate between conventional and alternative IVLE as a group, odd ratio (OR) was 0.66 (CI 0.36–1.24; p = 0.16), 1.71 (CI 0.84–3.73; p = 0.15) and 0.90 (CI 0.55–1.49; p = 0.73) respectively (as shown in table 1). The length of stay in log-scale was significantly lower in alternative IVFE as a group (p = 0.03). There were no difference in terms of mortality, readmission and infection rate between conventional IVLE versus each of the alternative IVLE.

Table 1: Clinical outcomes of IVLE versus alternative IVLE as a group

<table>
<thead>
<tr>
<th>Variable</th>
<th>Conventional IVLE (n)</th>
<th>Alternative IVLE (n)</th>

Conclusion: Length of stay was significantly lower in alternative IVLE compared with conventional IVLE. However, there were no clinical difference in terms of mortality, readmission and infection between conventional and alternative IVLE in non critically ill patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Few prospective studies have been published on small number of patients. Data on complications and mortality rates are generally retrospective and only method of choice for medium- and long-term enteral feeding and is nowadays the mortality of patients after PEG insertion or PEG replacement. This is a multicenter prospective study.

National Patient Safety Agency Report 2003/PSA05 Reducing the harm caused by misplacnon gastrostic feeding tubes 2005
Lee S and Mason E. Competence in confirming correct placement of nasogastric tube. BMJ 2005. In 2011 the NPSA made this a ‘never event’. The only acceptable methods of checking the position of an NG tube are: pH < 5.5 on aspirate or confirmation on CXR (CXR) by competent medical staff. Reporting a CXR for NG tube position is a frequent request particularly for junior doctors out of hours. Pracise varies across the UK - some trusts require NG checking to be done only by senior clinicians (medical registrars or consultants) and some only allow reporting by a consultant radiologist. We assessed documentation of NG position on CXR by medical registrars from the region to find out if documentation was adequate, as would be expected of senior clinicians. NPSA guidance suggests four points should be documented in the medical notes to confirm NG position: 1. Does the tube follow the contours of the oesophagus and avoid those of the bronchi? 2. Does the tube clearly bisect the carina or the bronchi? 3. Does it cross the diaphragm in the midline? 4. Is the tip clearly visible below the left hemidiaphragm? All four criteria were met in only 17.6% of responses and answers were considered incorrect in 20.5%. An aide-memoir sticker with an abbreviated version of the above four points, time, date, doctor signature and whether tube is safe to use or not with Yes/No answers, is used on some wards in Southampton and we assessed whether its use would improve quality of reporting both a correctly placed and misplaced NG tube.

Aims & Methods: Medical registrars from first to final year of specialist training and from various specialties were presented with a CXR showing a correctly sited NG tube and were asked to complete a sticker answering yes or no, to check position and whether it was safe to use. Following this they were presented with an incorrect CXR showing an incorrectly sited NG tube and asked to use the sticker to check position. The CXR was projected and anonymous responses collected after sufficient time for the group to complete both stickers.

Results: 31 complete responses were obtained for the correctly sited tube with 58% stating that it should be used and 42% that they would not use the tube without further review. 10 incomplete responses were obtained and therefore 86% of responses met NPSA guidance for reporting CXR for NG position. 28 complete responses were obtained for the incorrectly sited tube and 100% stated that the sticker should not be used.

Conclusion: Use of the sticker increased compliance with NPSA guidance for reporting NG tube position from 17.6% to 86%. The misplaced tube was correctly reported and not used in 100% of responses. The correctly sited tube was reported as safe to use in 58%. The CXR used was of an anonymous real patient and was slightly rotated to reflect a real-life scenario which meant the tube was slightly off the midline. In this real-life scenario some trainees would be happy to make a judgement considering these factors and others may be cautious and follow the sticker's examples. We assessed documentation of NG tube position on CXR by medical registrars from the region to find out if documentation was adequate, as would be expected of senior clinicians. NPSA guidance suggests four points should be documented in the medical notes to confirm NG position: 1. Does the tube follow the contours of the oesophagus and avoid those of the bronchi? 2. Does the tube clearly bisect the carina or the bronchi? 3. Does it cross the diaphragm in the midline? 4. Is the tip clearly visible below the left hemidiaphragm? All four criteria were met in only 17.6% of responses and answers were considered incorrect in 20.5%. An aide-memoir sticker with an abbreviated version of the above four points, time, date, doctor signature and whether tube is safe to use or not with Yes/No answers, is used on some wards in Southampton and we assessed whether its use would improve quality of reporting both a correctly placed and misplaced NG tube.

**Contact E-mail Address:** meave.tierney@nhs.net

**Introduction:** Intestinal failure patients by definition have reduced ability to absorb fluid and macronutrients through the gastrointestinal tract. Type two intestinal failure patients require months of intravenous nutrition (parenteral nutrition) for weeks or months either in hospital or at home. Type three intestinal failure patients generally require long-term parenteral nutrition (PN), which is given at home (HPN) and may be life-long. In addition to a reduction in the ability to absorb macronutrients, patients on long-term PN have a reduction in absorption of micronutrients (copper, zinc, selenium and manganese) and vitamins (A, B12, D and E) which are required for metabolism and enzymatic reactions at a cellular level. PN is routinely supplemented with micronutrients and should ideally be able to occur at high levels and deficiency can cause a variety of symptoms. ESPEN guidelines recommend that serum vitamin and trace element levels be checked at baseline and at least once per year. NICE guidelines specify more frequent monitoring for in-patients and that selenium, manganese and vitamin D should be checked three to six monthly in HPN patients. Some trace elements (copper and zinc in particular) are affected by acute illness. Current local practice is to avoid checking levels until there is evidence that inflammation or infection has resolved.

**Aims & Methods:** Our aim was to audit the frequency of micronutrient screening in our cohort of HPN patients. All type two and three intestinal failure out-patients were included. Current in-patients were excluded due to the effect of acute illness on micronutrient levels. Patients on parenteral fluid rather than nutrition were excluded as current guidelines give recommendations for HPN patients and do not specify recommendations if fluid alone is required. A search of the blood results system was performed for all micronutrient results from one full year to the date of the search. Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local trusts do not have the laboratory facilities to check micronutrient levels so they tend to be done in Southampton. If no results were available on the Southampton system then the local hospital was contacted for local results if available.

**Results:** 57 home parental nutrition patients were identified. 51 (89.5%) of these patients had micronutrients checked at some point during their care. 44 of 49 (89.7%) had micronutrients checked within one year (two of the 51 had only recently so did not have results within a year). 32 (61.5%) of those who had micronutrients checked had them done within the last six months. 6 patients had never had micronutrients checked. One had them requested just prior to the time of audit but results were not yet available. Two were out of area and had not been seen within the last year. One of these commenced PN in 2015 and found it difficult to attend clinic. The other had not been seen in clinic due to an administrative error and has now been seen with micronutrients requested. Two further patients had never had micronutrients checked due to a persistently raised CRP.

**Conclusion:** Despite a lack of clarity between guidelines about the frequency of monitoring of micronutrients, it is recommended that HPN patients receiving long-term intravenous nutrition should have regular monitoring to reduce risk of deficiency or toxicity. The majority of our cohort of HPN patients had micronutrients checked annually and over half were checked six monthly. This is compliant with ESPEN guidelines; however, we need to aim for 100%. We have introduced a template to use in clinic to trigger review of results and request micronutrients when required. Alongside this we have introduced a virtual ward round to remotely review all out-patients regularly and plan ahead to request blood tests when required. Following the introduction of these measures we will repeat the audit to find out if the situation has improved.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Early recognition and delivery of nutritional care by physicians has been shown to improve outcomes in malnourished hospitalized patients. However, physicians encounter multiple barriers in providing appropriate nutrition to hospitalized patients. Comprehensive nutrition assessment and nutritional training in medical education have been introduced to overcome these barriers, there appears to be a discrepancy in practice amongst physicians despite the availability of these resources.

**Aims & Methods:** We aim to assess the knowledge and attitudes of physicians towards clinical nutrition in a large tertiary teaching hospital in Singapore. An anonymous questionnaire comprising 15 multiple-choice questions from standard nutrition textbooks was administered. The questionnaire was designed to assess (a) recognition of nutritional needs of hospitalized patients, (b) knowledge on the role of clinical nutrition, and (c) application of nutritional intervention in common clinical practice. We included consultants, fellows and residents working in units where nutritional problems were common. Finally, we conducted a separate 5-question opinion survey to assess each participant’s nutritional training and exposure, based on a 5-point Likert scale ranging from “strongly agree” to “strongly disagree”.

**Results:** A total of 305 physicians volunteered to participate in this study. Forty (15%) did not reveal their specialty or staff grade and were excluded from analysis. The remaining 265 responders comprised 77 (29%) consultants, 58 (22%) fellows, and 130 (49%) residents. Amongst them, 232 (87%) were from medical disciplines and 33 (13%) from surgical disciplines. The median aggregate score (out of a maximum score of 15) obtained by consultants, fellows and residents was 6.0±2.2 (range 2–12), 7.0±1.8 (range 3–11) and 7.0±1.8 (range 1–10) respectively. All 3 grades of physicians achieved less than 50% of the maximum possible score. No significant difference in median aggregate score was observed between physicians from medical disciplines (6.5±1.9) and those from surgical disciplines (7.0±1.8). However, gastroenterologists performed significantly better than non-gastroenterologists (median aggregate score 9.0±2.2 vs 6.0±1.8, p < 0.001). In the opinion survey, a majority of physicians (63%) believed that nutrition-related teaching was inadequate during residency training and 44% felt that clinical nutrition was accorded insufficient attention during ward rounds. Only 33% of responders reported that they performed nutritional screening on admission, and a mere 10% were confident in providing nutrition counselling to malnourished patients. Interestingly, their overall performance was not different from that of other participants (see Table 1).

**Table 1:** Median aggregate scores by grade, specialty and response in opinion survey

**Conclusion:** Our study highlights that knowledge on nutrition and its clinical application to hospitalized patients remains inadequate across all physician grades, especially amongst non-gastroenterologists. The current state of clinical nutrition-related teaching during residency training falls short of achieving its goals, and may need re-examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
GASTRODUODENAL DISEASE RESISTANCE IN ARMENIAN CHILDREN WITH 

median follow up of 504 days (30–1290) clinical success was noticed in 29 children out of 47 children were excluded from the study due to both histology and culture cultured on 5% sheep blood Columbia agar and selective Hp media. Antibiotic resistance to doxycycline also was seen, despite limited use of this antibiotic in therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). All strains were susceptible (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and/or duodenitis in 28 (70%), atrophic gastritis in 5 (12.5%), gastric glandular dysplasia in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available14: all but 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacin (100%), 6 strains were tested and found susceptible to nitazoxanide.

P0641 HIGH RATE OF HELICOBACTER PYLORI ANTIBIOTIC RESISTANCE IN ARMENIAN CHILDREN WITH GASTRODUODENAL DISEASE

T. Shahnian1, G. Amaryan2, M. Hovsepyan2, C. Braegger3
1Chair of Pediatrics 2, Yerevan State Medical University, Yerevan/Armenia
2Pediatrics, Arabkir Joint Medical Center, Yerevan/Armenia
3Division Of Gastroenterology And Nutrition, University Children’s Hospital Zurich, Zurich/Switzerland

Introduction: Because of high prevalence of gastric malignancies in the adult population, high Helicobacter pylori (Hp) prevalence in Armenia is suspected. Rising antibiotic resistance of Hp both in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.98 ± 4.10). Hp-associated GDD were diagnosed according to clinical, endoscopic and histological criteria. Antral biopsy was cultured on 5% sheep blood Columbia agar and selective Hp media.

Results: Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven out of 47 children were excluded from the study due to both histology and culture negative for Hp. Thirty-four (85%) were treatment-naive patients and 6 (15%) had received eradication therapy previously. Main clinical symptoms were recurrent epigastric pain 34 (85%), nausea 28 (70%) and vomiting 13 (32.5%). By endoscopy, gastritis was seen in 46 (100%), and/or duodenitis was seen in 18 (45%), non-erosive gastritis in 16 (40%), PUD in 3 (7.5%), normal mucosa in 3 (7.5%). Rapid urease test was positive in all antral biopsies (100%). Histology showed chronic gastritis and/or duodenitis in 28 (70%), atrophic gastritis in 5 (12.5%), gastric glandular dysplasia in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available14: all but 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacin (100%), 6 strains were tested and found susceptible to nitazoxanide.

Conclusion: The data indicate a high rate of resistance to conventional triple therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). High resistance to doxycycline also was seen, despite limited use of this antibiotic in Armenian paediatric practice. High susceptibility to nitazoxanide might be useful for follow up examination of specific eradication schemes for Armenia. High frequency of both erosive and non-erosive gastritis as well as high rate of gastric atrophy and dysplasia in these patients was noticed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Children’s gastric microbiota in the presence or absence of H. pylori (HP) has not been studied well.

Aims & Methods: We aimed to study the composition of the microbiota in the biopsy material of the antral part of the stomach, according to the 16S-rRNA sequencing, of children with chronic gastritis, in the presence or absence of HP, and also to compare it with the histological data. Biopsy materials of mucous tissue from antral part of the stomach were taken from 16 children aged 10–17 with chronic gastritis and after the preliminary extraction the biopsy materials were examined using the method of sequencing with a pair of oligonucleotide primers, which are specific for the conservative regions of the 16S-rRNA gene, on the Life Technologies Ion Torrent sequencer using the 318v2 chip. Bioinformatic processing was conducted using the QIIME package. The results were compared with the data from the histological examination of the biopsy materials from the same part of the stomach as well as with the results of diagnosis using rapid urease test AMR RUT Expert with digital Reader.

Results: 8 out of 16 patients were identified as HP(+)+ positive, 2 of them had HP in small amounts, 6 of them – in significant amounts. The dominant types of bacteria in the stomach of all children were Bacteroidetes, Firmicutes; in a lesser extent - Actinobacteria, Cyanobacteria, Fusobacteria. 64.1% of HP(+) patients’ microbiome was constituted of HP, among Proteobacteria it reached 75–99%, the amount of other bacteria herewith shor- tened, and the microbiota decreased. Non-helicobacter microbiota of children with small amount of HP was almost identical in composition as HP(-) patients’, the amount of other microbes was more numerous and diverse, also within Proteobacteria. The signs of inflammation in mucous coat of the stomach in case of HP presence were more pronounced than in HP absence, they corre- lated with the amount of HP.

Conclusion: Microbiome of the children’s stomach is diverse, it is similar to adults’. The infection from HP inhibits another microbiota and it is accompanied with the signs of mucous coat inflammation, which correlates with the amount of HP.

P0643 FEATURES OF CHRONIC GASTRITIS CAUSED BY CO- INFECTION OF HELICOBACTER PYLORI AND EBstadt BARR VIRUS IN PEDIATRIC PATIENTS

E. Spivak, R. Levi
Pediatric, Medical State University, Yaroslavl/Russian Federation

Contact E-mail Address: spivak58@mail.ru

Introduction: It is known that co-infection of the gastric mucosa with highly pathogenic Hp strains and the Epstein-Barr virus is a risk factor for the development of severe gastritis and gastric adenocarcinoma. However, the characteristics of such co-infection in children are not sufficiently studied.

Aims & Methods: The aim of this study is to estimate the role co-infection of highly pathogenic strains of Helicobacter pylori and Epstein-Barr virus in pediatric patients with chronic gastritis. Patients and methods. 190 children aged 8–17 with chronic Hp-associated gastritis were studied. Antral biopsies were taken and inflammation graded according to the Sydney system. Polymerase chain reaction (PCR) was used to detect the presence of Epstein-Barr virus (EBV), Helicobacter pylori (Hp) and its highly pathogenic strains in the gastric mucosa of the patients.

Results: Persistent EBV infection was found in 83 children (43.7%) with chronic gastritis of the antral and (or) gastric body areas. Helicobacter pylori strains that possess the virulence factors (cytotoxin-associated gen A (CagA), vacuolating cytotoxin gen A (VacA), induced by contact with epithelium (IceA), and blood group antigen-binding adhesion (BabA)) were detected in 49 patients (25.8%). In most cases, the association of two or more virulence factors in one patient was observed. It was found that 39 pediatric patients had co-infection of the highly pathogenic strains of Hp and EBV. The study revealed no significant effect of the variant of the gastric mucosa infection on the clinical manifestations of gastritis - the nature of intoxication, abdominal and dyspeptic syndromes. At the same time, the endoscopic and morphological data analysis has revealed a severe gastritis with the development of pangastritis and signs of gastric mucosa atrophy observed mainly in the antral region, in patients with co-infection (highly patho- genic strains of Hp + VEBA). In addition, by correlation analysis, we found that the increase and development of the inflammatory process in the gastric mucosa was mostly influenced by the presence of CagA-positive strains of H. pylori in combination with EBV. We found that children infected by EBV without highly pathogenic Hp strains had mild mononuclear and polymorphonuclear cell infiltration without atrophy.

Conclusion: Co-infection with highly pathogenic Hp strains and the Epstein-Barr virus in pediatric patients is significantly associated with severe gastritis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: v_hurduc@yahoo.com

**Introduction:** Treat the association between Helicobacter pylori infection and specific immunoglobulin E (IgE) antibodies to food allergens in symptomatic children. We conducted a prospective study of 394 symptomatic children (249 girls, age range 6 months-18 years), mostly with uninvestigated dyspepsia requiring endoscopy in our unit, from January 2015 to December 2016. All patients were evaluated for H pylori infection by at least two standard invasive tests and for specific immunoglobulin E antibodies to major food allergens (R-Biopharm, Germany). The nutritional status of patients was assessed in all cases by the new World Health Organization (WHO, 2007) growth charts. EPI-INFO version 7 was used for statistical analysis. A two sided p-value less than 0.05 was considered statistically significant.

**Results:** Active H pylori infection was documented in 246 (62.3%) cases. The allergic sensitization at least one of the food allergens identified in 134 of 394 patients (34%). The majority of IgE positive children (109 of 134 cases; 81.3%) were positive for cow's milk followed by egg (17.9%), wheat (7.4%), peanut (6.7%), soybean (3.7%). The allergic sensitization to food allergens was associated with abnormal levels of specific IgE antibodies to common inhalatory allergens in 55 of 134 cases (41.0%). Regarding the association of H pylori infection with an elevated serum IgE level to at least one of the food allergens tested, there was a significant positive correlation (p = 0.14). 173 of 344 (51.3%) patients positive for food specific IgE antibodies were H pylori infected and 57 of them (35.5%) were H pylori negative (Fisher exact test = 0.08). The assessment of the patients nutritional profile in relationship with H pylori infection and food allergy not significantly different between the two groups of the poor nutritional status (undernutrition and overweight).  

**Conclusion:** The recent decline of H pylori infection is not evident in our study. There was no association between H pylori infection and IgE mediated food allergy. Undernutrition and overweight were not associated with the H pylori infection and food allergy in our patients.  

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Imbalanced gut microbiota is suggested to be involved in the pathogenesis of coeliac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microbiota, have been recommended, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.

**Aims & Methods:** The aim of the present study was to assess the effect of prebiotic oligofructose-enriched inulin (OEI) administration on the quantitative gut microbiota characteristics of CD children following a strict GFD for ≥ 1 year. A randomized, placebo-controlled 12-weeks dietary intervention was conducted on 34 CD children (62.7% female, mean age 10 years) on GFD who were randomly assigned to prebiotic (OEI: 10 g/day) or placebo group (maltodextrin; 7 g/day). Before (baseline) and after the intervention, the anthropometric (weight, height) and biochemical blood parameters (C-reactive protein, creatinine, aspartate aminotransferase, alanine aminotransferase), quantitative gut microbiota characteristics (by real-time PCR) and concentration of short-chain fatty acids (by gas chromatography with a flame ionization detector) were assessed.

**Results:** Thirty CD patients completed the study. After 12-weeks intervention, the biochemical blood parameters remained normative in all CD patients, and the gut microbiota counts within eachexperimental group did not differ from their counts at baseline. However, in comparison with placebo group, Bifidobacterium counts was significantly (p = 0.01) higher in CD children consuming OEI-supplemented GFD. Moreover, the counts of Clostridium leptum group in children of prebiotic group did not show the decreasing tendency along the time of GFD, observed in placebo group. The changes were reflected inotol bacterial number after the intervention that was constant in prebiotic group but tended to fall in placebo group. Microbiota counts corresponded well with microbial metabolic activity. In comparison with placebo group, there was concentration of short-chain fatty acids in prebiotic group (50.27 vs. 69.95 µmol/g, p < 0.05), mainly due to a significantly higher acetate formation (28.82 vs. 44.06 µmol/g, p < 0.05).

**Conclusion:** The bile acids of GFD are promising, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients. Microbiota characteristics of CD children following a strict GFD administered OEI was not associated with restoration of gut microbiota.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0648 EVALUATING GLUTEN IMMUNOCOMPLEX PEPTIDES AS NON-INVASIVE MARKER OF GLUTEN-FREE DIET ADHERENCE IN PAEDIATRIC CELIAC DISEASE**

1Gastroenterology And Nutrition, Instituto Hispano-Pediatric, Seville/Spain  
2Departamento de Microbiologia y Parasitologia, Facultad de Farmacia, Universidad de Sevilla, Sevilla/Spain  
3Servicio De Analisis Clinicos., Hospital Universitario INGEA de Ceuta, Ceuta/Spain  
4Biomedal, Sevilla/Spain

Contact E-mail Address: aflonsorodriguez@shippedia.com

**Introduction:** Treatment for celiac disease (CD) is a lifelong gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods
offer an accurate measure of dietary compliance. Presence of gluten related sub- stances in faeces after one week that transit through gastrointestinal tract happened and confirms gluten ingestion.

**Aims & Methods:** Detection of gluten immunogenic peptides (GIP) in stools as a marker of GF adherence in CD paediatric patients was evaluated and compared against traditional methods of GFD monitoring. A prospective, non-randomized, multi-centre follow-up study, 2 years long, including 64 CD patients started on GFD when diagnosed was conducted (age range 0–18 years).

Fecal GIP was quantified by enzyme-linked immunosorbent assay (ELISA). Anti-tissue transglutaminase (anti-TG) IgA and anti-deamidated gliadin peptide (anti-DGP) IgA antibodies were measured simultaneously, during basal and follow-up visits at 0, 6, 12 and 24 months. Correlations between fecal GIP and serum antibodies were established by Cochran’s and Friedman tests.

**Results:** 62 patients (97%) had detectable GIP levels in stools, during basal visit, before initiation of the GFD, whereas 20.3% of the patients were found to have positive GIP after treated with a GFD. Dietary transgressions were more frequent in children over 8 years of age-46% of them showed more than one detected transgression. Anti-TG IgA remained in high concentrations in 48, 34, and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP was positive in 13, 4.5 and 0% of cases when tested at 6, 12 and 24 months follow-up. Both serological methods did not correlate with GIP in stools (p < 0.05).

**Conclusion:** The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of compliance to traditional serological methods to verify GF compliance in CD paediatric patients. The antibodies can be measured several days or even years to decrease after initiation of the GFD and reduction (but incomplete suppression) of gluten intake. The antibody is sufficient to detect and quantify antibodies in sera. Fecal GIP is a useful tool: 1) on the diagnosis of CD, to ensure that a sufficient amount of gluten has been ingested to allow a correct CD diagnosis. 2) on treatment, for monitoring of short-term and long-term GF compliance. 3) on the differential diagnosis of CD versus other non-compliance.

**P0651 META-ANALYSIS: PROTON PUMP INHIBITORS MODERATELY INCREASE THE RISK OF SMALL INTESTINAL BACTERIAL OVERGROWTH**

**T. Su, S. Chen** Department Of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University, Institute of Gastroenterology, Zhejiang University, Hangzhou/China

**Contact E-mail Address:** 1877085122@163.com

**Introduction:** PPIs have become one of the most commonly prescribed classes of medication. Although PPIs are generally well tolerated, accumulating evidence suggests that PPIs have long-term risks. One potential risk of PPI use is development of small intestinal bacterial overgrowth (SIBO), which is defined as >105 bacteria colony-forming units (CFU) per mL upon culturing upper gut aspirates. However, this is controversial due to conflicting results from prior studies.

**Aims & Methods:** The aim of this meta-analysis was to evaluate the association between use of PPIs and the risk of SIBO. We systematically searched the online PubMed, Embase, Cochrane Library databases and Web of Science for relevant articles before November 2016. Two researchers identified and extracted data independently. The pooled analysis was performed using generic inverse-variance random-effects model. Subgroup and sensitivity analysis were conducted to assess the stability and heterogeneity of the pooled results. The risk of publication bias was evaluated by examining funnel plot asymmetry, Egger’s test and Begg’s test. All statistical analyses were performed using Stata software version 13.

**Results:** A total of nineteen articles met the eligibility criteria for the meta-analysis. The pooled odds ratio (OR) showed a statistically significant association between increased risk of SIBO and PPI use (OR = 1.95 95% CI 1.20–2.43). No statistically significant publication bias was found based on the Egger’s test (p = 0.11) or Begg’s test (p = 0.147). Our meta-analysis has demonstrated an association between SIBO and PPI use in studies that employed small bowel aspirates culture and glucose hydrogen breath tests (GHBT) as diagnostic tests for SIBO. However, when the pooled analysis was limited to studies recruiting individuals with irritable bowel syndrome (IBS) population, no statistically significant association between PPI use and SIBO was observed, which suggests that PPI use does not affect the risk of SIBO among IBS patients.

**Conclusion:** Our meta-analysis shows that the use of PPIs moderately increases the risk of SIBO, which highlights the need for appropriate prescription of PPIs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2Laboratory, Republican Specialized Scientific-Practical Medical Center of Pediatrics, Tashkent/Uzbekistan

Contact E-mail Address: okamilova@mail.ru

Introduction: Nowadays food allergy continues to increase, especially in westernized countries and it is now recognized as a worldwide problem. Transforming growth factor-ß1 (TGF-ß1) is a profibrotic cytokine, which plays an important role in promoting the structural changes in food allergy. Also for patients with food protein - induced enterocolitis syndrome TNF-ß appears to have an important role.

Aims & Methods: The aim was to determine the significance of the Transforming Growth Factor - ß1 and Tumor Necrosis Factor - ß in children with food protein induced enterocolitis syndrome. It was examined 38 patients with FFIES at the age from 4 months to 3 years, the average age was 19 ± 4 months. The control group consisted of 11 healthy children of the same age. The determination of TGF-ß1 and TNF-ß in serum was performed by an enzyme immunoassay kit from Bender MedSystem (Austria).

Results: The level of TGF-ß1 in patients with FFIES exceeded the norm and was respectively 33.5 ± 1.6 ng/ml at norm 20.2 ± 2.1 ng/ml, p < 0.001. The indices of TNF-ß were also increased and amounted to 8.8 ± 1.3 ng/ml in comparison with the control group, p < 0.001. For TNF-ß2 it was characterized by an increase in specific antibodies IgE to cow’s milk in 18 (47.3%) children. In these observations, an increase in its values was established, especially in the group of children with high specific IgE levels to cow’s milk. It is likely that an increase in TGF-ß1 stimulates the release of TNF-ß, which supports chronic inflammation in allergic diseases.

P0653 THE ROLE OF GSTI & GSTM1 GENE POLYMORPHISMS IN NEWBORN'S OBESITY RISK

C.O. Marginean1, C. Marginean2, L.E. Melti1, C. Banescu3, M.O. Marginean3

Introduction: Newborns’ birth weight is influenced by maternal factors (mother’s weight at the onset of pregnancy, gestational weight gain - GWG), genetic, obstetrical and environmental factors, but also socio-economical ones. Excessive GWG, mother’s increased BMI and the adipose tissue mass determine a bigger birth weight and increase the risk of newborns’ obesity. Glutathione S-transferases (GSTs) is an oxidative stress-related gene which is associated with and ist complications.

Aims & Methods: The aim of the study was to investigate the role of mother-child GSTI & GSTM1 polymorphisms as independent risk factors for newborn’s weight, but also to establish correlations between these polymorphisms and anthropometrical parameters, and bioimpedance (BIA) ones, respectively. We assessed the anthropometrical parameters in both mothers and their newborns (BMI, body mass index, MUAC – medium upper arm circumference, TST – tricipital skin thickness, weight – W), BIA parameters in mothers, but we also determined the clinical, paraclinical and genetic parameters in both mothers and newborns.

Methods: We performed a cross-sectional study on 202 mothers and their newborns in a Clinic of neonatology & Gynecology and Obstetrics from Romania.

Results: We noticed that in newborns with W > 3000 gr there was a significant statistical correlation between weight and mother’s GSTI polymorphism (p = 0.046), birth at term (p < 0.001), with mother’s percentage of fat mass assessed by BIA (p < 0.001), and multi parity, respectively (p < 0.001). We obtained a tendency towards correlations between W > 3000 gr and basal metabolism rate (p = 0.083), and GWG seemed to be a protective factor for this W (p = 0.072). We also found that GSTM1 in newborns was a risk factor with tendency towards statistical significance in newborns with increased birth weight. We did not find any interaction effect between newborns’ and mothers’ GSTI and GSTM1 polymorphisms and anthropometrical parameters (p = 0.545 for M1 and p = 0.548 for M2 gene polymorphisms).

Conclusion: Mother’s GSTM1 is an independent risk factor for newborns’ W > 3000 gr, while mother’s GWG seems to be a protective factor for W > 3000 gr. Further studies are needed in order to determine the clear role of these polymorphisms in newborns’ obesity risk. This research was supported by the Research Grants of the University of Medicine and Pharmacy Tirgu Mures, Romania - “The role of genetic determination of the mother in child’s obesity correlated with measurements of bioimpedance and anthropometry” no.275/4.11.2017.

Introduction: Primary lactose intolerance (PLI) is a frequent condition caused by a genetically programmed and progressive loss of lactase expression. It is considered that PLI is the ancestral variant, while lactase persistence is caused by 2 polymorphisms: the dominant C/T13910 and G/A22018. Homozygotes (CC or GG) have detectable lactase levels. In clinical practice only half of people with PLI have symptoms. However, some studies showed that PLI subjects have lower dairy intake.

Aim & Methods: To investigate whether genetic predisposition to PLI influences the quality of life and dairy intake in a group of Romanian children. We conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study population included 87 children aged 6–17 years.

Results: Genotyping revealed 15 (17.2%) subjects had a CC genotype, 41 (47.1%) subjects had a CG genotype, 31 (35.6%) subjects had a GG genotype. Our results were consistent with Hardy-Weinberg equilibrium. We identified quality of life questionnaire and a dairy intake questionnaire. We used strip genotyping to assess the correlation between IPL and quality of life and dairy intake.

Conclusion: In our group genetic predisposition to IPL followed European standards. We did not find correlation between genetic predisposition to IPL and quality of life and dairy intake.

Introduction: Fibroblast growth factor-21 (FGF21) and omentin-1 have been recognized as potent antiadipogenic agents, with potential hepatoprotective activity.

Aims & Methods: The aim of this study was to evaluate hepatic FGF21 and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGF21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGF21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminant power for FGF21 serum level in differentiation between more and less extensive steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGF21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGF21 and omentin-1 mRNA levels (r = 0.73, p = 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (p = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In conclusion our study, which focused on hepatic FGF21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in liver of morbidly obese patients with NAFLD. mRNA levels were affected by clinical and biological abnormalities. In patients with more extent steatosis was associated with evident change in serum FGF21 concentration in morbidly obese women with NAFLD. The vast amount of fat, both visceral and subcutaneous in severely obese patients may affect FGF21 and omentin-1 serum levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: eva-mareike.becker@t-online.de

Introduction: CXUI (CUTL1) is a transcription factor belonging to homeobox proteins. It is responsible for driving the transcription of genes deemed to many cellular functions like proliferation, differentiation and cell death. It has been shown that its role can change and drive tumorigenesis. Up to now, its role is unknown in hepatic stellate cells. W

Aims & Methods: We focused on CXUI activity in hepatic stellate cells under hypoxic stress. LX-2 cells were treated with 100 ng/ml CoCl2 or kept at 37 °C at oxygen (-0.5%). Expression of hypoxia markers and activation markers was performed by RT-qPCR. Western blotting was performed to analyze the protein level of CXUI and HIF-1alpha. Transfection with plasmid containing a promoter sequence for HIF1alpha was performed simultaneously with CXUI knock-down.

Results: LX-2 cells treated for 6 hours with CoCl2 or low oxygen showed an over-expression or a restoration of COL1A1 and ACTA2 after knock down of CXUI. Additionally, CDKN1A, CDKN1B, VEGFA and HIF1alpha were up-regulated in LX-2 cells previously transfected with siCXUI. Protein level of CXUI was significantly down-regulated, whereas HIF1alpha protein was strongly up-regulated by hypoxia condition. Transcriptional activity of HIF1alpha is not correlated with CXUI expression.

Conclusion: CXUI controls the activation of hepatic stellate cells. Its knock down promotes the hypoxia response. CXUI could represent a key factor for controlling liver fibrogenesis. Its role in a liver fibrosis scenario needs to be further investigated.

P0658 LOUREIRIN B INHIBITS THE PROLIFERATION OF HEPATIC STELLATE CELLS VIA DOWN-REGULATING FRizzLED-7 A2

Z. Dept. Of Gastroenterology, First Peoples Hospital, Kunming/China

Contact E-mail Address: song715@163.com

Introduction: Liver fibrosis is the result of repeated healing repair and interstitial reconstruction after chronic liver injury. Activation of hepatic stellate cells represents a critical event in fibrosis because these cells become the primary source of extracellular matrix in liver upon injury. Inhibiting HSC’s activation, proliferation, extracellular matrix production and promoting HSC’s apoptosis are the important therapeutic approaches of liver fibrosis.

Aims & Methods: We aimed to investigate the anti-liver fibrosis ability of lourerin B and the molecular mechanisms involved it. After hepatic stellate cells
(HSCs), which were separated from Sprague-Dawley rat, were treated with differ- entially treated lutein B. MTT was employed to determine HSCs proliferation, western blot was used to test the expressions of Frizzled-4 receptor protein and α-SMA. In addition, enzyme-linked immunosorbent assay (ELISA) was performed to measure the content of α-SMA, TGF-β1 and VEGF in the conditioned HSCs supernatant, and reverse-transcription PCR (RT-PCR) were utilized to detect the expressions of Frizzled-4 and α-SMA genes.

**Results:** MTT test showed that the proliferation of HSCs was inhibited significantly with a time and dose dependent relationship by the treatment of lutein B. The IC50 concentrations of 11.83μg/ml (IC50 = 0.180μg/ml). Western blot analysis showed that the expressions of Wnt receptor Frizzled-4 protein and α-SMA were obviously lower in the group of lutein B treatment than that in the control group. Moreover, the Lutein B administration inhibited the proliferation of fibroblasts by -0.05% secretion in the cultured HSCs supernatant in different degree by the ELISA assay, and RT-PCR results revealed that Lutein B down-regulated the expressions of Frizzled-4 and α-SMA genes in the level of mRNA.

**Conclusion & Outcomes:** The Lutein B mediated anti-hepatic fibrosis by inhibiting the proliferation of HSCs through restraining the Wnt signaling pathway.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Macrophages play a pivotal role in the pathogenesis of non-alcoholic steatohepatitis (NASH) and are a major component of inflammatory cells infiltrated in NASH. However, the precise mechanism of how macrophages contribute to the pathogenesis of NASH remains unexplored.

**Aims & Methods:** We aimed to characterize the role and molecular regulators of macrophages in NASH and the therapeutic effects of macrophage depletion on NASH. C57BL/6 wildtype (WT) mice and transgenic LysM-Cre/DTR mice were fed a high-fat diet (HFD) to develop NASH.

**Results:** Hepatic macrophage marker CD68 expression was significantly higher in rats with NASH compared to control rats. Hepatic mRNA expression of pro-inflammatory cytokines, chemokines and their receptors was significantly upregulated in NASH compared to control rats.

**Conclusion:** In conclusion, we identified novel BA derivatives that directly modulate liver nuclear receptors, such as FXR and LXR, thus protecting liver cells from cellular toxicity and inflammation. These new molecules may be used as scaffolds for the development of targeted therapies for NASH.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is considered the hepatic manifestation of metabolic syndrome, with simple liver steatosis being capable of gradually progressing to inflammation, fibrosis, cirrhosis and even hepatocellular carcinoma. Still, disease pathogenesis is complex and no targeted therapies have yet been approved for NAFLD. Bile acids (BAs) constitute a wide class of steroid molecules with pleiotropic functions, contributing to the homeostasis of lipids and glucose. In the liver, they specifically modulate nuclear receptors from the NRI subfamily, such as Farnesoid X Receptor (FXR) and Liver X Receptor (LXR), thus tightly regulating bile acid synthesis and oxidation and storage of triglycerides.

**Aims & Methods:** Our aim was to screen BA derivatives for their potential to selectively activate FXR, thus protecting liver cells against free fatty acid (FFA)-induced lipid accumulation and lipotoxicity. Nineteen novel BA derivatives were assessed in silico molecular docking studies for FXR and LXR binding, and further evaluated in human cells using a FXR reporter assay. Assessment of FXR-dependent gene and protein expression was analyzed upon incubation of primary human hepatocytes and HepG2 cells with selected BA derivatives. In parallel, BA derivatives were co-incubated with oleic and palmitic acids (2:1) to assess the compound cell cytotoxicity and intracellular lipid accumulation.

**Results:** From the compound library, five BA derivatives showed stronger activation of FXR, compared with their natural precursors. Incubation of HepG2 cells with FAs led to a ~25% reduction in cell viability and ~55% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly induced FXR, RXR, SHP, BSEP, PXR, FGF19 and VLDLR mRNA levels, and repressed SREBP1-c and CYP7a1 mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to FXR. Furthermore, chemodendocholic acid (C5a)-based derivatives were found to be potent activators of FXR at lower concentrations than the parent compound.

**Conclusion:** In conclusion, we identified novel BA derivatives that directly modulate liver nuclear receptors, such as FXR and LXR, thus protecting liver cells from cellular toxicity and inflammation. These new molecules may be used as scaffolds for the development of targeted therapies for NAFLD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

4. Gaia S, Olivero A, Smedile A, Ruella M, Abate ML, Fadda M, et al. Autophagy mechanism is significantly activated in FLS-ob/ob mice, and its phosphorylated form resulted unvaried. Interestingly, Caffeine treatment caused a stronger reduction of autophagy markers level. FBS treated mice developed NASH-like features, including a reduction in hepG2 protein expression, which is not readily available in the country, and even if available in the near future, needs at least some months for planning and preparation and is costly. G-CSF (Granulocyte Colony Stimulating Factor) has shown both morbidity and mortality benefit in some studies in these groups of patients. By comparing the outcomes in our patients and not receiving G-CSF, we can suggest G-CSF therapy to reduce mortality and morbidity in these patients. Although most of the studies done in the role of G-CSF in ALCF (Acute-on-Chronic Liver Failure) and decompensated CLD (Chronic Liver Disease) have used a fixed dose of G-CSF (C21), our study has used a fixed dosage of 300mg of G-CSF subcutaneously twice a day for a total of 3 days (6 doses).

Aim and Methods: We aimed to study the role of G-CSF in the treatment of alcoholic hepatitis. Decompensated CLD and ALCF. From January 2016 to December 26, a total 49 patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure admitted in TUTH (Tribhuvan University Teaching Hospital) were studied. Patients were randomized (in a 1:1 ratio) to either the ‘GCSF + SMT’ (Standard Medical Therapy) group (cases) or the ‘SMT-alone’ (control) group according to computer-generated random numbers. Patients in G-CSF group received G-CSF 300mg twice daily for 3 days (total 6 doses) and CTP (Child Tarcot Pugh) and MELD (Model for End Stage Liver Disease) scores at enrollment and at Day 30 were compared in the two groups.

Results: A total of 49 patients (median age: 49 (range: 27–73) years, 70% males) were included in the study. 24 of them received G-CSF along with SMT and 25 received SMT alone. Baseline characteristics were similar in both the groups. The 3-day G-CSF therapy did not lead to any significant adverse effects. At one month, in GCSF+SMT group, 4 had died whereas in SMT alone group 15 had died. The survival rate in GCSF group whereas only 40% survived in control group (P = 0.002). Also significant improvement in CTP and MELD scores was seen in the group treated with GCSF at one month after therapy. Also, there were fewer complications of sepsis, hepatic encephalopathy and renal impairment in patients in the G-CSF group compared to the SMT alone group.

Conclusion: GCSF therapy improves survival and clinical outcome in patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure. It may be useful in patients who do not have access to transplant services and also to the patients awaiting transplantation to prevent worsening during the waiting period. Further studies are needed to explore whether lower doses (total 6 doses) of GCSF are as effective as higher doses (total 10 doses).

mononuclear layer containing stem cells is a novel approach for regeneration of liver. This therapeutic option is not complex and requires repeated PBMC transplantation.

**Aims & Methods:** To determine the outcome after intrasplenic or intraperitoneal injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronic hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; group I: 20 patients underwent (ABMSC) injection intrasplenic. Group II: consisted of 20 patients underwent (ABMSC) injected intra hepatic (right portal branch). Group III: (Control Group); consisted of 20 patients received traditional supportive treatment for chronic liver failure and symptomatic treatment of ascites and bleeding abnormalities. All groups of patients were followed regularly for nine months clinically, biochemically and ultrasonographically. Fatigue was assessed by the modified fatigue impact scale questionnaire before, during and at end of the study.

**Results:** Our study showed that proposed treatment was safe and effective. A total of 41,258 adults who underwent routine comprehensive health evaluations, including abdominal ultrasonography, were selected. We calculated the adjusted prevalence ratios (PRs) for components of MetS (high blood pressure (BP), impaired fasting glucose, low high-density lipoprotein cholesterol (HDL-C), and high triglycerides) according to NAFLD. Results: NAFLD was found in 13.8% of non-obese subjects and 52.3% of obese subjects. NAFLD was associated with both incident GO and CO. Inadequate physical activity was not associated with either. 2137 (72%) males and 2458 (78%) females (p < 0.001) were significantly associated with prevalent GO and CO (p < 0.001; 2.81, p < 0.001). Females gender (OR-1.78, p < 0.001) and low-educational level (p < 0.001), diabetes (p < 0.001), NAFLD (p < 0.001), and low household income (p < 0.001) were significantly associated with prevalent GO and CO. Talal (2012) found that obese patients with NAFLD had high triglycerides (TG) levels and decreased HDL-C levels compared to non-obese patients. In obese patients, the prevalence of NAFLD and MetS was significantly higher than in non-obese patients. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary. Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** It is well known that severe liver disease requires a liver transplant to be treated. But liver transplantation is not available in many countries. A possible option can be a transplantation of autologous bone marrow mononuclear layer containing stem cells which can stimulate liver regeneration. Proliferating cell nuclear antigen (PCNA) shows nuclei of dividing cells and may be useful for calculating proliferation index.

**Aims & Methods:** The aim of this study was to evaluate changes of proliferation intensity of liver cells in patients with alcoholic liver cirrhosis after autologous peripheral blood mononuclear cell (PBMC) transplantation. This uncontrolled open-labeled clinical trial was approved by Ethical committee of Ministry of Health of the Republic of Tatarstan, Russia. Eleven patients took part in the study, they received granulocyte colony-stimulating factor injections for 5 days for PBMC mobilization. On the 6th day PBMCs were collected and injected into the celiac trunk. Liver biopsies were obtained three times from each person on third and six month before and after transplantation of PBMCs into the celiac trunk (initial), third, and twelve months after the procedure. Liver biopsy specimens were embedded in paraffin and stained immunohistochemically with antibodies against PCNA. The PCNA labeling index was calculated as the number of PCNA-labeled nuclei for 1000 hepatocyte nuclei in each specimen and the results were expressed as percentage ratios. Statistical analysis was done by Wilcoxon test. We calculated the proportion of proliferating hepatocytes significantly increased (50.2 % vs. 17.0 %) (p < 0.04). Great increase in hepatocytes proliferation intensity coincided with biochemical improvements of serum bilirubin, ALT and alkaline phosphatase.

**Conclusion:** Our study showed that proposed treatment was safe and effective. We can conclude that after transplantation of autologous PBMC’s proliferation of hepatocytes greatly contributes to the liver regeneration and improvement of blood biochemical data in patients with alcoholic liver cirrhosis. However, effect of PBMC transplantation on long-term survival is not complex and requires repeated PBMC transplantation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
**P0668 THE USE OF THE FATTY LIVER INDEX TO DETERMINE THE PREVALENCE OF FATTY LIVER DISEASE (HEPATIC STEATOSIS) IN AN IRISH POPULATION**

L. Reynolds, L. Rabbitt, C. Goulding

Acute Medical Unit, University Hospital Galway, Galway/Ireland

Contact E-mail Address: laurajreymonds@gmail.com

Introduction: Worldwide, the prevalence of fatty liver disease (FLD) is increasing, particularly in countries with rising obesity rates, such as Ireland. Studies suggest that up to 25% of those with FLD can progress to non alcoholic steatohepatitis (NASH) and be at risk of its sequelae, including cirrhosis and hepatocellular carcinoma. Indeed, NASH is now the second most common indication for liver transplantation in the US. Despite this alarming data, there is no prevalence data for Ireland in relation to FLD.

Aims & Methods: We aimed to use a simple screening tool, the Fatty Liver Index (FLI) to identify those at risk of having fatty liver disease (FLD) amongst all comers presenting to an Acute Medical Unit (AMU) and to use this data as an indicator of prevalence of FLD in Ireland.

Methods: In this prospective cohort study, all patients attending the Acute Medical Unit (AMU) were invited to take part. Their height, weight and waist circumference were measured, and triglycerides (TG) were added to their 'routine AMU blood panel', which also included measurement of gamma glutamyl transferase (GGT). Exclusion criteria were as follows: known liver disease, excess alcohol intake (>17 units per week for males, >11 units per week for females), age <18 years, pregnancy, active malignancy. The Fatty Liver Index (FLI), an algorithm for identifying patients based on FLI risk was used to stratify patients into groups based on risk of having FLD. A FLI score of >60 is highly suggestive of having FLD, a score of 30-60 is indeterminate and a score of <30 is considered low risk for FLD. Ethical approval for this research was granted by the ethics committee of UHG.

Results: Data was collected on 316 participants; 58 were excluded, the majority due to either a history of alcohol excess or known liver disease. A total of 258 participants were therefore evaluated; 50% were male. One hundred and sixteen (45%) participants were >60 on the FLI, 57.3% of which were male. Only 16% of males had a FLI <30, compared with 44% of females. Males had a significantly higher FLI than females; 60.9 vs. 43.12 (p < 0.0001). Those with a FLI >60 had a mean weight = 93.5 kg and BMI = 31.5, vs. 64.9 kg and 22.4 respectively for FLI <30 (P < 0.0001). There was a statistically significant difference in all parameters measured between all 3 groups (p < 0.0001), apart from height, although there was a trend toward lower height in the FLI <30 group, most likely due to the fact that it was 73% female. When over 65 were looked at, there was no height difference between the 3 groups. Those with a FLI >60 were older than those with FLI <30, 54.6 vs. 48 (p = 0.01).

Conclusion: In this study looking at prevalence of fatty liver in Ireland, 45% of participants were found to be at high risk, and 70% were at high or indeterminate risk. Worryingly, only 16% of males fell into the low-risk group. Apart from weight, GGT, TG and BMI this study also showed age and male sex to be significant risk factors for developing fatty liver. This group clearly needs follow up to further evaluate and manage their fatty liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The clinical implications of non-alcoholic fatty liver disease (NAFLD) are still the topic of debate in human studies. It has been shown that fatty infiltration in pancreas correlates with metabolic risk factors and may represent significant manifestation of metabolic syndrome (MeS) in association with nonalcoholic fatty liver disease (NAFLD). The aim of our study was to determine the association of fatty pancreas (FP) in NAFLD patients with features of MeSand to determine a simple new noninvasive scoring system for FP prediction in NAFLD patients.

Aims & Methods: We conducted a cross-sectional study that included 143 subjects with NAFLD classified into two groups according to the severity grade of FP as follows: patients with non fatty pancreas and grade I light FP (n = 59) and patients with grade II severely and grade III highly FP (n = 84). Patients were analyzed for diagnostic criteria of MeS, underwent sonographic examination with adiposity measurements and liver biopsy. Liver fibrosis was evaluated semi-quantitative according to the METAVIR scoring system and using non-invasive markers of hepatic fibrosis (NAFLD fibrosis score (NFS), BARD score, FIB4, APRI, NALDFibroScore). Our study cohort consisted of 14% of males; diabetes mellitus (DM) was more frequent in patients with severely FP (P = 0.02), with greater portion of patients with HOMA-IR > 3. Higher values of fasting plasma glucose, total cholesterol, serum amylase and lipase were associated with presence of highly fatty pancreas (P = 0.052, P = 0.007, P = 0.014; P = 0.024, retrospectively). Values of hemoglobin A1c (HbA1c) > 6% were significantly associated with NAFLD patients with severely FP, highlighting its impaired function in MeS (P = 0.008). While no significant difference was found in the use of statins and hypotensives, higher number of patients with severely FP did not use antidiabetic agents and association was registered among NAFLD patients with use of metformin and glimepiride and the first FP group (P = 0.035). Out of all visceral fat amounts, only measures of mesenteric fat were associated with severely FP (P = 0.013). Results of our study determined highly significant association of NAFLD and NAFPD. Neither NAFLD non-invasive markers nor histological reports of liver fibrosis showed significant association with presence of fatty pancreas in NAFLD and NAFPD. In multivariate analysis of FP predictors in our study cohort, logistic regression approach was used. Model of predicting occurrence of FP was designed from multivariate logistic regression analysis. The probability was estimated with the equation: 0.627 + 0.640 * 0.593 + glucose (fasting glucose level) – cholesterol level – HOMA-IR – triglycerides – serum lipase – ultrasonography level of liver steatosis. According to the score values for different cut off levels, best ability in the prediction of severely FP has shown the score value above 6.5.

Conclusion: Our study demonstrated that pancreatic fat infiltration due to its clinical and structural presents a new and independent risk factor that is strongly associated with MeS manifestations, affects glucose metabolism and severity of NAFPD. Interestingly, significant association was registered among NAFLD patients

Introduction: Bispheanol (A BPA) is an endocrine disrupting chemical, a heterogonous group of chemicals usually found in food packaging or insecticide residues on vegetable crops, associated with type 2 diabetes mellitus (T2DM), cardiovascular disease, and enzyme abnormalities, and in general with the whole blood glucose homeostasis.

Aims & Methods: We have evaluated BPA plasma and urine levels in non-alcoholic fatty liver disease (NAFLD) patients compared to healthy subjects and we evaluated the possibility to eliminate this environmental factor after a BPA-free diet regimen. Furthermore, we evaluated, in human HepG2 cells, the effects of exposure to different BPA concentrations on both oxidative stress induction and cell proliferation. We enrolled sixty patients with histologic diagnosis of NAFLD with or without T2DM, before a BPA-free diet, and healthy subjects, by subjecting them to evaluation of body composition using bioimpedance analysis. In vitro, the proliferation of BPA-exposed HepG2 cells at two different concentrations (0.025 and 0.055 µM) was evaluated, both at high (H-HepG2), in order to simulate human hyperglycemia, and at low (L-HepG2) glucose concentrations, for up to 48 h of post serum exposure by T2DM.

Results: BPA levels were significantly higher in 60 NAFLD subjects, both in urine and in plasma (p < 0.0001) if compared to controls and, among this group, it appeared to be higher in 30 non-alcoholic steatohepatitis (NASH) patients compared to 30 simple steatosis (NAFL) ones (p < 0.05), independently from the presence of T2DM. After following a BPA-free diet for one month, NAFLD patients showed a significant reduction of BPA circulating levels (p < 0.05) without a significant reduction of urine levels, which represents the only way to eliminate BPA amount released into circulation by the liver reservoir. In fact subjects with a higher fat percentage in body composition showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a higher fat percentage in body composition in comparison with NAFL cases, while with 0.055µM increased proliferation compared to controls at 48h (p < 0.0001). Moreover, BPA increased TBARS levels at 48h in H-HepG2 cells versus controls.

Conclusion: Our study reveals a possible role of BPA as an environmental factor in the progression of NAFLD, particularly in obese and/or T2DM patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
with use of antidiabetic agents and the absence of highly fatty pancreas, indicating its potential protective role. Simple new noninvasive scoring system was designed from multivariate logistic regression analysis to estimate the occurrence of severely FP in NAFLD with best ability in the prediction in score values above 6.5.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for evaluation of liver histology as a routine pre-transplant checkup. Liver function tests, age, gender, weight, height, fasting plasma glucose, thyroid hormones, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist for steatohepatitis and steatosis. Individuals with a history of chronic liver disease, hepatitis B or C infection, hepato-biliary cancers, those with > 20 grams/day alcohol consumption, and individuals receiving medications causing hepatic steatosis were excluded from the study.

Results: A total of 210 individuals (130 women and 80 men) were included. Seventy six individuals (36.19 %) had hepatic steatosis and 19 individuals had steatohepatitis (9.04 %) in liver histology. Mean age of individuals with and without hepatic steatosis were 32.9 ± 6.69 and 31.8 ± 6.72 years respectively (P = 0.26). In univariate analysis higher weight, triglyceride, total cholesterol, alanine aminotransferase (ALT), alkaline phosphatase, fasting blood sugar (FBS) and thyroid stimulating hormone (TSH) were associated with hepatic steatosis (P < 0.05). Serum T4 and T3 were not associated with hepatic steatosis (P > 0.05). In regression analysis, higher TSH, higher alkaline phosphatase, higher ALT and higher TSH (OR = 1.36; 95 % CI: 1.02–1.80, P = 0.03) were independent predictors of hepatic steatosis. In regression analysis, higher serum TSH was independently associated with steatohepatitis compared to those without steatohepatitis (6.83 ± 6.04 mIU/L and 2.10 ± 1.27 mIU/L) (OR = 2.11; 95 % CI: 1.45–3.07, P < 0.001). A cutoff value of 3.75 mIU/L for TSH was predictor of presence of steatohepatitis in liver biopsies (sensitivity = 75%; specificity = 89%; AUC = 0.754; P = 0.004).

Conclusion: Higher serum TSH is associated with hepatic steatosis and steatohepatitis in euthyroid subjects. Thyroid hormones may have crucial role in hepatic steatosis and may be targeted for treatment of NAFLD patients.

P0673 DIFFERENCES BETWEEN BY-PASS AND SLEEVE GASTRECTOMY ON CLINICAL AND LABORATORY STATUS 6 AND 12 MONTHS AFTER INTERVENTION IN BARIATRIC SUBJECTS

M. Dacor1, S. Palumiano2, F. Masutti1, V. Lanzotti3, R. Patti2, R. M. Buonocore2, C. Tiribelli1, S. Nikeghbalian2, B. Geramizadeh2, S. Ali Malek-Hosseini2

Introduction: In patients with morbid obesity, dietary treatment and physical activity are the first line of treatment, but if not responding, bariatric surgery is usually used for weight loss. The main surgical procedures are the adjustable gastric banding (GBP) and sleeve gastrectomy (SG) and gastric bypass (GBP), and they are choices in function of BMI, age and comorbidity. Both techniques have proven effective in weight loss. It is known that liver fibrosis evaluation with Point Shear Wave Elastography (pSWE) is difficult in these patients.

Aims & Methods: To study the difference between SG and GB and their impact on main clinical and laboratory hepatic metabolic indicators and scores 6 and 12 months after the intervention and pSWE at 12 months. We studied 68 obese subject candidate to bariatric surgery (45 female, 23 male). 28 underwent GBP and 40 SG. Blood tests, physical examination were assessed before surgery, after 6 months (68 patients) and after 12 months (51 patients) and pSWE after 12 months.

Results: In the comparison between GBP vs SG there was a statistically significant difference in the reduction in Fatty Liver Index (61 % vs 37%, p = 0.015), waist circumference (26 % vs 18 %, p = 0.045), BMI (34 % vs 28 %, p = 0.016), total cholesterol (23 % vs 0 %, p = 0.005), ALT (increased by 15 % in GBP, decreased by 40 % in SG, p = 0.023) while no differences were observed in the other indicators considered. Ferritin level increased (52 %) in SG and decreased (27 %) in GBP, p = 0.02). No difference was observed for pSWE.

Conclusion: This study showed some significant differences in clinical and laboratory terms between the two types of intervention, in fact GBP seems to have a more powerful effect on weight loss and all related markers: all steatosis scores (FLI, HSI, LAP), BMI, waist circumference. This can be explained by better malabsorptive effect of this intervention and by a lower BMI starting point for reasons related to the intervention technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Seoul National University Hospital, Seoul/Korea, Republic of Korea

Introduction: Polycystic liver disease (PLD) occurs in the setting of different genetic disorders: autosomal polycystic liver disease (ADPLD) and autosomal polycystic kidney disease (ADPKD). These patients may develop hepatoesplenomegaly as a result of multiple fluid-filled cysts. It is unclear whether PLD severity differs between ADPLD and ADPKD. Height adjusted liver volume (HTLV) reflects with symptomatic disease and diminished quality of life. We assessed hepatoesplenomegaly with HTLV, as an objective parameter, in a large cohort of ADPKD and ADPLD patients.

Methods: PLD patients, defined by >10 liver cysts on radiological imaging, were included in the international PLD registry. The cases were identified from clinical records at the University Leuven (Belgium), Seoul National University Hospital (South-Korea) and Radboud University Hospital Nijmegen (the Netherlands). In a cross-sectional analysis, we selected patients when height adjusted total liver volume was measured prior to liver reducing therapy. We performed univariate and multivariate analyses to explore risk factors associated with severity of disease. Results: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 ADPKD and 112 ADPLD) could be selected. In the ADPKD + PLD group height adjusted liver volume is significantly lower compared with ADPLD patients (1050 ml/m vs 1922 ml/m; p = 0.000). Females have higher HTLV than men in both ADPKD and ADPLD. Severe disease (HTLV > 3.200ml/m) is more prevalent in ADPLD. In this group, gender and age are independent predictors for severity of disease.

Conclusion: In this cohort more ADPLD patients had moderate to severe PLD compared with ADPKD. Longitudinal studies are needed to further explore the differences in the national course of PLD phenotype between ADPLD and ADPKD patients and to identify new risk factors.

Introduction: Nonalcoholic fatty liver disease (NAFLD) affects about 1 billion people worldwide. Those with non-alcoholic steatohepatitis (NASH) among NAFLD patients have increased mortality rates compared to the general population, with cardiovascular diseases being the leading cause of death. Identifying parameters associated with cardiovascular disease is of major importance, both in terms of prognosis, as well as in terms of therapeutic attitude.

Aims & Methods: Our aim was to quantify the risk of developing atherosclerosis as a main cardiovascular risk factor, in NAFLD patients and to identify a screening strategy for those patients. We included patients with NAFLD and metabolic syndrome (MS) into 2 arms: with NAFLD and MS, and with NAFLD without MS. NAFLD diagnosis was based on clinical, biological and ultrasound determinations. We used FibroMax for evaluating the hepatic modifications (presence of liver fibrosis). The Rho of CPA (Rho = 0.8, p = 0.001). CAP score correlated significantly with fibrosis and effectively diagnosed steatosis > 5% (AUROC 0.82, 95% sensitivity, 60% specificity), but could not distinguish between grades. Conclusion: We have developed an automated software, using low-resolution images to provide a rapid, easily performed, objective assessment of steatosis and fibrosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO676 DEVELOPMENT AND VALIDATION OF AN AUTOMATED SYSTEM FOR ASSESSMENT OF LIVER STEATOSIS AND FIBROSIS IN ROUTINE HISTOLOGICAL IMAGES FROM PATIENTS WITH NAFLD

Introduction: Liver biopsy is the reference standard for diagnosing and staging non-alcoholic fatty liver disease (NAFLD). Steatoasis grade and fibrosis stage are typically reported using semi-quantitative scores. Inter- and intra-observer variability in the current scoring systems may impact upon histological staging, and consequently upon the interpretation of responses to interventions in clinical trials.

Aims & Methods: We developed an automated method for steatosis and fibrosis quantification using biopsies of NAFLD patients. We further validated Liver Stiffness Measurements (LSM) and controlled attenuation parameter (CAP) in this group, using quantitative assessment as reference. 246 consecutive patients with biopsy-confirmed NAFLD and transient elastography within 3 months of the biopsy were evaluated. Biopsies were independently scored by two histopathologists and digitalised at 2x magnification. Areas of steatosis and fibrosis were annotated manually using the NDP.view2 to facilitate machine learning. Each image was then analysed by the automated software: fat percentage (%fat) and coefficient of Proportionate Area (CPA) computed by the software were compared with the manual annotation. They were also correlated with LSM and CAP.

Results: There was an excellent concordance between manual and automatic measurements, with inter-class correlation coefficient, ICC = 0.98, (95%CI = 0.96–0.99, p < 0.0001). There was good correlation between %fat and steatosis grade, but with significant overlap between groups. Results were similar between CPA and histological stage. LSM was significantly associated with CPA (Rho = 0.8, p = 0.001). CAP score correlated significantly with %fat (Rho = 0.45, p = 0.002) and effectively diagnosed steatosis > 5% (AUROC 0.82, 95% sensitivity, 60% specificity), but could not distinguish between grades. Conclusion: We have developed an automated software, using low-resolution images to provide a rapid, easily performed, objective assessment of steatosis and fibrosis in NAFLD, with excellent correlation with experts’ annotation. Objective measures would be helpful in the assessment of therapeutic response in clinical practice and in clinical trials for patients with non-alcoholic fatty liver disease.

Introduction: Today, nonalcoholic fatty liver disease (NAFLD) is the most prevalent form of liver disease and it is an increasingly frequent cause of cirrhosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

United European Gastroenterology Journal 5(S)
Aims & Methods: Aim of our study was to compare two non-invasive methods: fibroscan on serum markers and transient elastography (TE). We included 152 patients with NAFLD, 40 males (26.31%) and 112 females with age from 23 to 79 years.53 patients (23.02%) were overweight, 9 patients had normal weight and 24(15.79%) had severe obesity. In all patients we calculated FIB-4 scores: BARD, BIb-FS and NAFLD Fibrosis score (NAFLD-FS). Blood samples were collected to determine amionotransferases, glucose, albumin level, platelet count. The abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale. The same physician using conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when estimated cutoff of F2 was 7.1 kPa, severe fibrosis (F3) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value >12.5 kPa.

Results: 86.84% patients had metabolic syndrome and 51.31% had diabetes mellitus.40 patients had mild steatosis, 59 had moderate and 53 had severe steatosis. After we performed TE 69.07% of patients had no significant fibrosis, 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95%, CI 0.74-0.9). 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95%, CI 0.74-0.9). Sensitivity and specificity for cutoff 7.1 kPa was 0.74 respectively 0.79 to exclude significant fibrosis. NAFLD-FS correlated stastistic significant with TE (p < 0.0001). BARD score did not correlate with TE and NAFLD-FS for significant fibrosis.FIB-4 correlated with TE for high degree fibrosis (p = 0.004).

Conclusion: NAFLD-FS, FIB-4 and TE can be used together to evaluate the progression of fibrosis in NAFLD and to select the patients for liver biopsy. In our study BARD score was not useful in detection of high degree fibrosis.

P0679 EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) ON MORTALITY AND COMPLICATIONS VIZ. SEPSIS, ENCEPHALOPATHY, HEPATORENAL SYNDROME, AND GASTROINTESTINAL BLEED IN SEVERE ALCOHOLIC HEPATITIS: A RANDOMIZED CONTROLLED STUDY

A. Sharma

Gastroenterology And Hepatology, Fortis Escorts Hospital Jaipur, Jaipur/India

Contact E-mail Address: abhineet11005@yahoo.com

Introduction: Severe alcoholic hepatitis has very high short-term mortality. Compared to standard medical therapy (SMT), GCSF improves clinical and biochemical profiles, morbidity and mortality in these patients. We evaluated efficacy of G-CSF in modulating the disease course of severe alcoholic hepatitis over a period of 3 months in terms of mortality, morbidity by Discriminant function (mDF), Child–Turcotte–Pugh (CTP) and Model for End-Stage Liver Disease (MELD) score and various complications viz. sepsis, GI bleed, encephalopathy, hepatorenal syndrome (HRS) in comparison to SMT. We also studied the mobilising effect of GCSF on bone marrow stem cells measured by counting CD34+ cells from peripheral blood.

Aims & Methods: The present study was performed to evaluate the safety and efficacy of GCSF on mortality and complications viz. sepsis, encephalopathy, hepatorenal syndrome (HRS), and gastrointestinal bleed (GI Bleed) and also to investigate whether G-CSF therapy could improve the indices of severity of liver disease, such as Discriminant function (mDF), Child–Turcotte–Pugh (CTP), Model for End-Stage Liver Disease (MELD) score in patients with severe alcoholic hepatitis. 50 patients with severe alcoholic hepatitis were randomly assigned to groups A and B (25 in each). Both groups were given SMT, while in addition, patients in group A were given 5iu/kg GCSF subcutaneous (10 doses for 5 days). We assessed survival, changes in CTP, MELD and mDF scores and the development of complications till 90 days.

Results: The baseline parameters in both groups were comparable. On day 6 group A had higher mean leukocyte and CD34 counts than group B (p = 0.03). In 90 days follow up 17 patients in group A (68%) and 9 patients in group B (36%) survived (p = 0.04). Mean changes for different scores were greater in group A then group B i.e. CTP (~41.97% vs ~8.84%), MELD (~50.89% vs 10.09%) and mDF (~74% vs 18%) (p < 0.001). The percentages of patients who developed HRS, HE, or sepsis were lower in group A than in group B (28% vs 64%, 32% vs 64%, and 28% vs 68%, respectively) (p < 0.001). There was no significant difference in GI bleed in both groups.

Conclusion: In severe alcoholic hepatitis, GCSF therapy significantly improves the survival. It also significantly reduces CTP, MELD, and mDF scores and prevents the development of complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Steatosis/steatohepatitis is one of the most common liver diseases with increasing prevalence and results from excessive alcohol consumption (alcoholic liver disease) or nonalcoholic fatty liver disease (NAFLD). The differential diagnosis is of paramount importance as they have different management and therapeutic approaches, being liver biopsy the gold standard for establishing the diagnosis. The distinction between these two entities without biopsy is
difficult due to the unreliable history of alcohol consumption and lack of sensibility of a single marker. In order to overcome these difficulties, a C6 ANI (alcoholic liver disease/nonalcoholic fatty liver disease index) was created for a non-invasive determination of fatty liver diagnosis.

**Aims & Methods:** The aim of this study was to evaluate the reliability of ANI as a non-invasive diagnostic tool for NAFLD from ALD. A retrospective study between 2010 and 2015 in patients with definite diagnosis of NAFLD and ALD based on clinical, biochemical and histological criteria was performed. ANI scoring system in the differentiation of ALD and NAFLD was evaluated through the area under the receiver-operating curve (AUROC). ANI score was calculated through Mayo Clinic formula.

**Results:** This study was carried out in 22 patients with ALD and 120 with NAFLD, 87 men (61.3%) with a median age of 51 ± 13 years. NAFLD patients presented higher body mass index (BMI) of 28.9 ± 5.9 vs 23.9 ± 6 in ALD. ANI showed a sensitivity of 81% and specificity of 79% for the diagnosis of ALD with a cut-off value of -1.96 [AUROC 0.806 (0.715-0.898), p < 0.001]. ANI greater than -1.96 indicates a diagnosis of ALD whereas ANI less than -1.96 indicates diagnosis of NAFLD.

**Conclusion:** ANI scoring system is a non-invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for live biopsy. ANI greater than -1.96 suggests the diagnosis of ANI and ALD lesser than -1.96 suggest NAFLD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Iron-dependent cell death and its inhibitors can improve cell biochemical and lipid peroxidation, cytokines and mitochondrial dysfunction. Ferroptosis is an injury type that is not clear yet, and its pathogenesis is mainly related to oxidative stress, which is also increased year by year. However, the mechanism of alcohol-induced liver injury in China, alcohol consumption is growing and the incidence of alcoholic liver injury is growing public health problems. With the improvement of living standards in China, alcohol abuse and alcohol dependence have become the world’s major health problems. Alcoholism, hepatotoxic reactions were of grade I and in 2 (5%) – of grade II level, with no statistically significant changes in protein synthesis liver function. On the 56th day of treatment in 7 (15.9%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.8 times, AST – in 1.3 times, ALP – in 1.6 times, GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I. In group II hepatitis was detected in 26 (65%), which was characterized by the increased activity of ALT and AST in 2.6 and in 2.3 times respectively, GGT and ALP in 2.6 and 3.7 respectively, the level of total bilirubin increased in 3.6 times (p < 0.05), of which in 10 (25%) patients hepatocellular reactions were of grade I and in 16 (40%) – of grade II level.

Conclusion: The presence of the outcome results in a significant increase in the frequency and degree of hepatic reactions in patients with AL during chemotheraphy.

P0685 AMANITA PHALLOIDES HEPATOTOXICITY: 20-YEAR EXPERIENCE IN A GASTROENTEROLOGY INTENSIVE CARE UNIT
C. Atalaia Martins, J. Carvalheiro, P. Ferreira, P. Marques, I. Tomé Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra/Portugal
Contact E-mail Address: catarinataliaamartins@gmail.com

Introduction: Ingestion of amatoxin-containing mushrooms is a rare medical emergency. Amanita toxins cause massive hepatic necrosis and acute liver failure. Liver transplantation can be life-saving but liver transplantation criteria are complex and not consensual. Mushrooms poisoning is associated with a high mortality rate.

Aims & Methods: We conducted a retrospective analysis of demographic, clinical, therapeutic and prognostic data of all patients with Amanita phalloides poisoning admitted to a Gastroenterology Intensive Care Unit (GIUC) of a tertiary hospital between 1997 and 2017.

Results: A total of 27 patients were included: 55.6% were male and the mean age was 53 ± 15 years old (range, 16–75). The most frequent initial symptoms were vomiting (88.9%), diarrhea (70%) and abdominal pain (74.1%). The mean time between ingestion and onset of symptoms was 10.1 hours and GIUC admission was 59.0 hours. At admission 33.3% presented hepatic encephalopathy (25.9% grade 1; 3.7% grade 3 and 3.7% grade 4). Laboratory characterization at admission: mean INR was 4, total bilirubin 3.5 mg/dL, creatinine 1.9 mg/dL and factor V 25.8%. The different criteria for emergent liver transplantation were assessed: 37% (n = 10) met Child’s criteria. 59.3% (n = 16) met King’s College criteria, 35.3% (n = 9) met Gancz criteria and 40.7% (n = 11) met Escudé criteria. 44.4% (n = 12) of patients met at least one admission and 33% during hospitalization. Regarding specific medical treatment: 92.6% received siltibine, 59.3% acetacylethine and 48.1% penicillin. In the group of patients with emergent liver transplantation criteria, 63% were effectively transplanted. In the sub-group of patients who met criteria but were not transplanted (n = 6): in 66.7% (n = 4) the reason was absence of donor, in 16.7% (n = 1) there was liver function recovery and in 16.7% (n = 1) a contraindication was found (irreversible intestinal ischemia diagnosed intraoperatively). The mortality in this sub-group was 83.3%. The mortality rate in transplanted patients was 60%. All patients without emergent liver transplantation criteria survived.

Conclusion: Amanita phalloides poisoning has a severe and rapidly progressive presentation, often with indication for liver transplantation. Patients are admitted late to GIUC. Mortality rate remains high even in transplanted patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Binge drinking among young students is a risk factor for the development of alcohol use disorder. The aim of this study was to assess the prevalence of alcohol use disorder, its characteristics and factors associated with it.
Contact E-mail Address: gabriele.vassallo86@libero.it

Introduction: Binge drinking is a common pattern of alcohol consumption among young population. At present few data are available on the possible relationship between binge drinking and alcohol use disorder (AUD) in adolescent. The aim of this study was to assess drinking habits, patterns of alcohol consumption, smoking habits, use of illicit drugs, the prevalence of binge drinking and AUD among young students. The correlation between binge drinking and AUD was also investigated.

Aims & Methods: This study was performed on 2704 subjects attending high school. Questionnaires regarding socio-demographic data, anthropometric characteristics, pattern and amount of alcohol intake, smoking habits, use of illicit drugs, and physical activity were administered to students. Moreover Italian versions of AUDIT, STAI-Y1, STAI-Y2 and ZUNG scale were administered.

Results: Alcohol intake was reported by 2126 students (79%); among them 1278 subjects that reported binge drinking behavior than in those that did not report binge drinking (p < 0.0001).

Conclusion: Alcohol consumption and abuse among young students is alarming. Binge drinking behavior among young students seems to be very common and it seems a risk factor for the development of AUD.

Introduction: Severe alcoholic hepatitis (SAH) remains a condition which bears high mortality and morbidity rates, as well as high healthcare costs. This is why adequate selection of patients who will benefit the most from corticotherapy is of utmost importance. Although serum biomarkers are available (Maddrey Discriminant Function - MDF), the diagnostic of SAH relies on liver biopsy. Previous metabolomic studies have shown a core metabolic phenotype represented by decreased serum lysophosphatidylcholines (LPC) and increased serum bile acids that occurs relatively early in liver diseases regardless of etiology, and remains stable in their evolution, including liver cirrhosis and hepatocellular carcinoma (1). Our previous work also showed that decreased LPC levels are associated with alcoholic liver disease (ALD).

Aims & Methods: The aim of the study was to assess the metabolic profile of patients with ALD and to identify potential new biomarkers associated with severity. Between December 2015 and September 2016, 64 patients with biopsy proven AH were included (38 with SAH - MDF ≥ 32 and 24 with non-severe AH - MDF < 32). Fasting serum was stored at -80 degrees after centrifugation at 5000 rpm for 10 minutes. Specific purification protocol metabolomic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system, equipped with a Dionex quaternary pump delivery system and a Bruker Daltonics MaXis MS detection equipment (version 2012). Biostatistical analysis The chromatograms obtained were processed using CompassDataAnalysis_4.2 software (Bruker, Germany) and about 3000–4000 molecular masses were identified. Those data were further processed using ProfileAnalysis (Bruker, Daltonics): time alignment, normalization by sum of bucket values in analysis, 80% bucket filter, internal recalibration, etc. The matrix obtained was further processed through MetaBioAnalysis, to analyze samples through univariate and multivariate statistical analysis.

Results: Univariate and multivariate statistical analysis by MetaBioAnalysis identified 10 potential biomarkers. Among them, LPC (18.0) showed good discrimination for SAH (AUC = 0.804) with significantly lower values as compared with non-severe AH (0.38 fold change, p = 6 × 10^-11).

Conclusion: SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolomic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

3. Scott RA, Austin AS, Kolhe NV, McIntyre CW, Selby NM. Acute kidney injury (AKI) criteria (0.682 vs 0.533; 0.678 vs. 0.588; 0.618 vs. 0.509, p < 0.05) and higher in-hospital, 28 and 90-day mortality was significantly higher than the AUC of conventional hepatorenal failure staging (18.77% vs. 11.20%, p < 0.0001), urinary tract infection (13.13% vs. 8.68%, p = 0.0052) and sites of infections such as pneumonia (14.99% vs. 10.50%, p = 0.0111), peritonitis (14.29% vs 2.52%, p < 0.0001), sepsis (25.63% vs. 9.52%, p < 0.0001), biliary tract infection (7.14% vs. 3.22%, p = 0.0008) and cellulitis (11.62% vs. 3.98%, p = 0.0207) increased risk for HE. HE (adj HR, 0.90, 95% CI 0.76–1.06, p = 0.02) and infections (adj. HR, 1.13, 95% CI 0.93–1.38, p = 0.23) increased hazards of death but did not reach statistical significance.

Conclusion: This is the first reported case-control study of HE in Taiwan. The study provides further evidence that infections are strongly associated with HE development among patients with decompensated cirrhosis, and the hospitalization severity of liver disease and in-hospital and short-term mortality among patients with and without AKI. Compared the accuracy of the conventional criteria vs. ICA-AKI criteria in the prediction of mortality.

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and confirmed by computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal variceal bleeding or death.

Results: During the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49±12.2 years: 33 (68.7%) were males; 60.4% had viral cirrhosis; mean Child-Pugh score was 7.2±2.6 and mean follow up was 12.3±9.1 months (range 1–29 months). All the patients had occlusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, P=0.062), bleed related mortality (9.5% vs. 11.1%, P=0.027) and overall mortality (23.8% vs. 22.2%, P=0.044) respectively. Adverse events in carvedilol group were hypotension (n=2), requiring cessation of therapy, while and dyspnea (n=3) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 atrioventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to propranolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

Contact E-mail Address: smxavier@gmail.com

Introduction: The ALBI score was recently developed to assess the severity of liver dysfunction, taking into account albumin and bilirubin levels. We aimed to assess its prognostic performance in patients with liver cirrhosis complicated with upper gastrointestinal bleeding (UGIB) while comparing it with Child-Pugh (CP) and MELD scores.

Aims & Methods: Retrospective uncenter study, including consecutive adult patients with cirrhosis admitted for UGB between January 2011 and November 2015. Clinical, analytical and endoscopic variables were assessed and ALBI, CP and MELD scores at admission were calculated. Statistical analysis was performed using SPSS v21.0 and MedCalc v.16.4.3, and a two-tailed p value <0.05 was defined as indicating statistical significance.

Results: Included 111 patients with a mean age of 57±12 years, 76.6% were males. Liver cirrhosis was most frequently alcoholic (89.2%) and the most common etiology for UGIB was variceal hemorrhage, in 75.5% of patients. During the first 30 days of follow-up 10 patients died (1st year mortality of 10.8%). During the first year of follow-up another 10 patients died (1st year mortality of 19.8%). When comparing the three scores, regarding in-stay and 30 days mortality, only ALBI score showed statistical significant results, with an area under the curve (AUC) of 0.82 (p <0.01) for both outcomes. Regarding 1st year mortality, AUC for ALBI, CP and MELD scores, were 0.71 (p <0.01), 0.64 (p <0.05) and 0.66 (p=0.02), respectively, while for global mortality AUC were 0.75 (p <0.01), 0.72 (p <0.01) and 0.72 (p <0.01), respectively. When comparing the AUC of the three scores, no significant differences were found regarding 1st year mortality and global mortality.

Conclusion: In our series, ALBI score accurately predicted both in-stay and 30 days mortality (0.82 (p <0.01)), while CP and MELD scores weren’t able to predict these outcomes. All scores showed a fair prognostic prediction performance regarding 1st year and global mortality. These results suggest that ALBI score is particularly helpful in the assessment of short term outcomes, with a better performance than the most commonly used scores, and may assist the clinician in the stratification of care at admission and maybe even in the referral to liver transplant.

Contact E-mail Address: gilda_i215@yahoo.com

Introduction: Portal vein thrombosis (PVT) is recognized as an independent factor of variceal bleeding. Beta blockers are the mainstay treatment to prevent variceal bleeding in cirrhotic patients. Carvedilol has been shown to be equal to propranolol in preventing first bleeding in cirrhotic patients, however, the efficacy of this policy in patients with PVT is unknown.

Aims & Methods: To investigate the clinical impact of subclinical high TRPG on survival after living donor liver transplantation. In cirrhosis patients, mPAP-FIO2<0.6 may not accurately reflect the congestive pressure to the liver, as the pressure might escape via a pulmonary shunt. Subclinical high TRPG is an important marker for predicting congestive pressure gradient is a risk factor for survival after living donor liver transplantation. Patients exhibiting a tricuspid regurgitation pressure gradient (TRPG) >15 mmHg were categorized as potential candidates for OLT and were accepted not only for deceased donor LT (DDLT), but also for living donor related LT (LDDLT). However, the post-OLT course of PHT complica-

**Introduction:**
Increased liver frequency (CFF values ≤39 Hz identify cirrhotic patients with minimal hepatic encephalopathy (mHE) and predict their risk of developing overt hepatic encephalopathy (oHE). However, these results have been obtained in cirrhotics with advanced liver disease suffering a previous episode of liver decompensation (74% of patients) or oHE (14% of patients).

**Aims & Methods:** Herein, we evaluated the effectiveness of CFF in predicting the first episode of oHE in compensated cirrhosis (DC).

**Results:** A total of 134 selected patients and 150 healthy subjects were evaluated using CFF. A CFF value was considered normal when ≥39 Hz and pathological when ≤39 Hz. At baseline, we evaluated demographic characteristics, laboratory tests, model for end-stage liver disease (MELD) score, and Child-Pugh class in all patients. Then, they were followed up for 31.5 ± 18.9 months and received clinical examinations and laboratory tests every six months.

**Results:** At baseline, all controls had a CFF >39 Hz with a mean value significantly higher than that observed in 93 patients with CFF <39 Hz (p < 0.001), while the remaining 41 patients showed a CFF ≥39 Hz. Our analysis demonstrated a significant correlation between CFF and MELD (r = 0.49, p = 0.0003), while the prevalence of CFF values <39 Hz significantly increased with the progression of the Child-Pugh class (p = 0.003). Interestingly, the CFF value at baseline was predictive of the first episode of HE both by log-rank test (p = 0.001) and Cox regression analysis (HR = 5.623; 95% CI = 2.433, 12.991; p < 0.001).

**Conclusion:** We demonstrated, for the first time, that CFF predicts the first episode of oHE in a population of compensated cirrhotics that never experienced HE. Cirrhotic patients should be routinely screened by CFF to identify patients at risk of oHE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**
randomized to placebo or LRGG treatment, for 2 months. In all intention to treat and per protocol patients, demographic characteristics, laboratory test, model for end-stage liver disease (MELD) score, and Child-Pugh class were evaluated.

**Results:** CFF value increased in both LRGG and placebo groups at the end of 2 months. In all intention to treat and per protocol patients, demographic characteristics, laboratory test, model for end-stage liver disease (MELD) score, and Child-Pugh class were evaluated.

**Conclusion:** The risk of development of chronic HCV infection was associated with T allele carriage of TLR3rs3775291 SNP. While the carriage of C allele of TLR7 rs3853839C allele was associated with spontaneous HCV clearance in both male and female subpopulations in Egyptian families. Disclosure of Interest: All authors have declared no conflicts of interest.

**P0704 IMPROVEMENT OF LIVER STIFFNESS VALUES MEASURED BY TRANSITION ELASTOGRAPHY AFTER CHRONIC HEPATITIS C TREATMENT WITH DIRECT ACTION ANTIVIRALS AND EVOLUTIVE CORRELATION OF THROMBOCYTOPENIA AND PRESENCE OF ESOPHAGEAL VARICES**

M. Perez Ferrer,1 I. Maestro Prada,2 A. Mcgee,2 J.L. Castro Urda,1 L.A. Castillo Hernandez,1,2 C. Garcia Ramos1

1Gastroenterology, Hospital Severo Ochoa, Leganes/Spain
2Epidemiology, University Historiario Móstoles, Móstoles/Spain

**Introduction:** Improvement in liver stiffness (LS) measured by transient elastography (TE) has been observed in patients with chronic hepatitis C treated with direct action antivirals (DAA).1,2 The Baveno VI guidelines1 propose that patients with compensated advanced chronic liver disease (cACLD), LS measurement <20 kPa and a platelet count ≥150,000/μL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant oesophageal varices (EV).3 These improvements have been validated recently.4

**Aims & Methods:** The aim of this study was to quantify LS and thrombocytopenia (quantitatively (measured in Kilopascals) and qualitatively (Stages of F0–F4 fibrosis) in a stationary phase after the sustained virological response (SVR) in patients with cACLD (14). The secondary objective was to assess whether this improvement in LS measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI Criteria.

**Results:** 84 patients (49 men and 35 women) with cACLD were included in the study. Median TE on baseline (BL) prior to DAA treatment was [mean (range), 23.86 (12.5–75) kPa] and decreased to [mean (range), 15.6 (4.8–75) kPa] at SVR 24 and [mean Range], 16.19 (3.62–75) kPa] at SVR > 54. Both were statistically significantly lower showing a decrease in LS around 30% between BL and SVR 24 and 44% between BL and SVR > 54. We did not find any statistically significant differences between SVR 24 and SVR > 54. Regarding the probability of qualitative improvement of the LS (improve from F4 to F3 or less) the AUC was 0.8 with 17.9 kPa as the cut-off point which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12, PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15 kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV). 17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with big EV). There were only 3 cases of EV misdiagnosed by Baveno VI Criteria. We did not find any significant differences in platelet levels or in the regression of varices.

**Conclusion:** This study validates improvement in LS measurements as a useful tool in the clinical management of the patient. The Baveno VI criteria are a useful tool in daily practice to avoid unnecessary UE. Further investigation with larger samples is needed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Although the conventional IFN-based therapy has made a significant achievement in treating patients with hepatitis C virus (HCV), including the preventive effect of hepatocarcinogenesis after achieving sustained virological response (SVR), patients intolerant of IFN, such as those with advanced age or liver cirrhosis (LC), could not savor its privilege. The appearance of direct-acting antivirals (DAAs) provided almost every patient with the chance to receive the treatment without any serious adverse effects (AEs). In addition, SVR could be highly expected in more than 95% of patients treated with DAAs. However, the preventive effect of DAAs for the future hepatocarcinogenesis following eradication of HCV remains unknown. In our facility, the association of DAAs to hepatic fibrosis stage (F) and development of hepatocellular carcinoma (HCC) within 2 years after achieving SVR.

Aims & Methods: We evaluated the clinical features of patients developing HCC after confirming SVR with DAAs against HCV. One hundred and fifty-three patients achieving SVR defined as negative HCV-RNA 12 weeks after cessation of DAA (oral combination therapy with Daclatasvir/Asunaprevir, Ombitasvir/Paritaprevir/Ritonavir, Sofosbuvir/Ledipasvir, or Sofosbuvir/Ribavirin) were enrolled in this study. No gender, male/female: 79.2, genotype: 2/2 122/31 chronic hepatitis/ LC 124/29, PLT 15.3 ± 0.5 × 10^12/L, ALT 44.9 ± 3.6/19.5 ± 1.1 IU/L, APRI 1.3 ± 0.4/0.7, Wisteria floribunda agglutinin positive M2-binding protein (WFA(þ/þ)-M2BP) 3.3 ± 0.5 COI, ALP 12.1 ± 2.4 mAU/mL, PI-IVK 28.8 ± 4.3 mAU/mL. All patients were divided into 2 groups (A: 9 patients with HCC developing after SVR achievement, B: 144 without HCC after achieving SVR). Serum parameters (PLT, WFA(þ/þ)-M2BP, FIB-4 index, APRI, ALT, ALB, AFP, PI-IVK) and age were evaluated between 2 groups. Results: In group A, significant declining (pre-DAA treatment/the time of achieving SVR) was observed in ALT (44.9 ± 3.6/19.5 ± 1.1 IU/L), APRI (1.3 ± 0.4/0.7), WFA(þ/þ)-M2BP (3.3 ± 0.5/0.7 COI), FIB-4 index (3.7 ± 0.2/0.7 COI) and APRI (1.2 ± 0.1/0.7 ± 0.5), and significant increase in ALB (44.9 ± 3.6/19.5 ± 1.1 IU/L) and PLT (44.9 ± 3.6/19.5 ± 1.1 IU/L). In group A, significant declining was observed only in ALT (45.3 ± 10.9/16.7 ± 2.2 IU/L). This result indicates that DAA treatment significantly ameliorates parameters related with hepatic fibrosis as well as hepatic inflammation in group A. However, it led to the significant amelioration only in the parameters related with hepatic inflammation in group A. Next, focusing on parameters after achieving SVR, WFA(þ/þ)-M2BP (A: 3.4 ± 0.6/B: 1.7 ± 0.2 COI) and FIB-4 index (5.7 ± 1.8/3.1 ± 0.2) were significantly higher and Apri (0.6 ± 0.4/1.1 ± 0.3) were higher and Alb (3.8 ± 0.2/4.0 ± 0.3 g/dL) was significantly lower in group A comparing with group B. When dividing group A into 2 groups (C: new occurrence of D: recurrence), APRI (3.0 ± 1.3/2.7 ± 1.2 COI) and FIB-4 index (3.7 ± 1.8/2.4 ± 1.6 ± 0.2) were significantly lower and Alb (44.9 ± 3.6/1.1 ± 0.3 ± 0.4 g/dL) were lower in group D than group C, although no significant difference was seen between 2 groups. This result suggests that there might be more patients with progressive hepatic fibrosis in group D comparing with group C. Finally, when univariate analysis showed WFA(þ/þ)-M2BP, FIB-4 index and Alb were significantly associated with the development of HCC after achieving SVR with DAA against HCV, multivariate analysis revealed only Alb was the significantly independent factor contributing to HCC development after SVR achievement. Conclusion: Low level of serum albumin as well as the progression of hepatic fibrosis could be associated with the development of HCC after confirming SVR with DAA to HCV. Disclosure of Interest: All authors have declared no conflicts of interest.

P0707 EARLY OCCURRENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HEPATITIS C VIRUS TREATED WITH DIRECT-ACTING ANTIVIRALS

Department Of Surgery, Hyogo College of Medicine, Nishinomiya/Japan

Contact E-mail Address: shai1005@hyo-med.ac.jp

Introduction: Direct-acting antivirals (DAAs) are novel antiviral drugs for hepatitis C virus (HCV) and have enabled the achievement of a high rate of sustained
virological response (SVR) [1]. However, the impact of DAAs on the occurrence of hepatocellular carcinoma (HCC) and HCC recurrence after curative hepatic resection of HCC has been recently discussed [2, 3], but remain unclear.

Aims & Methods: The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and January 2016 were reviewed to clarify the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

Results: SVR was achieved in 21 patients treated with interferon (IFN)-based regimens of DAAs with IFN at hepatocytome. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: –123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 35 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatocyte, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.3% and 83.0% in patients after SVR treated with DAAs (n = 25), 90.9% and 71.8% in patients with IFN-based regimens (n = 26) and 57.8% and 19.7% in patients without SVR (n = 46), respectively, regardless of the timing of hepatocyte, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR (p < 0.05), but was not markedly different according to the antiviral treatments (p = 0.504).

Conclusion: While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

P0708 EFFICACY AND SAFETY OF SOFOBUVIR AND RIBAVIRIN IN HCV POSITIVE PATIENTS WITH RENAL IMPAIRMENT
M.O. T. Butt
Gastroenterology And Liver Transplant, Shifa International Hospital, Islamabad, Islamabad\Pakistan

Contact E-mail Address: mosamabutt2016@gmail.com

Introduction: Hepatitis C virus infection is a leading cause of chronic liver disease affecting more than 170 million people worldwide. HCV infection in the setting of renal impairment is not uncommon. Despite the major developments in the treatment of HCV, treatment of this sub group of patient with impaired renal function is still a challenge.

Aims & Methods: The aim of this study is determine the efficacy and safety of sofosbuvir and ribavirin in HCV positive patients with renal impairment. All consecutive patients of HCV related liver disease with creatinine clearance less than 50 ml/min were included in the study. Data was collected for tolerability, efficacy and on treatment adverse event. The patients received sofosbuvir and dose adjusted Ribavirin according of CrCl. Virological response was checked at 1 month (RVR), 3 months (EVR) and at the end of treatment.

Results: A total of 31 patients were included in the study were 31 out of which 17(54.8%) were male. Mean age was 52.23 ± 17.6 years while the mean BMI was 25.0 ± 4.3 kg/m2. 10 (32.25%) patient were on regular hemodialysis. 26 (83.9%) patients had CTP-A while 5 (16.1%) had CTP-B disease. Majority of the patients received each Interferon and Peg interferon therapy. Treatment was stopped in 2 (6.5%) patients because of disease decompensation while 3 (9.7%) were lost to follow up. ETR was achieved in 25 (96.1%) out of 26 patients who completed treatment. Similarly 12 (80.0%) out of 15 patients had achieved SVR-12 so far. During the therapy 10 (32.3%) patients had adverse events, 6 (19.4%) suffered from depression while 4 (12.9 %) developed grade II anemia.

Conclusion: In resource constraint population where newer DAAs are not available an combination of sofosbuvir and low-dose ribavirin in patients with renal impairment seems to be better tolerated and efficacious in terms of achieving the virological response.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

Aims & Methods: The aim of this study was to assess HRQoL impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACIT- F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched according to sex and age with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.

Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT- F utility scores (43.2 ± 35. vs 49.5 ± 35.5, p < 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6% (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs. 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2; p < 0.05) compared to the study group.

Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

P0710 SOFOBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS. AN EXPERIENCE FROM TERTIARY CARE HOSPITAL
A. A. Langakah
Gastroenterology Section, Medical Unit Iv, Jinnah Postgraduate Medical Centre, Karachi Pakistan

Contact E-mail Address: dralaikbar12@gmail.com

Introduction: Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advent of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the cornerstone in treat-ment of HCV. Most trials have been conducted in HCV genotype 1 and data for Interferon free regimens in genotype 3 (GT-3) is limited especially in cirrhosis.

Aims & Methods: We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RIB) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response after 6 months of completion of treatment. Adverse events were recorded on designed proforma on serial follow-up visits.

Results: The cohort consisted of 9 1consecutive patients out of which 41 were compensated cirrhotics and 50 had decompensated cirrhosis. The mean age was 53.4 ± 11years. Males were 47 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84.4%) treatment naive patients compared to treatment experi-enced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naïve patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 g/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.

Conclusion: Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

P0714 UTILITY OF A NEW FUNCTION IN 3D SIM-NAVIGATOR: ELECTRIC FIELD, WHICH INDICATES THE PREDICTED

Gastroenterology And Hepatology, Osaka Red Cross Hospital, Osaka;Japan
Introduction: The presence of fat droplets in the hepatocytes (micro- or macro-vesicular hepatic steatosis) under condition of chronic diffuse liver disease (CDLD) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM) for the selective detection of liver. Hypothesis: The ACM as novel real-time ultrasound approach can be used for noninvasive hepatic steatosis diagnosis, allows clinicians to monitor disease progression and response to treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The presence of fat droplets in the hepatocytes (micro- or macro-vesicular hepatic steatosis) under condition of chronic diffuse liver disease (CDLD) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM) for the selective detection of liver.

Aims & Methods: From total of 327 patients who underwent to comprehensive abdominal US scan and 90 of them were diagnosed with CDLD liver, according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement on SonoelP device (Ultrasin, Ukraine), with a 1–6 MHz convex transducer in the right and left lobes. For diagnostic accuracy assessment (used ACM standard), a correlation with CAP measured by Fibroscan (Echosens, France) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed using ROC-analysis.

Results: On the stage of steatosis according to B-mode median, 25 and 75%, the ACM is as follows: control group 1.57 (1.32–1.85), B-mode 1.51 (1, 1.78–2, 11), S2–2, 26 (20, 00–2.49) and respectively for S2–2, 7 (2, 00–2, 82) dB/cm. ACM value increase parallel the hepatic steatosis progression (p < 0.001), which was also accompanied with presence of very strong correlation between these parameters (r = 0.814, p < 0.001). In patient with NAFLD the association between maximum value of ACM and duration of T2DM and triglycerides (model 1, multiple correlation coefficient = 0.55; R² = 0.26; p = 0.004) and ALT (model 2, multiple correlation coefficient = 0.55; R² = 0.25; p = 0.005) were observed. After adjustment by the duration of T2DM the level of triglycerides (r = 0.44, p = 0.012) and activity of ALT (r = 0.44, p = 0.012) significantly correlated with ACM. The AUROC of ACM for steatosis diagnosis was 0.925 (95% CI 0.877–0.973). The optimal cutoff point was >2.2725 dB/cm, with sensitivity, specificity, PPV and NPV respectively 91.5, 77.3, 84.6 and 83.8%. ACM value prove significantly correlated with CAP (r = 0.630, p < 0.001).

Conclusion: The ACM as novel real-time ultrasound approach can be used for noninvasive hepatic steatosis diagnosis, allows clinicians to monitor disease progression and response to treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe. It favors the tumor support and angiogenic factors. Its aberrant expression in tumor turns its role as foe. It favors the tumor formation and angiogenesis.

Aims & Methods: Here, we show CUX1 activity during hypoxia in liver cancer cells. CUX1was knocked down and its targets were analysed by RT-qPCR in Hep3B cells under hypoxic and/or normal culture condition. The hypoxia condition was established by 24h treatment with 150 μM CoCl2 or with 0.5% O2 atmosphere. Hypoxia markers and CUX1 were analysed by RT-qPCR in Hep3B cells under hypoxic and/or normal culture condition.

Results: Hypoxia determined the up-regulation of HIF-1α (Hypoxia inducible factor-1-alpha) and a stable or up-regulated expression of its inhibitor FH1 (SLC2A1) up to 24 h prolonged hypoxia. VEGFA was significantly
overexpressed. Knock-down of CXU1 determined a significant down-regulation of HIF-1alpha, FHL-1 and VEGFA. Interestingly, the expression of CDKN1A was only attenuated after CXU1 knock down and hypoxic stress. HIF1alpha transcriptional activity is dependent by CXU1 expression.

Conclusion: CXU1 exerts an oncogenic role in liver cancer by sustaining the survival machinery of hypoxia. CXU1 silencing results in suppression of the hypoxia inducible factor and its target VEGFA causing a block of cell cycle in liver cancer cells modulated by the stable expression of CDKN1A.

Introduction: S-Adenosylmethionine (SAMe) is a kind of common liver-protecting medicine. Recent studies have shown that SAMe has the inhibitory effects on human hepatocellular carcinoma (HCC). But the specific mechanism has not been elucidated.

Aims & Methods: Here, we examine the effects and relevant mechanism of SAMe on human hepatocellular carcinoma cell HepG2 and mouse hepatocyte AML12. SAMe was treated with HepG2 cells which were treated with SAMe or not. And we used Western blot and QRT-PCR to confirm some of these genes. MTS and flow cytometry-based assays were carried out in response to SAMe treatment.

Results: A total of 472 SAMe-related genes were identified by RNA-Seq. We found that differentially expressed genes were enriched in cell cycle related signaling pathway significantly by the KEGG and GO Pathway enrichment analysis. Through the construction of protein-protein interaction network, we observed the module associated with cell cycle is in the middle of the whole network. All these results implied that cell cycle pathway may play a very important role in the regulation of SAMe effect on HepG2 cells. Then the RNA-Seq-characterized genes involved in cell cycle (MCM3, MCM4, and E2F1) were confirmed by Western blot and QRT-PCR in HepG2 and AML12 cells. MTS analysis showed that SAMe could diminish cell proliferation. And flow cytometry-based assays indicated that treatment with SAMe altered cell cycle kinetics S phase cell cycle arrest.

Conclusion: Altogether, our data enforce the evidence of SAMe possessing of antiproliferative action in liver cells, capable of up-regulating MCM3, MCM4 and E2F1 and cell cycle inhibition, and provide an important theoretical basis for the clinical chemoprevention and treatment in HCC of SAMe.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
Conclusion: Our results support the hypothesis that overexpression of BRG1 increases cell growth and cell invasion in HCC. Furthermore, the data highlight genes promoting proliferation and invasion that are being regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB, D, E and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.

P0720 PROGNOSTIC ROLE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN HEPATOCELLULAR CARCINOMA (HCC)

Sahloul, Sousse/Tunisia

Contact E-mail Address: Elleeuchghorbel.nour@yahoo.fr

Introduction: Inflammation may play an important role in progression, and a high neutrophil-to-lymphocyte ratio (NLR) has been reported as a poor prognostic indicator in several malignancies.

Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepatogastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33–87 years). The sex ratio was 3.22 (M/F = 58/18). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (43 patients-62.3%), hepatitis C virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice (P < 0.05). Otherwise, high NLR was significantly correlated with the presence of vascular invasion (P = 0.002), lymph node metastasis (P = 0.04), tumor multifocality (P = 0.01) and higher incidence of AFP > 200 ng/ml (P = 0.04).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0721 REIC/DKK-3 PROTEIN CONCENTRATION INDUCE THE POSITIVE EFFECT TO THE MORTALITY OF HEPATOCELLULAR CARCINOMA

A. Ohyama, D. Uchida, H. Shiraha, H. Sawahara, H. Kato, H. Okada

Gastroenterology And Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City/Japan

Contact E-mail Address: at841205@gmail.com

Introduction: The Wnt/b-catenin plays essential roles in the growth of hepatocellular carcinoma (HCC). The Dickkopf (Dkk) protein family (Dkk1-4) is known to inhibit Wnt signaling. REIC/Dkk-3, one of the Dkk family members, is known to negatively regulate Wnt/b-catenin signaling in various tissues, and particularly in the liver. We have previously reported that REIC/Dkk-3 protein expression tended to be declining in liver cancer patients with poor prognosis.

Results: In the present study, we measured the concentration of REIC/Dkk-3 protein in peripheral blood by ELISA in a total of 80 HCC patients and 50 healthy controls. The serum level of REIC/Dkk-3 protein was significantly higher in the HCC group compared to the control group (P = 0.04).

Conclusion: Our results suggested that REIC/Dkk-3 protein may be a prognosis marker in HCC patients. Further study is necessary with more number of HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0722 SURGICAL OUTCOME OF PATIENTS WITH FIBROLAMELLAR HEPATOCELLULAR CARCINOMA: DOES IT DIFFERS FROM COMMON HEPATOCELLULAR CARCINOMA?

E. El-Hanafy

Facultu Of Medicine, Mansoura University, Gastroenterology Surgical Center, Cairo/Egypt

Contact E-mail Address: dr_elah_elhanafy@yahoo.com

Introduction: Fibrolamellar hepatocellular carcinoma (FL-HCC) has conventionally been considered to be a histologic variant of hepatocellular carcinoma (HCC), with distinct clinicopathologic features. It is a rare primary hepatic malignancy that was first described as a pathological variant of HCC by Edmondson in 1956 [1]. The etiology of FL-HCC remains unclear. It typically occurs in normal livers without underlying liver fibrosis or cirrhosis [2]. In contrast to HCC which usually found in the presence of cirrhosis or chronic hepatitis [3], FL-HCC has been reported to occur in association with focal nodular hyperplasia (FHN) a type of benign liver lesion. Many series have mentioned that FL- HCC is less aggressive than conventional HCC [4]; however, other studies have failed to confirm the observation of a better outcome in FL-HCC [5]. Other studies reported that the survival was similar between common HCC and FL-HCC, and that may be related to the higher resectability rate which improve the survival of patients with FL-HCC [6].

Aims & Methods: The aim of this study was to evaluate the clinicopathological features and the surgical outcomes of patients with FL-HCC who were referred to our tertiary referral center over a 15-year period. This is a retrospective study including 22 patients with a pathologic diagnosis of FL-HCC who underwent hepatectomy over a 15-year period. Tumor characteristics, survival and recurrence were evaluated.

Results: There were 11 male and 11 female with a median age of 29 years (range from 21 to 58 years). Two (9%) patients had hepatitis C viral infection and only 2 (9%) patients had alpha-fetoprotein level > 200 ng/mL. The median size of the tumors was 12 cm (range from 5–20 cm). Vascular invasion was detected in 5 (23%) patients. Four (18%) patients had lymph node metastases. The median follow up period was 42 mo and the 5-year survival was 65%. Five (23%) patients had a recurrent disease, 4 of them had a second surgery with 36mo median time interval. Vascular invasion is the only significant negative prognostic factor.

P0724 MICROWAVE VERSUS RADIOFREQUENCY THERMAL ABLATION OF HEPATOCELLULAR ADENOMA: SAFETY AND EFFICACY

Introduction: Hepatocellular adenoma (HCA) is a rare benign tumor of the liver that typically presents in women within their reproductive years. The recent increase in the HCA prevalence is noticeably associated with the rising prevalence of obesity and the metabolic syndrome. Because of high risk of complications such as hemorrage, rupture and malignant transformation, appropriate treatment strategy should be considered. Given the success of image-guided ablation in treating malignant hepatic tumors, there is increased interest in treating benign masses with percutaneous ablation.

Aims & Methods: To investigate the efficacy and safety of Microwave versus Radiofrequency Ablation in management of HCA. Out of 320 Patients presented with hepatic focal lesions over 1 year, data of 15 patients diagnosed to have HCA were collected retrospectively. The diagnosis of HCA in those patients was based on radiological findings using triphasic pelvi-abdominal CT, dynamic MRI or cytopathological examination of FNAC for those whose radiological findings were not conclusive. The size of the all tumors was ranged between 2.5 to 3.4 cm. Tumors were selected for treatment by percutaneous ablation after review at a multidisciplinary that included radiologist, hepatologists, hepatobiary surgeons. Decisions to pursue percutaneous ablation therapy were based on a multidisciplinary discussion of multiple factors, including patient preference, number and location of tumors impacting the extent of a possible liver resection and hepatic reserve and the decreased morbidity compared with surgery. The number and location of tumors impacting the extent of possible liver resection.

Contact E-mail Address: el_naqeeb@yahoo.com

Conclusion: Percutaneous ablation of HCA using Microwave or Radiofrequency thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA. Of note Microwave ablation is much more efficient in treating larger lesions through single puncture in contrast to Radiofrequency which needs more than one puncture.

P0725 METABOLIC DISORDERS ACROSS HEPATOCELLULAR CARCINOMA IN ITALY

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the natural history of HCC patients is not established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.LI.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hypertriglyceridemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features (p=0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups. Diabetic patients showed a lower survival (p=0.046). MELD score, HCC

References

P0726 LIVER VOLUME AS A PREDICTOR OF RISK FOR HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS C PATIENTS
N. Kang, J.W. Chung, J. Kim
Internal Medicine, Seoul National University Bundang hospital, Seong-Nam city/Korea, Republic of

Contact E-mail Address: namkyunym@gmail.com

Introduction: Chronic hepatitis C virus (HCV) infection pose risk for develop-
ment of hepatocellular carcinoma (HCC), even after viral eradication with effec-
tive antiviral therapy. Therefore, risk prediction is clinically important for effec-
tive surveillance of chronic hepatitis C (CHC) patients, but up to now, risk predic-
tion of HCC remains unsolved compared to chronic hepatitis B. The liver volume has been reported to correlate with the severity of liver cirrhosis, but it is not known whether decreased liver volume predicts the HCC risk in CHC.

Aims & Methods: The aim of this study was to assess the significance of liver volume in the prediction of HCC risk in CHC patients. A retrospective cohort of 101 CHC patients who received 4-phase dynamic CT imaging studies during surveillance for liver volume and outcome of surveillance. Liver volumes were measured on portal venous phase of CT image and corrected for body weight and height: liver volume index (LVI) = ratio of the expected stan-
dard volume to the measured liver volume. Kaplan–Meier analysis with the log-
rank test used to compare HCC. Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with decreased liver volumes. Presence of liver cirrhosis was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show-
that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CL: 12.44–244.28, P < 0.001; HR: 3.10, CL: 1.26–7.51, P = 0.012, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0727 HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELULAR CARCINOMA TREATED WITH SORAFENIB
M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hirai
Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact E-mail Address: masaochiphi@hotmail.co.jp

Introduction: Sorafenib is a multi-thyrosine kinase inhibitor classified as a neo-
vascularization inhibitor. A previous study indicated that the administration of a thyrosine kinase inhibitor, cetuximab, significantly prolonged the patient survival, except for diabetes.

Skin toxicity of sorafenib was evaluated in patients with HFS. HFS grading was conducted according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.0. Patients with grade 1 or higher dermal disorder were regarded as having HFS, and grade 0 patients as not having HFS. For HFS evaluation, a double-check system was adopted: primary evaluation based on a specific evaluation sheet at the Pharmacists’ Outpatient Clinic and final evaluation by physicians at the outpatient clinic. We examined the influence of HFS on the effects of treatment after the introduc-
tion of sorafenib in 42 patients with a history of multidisciplinary treatment, such as transcatheter arterial chemobloembolization (TACE), between May 2009 and March 2017.

Results: Grade 1 or higher HFS was observed in 22 patients (53%), and it was absent in 20 (47%). Overall, the median sorafenib administration period was 2.1 months. In the HFS-free and HFS groups, it was 0.9 and 2.7 months, respectively (P < 0.001). Survival analysis was performed using the Kaplan–Meier method. Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively (P = 0.001). Multivariate analysis showed that liver volume index (LVI) of HFS was an independent factor (hazard ratio, 0.41; 95% CI, 0.19 to 0.88; p = 0.023) and administration period (hazard ratio, 0.45; 95% CI, 0.20 to 0.98; p = 0.045) were significant predictive factors. The following were not significant predictive fac-
tors: age, BCLC staging, dosage, and tumor markers.

Conclusion: The prognosis of hepatocellular carcinoma patients receiving sorafe-
nib treatment was closely related to the presence of HFS and administration period. HFS was a predictor of outcome in patients with hepatocellular carci-
noma treated with sorafenib. This study indicated that a multi-thyrosine kinase inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated for cetuximab. HFS reduces the quality of life (QOL), and it is a sorafenib adminis-
trating-inhibiting factor. In our hospital, a system for patients to initially con-
sult the Pharmacists’ Outpatient Clinic, followed by the feedback of grade-based HFS control strategies to physicians at the outpatient clinic, was established.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Rabat, Ibn Sina Hospital, Rabat/Morocco

Contact E-mail Address: Ibtissamnakihcha@gmail.com

Introduction: Hepatocellular carcinoma is the most common primary tumor of the liver and is estimated to cause more than a quarter of a million deaths each year throughout the world. Extrahepatic metastasis of HCC occurs in about 30–50% of patients, and it depends on HCC stages.1 The most frequent site is lung, followed by lymph node, bone, and adrenal gland.2 Extrahepatic metastases to unusally sites from HCC have been reported in a few case reports. We report cases of patients with unusual extrahepatic metastatic sites from HCC.

Aims & Methods: We carried out a retrospective study of 16 patients with unus-
al metastasis of hepatocellular carcinoma out of 1047 cases of HCC treated at the hepatagastroenterology department "Medical C" of the IBN SINA University Hospital during the past 22 years. The diagnosis was suspected based on clinical signs and imaging data, and confirmed by histology when the biopsy of the metastasis was possible, were excluded from this study, patients with lung metastasis, lymph node and portal thrombosis.

Results: Our study included 16 patients, 10 men and 6 women with a mean age of 58.5 years ranging from 37 to 75 years. 13 patients had cirrhosis due to hepatitis C virus, 1 patient had a cirrhosis due to viral B infection and 2 patients had HCC with annciorrhic liver. All patients had one or more HCC, ranging in size from 2 to 10 cm. The AFP was normal in 11 cases and elevated in 4 cases (>200 ng/mL). We collected 4 cases of adrenal metastases, 3 costovertebral metastases, 2 gastric metastases, 2 brain metastases, 1 cranial metastasis, 1 cla-
vicular metastasis, 1 ovarian metastasis, 1 nasopharyngeal metastasis, and a case of metastasis in the path of percutaneous biopsy of HCC. In 4 cases the diagnosis of HCC and metastasis was synchronous while in 12 cases median time from diagnosis of hepatocelel carcinoma to extrahepatic HCC was 15.5 months.

Conclusion: The incidence of unusual and extrahepatic metastasis of HCC diag-
nosed during clinical course was not frequent. The diagnostic procedures for extrahepatic metastasis were standardized, however considering the substantial advances in treatment of HCC, the detection of extrahepatic HCC is crucial for patients to receive appropriate therapy, which ultimately determines patient survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0730 EPIDEMIOLOGICAL STUDY OF HISTOLOGICALLY PROVEN ADVANCED HEPATOCHOLANGIOCARCINOMA: AN AGED MULTICENTER RETROSPECTIVE STUDY IN FRANCE

Introduction: Hepatocholangiocarcinoma is a rare primary hepatic tumor com-
bining features of both, cholangiocarcinoma and hepatocellular carcinoma (CHC-ICC). Few data concerning the epidemiology of hCHC-ICC have been reported, mainly from surgical series in Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of historically proven advanced CHC patients in a French population. Data from patients treated for historically proven CHC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients were included (76.6% of men, median age 64 years [extreme 37–88]. Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively,
P0731 A PROPOSAL FOR MODIFICATION OF BARCELONA CLINIC LIVER CANCER SYSTEM FOR HEPATOCELLULAR CARCINOMA STAGING BASED ON KOREAN MULTICENTER REGISTRY DATABASE

J. Cheong, H. Cho
Gastroenterology, Ajou University Hospital, Suwon/Korea, Republic of Korea

Contact E-mail Address: jaeyoun620@gmail.com

Introduction: Barcelona Clinic Liver Cancer (BCLC) C stage is defined as patients with preserved hepatic function and one of those adverse predictors including performance status (PS) 1–2, vascular invasion (VI), or extrahepatic spread (EHS). Therefore, BCLC C demonstrates extreme heterogeneity because patients with PS 1–2 are categorized to BCLC C regardless of tumor burden, VI or EHS. This study aimed to modify BCLC system based on PS to derive more relevant staging system.

Aims & Methods: A total of 7501 subjects, who were registered in Korean Liver Cancer Study Group during the period 2008–2013, were analyzed. Kaplan-Meier analysis was used to compare overall survival (OS). The relative goodness-of-fit between staging system was compared by Akaike information criterion (AIC) and integrated area under the curve (iAUC).

Results: Two modified BCLC (mBCLC) systems (#1 and #2) were derived by reducing role of PS in BCLC system. The patients with PS 1 or 2 without VI or EHS were reassigned to stage 0, A, or B according to their tumor burden. Prognostic accuracy was compared between mBCLC systems and original BCLC by AIC and iAUC. As a result, mBCLC#2 system identified as most explanatory and desirable model for HCC staging by showing smallest AIC value (AIC = 70888.01) and largest iAUC (iAUC = 0.722), while original BCLC showed the biggest AIC value (AIC = 70897.17) and smallest iAUC (iAUC = 0.705). The mBCLC#2 stage C was further sub-classified into C1, C2, C3 and C4 according to the variables which selected by statistical and clinical importance. The C1-C4 sub-groups showed significant different OS distribution between groups (P = 0.001). The mBCLC#2 stage C was further sub-classified into C1, C2, C3 and C4 according to the variables which selected by statistical and clinical importance. The C1-C4 sub-groups showed significant different OS distribution between groups (P = 0.001).

Conclusion: Modification of BCLC system based on PS derived accurate and relevant modified BCLC system for HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Microbiotas, as part of our bodies, actually affect the body's metabolism, defense and digestion. Gut microbiotas are the typical examples and they are mainly regulated by bile acids. Each bile acid has different properties, and the inhibition or promotion effects of microbiotas are very diverse. Each individual has a characteristic microbial distribution and composition within the intestinal tract, presumably related to the composition of their respective characteristic bile acids. The bile acids released into the intestinal tract, are mostly reabsorbed (about 95%) through the enterohepatic circulation and recycled. If a certain bile acid is continuously orally-supplied, the ratio of supplied bile acid to the total bile acid is gradually increased due to the continuous enterohepatic circulation. It has been reported that changes in the composition of intestinal bile acids cause dysbiosis, and it is presumed that an artificial change in the composition of bile acid can be an effective method of controlling the proliferation of target microbiotas.

Aims & Methods: First, we wanted to identify the effects of certain bile acids on each microbiota. We observed the effect of bile acids in human body (cholic acid, chenodeoxycholic acid, deoxycholic acid). We used disk diffusion method, used for antibiotic susceptibility test. Second, we intended to observe actual intestinal microbial changes through the supply of specific bile acids in animal models. Specific bile acid (UDCA), which is available as probiotics, was mainly inhibited by hydrophilic bile acids. Inversus fecalis and Klebsiella pneumoniae, which are frequently observed in bile during biliary infections, did not form a large inhibitory zone of bile acids. Escherichia coli, which is occasionally found in the lower intestinal tract, proliferated more around bile acid. Other microorganisms, which caused biliary infections in various organs in the body, showed various patterns. As a result of relative quantitative analysis (RT-PCR) based on the control group, the ratio of Fermentes to Bacteroides was decreased in the group treated with UDCA for 3 weeks. Next, to minimize the role of endogenous bile acid, we used bile duct ligation rat model. Next generation sequencing (NGS) method was used to analyze the changes of microorganisms according to the supplied amount of UDCA. Examinations were divided into three groups for 3weeks, considering the capability of commercial UDCA product: control group; 10mg/kg/day group; and 15mg/kg/day group. Fecal contents were collected from cecum of sacrificed rats.

Results: Each bile acid formed various inhibitory or promoting regions in target strains. Saccharomyces bouardi and Lactobacillus casei, which are commercially available as probiotics, were mainly inhibited by hydrophilic bile acids. Entrocococcus fecalis and Klebsiella pneumoniae, which are frequently observed in bile during biliary infections, did not form a large inhibitory zone of bile acids. Escherichia coli, which is occasionally found in the lower intestinal tract, proliferated more around bile acid. Other microorganisms, which caused biliary infections in various organs in the body, showed various patterns. As a result of relative quantitative analysis (RT-PCR) based on the control group, the ratio of Fermentes to Bacteroides was decreased in the group treated with UDCA for 3 weeks. In the cholestatic model, NGS showed changes in the proportion of intestinal microbiota and an increase in diversity after 3 weeks of UDCA supply.

Conclusion: The effects of various kinds of bile acids on microbiotas are very diverse, and the oral administration of certain bile acids may cause changes in microbial environment in the intestinal tract. Finally, oral feeding of hydrophilic bile acids can be used as a therapeutic treatment for dysbiosis by controlling the microbial environment in the intestinal tract.

Introduction: Inhibition of microRNA-21 (miR-21) prevents necroptosis in the mouse pancreas. In turn, we recently showed that necroptosis contribute to hepatic necro-inflammation in the common bile duct ligation (BDL) murine model.

Aims & Methods: We aimed to evaluate the role of miR-21 in mediating deleter-
ious processes associated with cholestasis. The functional crosstalk between miR-
21 and necroptosis was investigated in vitro. miR-21 expression was evaluated in the liver of primary biliary cholangitis (PBC) patients. C57BL/6 wild-type (WT) or miR-21-deficient (miR-21−/−) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

Results: Studies in miR-21−/− primary mouse hepatocytes established a func-
tional link between miR-21 and necroptosis through cyclin dependent kinase 2 associated protein 1 (CDK2AP1). miR-21 expression increased in the liver of PBC patients compared to healthy. miR-21−/− mice displayed decreased serum levels of liver injury markers compared with WT mice, accompanied by reduced hepatocellular degeneration, oxi-
dative stress and pro-fibrogenic gene expression. Hallmarks of necroptosis were decreased in the livers of BDL miR-21−/− mice, via relieved repression of CDK2AP1. Further, miR-21−/− mice displayed improved adaptive response in the expression of bile acid homeostasis-associated genes.

Conclusion: miR-21 ablation ameliorates liver damage and necroptosis in BDL mice; miR-21 should be considered as a promising therapeutic target in cholestatic liver diseases. P0735 THE EVALUATION OF TRANSPAPILLARY ENDOSCOPIC GALLBLADDER DRAINAGE WITH THE USE OF INTRADUCTAL ULTRASONOGRAPHY

Gastroenterology, New Tokyo Hospital, Chiba/Japan

Contact E-mail Address: dr2007t@g2.so-net.ne.jp

Introduction: The number of indications for endoscopic transpapillary gallblad-
der drainage (ETGBD) to treat cholecystitis patients has increased, and we aim to clarify the aging of the population and prescribing antithrombotic agents. ETGBD is one of the challenging procedure because it is difficult to identify the cystic duct (CD) orifice. From November 2015, we performed with ETGBD using intraduc-
tural ultrasonography (IDUS) complementarily. The CD orifice can be identified using IDUS, resulting in cannulation in to the CD. We investigated the success rate and clinical outcomes of ETGBD in combination with using IDUS.

Aims & Methods: ERCP was performed in 1000 patients (1400 times) at New Tokyo Hospital, from January 2013 to December 2015. A total of 97 patients underwent ETGBD, 58 patients with IDUS and 39 without IDUS. In this study, we investigated the success rate of ETGBD retrospectively. The suc-
cess of ETGBD was defined as cannulation into the gallbladder within two trials. Results: The mean age and male proportion of patients in the group with IDUS was similar to that in the group without IDUS (74.5±11.4 vs 73.3±11.3; P=0.600 and 18/40 and 13/26; P=0.828). The procedure success rate was 78.4% (76/97) in total; 86.2% (50/58) in the group with IDUS and 66.7% (26/39) in the group without IDUS. Using IDUS under fluoroscopic image allowed all patients in the group with IDUS to identify the CD orifice. ETGBD procedures in eight patients were unsuccessful because of a highly flex-
ion of the CD in seven patients and an obstruction of the CD orifice caused by tumor invasion in one patient. Although both groups developed mild pancreatitis (one patient in the group with IDUS, and two patients in the group without IDUS), no significant difference was observed in the two groups (P=0.563). All patients were successfully managed with conservative treatment. There were no any other complications in the two groups.

Conclusion: The success rate of ETGBD in the group with IDUS was significantly higher than that in the group without IDUS. IDUS is may be useful as a com-
plementary option of endoscopic gallbladder drainage.

Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endo-
sopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTC failed and when deemed feasible by a dedicated multidisciplinary team including a hepatopancreato-bili-
ary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

Results: Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transaction of the bile duct (type D/Nstrasser type E injury). Primary success rate of RV was 94% (44/47 patients). Reasons for failure (N = 3) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to

during the endoscopic procedure, and total number of endoscopic procedures differed significantly between the two groups. The median number of stones was one (range 0-5) and two (range 1-5) (P=0.013), while the median diameter of the largest stones was 9 mm (range 0.27) and 14 mm (range 3-23) (P=0.001) in the complete and incomplete stone removal groups, respectively. During the referral period, OS was 33.9% and 41.9% and DDS was 5.56% and 3.23% in the complete and incomplete stone removal groups, respectively. Kaplan-Meier analysis found no significant difference in OS and DDS between the two groups (P=0.187 and P=0.581, respectively).

Complete stone removal might not be always necessary in extremely elderly patients aged 90 years and older.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endo-
sopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospec
surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojejunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N = 4.7%). No life-threatening adverse events and no 30-day mortality occurred.

Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.

Disclosure of Interest: All authors have declared no conflicts of interest.

2. Booij KAC, de Reuver PR et al. Long-term Impact of Bile Duct Injury on Morbidity, Mortality, Quality of Life, and Work Related Limitations. 2017
61.5 years old. There were 17 patients (38.6%) with intrahepatic cholangiocarcinoma, 9 patients (20.5%) with perihilar cholangiocarcinoma, 7 patients (15.9%) with extrahepatic cholangiocarcinoma and 11 patients (25.0%) with gallbladder cancer. All patients had stage IV disease and median number of prior anticancer treatments of patients was 2 (range 1–5). After an average of 1.5 months of treatment (range 0.5–10.0 months), three patients (6.8%) presented with disease as best overall response, 23 patients (52.3%) presented progression and 18 patients (40.9%) could not survive until response evaluation. Median progression free survival was 1.7 months (interquartile range (IQR) 0.8–2.3 months) and median overall survival from study enrollment was 2.5 months (IQR 1.4–4.9 months). During treatment, 25 patients (55.6%) could maintain tolerable general condition without increasing ECOG PS, and 35 patients (79.6%) could maintain or decrease the requirement for morphine as pain killer. During treatment, there were 12 cases (12/44, 27.3%) of seventh grade 3 adverse events (AE) and no cases of grade 4 AE. Most common AE was ALT/AST elevation (11/44, 25%) followed by anemia (10/44, 22.7%). The major causes of the drop outs from study were due to disease progression or patient’s death (30 cases, 66.7%), and there were only 5 cases (11.5%) who dropped out due to adverse drug reactions or severe AE.

Contact E-mail Address: ficaillo@free.fr

Introduction: ESGE stated in 2012 that more than 50% of the liver had to be drained in case of unresectable hilar liver stenosis, however it remains unclear if unilateral or bilateral palliative drainage has to be performed for this kind of stenosis. Our policy is to try to drain the most possible segments of the liver in case of hilar stenosis. The aim of our study was to evaluate the efficiency of hilar drainage in function of the number of segments drained.

Aims & Methods: The study is a retrospective analysis of a prospective registry of drainage of malignant stenosis of the hilum. Drainage were performed by 5 operators performing ERCP, EUS-drainage, and per-cutanous drainage. The choice of the technique was left to the appreciation of the operators. All techniques could be associated. A Ct-scan or MRI was performed before and after drainage to decide the plan of the drainage and to evaluate efficiency and quality of the drainage. All drainages were performed under general anesthesia in an intubated patient. The quality of the drainage was evaluated by calculation of the percentage of drained segments. This percentage was calculated by dividing the number of liver segment drained with the number of liver segment. The stricture was managed by removal or dilatation of the stricture in the cases of segments with the segments resected in case of surgery, and/or the segments with invasion of more than 50% by tumor. The aim of the study was to evaluate the effect of the quality of the drainage on the patients survival. Quality of the drainage was defined by the percentage of liver segments drained.

Results: 60 (38 men) patients were included from from 01/2015 to 07/2016. Mean age = 69.84 years old. The classification of the stenosis was type II for 17 (29%) patients, type III for 20 patients (34%), type IV for 22 (37%). Histology corresponded to CCK < 43%, metastatic from colorectal cancer for 15 patients (25%) and others cancers for 19 (32%). Median follow-up was 8.5 months (5.5–16.5). The median of survival was 5 months (2.3–12.3). In unvaried and multi varied analysis there was a significant correlation between the percentage of segments drained > 80% (p < 0.05) and the survival. The other factor with impact on the survival was an invasion of the liver > 50% by tumor. There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the quality of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.77 (0.65–0.88).

Conclusion: The survival of patient with a malignant stenosis of the biliary confluence is highly correlate with the rate of the liver segment drained.

Disclosure of Interest: All authors have declared no conflicts of interest.
differentiating between (pre)malignant and benign polyps (p = 0.174 and p = 0.589 respectively).

Conclusion: Diagnostic accuracy of TAUS for diagnosis gallbladder polyps is moderate and decreases further when differentiating between polyp types. TAUS would regularly provide false positive results, leading to unnecessary surgery. There was no evidence that diagnostic test accuracy of EUS was better than TAUS. Further studies of high methodological quality are needed to determine diagnostic accuracy of EUS and TAUS for differentiating between polyp types.

This abstract is based on a pre-peer review draft of a Cochrane Review.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigators have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubble contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

**Aims & Methods:** The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polypoid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Perfluorobutane-based contrast agent and high MI contrast mode was used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement. Subsequently, patients were stratified according to lesion size at the largest diameter, and the diagnostic accuracy for gallbladder cancer in B-mode and CEUS were assessed.

**Results:** Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity (p < 0.01). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) (p < 0.01). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/19), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (33/36) on CEUS, and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

**ASSOCIATION OF CIRCULATING ADIPONECTIN LEVELS AND TUMOR STAGE IN BILIARY TRACT CANCER**

A. Saray, B. Gogov, N. Zubcevic, D. Prohic, A. Mehmedovic’, A. Pahalovic’

Department Of Gastroenterology And Hepatology, Clinical Center University of Sarajevo, Sarajevo/Bosnia And Herzegovina

**Introduction:** Multiple recent studies have indicated that some of adipose tissue-derived hormones may significantly influence the growth and proliferation of GI tumors including liver cancer (1, 2). However, the role of adipokines such as adiponectin and leptin in biliary tract cancer have not been well studied before. The aim of the study was to analyze plasma concentrations of adiponectin and leptin in cholangiocarcinoma (CC) patients and to compare these concentrations to clinicopathological parameters.

**Aims & Methods:** Baseline levels of adiponectin and leptin were determined in 38 consecutive patients with newly diagnosed cholangiocarcinoma and 38 healthy control subjects. The association between adiponectin and leptin and tumor stage was evaluated using nonparametric Spearman’s correlation test. Control subjects were matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

**Results:** Overall median adiponectin concentrations were lower in CC patients versus control subjects (5.1 vs 9.3 mg/mL, P = 0.001). In CC patients with T stage 2-4 (n = 22) median adiponectin concentrations were significantly lower than in CC patients with T stage 1 (n = 16) (3.8 vs 6.6 mg/mL, P = 0.001). The mean leptin levels were not significantly decreased in CC patients (P = 0.45). Adiponectin concentrations were inversely correlated with tumor T stage (r = −0.811, P = 0.01) of CC patients. Higher adiponectin levels at baseline were associated with increased overall survival in T stage 2-4 patients (Cox F test = 2.139, P < 0.05).

**Conclusion:** This study identified an association between adiponectin levels and tumor stage suggesting a potential role for adiponectin in progression of cholangiocarcinoma. Furthermore these results suggest, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with CC. Our results support the hypothesis linking adipose-tissue derived hormones levels to growth of obesity-associated cancers (3). Adipokines appear to play an important role in risk prediction and management of cholangiocarcinoma patients.

P0745 TreatMET BODY MASS INDEX AND WEIGHT CHANGE DURING INITIAL PERIOD OF CHEMOTHERAPY AFFECT SURVIVAL OUTCOME IN ADVANCED BILIARY TRACT CANCER PATIENTS

Seoul National University College Of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul/Korea, Republic of

Contact E-mail Address: schmeiche80@gmail.com

Introduction: Recent studies have been conducted to investigate the association between obesity and survival in cancer patients. Cancer has a significant influence on the nutrient status of patients and obesity can affect on the pharmacokinetics of anti-cancer drugs. The impact of obesity on survival is known to vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence.

Aims & Methods: We performed this study to investigate the association between HER2 status and survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows: underweight, <18.5 kg/m²; normal, 18.5-22.9 kg/m²; overweight, 23-24.9 kg/m²; obese, ≥25 kg/m².

Results: Median OS was 12.1 months for underweight patients, 10.5 months for normal patients, 16.1 months for overweight group, 13.6 months for obese patients, respectively. (p = 0.047) Univariate analysis showed that BMI, local status, and disease, operation, radiotherapy and ECOG performance were significantly associated with better survival. Compared with normal patients, overweight patients (BMI 23-24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.49, CI 0.33-0.72; 95% p = 0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival.

Conclusion: Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0746 THROUGH THE CATHETER BIOPSY METHOD FOR BILIARY CARCINOMA

T. Okuzono
Department Of Gastroenterology, Sendai Kousei hospital, Sendai/Japan

Contact E-mail Address: okuzonotoru@gmail.com

Introduction: To perform curative operation of biliary carcinoma, the pre-operative identification of exact proximal and distal margins is important. A biopsy forceps that is conventionally inserted to common bile duct via duodenum ampulla is guided with an antecedent guide wire. Cannulation of the bile duct with the biopsy forceps may sometimes be difficult in cases where no sphincterotomy is performed, placing the patient at risk of post-ERCP pancreatitis after multiple attempts to advance the forceps into the duct. Pancreatobiliary endoscopists have reported the biopsy methods. This was a retrospective review of bile duct biopsies with this technique.

Aims & Methods: The aim of this study was to assess the feasibility and safety of the biopsy methods. This was a retrospective review of bile duct biopsies with this new method conducted in Sendai Kousei hospital from February 2015 to October 2016. All patients who had biliary stenosis were included. Patients' demographic data, technical success, adverse events and the diagnostic accuracy were evaluated.

Results: A total of 95 biopsy procedures were performed in 40 patients. The technical success rate was 95% (90/95). Post-ERCP pancreatitis occurred in 1 of 40 patients (2.5%, 1 grade 1 patient). There were no other adverse events like perforation or bleeding. The diagnostic yield of biopsy procedures was 100% (7 of 7 patients).

Conclusion: The new biopsy methods to biliary stricture were feasible and safe. It opens up exciting possibilities for endoscopic preoperative diagnosis of the biliary carcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with perihilar cholangiocarcinoma (PHC) have few treatment options and a poor prognosis. Most staging models for patients with PHC are based on imaging with potentially resectable disease and are not applicable to the vast majority of patients.

Aims & Methods: The aim of this study was to develop a prognostic score for all PHC patients using variables available at presentation. All consecutive patients with PHC (irrespective of tumor stage and treatment) in two tertiary referral centers between 2002 and 2014 were identified and included. Baseline patient and tumor characteristics were collected from medical records. Cox proportional hazards regression was used for multivariable analysis. Age, BMI, bilirubin, CA 19-9, and tumor size were modeled as continuous covariates.

Results: A total of 674 patients were included of whom 342 (50.8%) had unresectable disease at presentation and 176 (26.2%) underwent exploratory laparotomy. Multivariable analysis identified age (HR 1.41 (95% CI 1.23-1.63)), BMI (HR 1.11 (95% CI 1.05-1.17)), serum bilirubin level (HR 1.45 (95% CI 1.21-1.71)), CA 19.9 serum level (HR 1.22 (95% CI 1.07-1.38)), tumor size (HR 1.33 (95% CI 1.14-1.56)), WHO performance status 3-4 (HR 1.48 (95% CI 1.10-1.95)), suspected distant metastases on imaging (HR 1.69 (95% CI 1.29-2.20)), and main bile duct involvement (HR 1.51 (95% CI 1.21-1.84)) as independent prognostic parameters.

Conclusion: PHC patients undergoing exploratory laparotomy have a high risk of an adverse outcome. A prognostic risk score for adverse outcome may help clinicians to inform patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0748 A NEW PROGNOSTIC MODEL FOR PATIENTS WITH PERIHILAR CHOLANGIOCARCINOMA

Introduction: Patients with perihilar cholangiocarcinoma (PHC) have few treatment options and a poor prognosis. Most staging models for patients with PHC are based on imaging with potentially resectable disease and are not applicable to the vast majority of patients.

Aims & Methods: The aim of this study was to develop a prognostic score for all PHC patients using variables available at presentation. All consecutive patients with PHC (irrespective of tumor stage and treatment) in two tertiary referral centers between 2002 and 2014 were identified and included. Baseline patient and tumor characteristics were collected from medical records. Cox proportional hazards regression was used for multivariable analysis. Age, BMI, bilirubin, CA 19-9, and tumor size were modeled as continuous covariates.

Results: A total of 674 patients were included of whom 342 (50.8%) had unresectable disease at presentation and 176 (26.2%) underwent exploratory laparotomy. Multivariable analysis identified age (HR 1.41 (95% CI 1.23-1.63)), BMI (HR 1.11 (95% CI 1.05-1.17)), serum bilirubin level (HR 1.45 (95% CI 1.21-1.71)), CA 19.9 serum level (HR 1.22 (95% CI 1.07-1.38)), tumor size (HR 1.33 (95% CI 1.14-1.56)), WHO performance status 3-4 (HR 1.48 (95% CI 1.10-1.95)), suspected distant metastases on imaging (HR 1.69 (95% CI 1.29-2.20)), and main bile duct involvement (HR 1.51 (95% CI 1.21-1.84)) as independent prognostic parameters.

Conclusion: A new prognostic score was created to predict survival for patients with PHC from the time of presentation. Discrimination using Kaplan-Meier analysis for the effect of change in body weight and BMI to the overall survival in advanced biliary tract cancer patients with good performance status.
Meier curves, and calibration curves revealed good predictive abilities. The risk score identified patients with a 1-year survival probability ranging from 15% to 73%.

Conclusion: We developed a prognostic score to predict overall survival for PHC patients using eight independent prognostic factors available at presentation. This score may help to inform patients and guide individualized treatment decision making.

Introduction: Malignant biliary obstruction has a poor prognosis unless secondary to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

Aims & Methods: The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

Results: 490 555 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%), followed by liver and intraductal bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.6% for 7 day, in hospital and 30 day respectively. In multivariate analysis male gender (OR 1.14, (95% CI 1.08–1.19), p < 0.001); increasing by age quintile 64–71 (1.34, (1.23–1.47) p < 0.001), 72–77 (1.57, (1.44–1.72) p < 0.001); and previous renal failure (1.92, (1.77–2.09), p < 0.001) were associated with increased mortality. The TM6SF2 genotype carriers also showed a tendency towards increased mortality levels and a positive correlation between ALT levels and triglyceride concentrations (p = 0.003) and a higher central retinal artery equivalent (p = 0.020) compared to the major allele carriers. Carrying the TM6SF2 T allele in addition to carrying the PNPLA3 ‘risk’ allele, did not significantly increase the odds ratios for increased ALT concentrations. The prevalence of the metabolic syndrome did not differ between the different PNPLA3 genotype carriers nor between the TM6SF2 genotype carriers.

Conclusion: Despite significantly higher liver transaminase levels and a positive correlation between ALT levels and triglyceride and fasting insulin concentrations in PNPLA3 G allele carriers, these children did not have a more deteriorated cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

P0750 EARLY DEVELOPMENT OF NONALCOHOLIC FATTY LIVER DISEASE IN GENETICALLY PREDISPOSED CHILDREN: WITH OVERWEIGHT AND OBESITY DOES NOT COINCIDE WITH METABOLIC DERANGEMENTS

K. Karnebeck, J. Plat2, A. Vreugdenhil2
1Department Of Pediatrics, Maastricht University Medical Centre, Maastricht/Netherlands
2Department Of Human Biology, School Of Nutrition And Translational Research In Metabolism (nutrim), Maastricht University, Maastricht/Netherlands

Contact E-mail Address: kylie.karnebeck@umc.nl

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738409) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver parameters and cardiometabolic disturbances coincide in children and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

Aims & Methods: One hundred and seventy-four children (49% boys) from the Children for Overweight Adolescent and Children’s Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 I148M and TM6SF2 E167K. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

Results: Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in PNPLA3 G allele carriers as compared to the C allele carriers (ALT: CC 21, (19–22); GG 26, (20–30), p = 0.034; 50); GG 27, (21, 00–40, 00); GG 30, (26, 00–36, 00) (p = 0.004)). The odds ratio for having ALT levels above the cut-off values increased for every PNPLA3 G allele, with an OR of 2.51 (1, 22, 5; p = 0.015 for the PNPLA3 GG genotype and 5.54 (1, 51, 20, 02, p = 0.009 for the GG genotype, compared to the CC genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers.

The TM6SF2 T allele carriers also showed a tendency towards increased transaminase levels, but a significantly healthier cardiometabolic profile (lower total cholesterol (p = 0.028), LDL cholesterol (p = 0.015) and triglyceride concentrations (p = 0.003) and a higher central retinal artery equivalent (p = 0.020) compared to the major allele carriers. Carrying the TM6SF2 T allele in addition to carrying the PNPLA3 ‘risk’ allele, did not significantly increase the odds ratios for increased ALT concentrations. The prevalence of the metabolic syndrome did not differ between the different PNPLA3 genotype carriers nor between the TM6SF2 genotype carriers.

Conclusion: Despite significantly higher liver transaminase levels and a positive correlation between ALT levels and triglyceride and fasting insulin concentrations in PNPLA3 G allele carriers, these children did not have a more deteriorated cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

Introduction: Pediatric chronic liver diseases are becoming a public health issue. Ultrasound based elastographic techniques have emerged as non-invasive methods of pediatric liver fibrosis assessment. The most recent are two dimensional shear wave elastography (2D SWE) techniques. While it seems to be highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation.

Aims & Methods: We aimed to investigate the number of liver stiffness measurement (LSM) needed for a high-quality evaluation using a 2D SWE technique. We conducted a prospective study which included 73 children (age range: 3–17 years, mean age 11.73 ± 3.35 years, 37% girls, mean body mass index (BMI) 25.12 ± 7.38 kg/m2). We used the 2D-SWE.GE (Logiq E9, GE Healthcare, Chalfont St Giles- UK), with a C1-6-D probe. One examiner performed 10 LSM for each child. We randomly extracted 1 LSM, 2 LSM, 3 LSM and 5 LSM from all 10 and calculated their respective medians. We employed the Friedman test to compare the medians of 1, 2, 3, 5 and 10 LSMs. We used the interclass correlation coefficient (ICC) to assess the agreement between the medians of 1, 2, 3, 5 and 10 LSMs.

Results: Medians calculated from 1, 2, 3, 5 and 10 LSMs were highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation. The TM6SF2 genotype carriers.

Conclusion: Despite significantly higher liver transaminase levels and a positive correlation between ALT levels and triglyceride and fasting insulin concentrations in PNPLA3 G allele carriers, these children did not have a more deteriorated cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

Contact E-mail Address: drradhikachavan@gmail.com

Introduction: Visceral artery pseudo-aneurysm are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreatitis. Angiembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.
Aims & Methods: We aimed to assess the technical feasibility, safety and effic-acy of percutaneous embolization as an alternative treatment option for visceral pseudo aneurysms. We retrospectively evaluated the data of patients who underwent percutaneous embolization at our institution from Feb 2007 to March 2017. All procedures were performed under ultrasound (US) guidance. Embolization technique, safety and efficacy of percutaneous embolization were analysed. At 30 days follow up US with color Doppler/dual phase computed tomography was done to see for recurrence of pseudoaneurysm.

Results: 23 patients (18-male) with mean age of 34.47 ± 7.28 (7-72) years, underwent direct percutaneous embolization for visceral pseudoaneurysm. Most common aetiology for pseudoaneurysm was trauma (3), paracentesis (3) and surgery (1). The site of pseudoaneurysm was- aorta (3) and gastroduodenal artery (1). Mean size of pseudoaneurysm was 0.6 (1–3.5) cm. Reasons for choosing percutaneous approach over transcatheter embolization included- technical difficulties in 11 patients, excess collateral feeding artery in 5 patients, and recurrence after previous embolization in 6 patients. Agents used for embolization- glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3 ± 2.11 (8–16) minutes and fluoroscopy exposure time was 2.4 ± 1.34 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success-100%). Mild adverse events included - local site pain in 19 (80%) patients. Moderate adverse event included - splenic infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 910 days (30–3186) there was no recurrence of pseudoaneurysm (clinical success-100%).

Conclusion: Percutaneous embolization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding transcatheter approach.

Introduction: Chronic (CP) and autoimmune pancreatitis (AIP) are characterized by CP pig as proreres. Whether CP is autoimmune is still unclear. AIP is considered mostly a T-cell mediated disease; however, in induction of chronic pancreatitis macrophages play a pivotal role. Cyclin dependent kinase (cdk) inhibitors are critical regulators in inflammatory disease as cdk inhibitors, activate proliferation, differentiation and differentiation of lymphocytes and b cells. In particular, p21 has been described as a mediator of inflammation and various autoimmune diseases by regulating T-cell activation and promoting macrophage development. We therefore examined the role of p21-mediated inflammation in AIP.

Aims & Methods: Human pancreas samples from CP and AIP patients were evaluated for p21 expression. To investigate the effects of p21 in pancreatitis, we intercrossed lympothenos overexpressing mice (Tyel/Erat-Lta, b/b) - a model to study CP and AIP – with p21 deficient (p21−/−) mice. Infiltrating cells were visualized by immunohistochemistry, supported by gene expression analysis in an early and a progressive phase. Circulating autoantibodies and the presence of tertiary lymphoid organs (TLOs) were analysed to assess autoimmunity.

Results: p21 was upregulated in human CP patients but remained unchanged in AIP patients. p21 deficiency in LT mice (Ltp21−/−) prevented early pancreatic injury. LTp21−/− mice had normal serum amylase, reduced inflammatory gene expression and cell infiltrate. In acinar cells diminished proliferation and aberrant activation of non-canonical NF-κB pathway was observed. In contrast, 12 months old LT mice with and without p21 had similar inflammatory gene expression and T and B cell infiltration. Interestingly, LT and Ltp21−/− mice had comparable tertiary lymphoid organs (TLOs), autoantibodies and elevated IgG levels. However, acinar cell proliferation, acinar-to-ductal metaplasia and acinar non-canonical NF-κB pathway activation remained impaired in Ltp21−/− pancreata.

Conclusion: Our findings indicate that p21 is crucial for pancreatitis in LT-driven pancreatic injury. p21 is involved in early acinar secretion of inflammatory mediators that attract innate immune cells. However, p21 is not essential for humoral immune response, accountable for autoimmunity and lack of p21 does not rescue AIP. Importantly, p21 intercrossing reveals that p21 protects acinar cells less susceptible to proliferation and transdifferentiation. We therefore suggest that chronic and autoimmune pancreatitis follow different inflammatory processes.

Disclosure of Interest: All authors have declared no conflicts of interest.
Infectious complications are main causes of mortality in severe acute pancreatitis. Most infections in AP are intestinal origin. The Nod2/CARD15 (OLIGOMERIZATION DOMAIN-CONTAINING PROTEIN 2) and TNF-alpha and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007fs variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NO2 variants between groups. Serum IL-6, TNF-alpha and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NO2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has been shown to be a safe and effective minimally invasive treatment for walled-off necrosis (WON). However, in some cases, simple drainage is not sufficient to manage the symptoms of WON and step up approaches such as direct endoscopic necrosectomy (DEN) and surgical necrosectomy may be required. The association between the outcome of endoscopic treatment for WON remains unclear.
Aims & Methods: This study aimed to retrogradely correlate the clinical characteristic of WON with the outcome of endoscopic transmural drainage. 49 patients (38 males; mean age 60.79 ± 13.44) with symptomatic WON treated by an attempted EUS-TD initially were enrolled in this study. The relationship between the outcome of treatment and the clinical characteristics including morphological features of WON were assessed.
Results: The mean size of WON was 126.63 ± 46.79 mm. EUS-TD was technically successful in 48.49% (97.9%) patients and 26 (54.2%) improved with EUS-TD alone while 14 patients who underwent step up approach had multi-local (p = 0.05) and large size WON (p = 0.02) as compared to patients treated with EUS-TD alone. The extent of WON correlated significantly (p = 0.001) with the type of treatment. Gas bubbles sign within necrotic tissue on the abdominal CT imaging early after EUS-TD predicted the necessity of necrosectomy during the treatment (p < 0.001). Bleeding as adverse events was observed in 1 patients (6.2%). Two patients improved with conservative therapy and 1 patient underwent transcutaneous arteriolar embolization.
Conclusion: The step up approach is safe and effective for the treatment of WON. Multi-local, large size and extensive WON were important predictors for performing a step up approach. Gas bubbles sign within necrotic tissue after EUS-TD may help to perform necrosectomy.

Introduction: Patients with a first episode of acute pancreatitis can develop recurrent or chronic pancreatitis (CP). However, little is known about the incidence or characteristics of WON with the outcome of endoscopic transmural drainage. 49 patients with a first episode of acute pancreatitis from September 2012 - September 2015. We collected relevant information of disease course and follow up until June 2016. We chose to analyze these data according to etiology, explore the relevant characteristics of recurrence episode and performed univariate and multivariate regression of possible risk factors.
Results: During a median follow-up of 30.4 months, 411 cases were followed up continuously. The total recurrence rate is 29.7% (131/441), with a median recurrence interval of 6.5 (IQR 2.3–10.33) months. The recurrence rate and median recurrence interval of biliary group, hyperlipidemic group and other etiology group were 21.5% (57/265), 5.78 (I 2.92–9.92); 42.7% (30/71), 8.28 (IQR 5.85–16.30); 30.1% (26/85), 6.18 (IQR 2.60–9.07). To biliary AP, the recurrence interval of biliary group, hyperlipidemic group and other etiology group were 21.5% (57/265), 5.78 (IQR 2.52–9.92); 49.2% (30/61), 8.28 (IQR 2.52–9.92); 30.6% (26/85), 6.18 (IQR 2.60–9.07). To biliary AP, the recurrence group were 21.5% (57/265), 5.78 (IQR 2.52–9.92); 49.2% (30/61), 8.28 (IQR 2.52–9.92); 49.2% (30/61), 8.28 (IQR 2.52–9.92). To biliary AP, the recurrence rate was 27.5% (113/411), with a median recurrence time (F = 25.227, p = 0.00001), increased of thrombin (F = 19.428, p = 0.00004), fibrinogen concentration (F = 4.6046, p = 0.03568), D-dimers level (F = 28.456, p = 0.00001), and level of soluble fibrin-monomer complexes (F = 34.015, p = 0.00001), lack of activity of antithrombin III (F = 42.123, p = 0.0001), increased synthesis of C-reactive protein (F = 15.591, p = 0.0002), excessive production of proinflammatory cytokines (F = 21.976, p = 0.00001), IL-6 (F = 21.076, p = 0.00002), and TNF-a (F = 25.643, p = 0.00001). In acute pancreatitis patients with renal dysfunction was shown a direct correlation between severity of renal failure (SOFA score) and concentrations of IL-6 (R = 0.416484, p = 0.000504), CRP (R = 0.514726, p = 0.00011), D-dimers (R = 0.321619, p = 0.008456), soluble fibrin-monomer complexes (R = 0.290750, p = 0.017868), and duration of thrombin time (R = 0.296007, p = 0.015814).
Conclusion: The mechanism of the acute renal injury following acute necrotizing pancreatitis is complicated by the inflammatory cascades and hypercoagulative state are initiated this pathological process.
Disclosure of Interest: All authors have declared no conflicts of interest.

THE NEW IL13/FN1 RATIO PREDICTS SEVERITY IN ACUTE PANCREATITIS

Introduction: Acute Pancreatitis (AP) may be severe in up to 20% of patients with substantial morbidity and mortality, which is related to a generalized inflammatory response. In some patients, this severe inflammatory response is down-regulated; in others it escapes control. Our group has previously described a TH1 profile associated with poor prognosis in AP, and a TH2 profile associated with a mild or moderate condition.
Aims & Methods: Our aim was the development of an index for an early assessment of prognosis in AP. We analyzed 12 cytokines in 117 patients, upon...
admission to hospital. A receiver operating characteristic (ROC) analysis was built up to determine the cut-off point of severity. Later, a multiple discriminant analysis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to severity and mortality.

Results: ROC curves showed that TH1 cytokines IL-6, IFN-γ and TNF-α could be measured for the prediction of severe AP, while TH2 cytokines IL-4, IL-13, GM-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL-13 and IFN-γ were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks’ lambda = 0.855, p < 0.0001; Wilks’ lambda = 0.747, p < 0.0001, respectively). We calculated the IL13/IFNγ index. This ratio was significantly higher in patients with mild AP compared between groups (p=10−6.9). This difference was also observed between severe AP and the rest of the patients (p=0.007). The ROC curve was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity.

Conclusions: An IL13/IFNγ ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13/IFNγ ratio at hospital admission is associated with a good prognosis of AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0764 CLINICAL EFFICACY AND SAFETY OF EU-GUIDED LUMEN-APPOSING METAL STENT ASSISTED Pancreatic WAll-Off NECROSIS DRAINAGE: A REAL-LIFE EXPERIENCE IN A TERTIARY HOSPITAL

S.T. Law¹, C. De La Serna Higuera², M. Perze-Miranda³, P. Gil⁴
¹Department Of Medicine And Geriatrics, Tsuen Man Hospital, Hong Kong; Hong Kong PRC
²Gastroenterology And Hepatology, Rio Hortega, Valladolid; Spain

Introduction: Recently, lumen apposing metal stent (LAMS) has been developed and employed in abscess drainage. However, its use is limited by its cost [1] and its safety concerns as apparently associated with more adverse events.[2] The aim of this study was to investigate the efficacy and safety of LAMS in endoscopic ultrasound (EUS)-guided pancreatic wall-off necrosis (WON) drainage.

Aims & Methods: Patients All consecutive patients with necrotizing pancreatitis with WON who underwent EUS-guided drainage using LAMS during the period of 1st Jul 2012 and 30th Jun 2016 were retrospectively retrieved from the institution database. Necrotizing pancreatitis and WON were defined as according to the revised 2012 Atlanta classification. Those encapsulated fluid collection outside the pancreas were excluded from this study. The following data were collected: patient demographics, EUS and microbiologic features of the necrosis, procedural characteristics and their outcomes. Procedures All procedures were performed by 2 endosonographers. Once the WON was identified, a 19-gauge needle was inserted with 0.035-inch guidewire to allow for injection of the AXIOS device, which was then advanced to create the fistula tract by using the electrocautery tip. Once the delivery catheter was inside the WON, the distal and proximal flange of the stent were deployed subsequently under EUS and endoscopic guidance respectively. Outcome measures Primary outcome measures were: 1. technical success defined as stent deployment without any difficulty nor reposition; 2. clinical success defined as symptom resolution with the abscess size ≤2 cm on computed tomography (CT); Secondary measures are: 1. Stent revision due to its migration/dislodgment in case of unresolved abscess; 2. adverse events; 3. WON recurrence Data analysis Continuous variables were expressed as median and IQR. Categorical data were expressed as absolute numbers and percentages.

Results: The clinical characteristics of the patients and their WONs are shown in Table 1. In the cohort, the deployment of LAMS (AXIOS: 15 × 10 mm, n = 38; 10 × 10 mm, n = 8) was technically success in 45 (97.8%, 3 cases required 2nd attempt for proper deployment) cases while one case required to switch over to a fully-covered metal stent due to the lengthy insertion tract. 26 (60.9%) cases were managed with necrosectomy (median 1, IQR 2) in which 15 (32.6%) of them had concurrent nascocystic drainage prior to each procedure. 43 (93.5%) patients were treated successfully while two refractory cases required supernumerary insertion of a fully-coupled metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases: three were managed by local treatment and one by re-lumen apposing metal stent insertion and one with uncontrolled bleeding due to disseminated intravascular coagulopathy and then died of multiple organ failure. Ten cases were reported to have stent migration during management in which two cases were dissolved during necrosectomy while the others were found during follow-up.

(continued)
Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a common and serious adverse event following ERCP, with a reported incidence of 9.7% in unselected patients [1]. Given huge economic and clinical burden, effective approaches for post-ERCP pancreatitis prophylaxis remains a major priority for research. Nonsteroidal anti-inflammatory drugs (NSAIDs) have also been shown the potential efficacy in prophylaxis PEP across high-risk patients, especially for diclofenac or indomethacin [3–5]. Recently, a prospective, double-blind, controlled trial conducted by Levenick [6] and colleagues in the USA showed that the reduction in PEP using indo- methacin was not as significant as previously reported. In fact, even given cases of pancreatitis occurred in indomethacin group compared with placebo group. Subsequently, a high-quality meta-analysis also concluded that there is no prophylaxis for the prevention of PEP among average-risk patient[7]. These findings raised the question that whether administration of rectal indomethacin should be recommended in average-risk patients. 

Aims & Methods: We aimed to determine the beneficial effect of rectal indomethacin in the prevention of post-ERCP pancreatitis in average-risk of patients. We systematically searched Cochrane Central Register of Controlled Trials, PubMed, and Scopus and were included studies up to October 2016. Studies that evaluated rectal administration of indomethacin in the prevention of post-ERCP pancreatitis were included in the analysis. We adopted a random-effects model to calculate overall relative risk (RR) and 95% confidence interval (CI).

Results: We identified ten randomized clinical trials from initial search and finally included in the meta-analysis. Administration of rectal indomethacin significantly reduced the incidence of PEP in combined population (RR, 0.63; 95% CI, 0.50–0.77). There was no significant heterogeneity across included studies (I² = 14.2%, P = 0.31). In subgroup analysis, rectal indomethacin was effective in both high-risk (RR, 0.49; 95%CI, 0.35–0.71) and average-risk (RR, 0.69; 95%CI, 0.55–0.86) patients and reduced the risk of mild and moderate to severe pancreatitis. The overall results remained unchanged and robust in sensitive analysis. There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Rectal administration of indomethacin is an effective approach to prevent the incidence of post-ERCP pancreatitis both in high-risk and average-risk population undergoing ERCP. However, more high-quality randomized controlled trials are needed to further investigate the optimal timing for administration of indomethacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13–50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 2 to 8%. Both epidemiology and outcomes are variable according to the different countries. Furthermore, few studies have considered the impact of hospital units on AP outcomes.

Aims & Methods: To evaluate both the trend and outcomes of acute pancreatitis according to the admitting hospital units: Surgery, Internal/General Medicine, Gastrointestinal (GI) Unit, Intensive Care Unit (ICU). This is a retrospective
cohort study based on the anonymous computerized database of hospital discharges in Veneto Region (North-East of Italy). The principal diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto population was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG 191–194, 199–201 which identified biliopancreatic surgery) were reported according the Admitting Hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied.

**Results:** During the analysed period, 23,389 overall hospitalizations for AP, annual hospitalizations of 32 patients/100,000 inhabitants and in-hospital mortality of 7.2% were observed. Characteristics of the patients were: mean age: 62.2 ±/−19.3ys, 54% Males (M); Female (F) mean age: 65ys+/−19.3ys, male mean age: 59.4+/−19.3ys (p = 0.05). Hospitalizations was higher in males (M: 35.4, F: 28.4, OR 1.24 (95% CI: 1.20–1.27, p < 0.05) and it increased in a stepwise progression from youngest to oldest patients (from 4.4 to 151.2 p < 0.05); a similar trend was observed when considering in-hospital mortality (from 0.5 to 10.3%, p < 0.05). From 2001 to 2015, hospitalization (32.4 to 29.5, p = 0.04), in-hospital mortality (1.41 to 0.79, p < 0.05) and need for surgery (NFS: 5.6% to 3.0%, p < 0.05) trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 34 to 63, p < 0.05) and Gastrointestinal (GI) Units (from 14 to 29, p < 0.05). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality (OR: 0.37, CI 95%: 0.28–0.49, p < 0.05) and an high NFS (OR: 2.88, CI 95%: 2.18–3.41, p < 0.05).

**Conclusion:** During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a best outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0767 COMPARISON OF CLINICAL COURSE AND OUTCOME OF ACUTE PANCREATITIS, RECURRENT ACUTE PANCREATITIS, ACUTE ON CHRONIC PANCREATITIS**

Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

**Contact E-mail Address:** dibhya.sharma@yahoo.com

**Introduction:** Recurrent acute pancreatitis (RAP) and acute on chronic pancreatitis (ACP) are likely to have less severe disease and local complications in comparison with acute pancreatitis (AP) possibly due to underlying chronic changes or fibrosis. However there is lack of literature regarding comparative studies between the natural course of disease and outcome of patients of AP vis-à-vis that of RAP and ACP.

**Aims & Methods:** This study was conducted to compare the clinical course and outcomes of patients with AP, RAP and ACP. 248 consecutive patients with diagnosis of AP, RAP or ACP were included during study period. Outcome measures studied were severity, organ failure (OF), persistent organ failure (pOF), need for ICU stay, ventilator and hemodialysis, need for percutaneous catheter drain (PCD), surgery and mortality.

**Results:** Of 248,158 (64%) patients had AP, 45 (18%) patients had RAP and 43 (18%) patients had ACP. 86 (54%) of AP, 4 (0%) of ACP and none of patients in RAP group had severe AP according to revised Atlanta classification (p < 0.001). On comparison of OF, 101 (63%: of whom 54% had pOF) of AP, 6 (13%; of whom 9% had pOF) of ACP and none of RAP patients developed OF (p < 0.001). PCD and surgery requirement were seen in 89 (56%) & 9 (6%) of AP, 5 (11%) & 4 (9%) of ACP and none of RAP patients respectively (p < 0.001).

**Conclusion:** During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a best outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

**P0768 ACUTE PANCREATITIS IN PATIENTS WITH IPMNS: RETROSPECTIVE STUDY OF 346 PATIENTS OBSERVED FROM 2009 TO 2016**

L. Brozzi, A. Amadio1, F. De Marchi1, R. Teresa Marzit2, I. Breoni1, P. Campagnola1, S.F. Ciriò1, A. Gabbrielli1, L. Frulloni1
1 Medicine, AOUI Verona-Pancreas Center, verona/Italy
2Gastroenterology, University of Verona, Verona/Italy

**Contact E-mail Address:** Lorenzo.brozzi89@gmail.com

**Introduction:** In literature the frequency of acute pancreatitis (AP) in patients with IPMNs varies between 12 and 65%, but most of studies are from surgical series or often pancreatitis occurred after surgery was included. Furthermore, most of the studies includes in the diction of "symptomatic IPMNs" the presence of less severe disorders, such dyspeptic symptoms, making series unclear.

**Aims & Methods:** The aim of this study was to investigate the correlation between the cut-off of IPMN and acute pancreatitis and to determine the frequency of each in the different characteristics from asymptomatic IPMNs patients, evaluate the possible differences between type and localization of IPMNs in occurrence of acute pancreatitis and his disease severity. A retrospective analysis was performed on all observed patients with IPMN-MD. IPMN-BD and mixed type and followed at Gastroenterology Unit in the period between January 2009 and March 2016. In the study patients an instrumental or histological diagnosis of IPMNs were included.

**Results:** Studied 346 patients (164 males and 182 females, mean age at the first report 61.6 ± 12.2 years). At the time of radiological diagnosis, 45% were asymptomatic, 51% had had symptoms, while 4% of data were missing: the frequency of AP (excluding biliary etiology) of all 346 patients with IPMN was 26%. AP was edematous in 85% of patients and necrotic in 15%. We found increased frequency in patients with PA with IPMN of the main pancreatic duct (MD and mixed), and unilocular type. The localization to the body seems to be more correlated with the presence of AP. The number of cysts (for IPMN-BD and mixed type) was significantly lower in patients who have had AP.

**Conclusion:** Our medical extraction series confirms that the PA is an event that occurs in 26% of patients with IPMNs, with a prevalence of the male sex, it is associated with a IPMN central and mixed type, predominantly located in the body. The pancreatitis is not associated with malignancy in resected patients.

**P0769 APOLIPOPROTEIN B AND A-I RATIO PREDICTS SEVERE ACUTE PANCREATITIS**

J. Kim, K. J. Lee
Internal Medicine, Yonsei University Wonju College of Medicine Dept. of Internal Medicine, Wonju/Korea, Republic of

**Contact E-mail Address:** jawkim96@yonsei.ac.kr

**Introduction:** Severe acute pancreatitis (SAP) has a considerable mortality and morbidity rate. Although many indices have been developed to classify the severity of acute pancreatitis (AP), there is no ideal method for predicting SAP. The ratio of apolipoprotein B to A-I (apoB/A-I) is associated with metabolic syndrome and inflammatory status.

**Aims & Methods:** This study aims to investigate the association between severity of AP and serum apoB/A-I ratio. Patients with AP were prospectively enrolled at Yonsei University Wonju College of Medicine from March 2015 to August 2016. The severity of acute pancreatitis was assessed according to the revised Atlanta classification criteria (Atlanta 2012).

**Results:** Of 191 patients with AP, 134 (70.2%) were classified as mild AP, 42 (22%) as moderately severe AP, and 15 (7.9%) as SAP. The apoB/A-I ratio was highest in patients with SAP compared with those with mild and moderately severe AP (p < 0.001). TheapoB/A-I ratio positively correlated with Atlanta classification, computed tomography severity index, and Bedside index for severity of AP. The apoB/A-I ratio showed the highest ability to predict SAP in patients with AP compared with apolipoprotein B or apolipoprotein A-I alone.

**Conclusion:** Serum apoB/A-I ratio appears to have value in predicting SAP in patients with AP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The Scandinavian-Baltic-Pancreatic-Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

**Aims & Methods:** We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNHEIM classification were included. Structural changes were graded according to the M-ANNHEIM-classification. A subgroup was also scored by the modified Cambridge score.

**Results:** The database contains 932 patients (623 men). The M-ANNHEIM-score was present from 446 subjects and both imaging scores from 93 subjects. According to M-ANNHEIM subjects were graded as 0: Normal (8.1%), 1: Correlation to the clinical data.

*p < 0.05 (Kruskal-Wallis). No other differences reached significance. Values: mean (SD) or median [IQR-range]. Malnutrition: BMI < 18.5.

**Conclusion:** Subjects with marked structural changes had the highest lifetime smoke-doses. There was poor correlation of structural changes to the clinical features. The two imaging scores demonstrated acceptable correlation and agreement. Poor agreement in normal/minimal-change groups may reduce the value of the scores where they are most needed. The results are presented on behalf of the SBPC study group.

**Introduction:** In patients with chronic pancreatitis (CP) malabsorption of vitamins D and K, alcoholism, smoking and inflammatory status contribute to low bone mineral density (BMD). A recent meta-analysis estimated the prevalence of osteoporosis (25%) and osteopenia (40%) in CP and highlighted limitations of the reviewed studies.

**Aims & Methods:** To evaluate the prevalence of osteoporosis and osteopenia in patients with CP and to investigate the correlation between BMD and CP features, and vitamin D and PEI. This is a multicentre cross-sectional study (P-BONE, a Pancreas 2000 project) on prevalent CP patients. The Diagnosis and severity of the disease was defined according to the M-ANNHEIM classification. Clinical information and biochemical variables were recorded; PEI was assessed by clinical case. Standardized Osteodensitometry was performed by dual-energy x-ray absorptiometry (DEXA).

**Results:** 211 consecutive CP patients were enrolled at 6 Centres (67% M; mean age 60 ± 13 years). Osteoporosis was diagnosed in 42% and osteopenia in 22% of cases. Alcoholism was associated with vitamin D deficiency (20%) and with low levels of fecal elastase (p < 0.02) and with lower level of vitamin D (p < 0.001) but not with osteopenia or osteoporosis. Female sex and older age seems to be associated with a higher risk of developing osteoporosis (OR 4.5 95% CI 2–9.8 p 0.001; OR 1.09 95% CI 1–1.3 p 0.01) while a higher BMI is associated with a reduced risk of its occurrence (OR 0.89 95% CI 0.77–0.94 p 0.001).

**Conclusion:** The present data confirm a high rate of osteoporosis in CP patients. However, there was apparently no correlation between BMD, pancreatic exocrine function, severity of the disease or vitamin D levels. Other factors, such as vitamin K might deserve investigation for their possible relationship with bone mineral density in CP patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0772 NATURAL HISTORY OF PANCREATITIS ASSOCIATED WITH SPINK1 MUTATIONS

N. Muller1, O. Hentic1, F. Maire1, P. Ruszniewski1, P. Levy2, V. Rebourcs2

Contact E-mail Address:nelly.muller@aphp.fr

**Introduction:** SPINK1 is a gene coding for the inhibitor of the cationic trypsino-

ogen. Heterozygous mutations prevalence is estimated at 2%. They are recognized as a risk factor for chronic pancreatitis. However few data are available regarding the natural history and the risk of complications in these patients.

**Aims & Methods:** A prospective monocentric study was carried out from 2000 to 2016 to describe the natural history of SPINK1 mutation related pancreatitis. All patients referred for idiopathic acute and/or chronic pancreatitis with a SPINK1 mutation were included and followed annually. Epidemiological, genetic, clinical and morphological data were collected.

**Results:** We included 158 patients. Mutations of SPINK1 were: heterozygous (65%), homozygous (8%) N34S, others (27%). Median age at first symptoms was 42 years. At diagnosis was 20 [2-73] and 29 years [3-76]. During follow-up (median length:7.4 years), clinical manifestations were pancreatic pain (73%), pseudo-cyst (15%), acute pancreatitis (77%), cholestasis (6%), exocrine pancreatic insufficiency (EPI) (33%), diabetes (15%) and pancreatic adenocarcinoma (n = 6.4%). Calculations and duodenal abnormalities were found in 56% and 62%. Endoscopic treatment and surgery were performed for 16% and 14% of the patients. Four patients died including 3 due to pancreatic cancer). The risk of pancreatic cancer at 55, 60, 70 and 75 years was 9.4%, 14.7%, 28.9% and 46.7%. Risk factors of cancer were calcifications (p = 0.03) and EPI (p = 0.04).

**Conclusion:** SPINK1 mutations should be searched for in young patients with idiopathic pancreatitis. Risk of pancreatic cancer is probably underestimated.
Cancer screening should be discussed especially in case of pancreatitis with calcifications.

Introduction: The Scandinavian-Baltic-Pancreatic-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal, B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes.

<table>

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and CFTR currents) is diminished in CP.

Aims & Methods: In this study we would like to understand which smoking has any effects on pancreatic ductal fluid and HCO3\(^{-}\) secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water by a smoking machine. Intracellular Ca\(^{2+}\) concentration and pH were evaluated by microfluorometry. Flow secretion was measured by video microscopy. CFTR currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO3\(^{-}\) secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO3\(^{-}\) secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na\(^{+}\)/H\(^{+}\) exchanger and Na\(^{+}\)/HCO3\(^{-}\) cotransporter and also forskolin-stimulated C\(^{2+}\) current of CFTR C\(^{2+}\) channel. CSE incubation altered the pattern of carbobach-induced Ca\(^{2+}\) signal in pancreatic ducts suggesting that smoking could inhibit effects may be regulated by calcium signalling.

Conclusion: Cigarette smoking and CSE inhibits pancreatic ductal fluid and HCO3\(^{-}\) secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKPN.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0775 HISTOLOGICAL DIAGNOSIS WITH RAPID ON-SITE EVALUATION IN ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION OF PANCREATIC SOLID LESIONS

Introduction: Rapid on-site cytologic evaluation (ROSE) for determining the suitability of a specimen often provides high efficacy of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). In our center, we propose an additional role of ROSE in histological diagnosis aimed at improving diagnostic accuracy.

Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both EUS-FNA and surgical resection for pancreatic solid lesions at our university hospital. We retrospectively compared the diagnostic performance of ROSE during EUS-FNA with the final diagnosis confirmed by surgically resected specimens. Diagnosis by ROSE using Diff-Quik\(^{\text{TM}}\) was carried out by both a cytopathologist and an endoscopist.

Results: The median of needle passes required for ROSE was 1 (range, 1–5). Final diagnoses for the 215 lesions were pancreatic ductal adenocarcinoma (PDAC; n = 162), pancreatic ductal adenomatous carcinoma (PDAC; n = 9), pancreatic neuroendocrine tumor (PNET; n = 30), solid pseudopapillary neoplasm (SPN; n = 9), metastatic tumors (n = 4), and acinar cell carcinoma (ACC; n = 1). Primary lesions for metastatic tumors in the pancreas were renal cell cancer (RCC; n = 2), small cell lung cancer (SCLC; n = 1), and colon cancer (n = 1). ROSE could not diagnose 14 cases. When adenocarcinoma (including suspicious SPN) was suspected by ROSE, ROSE diagnosed 94.6% (159/168) of adenocarcinomas. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, ROSE diagnosed 96.4% (27/28) of special type tumor.

Conclusion: All adenocarcinomas suspected by ROSE were malignant tumors. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, diagnostic accuracy of ROSE was 96.4%. Diagnostic accuracy using ROSE is high agreement in final histological diagnosis. It is suggested that ROSE may also be useful for diagnosis of special type tumor.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignanent lesions are limited, which shows an evident need to understand the pathomechanism leading to PDAC and find a suitable marker for early detection. Initial processes in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins found abundantly in the stomach where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KrasG12D Pit1Cre (KC) mice, a mouse model with predisposition to pancreatic cancer, revealed strikingly high gastrokine expression. We will further analyze the involvement of GKNs in the development and progression of PDAC and explore the possibility to use them as biomarkers.

Aims & Methods: We investigated GKN2 expression by qPCR in human and mouse pancreas samples. The presence of GKN1 was verified by western blot and immunohistochemistry (IHC) in mouse pancreas. Mouse pancreatic juice and serum were analyzed by proteomic analysis. To investigate the role of GKNs in carcinogenesis in vivo, we established mouse models by intercrossing KC mice with Gkn1−/− and Gkn2−/− mice respectively. The capacity of acinar cells lacking Gkn1 and Gkn2 to transdifferentiate into ductal lesions in vitro was tested.

Results: GKNs were upregulated during early stages of pancreatic carcinogenesis in mouse and peri-tumoral human pancreas. GKNs were absent in healthy pancreas and tumor tissue. IHC showed specific GKN1 expression in premalignant PanIN lesions, while GKN2 positive cells were also localized in the stroma. ELISA and proteomic analysis in mice confirmed the secretion of GKNs into pancreatic juice. Preliminary results from the first timepoint of analysis showed accelerated tumor development in GKN1−/− and GKN2−/− mice. Wild type acinar cells transdifferentiated into ductal lesions in vitro only in the presence of TGFA. On the contrary, Gkn1−/− and Gkn2−/− acinar cells transdifferentiated spontaneously, and resulted in a higher number of ADMs.

Conclusion: We identified for the first time specific gastrokine expression in pre-neoplastic lesions in human and mouse pancreatic tissue. The secretion into pancreatic juice during carcinogenesis could make gastrokine a potential biomarker for the detection of early pancreatic premalignant lesions. With our mouse models we will provide in vivo evidence on the role of GKNs as potential tumor suppressors in the pancreas.

P0778 AUTOPHAGY IS ESSENTIAL FOR PANCREATIC CANCer DEVELOPMENT IN A NEW HUMANIZED GENETICALLY-MODIFIED ADULT MOUSE MODEL

C. Tang1, X. Jia1, R. Luo2, Q. Tu1, X. Zhao2

1Gastroenterology, West China Hospital, Sichuan University, Chengdu/China
2Kunning Institute of Zoology, Kunming/China

Contact E-mail Address: jiaxintong22@gmail.com

Introduction: Pancreatic cancer is one of the deadliest malignancies and there are no effective therapies for it. According to a search of The Cancer Genome Atlas (TCGA), alterations in Kirsten rat sarcoma (KRAS), Tumour protein (TP)53, (lentiviruses-KTCC) were determined by western blot. The protein levels of ATG7, LC3, LAMP-1 and decreased P62 protein was observed in the pancreatic tumour tissues. In vitro, the protein level of LC3 in the lentiviruses-KTCC infected primary cells was increased by 6 times when compared with that in the control primary cells (P = 0.0104).

Conclusion: An adult mouse model of pancreatic cancer can be generated by altering Kras, Tp53, Cdkn2a and Cdkn2b genes. Besides, increased autophagy was measured during the development of pancreatic cancer in vivo. These findings provide considerable insight into the role of autophagy in pancreatic cancer and autophagy inhibition might be a potential target in treating pancreatic cancer.

Introduction: Hyperthermia as a positive additive to chemotherapy is described in multiple studies. Despite controversial results hyperthermic intraoperative chemotherapy (HIPEC) is a standard treatment option for some types of gastrointestinal cancer that invades peritoneum. However, the results of clinical data and basic research are uneven. Moreover, there is a lack of fundamental knowledge about additive cytotoxic effect of hyperthermia on cancer cells of different origin.

Aims & Methods: Our aim was to analyse gastrointestinal cancer cell response to various hyperthermia levels, accompanied by chemotherapy, in a manner of cell cytotoxicity, apoptosis and intracellular cisplatin concentration. Cancer cell lines of gastric (AGS), pancreatic (T4M4) and colorectal (Caco-2) origin were exposed to cisplatin and different temperature regimes (37°C to 45°C) either in isolated manner, or in combination. Cells were treated for one hour, mimicking HIPEC timing in clinical setting. The intracellular concentration of cisplatin was measured immediately after experiment by mass spectrometry. 48 hours later changes of cell viability and apoptosis rates depending on temperature in addition to cisplatin treatment were evaluated by MTT and Annexin/AAD flow cytometry respectively.

Results: The response of AGS to hyperthermia was as implied. Viability of the cells was gradually decreasing by raising the temperature. Caco-2 cells had no significant response to temperature rise up to 42°C, but at 43°C viability dropped by 14% constantly remaining at higher temperatures. T4M4 cells acted in unprece-dented manner, whereas decreasing viability by 30% in the interval between 37°C to 42°C and 20% increase at 43°C was observed. Following simultaneous exposure to hyperthermia and cisplatin we observed no additive temperature alteration in interval between 37°C to 45°C. However, at particular temperature regimes, we observed temporary proliferation increase: AGS – at 42°C (33%); T4M4 – at 43°C (32%). Higher temperatures dramatically inhibited AGS – by 70%, T4M4 - by 76%. There was the linear pattern of slight decrease (up to 26% at 45°C) of viability in Caco-2 cells. Isobologram analysis of combined hyperthermia and cisplatin treatment revealed strong antagonism of hyperthermia and chemotherapy in all analyzed cell lines. Nevertheless, hyperthermia of 43°C in addition to cisplatin promoted apoptosis of AGS cells by 33%, Caco-2 by 26%, T4M4 by 19%. Moreover, application of hyperthermia (43°C) could contribute to increase of intracellular cisplatin concentration by 30%, 20% and 18% AGS, Caco-2 and T4M4 cells respectively.

Conclusion: Our results indicate that there is no linear contribution of hyperthermia and chemotherapy in all analyzed cell lines. Therefore, in clinical setting it should be applied individually, regarding cancer type. Moreover, particular temperatures can worsen the treatment and increase cancer cell growth.

Introduction: For the past decades, cachexia has been recognized as a major cause of morbidity and mortality in patients with malignant tumors, and the complete understanding of its mechanisms is a priority. In the gastrointestinal tract, cachexia is often associated with the presence of cytokines promoting inflammation, immune cell infiltration, immune cell exhaustion, and cell death. In addition, the presence of autophagic protein LC3, autophagy related protein 7 (ATG7), LAMP-1 and decreased P62 protein was observed in the pancreatic tumour tissues. The role of cachexia in the progression of pancreatic cancer has not been fully elucidated.

Aims & Methods: We aimed to investigate autophagy response in a new humanized genetically-modified adult mouse model of pancreatic cancer. To induce pancreatic cancer, lentiviruses expressing oncogenic Kras (lentiviruses-KTCC) were injected into pancreas of 9-week old adult mouse. Autophagy was detected by immunofluorescence staining for autophagic protein light chain-3 (LC3)-3 and Lysosomal-associated membrane protein 1 (LAMP-1). Additionally, the expression of autophagic protein LC3, autophagy related protein 7 (ATG7), LAMP-1 and P62 were determined by western blot.

Results: Mice developed pancreatic cancer ten weeks after lentiviruses-KTCC injection, both in macrography and histopathology analysed. The mRNA levels of autophagic genes Atg7 and Atg12 were up regulated. In addition, the LC3 and LAMP-1 positive area increased significantly. Co-localization of LC3 and LAMP-1 was found in pancreatic tumour sections. Moreover, the increased protein levels of ATG7, LC3, LAMP-1 and decreased P62 protein was observed in the pancreatic tumour tissues. In vitro, the protein level of LC3 in the lentiviruses-KTCC infected primary cells was increased by 6 times when compared with that in the control primary cells (P = 0.0104).

Conclusion: An adult mouse model of pancreatic cancer can be generated by altering Kras, Tp53, Cdkn2a and Cdkn2b genes. Besides, increased autophagy was measured during the development of pancreatic cancer in vivo. These findings provide considerable insight into the role of autophagy in pancreatic cancer and autophagy inhibition might be a potential target in treating pancreatic cancer.

Introduction: Cachexia is a multifactorial syndrome, characterized by the loss of skeletal muscle mass which is not fully reversible by nutritional support. Activin play a dominant role in the development and progression of cachexia and also in tumor cell growth in pancreatic adenocarcinoma via non-SMAD (MAPK, PI3K/Akt) pathways. Cachexia might be a keypoint in pancreatic ductal adenocarcinoma (PDAC) pathway. Ezrin pathway as a intracellular cytoskeleton biomarker is related to the cytoskeleton involvement are lacking and their relationship with the cachexia is not known. Ezrin is involved in intracellular signaling and adhesion, by linking in the PI3K/Akt pathways.

Aims & Methods: Our goal was to assess the significance of activin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n = 115) and a matched control group (n = 124). The plasma levels of activin A were analyzed using western blot. The t test was used to determine the differences between the two groups, Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: Activin was overexpressed more frequently in PDAC compared to controls (p = 0.001), and has been closely related to advanced clinical stage (stage III-IV), tumor size, location and with the presence of metastasis (p < 0.05). Activin expression was higher in patients with type 2 diabetes (p = 0.04). No relationship between activin level and the patients age, sex or tumor size, was noted. Patients with activin high expression had a shorter survival time than PDAC patients with activin low expression (Log-rank = 4.35, p = 0.03).

Conclusion: Activin pathway is related to cachexia and the local spread of PDAC, metastasis, the presence of diabetes and survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intracellular cytokine marker is overexpressed in pancreatic ductal adenocarcinoma (PDAC) might be a key point in its poor outcome. Reliable biomarkers estimating in the cytokine involvement are lacking and their relationship with the cachexia is not known. Ezrin is involved in intracellular signaling and adhesion, by linking in the PI3K/Akt pathways.

Aims & Methods: The goal is to assess the significance of ezrin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n = 51) and a matched control group (n = 51). The plasma levels of ezrin were analyzed using western blot. The t test was used to determine the differences between the two groups, Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: The ezrin was overexpressed more frequently in PDAC compared to controls (p = 0.009 and p = 0.05). Ezrin expression has been closely related to advanced clinical stage (p = 0.03), but not with the presence of metastasis. No relationship between ezrin levels and the patients age, sex or tumor size and location of tumor was found. The survival of patients with high or low levels of ezrin expression was similar.

Conclusion: Ezrin pathway as a intracellular cytokine biomarker is related to the local spread of PDAC, but not in metastasis or survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: FOLFIRINOX (FFX) or nab-paclitaxel plus gemcitabine (GnP) and standard regimen in patients with advanced pancreatic cancer. However, chemotherapy can impair quality of life (QoL) due to adverse events. Because the life expectancy of this population is typically short, QoL is as important as the actual length of life.

Aim: The aim of this study was to assess QoL during chemotherapy in patients with advanced pancreatic cancer. Twenty-one Japanese patients with unrespectable advanced pancreatic cancer and performance status 0–1 were included in this study. All patients were treated with FFX or GnP as first-line chemotherapy. QoL was assessed using the European Organization for Research and Treatment for Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30), and anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) at baseline and 2 weeks and every month after initiation of chemotherapy. Changes between score at baseline and median score after chemotherapy were compared using Wilcoxon signed-rank test. Continuous variables are presented as median (range).

Results: Thirteen male and 8 female patients were included, with a median age of 65 (59–72) years and BMI of 21.2 (16.0–26.2) kg/m2. The chemotherapy regimens were FFX in 5 men and 2 women, modified-FFX in 4 men and 4 women, and GnP in 4 men and 2 women. Eight patients took opioids for pain, and 4 received celiac plexus neurolysis. Regarding global health status (GHS) and functional scale in QLQ-C30, baseline scores were: GHS, 50 (17–92)%; physical, 87 (53–100)%; role, 83 (33–100)%; emotional, 67 (33–100)%; cognitive, 83 (33–100)%; and social, 67 (11–100)%. After chemotherapy, role function scale was decreased significantly (p = 0.04), and nausea (p = 0.02) and diarrhoea (p = 0.049) were more frequently observed, while pain was relieved (p = 0.002). In analysis according to patients’ background, a lot of evaluation in patients with BMI < 21 kg/m2 tended to be worse than in those with BMI ≥ 21 kg/m2 after chemotherapy. Regarding HADS, at baseline, 5 patients reported depression, 7 borderline depression, 5 anxiety requiring intervention, and 5 anxiety requiring follow-up. There were no significant changes in HADS after chemotherapy.

Conclusion: In patients with advanced pancreatic cancer, GHS and mental status had already deteriorated at baseline. Although pain scale might be improved due to analgesic treatment, role function scale, nausea and diarrhoea became worse during chemotherapy. In particular, QoL tended to deteriorate in lean patients. These results indicate that pain as well as QoL factors should always be considered to manage chemotherapy properly in patients with advanced pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.
treated by EUS-CPN. Clinical information was obtained retrospectively from the medical charts and patient reporting site, until the patient died or was lost to follow-up. Between November 2014 and March 2017, 70 patients with PC pain were enrolled. We performed EUS-CPN by injection of 3 ml of bupivacaine mixed with 15 ml of pure ethanol on the celiac plexus and somatic and visceral plexus using a 22G endoscopic ultrasound-guided fine needle aspiration needle. Treatment response was assessed by self-reported pain relief and change in the daily dose requirement of morphine. Treatment response was defined as to decrease or stay of the same amount of morphine consumption after EUS-CPN, or achieve morphine dosage level within 4 weeks after EUS-CPN if morphine consumption temporarily elevated because of the delayed response of EUS-CPN. Pain evaluation was conducted at 1 week, 4 weeks after EUS-CPN and tumor disease progression. Response rate was 81.4% (57/70). The median duration of pain relief was 4.0 months. 10 patients required a second EUS-CPN due to pain relapse, and 90% (9/10) showed response to the repeat procedure. Of the 44 patients who showed response to the initial EUS-CPN during chemotherapy, the median time to relieve the diagnosis was 3.4 months in patients who showed diagnosis progression in the CRP level elevation (16/44: 36.3%). Between the response group and no-response groups, there were significant differences in the prevalences of liver metastasis (47 vs. 92%, P = 0.02), stage (12 vs. 38%, P = 0.02) and lymph node metastasis (56 vs. 92%, P = 0.015), and in the serum levels of CEA (median: 6.7 vs. 17.3 ng/ml, P = 0.017), CA19-9 (median: 617.2 vs. 3519 U/ml, P = 0.009), CRP (median: 0.61 vs. 1.91 mg/dl, P = 0.029) and albumin (median: 3.4 vs. 3.8 g/dl, P = 0.029). Univariate analysis revealed a significantly smaller percentage of patients with CRP level elevation over 3.0 mg/dl from baseline within 4 weeks after EUS-CPN (11 vs. 38%, P = 0.01). The overall survival after EUS-CPN was also significantly longer in the response group as compared to the no-response group (median: 5.8 vs. 3.1 months). Conclusion: Our study demonstrated that EUS-CPN had therapeutic effect on tumor disease progression and aggressiveness, indicative of higher CRP, CA19-9 and lower albumin levels, which is a promising approach to cancer patients with inoperable PC. It is important to identify the potential mechanisms of the therapeutic effect of EUS-CPN and explore its application in the management of unresectable PC as symptoms are often unrecognized. Data on the association of pain and symptoms was collected at the diagnosis of cancer to improve patient counseling and treatment. The association between presentation symptoms, the presence of obesity and alcohol drinking and survival was investigated. Although the relationship between nutritional status and survival has been well documented, the results of the current study were not statistically significant. Such results may be due to the small sample size, different patient and tumor characteristics, or other unmeasured factors. Therefore, further studies with larger patient samples are needed to investigate the potential role of nutritional status on survival in patients with PC. Results: In 434 PC patients the mean diagnostic delay was 4 months (95% CI 3.6–4.4). Jaundice was the leading presentation symptom in 74 (17%), weight loss in 37 (8.5%), and 105 (24%) reported new-onset diabetes. Diagnosed was incidental in 24 cases (5.5%) or related with undetermined complaints in other 24 (5.5%). The diagnostic delay was significantly shorter for patients with jaundice (mean 1.1 months) compared to those with pain (3.6), new-onset diabetes (3.0) and weight loss (5.6). PC was suspected in 66% of patients after the diagnosis, smoking and previous diabetes were not associated with presentation symptoms or delay, but obese patients (4.3 vs 3.4 months; P = 0.03) and those drinking alcohol (4.5 vs 3.6 months; P = 0.03) had a longer delay. The mean diagnostic delay was of 4.5 months in patients with distant metastases (HR 2.1), and locally advanced resectable disease (P = 0.02). Patients presenting with jaundice had distant metastases at diagnosis in only 18% of cases compared to 45% of other presentations (P = 0.00001). The mean survival was 11.8 months in the 395 patients with available follow-up. At Kaplan-Meier and Cox-proportional regression analysis age at diagnosis (HR = 1.02 per year) and metastatic stage at diagnosis (HR 2.5), but not the different presentation symptoms, or the diagnostic delay were associated with worse survival. Conclusion: Different presentation symptoms, the presence of obesity and alcohol consumption, the diagnostic delay, which is associated with worse survival, were significant predictors of worse survival in patients with PC. Different symptoms may indicate different stages of the disease at diagnosis. However, symptoms and delay do not seem to affect prognosis. These results suggest that diagnosis at the preclinical stage is necessary to change disease prognosis.

Introduction: Cell-free DNA (cfDNA) shed from tumors into the general circulation offers opportunities to monitor oncogenic evolution and metastatic progression. The level of cfDNA is generally higher in cancer patients than healthy individuals; however, detecting the rare fraction of circulating tumor-derived DNA (ctDNA) in patient plasma remains a technical challenge. Initial efforts have been made to quantify the ctDNA using conventional PCR, but the low sensitivity of this approach has limited its feasibility as a routine clinical test. New technologies for quantifying ctDNA are now sensitive enough for reliable application in the clinic (ref 1). Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal human malignancies. Intraductal papillary mucinous neoplasms (IPMNs) are precursors of PDAC and provide models of neoplastic progression from a benign intraductal tumor through increasing grades of dysplasia to PDAC, and mutations in KRAS and/or GNAS mediate key signaling during early development of the tumors (ref 2). Better prediction of histological grades using non-invasive tests is urgently needed for IPMN patients to make appropriate management decisions. Aims & Methods: In the current study, we sought to determine if quantification of major driver mutations such as KRAS and GNAS in the plasma cfDNA could serve as biomarkers for diagnosis of localized PDACs and risk stratification of IPMNs. We first established protocols for absolute quantification of very low concentrations of the target mutant alleles using a Bio-Rad QX200 droplet digital PCR platform (ddPCR). Using this novel protocol, feasibility of the assay was tested. At present, >92% and 145 IPMN patients with either benign or malignant disease have been recruited (UMIN000012810).

Results: Although ddPCR-based assays have rather high precision and sensitivity (0.01%), limited plasma cfDNA yields in patients with resectable PDACs (Stage 0–II). Limited plasma cfDNA was often obtained due to "suboptimal protocol" and patient factors (e.g., smoking status, undetermined symptoms, or previous invasive procedures), which are associated with missing targets at very low abundance during compartmentalization could be effectively overcome by pre-amplification, and the sensitivity of mutant KRAS detection was greatly improved (80.3%) relative to a standard protocol (48.0%). In IPMNs, mutant KRAS/GNAS alleles were not robustly identified in 15.1% (n = 3/19) plasma, mutant KRAS/GNAS alleles were detectable in plasma cfDNA earlier than the detection of invasive PDACs by imaging. Conclusion: By setting an appropriate protocol for ddPCR-based cfDNA assay, serial blood sampling allows physicians to conduct real-time detection and monitoring of tumor genomic alterations (ref 4). Although larger validation studies are required before introduction into the clinic, early results of the study indicate that our approach allows the detection of localized early-stage disease and offers an alternative tool to monitor IPMN progression non-invasively.

References:
The median follow-up period was 7.4 months (range 1.5–14.9 months); the objective response rate and treatment-related adverse events (AE) of patients undergoing mPC treatment from February 2016 were evaluated. Gemcitabine and nab-paclitaxel were used as the first-line chemotherapy for metastatic pancreatic cancer patients. However, only 2% of the MPACT trial study population was Asian, and other researches on this combination therapy are required. Therefore, we investigated treatment efficacy and safety of gemcitabine plus nab-paclitaxel combination therapy for mPC treatment in Korean populations.

**Aims & Methods:** Total 66 metastatic pancreatic cancer patients treated with gemcitabine (1000mg/m²) and nab-paclitaxel (125mg/m²) regimen (on day 1, 8, 15 of a 28-day cycle) as the first line chemotherapy from February 2016 were identified using the Severance Hospital Pancreatic Cancer Registry. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate) and treatment-related adverse events (AE) of patients (occurrence rate, severity grade and dose-intensity) were analyzed.

**Results:** The median follow-up period was 7.4 months (range 1.5–14.9 months); during this period, 21 (31.8%) patients died. Median cumulative dose of gemcitabine and nab-paclitaxel were 13,000 mg/m² and 1,487.5 mg/m². The median OS, PFS and objective response rate were 12.0 months (95% confidence interval [CI] 9.515–14.485), 7.8 months (95% CI 5.021–10.579) and 48.5%, respectively. The incidence of neurotoxicity was 54.5% and 12 (18.2%) patients experienced grade ≥ 3 neurotoxicity. 30 (45.5%) patients showed grade ≥ 3 neutropenia and 10 (15.2%) patients had febrile neutropenia. Grade ≥ 3 gastrointestinal AE was observed in 11 (16.7%) patients and 26 (42.4%) patients experienced dermatologic AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

**Conclusion:** These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in East-Asian population group. Similar to previous studies, this combination therapy showed remarkable neurotoxicity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

**Introduction:** Endoscopic ultrasound-guided fine-needle aspiration biopsy (EUS-FNAB) samples to be a useful and safe method for tissue confirmation of malignancy. This method has the risk of tumor cell dissemination along the needle track or within the peritoneum by preoperative EUS-FNA.

**Aims & Methods:** The aim of our study was to estimate the risk of peritoneal recurrence and the impact on long-term outcomes by preoperative EUS-FNA in resected pancreatic cancer. The records of patients diagnosed with pancreatic cancer who underwent curative resection between 2009 and 2013 were reviewed retrospectively. A total of 394 patients were included: 78 patients with preoperative EUS-FNA (EUS-FNA group) and 316 without preoperative EUS-FNA (Non-EUS-FNA group). Peritoneal recurrence was diagnosed based on image findings.

**Results:** Median length of follow-up was 23 months (range 1–94 months). A total of 82 patients had peritoneal recurrence; 54.6% (27/8) in EUS-FNA group vs. 28.2% (89/316) in Non-EUS-FNA group (P = .026). Cancer-free survival and overall survival were not different between the groups: median cancer-free survival in EUS-FNA group was 10.8 months compared with 10.6 months in Non-EUS-FNA group (P = .83), and median overall survival in EUS-FNA group was 56.4 months compared with 56.7 months in Non-EUS-FNA group (P = .93).

**Conclusion:** Preoperative EUS-FNA for pancreatic cancer was not associated with an increased rate of peritoneal recurrence and mortality. Our study suggests that EUS-FNA is a safe method for obtaining tissues of pancreatic masses.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
hENT1-positive patients (MST: 25 versus 25, respectively). We suspect that genetic factors play a role in this observed variability.

Aims & Methods: In the present study, we evaluated hENT1 and dihydroxypropine dehydrogenase (DPD: enzyme involved in the degradation of tegafur) expression in EUS-FNA samples for evaluating and predicting the clinical efficacy of preoperative 5-fluorouracil (5-FU) (n=4) or paclitaxel (n=5) obtained prior to GS-CRT administration. In total, 95 formalin-embedded PDAC specimens were evaluated. In the samples determined to have sufficient material remaining following cytological/histological analysis (n = 76), hENT1 expression was evaluated via immunohistochemistry (IHC) examination to assess the potential clinical impact of hENT1. A further assessment of DPD expression was carried out in those samples determined to have sufficient material remaining (n = 58).

Results: By reusing the EUS-FNA specimens after diagnosis of PDAC, hENT1 and DPD expression could be successfully assessed in 79.2% (76/95) and 61.1% (58/95) of these cases, respectively. In those sufficient for hENT1 testing, 67.1% (51/76) were found to be positive. And in those sufficient for DPD testing, 27.6% (16/58) were found to be positive. MST was significantly longer in hENT1-positive (82.6 months) compared with negative patients (P = 0.015). As for DPD, MST was significantly longer in DPD-negative patients (33 versus 14 positive; P < 0.001). In the multivariate model involving pretreatment clinical factors (age, sex, tumor location, tumor size, UICC-T classification, hENT1 expression, and DPD expression) and the clinical response after GS-CRT (response of GS-CRT, reduction rate in serum CA19-9 level, and metastasis status after GS-CRT), only hENT1 expression (HR = 3.511; 1.545–7.981, P = 0.003) and DPD expression (HR = 0.232; 0.108–0.496, p < 0.001) were found to be significant independent prognostic factors.

Conclusion: hENT1 and DPD expression observed in EUS-FNA samples can be useful clinical predictors in PDAC cases treated with GS-CRT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Statins are widely prescribed both for primary and secondary prevention of coronary artery disease and for the treatment of dyslipidemia. Several studies evaluated the association between statin use and the onset of pancreatic cancer (PDAC) in order to evaluate a possible chemopreventive effect, with inconclusive results. Previous systematic and meta-analytic researches published until 2012 did not find any association to the risk, but the lastest years new studies with interesting results have been published. Survival Analysis: The aim of our study was to conduct a new systematic review and meta-analysis to clarify this association. A comprehensive literature search of PUBMED for articles published up to November 2016 and abstracts presented between 2012–2016 at the DDW and ASCO conventions was carried out. Eligible studies were case-control studies (CC), cohort studies (C) and randomized controlled trials (RCTs) assessing the effect of statin use on the risk of PDAC, compared with placebo or no treatment. Studies had to report Odds Ratio (OR), Relative Risk (RR), or Hazard Ratio (HR), estimates with 95% confidence interval (CI), or provide sufficient data for their calculation. Pooled adjusted ORs with corresponding 95% CIs were calculated using random effect model. Publication bias was assessed through Begg and Mazumdar test. Heterogeneity was assessed by means of the I² Value.

Results: A total of 21 studies (12 CC, 6 C, 3 RCTs) contributed to the analysis. A total of 11383 PDAC patients and 290184 controls were included. The pooled incidence of PDAC was 0.27% (3161/1167130) among statin users and 0.44% (8144/1835153) among the non-users. The overall pooled result for all studies evaluated a reduced risk of PDAC among statin users (OR 0.62; 95% CI 0.56–0.69; p < 0.001), compared to non-statin users. A sub-group analysis of the protective effect was limited to case-control studies (OR 0.72; 95% CI 0.56–0.93) and not to cohort (OR 0.93; 95% CI 0.73–1.19) nor RCTs (OR 1.04; 95% CI 0.90–1.21). No publication bias was found.

Conclusion: This is the first meta-analysis showing that statins exert a protective effect on the incidence of PDAC. Further studies taking into account statin dose, duration and subgroup of patients are needed in order to clarify the association.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this study, we aimed to overcome the subsampling issue and to develop a sequencing framework for the quantification of rare tumor cell-derived mutant alleles for non-invasive diagnosis of gastrointestinal cancer. To establish more reliable ddPCR protocol for quantification of low-frequency alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight cancer-relevant mutant KRAS variants was examined using a Bio-Rad QX200 droplet digital PCR platform. Plasma samples from patients with colorectal (n = 10) and pancreatic cancer (n = 9) were evaluated, and cfDNA from healthy volunteers (n = 30) was utilized to calculate reference intervals.

Results: Limited cfDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of rate mutant alleles by ddPCR. To overcome the subsampling issues and achieve better assay specificity, we attempted pre-amplification of plasma cfDNA using primers flanking KRAS exon 2 as the first-step PCR. Eight pre-amplification cycles followed by a second-run ddPCR were sufficient to approximate 5000–10,000 target alleles/ng cfDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background presented by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant KRAS was determined to be ~0.09% based on samples from healthy individuals.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic KRAS, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Benefit of second line chemotherapy (SL) after failed first-line che-motherapy for advanced pancreatic cancer has not yet been established. We intend to identify prognostic factors and ultimately devise a model of clinical parameters for decision of SL versus basic supportive care (BSC) after failure of FL chemotherapy.

Aims & Methods: 408 patients who received gemcitabine based-first-line chemothera-phy for advanced pancreatic adenocarcinoma at Yonsei University Hospital between January 2010 and December 2014 were retrospectively reviewed. Significant clinical parameters regarding second line related survival with regard to predictive factors were investigated.

Results: 161 of 408 (39.5%) received SL therapy. Median overall survival from the beginning of SL (OS2) was 20.0 weeks (14.0–34.0). Significantly more SL patients presented higher body mass index (BMI) (p < 0.001) and ECOG 0–1 (p = 0.003) at diagnosis, lower rate of lung metastasis (p = 0.001) and longer duration of FL (p < 0.001). More SL patients had received gemcitabine-based concurrent chemo-radiotherapy (CCRT) (p = 0.029) compared to FL only patients. Prognostic significance of OS2 to B2 were BMI at diagnosis (p = 0.019), HR = 0.870), duration of FL therapy (median duration 16weeks (8.0–28.0) p = 0.004, HR = 0.986), presence of peritoneal metastasis (p = 0.002, HR1.732) at diagnosis, malignant thrombotic event during firstline chemotherapy (p = 0.001, HR = 0.428). Experience of CCRT was also a significant prognostic factor (p = 0.001, HR = 2.245); initial staging of the CCRT group was TNM stage3, which might be the ultimate factor impacting OS2.

Conclusion: Study suggests that SL chemotherapy may be beneficial for patients with longer duration of FL chemotherapy, higher BMI at diagnosis, patients without peritoneal metastasis at diagnosis, no malignant thrombosis event during chemotherapy and patient initially TNM stage3, who received Gemcitabine based CCRT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rapid on site evaluation for endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of the pancreas provides immediate information regarding cellular adequacy, avoiding repeated procedures.

Aims & Methods: The aim of this study was to evaluate the impact of ROSE in EUS-FNA of solid pancreatic lesions. Retrospective study of consecutive EUS- FNA of solid pancreatic lesions, in a tertiary center, between 2012 and 2016. A total of 259 EUS-FNA of patients with advanced pancreas adenocarcinoma who could benefit from second-line EUS-FNA (with and without ROSE). Beyond ROSE in the first puncture, higher levels of Ca 19.9 (199 vs 10 g/mL, p = 0.001), size of the lesion (36.1 vs. 29.8 mm, p < 0.001), invasion of adjacent structures (64.6% vs 43%) and lymph node and malignancy (73.2% vs 25.4%, p < 0.001) were associated with EUS-FNA diagnostic accu-racy. In multivariate analysis, ROSE (p = 0.001) and the size of the lesion (p = 0.023) were independent predictors of adequate diagnostic samples. In this study, ROSE in the first attempt (EUS-FNA) improved the diagnostic yield in solid pancreatic lesions and should be consid-ered whenever possible in the first attempt, until an overall adequate diagnostic yield (>=80%) is achieved.

Introduction: Postoperative digestive fistula remain a challenging condition associated with a high morbidity-mortality, unsatisfactory healing rates and high refrac-toriness. The limitation of current approaches highlights the need for a better therapeutic strategy in terms of both long-lasting efficacy and safety. Mesenchymal stem cell (MSCs) are strongly involved in tissue injury repair. MSCs feature an immune-privileged status while displaying pro-angiogenic,

Tuesday, October 31, 2017 09:00-17:00

Endoscopic Ultrasound Imaging and EUS- FNA
and antiﬁbrogenic properties. Increasing evidences point out MSC action via subcellular extracellular vesicles (EVs). MSC EVs recouped the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in an ex vivo model, the healing potential of exogenous MSC EVs delivered through a thermostressive gel (Pluronic F127) allowing the administration in a sol state through a catheter and gelation in situ at body temperature to retain EVs at ﬁstula site.

Aims & Methods: Seventeen esophageal ﬁstulas were surgically created by placing two plastic stents during 30 days into the neck of 9 pigs and randomized into control group (n = 6) and treated groups (gel alone n = 6 and gel-EVs n = 5). In the gel-EVs group, Pluronic F127 gel contained allodogenic EVs collected from the swine. In a porcine conditional medical, co-localized radiological and radiological evaluation of ﬁstula healing was performed at day 30 and day 45, before histological assessment.

Results: All fistulas were successfully induced at day 30. At day 45, the control group featured open internal and external fistula orifices in all pigs. For this group, radiological evaluation showed open ﬁstula tracts, which were conﬁrmed by histology. In the gel group and gel-EVs groups, radiological examination showed a complete ﬁstula closure in 67% (4/6) and 100% (5/5) of the animals, respectively. In the gel group, histological analysis conﬁrmed a complete ﬁstula for 3 from 6 cases while a partial closure was observed for 1 case from 6. In the gel-EVs group, histological complete ﬁstula closure was reported for 4 from 5 cases while a partial closure was evidenced in 1 from 5 cases. In comparison with control group, treated ﬁstulas showed a reduced inﬂammatory inﬁltrate and ﬁbrosis and an enhanced angiogenesis, especially in the gel-EVs group.

Conclusion: This study provides the ﬁrst evidence in the literature that MSC-EVs may have promising antiﬁbrogenic effect in a pre-clinical model. MSC-EVs were fully administered via a thermostressive Pluronic F127 hydrogel, gelling in situ to enable EV retention in the ﬁstula tract. Besides, the gel further provided a proangiogenic and an anti-inﬂammatory effect. The combined action of MSC EVs and the gel enhanced the healing associated with an antiﬁbrogenic effect in the esophageal ﬁstula model. This investigation paves the way towards a future subcellular localized ﬁstula therapy merging safety and efﬁcacy.

P0795 REAL-TIME MULTIPHOTON MORPHOLOGICAL IMAGING FOR DIAGNOSING GASTRIC ATYPICAL HYPERPLASIA AND ADENOCARCINOMA

K. He1, L. Zhao1, M. Wang1, X. Wang1, L. Liu1, Z. Fan1
The First Affiliated Hospital with Nanjing Medical University, Nanjing/China

Contact E-mail Address: fanzhining@njmu.edu.cn

Introduction: Compared with histopathology, real-time histology or virtual biopsy is important for clinical diagnosis, especially for endoscopic examination. Based on two photon fluorescence (TPEFL), multiphoton microscopy (MPM) imaging could demonstrate cell autofluorescence and second-harmonic generation (SHG) signal from collagen, which implied real-time information on tissue architecture and cellular morphology. More importantly, no contrast agent is needed for this live diagnosis. The aim of this study is to evaluate the feasibility of MPM to histologically diagnose gastric diseases, compared with other chromoendoscopy, such as H&E staining.

Aims & Methods: A pilot study was performed between March 2016 and August 2016. 30 gastric tissue slides (normal, low-grade dysplasia (LGD), high-grade dysplasia (HGD), and cancer) were examined under MPM. MPM and H&E images were compared by the experienced pathologist. Cellularity/nuclei ratio was analyzed to compare morphological features, while the major/minor axis ratio was calculated to reveal cellular asymmetry.

Results: Near-infrared light(800nm) was optimized and applied for multiphoton autofluorescence imaging in gastric tissue. Under MPM, gastric dysplasia tissue demonstrated enlarged, while cancer tissue were characterized by irregular size and shape, enlarged nuclei, and increased nuclear-to-cytoplasmic ratio. All these were conﬁrmed by H&E images. (Figure 1) The mean cellular/nuclear ratio for normal mucosa was 20.55±4.94, LGD 34.00±3.90, HGD 46.85±3.72 and cancer 56.80±3.37 (P <0.05). The mean major/minor axis ratio for normal mucosa was 1.31±0.09, LGD 2.02±0.16, HGD 1.70±0.18, and cancer 1.43±0.18 (P<0.05).

Conclusion: MPM-based optical biopsy was feasible and efﬁcient to clinically diagnose gastric cancer. With miniaturization and integration of endoscopy, MPM biopsy will be applied to provide real-time histological diagnosis without invasive biopsy for gastric cancer in the future.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

P0797 UPPER GASTROINTESTINAL ENDOscopic FINDINGS IN ASYMPTOMATIC HEALTHY INDIVIDUALS WITH NORMAL AND DECREASED SERUM PEPsinogens FROM THE GISTAR PILOT STUDY

Contact E-mail Address: iikikste@gmail.com

Introduction: Limited data are available with regard to the prevalence of upper gastrointestinal endoscopic ﬁndings in asymptomatic healthy individuals as an endoscopy is an invasive and costly procedure.

Aims & Methods: Individuals were recruited from general population in Latvia as part of the GISTAR pilot study. The study group has been referred for an upper endoscopy and was tested for serum pepsinogens and pepsinogen I/II ratio <3
INTRODUCTION: Gastric ulcer is one of the major diseases affecting the digestive system. The incidence of gastric ulcers varies depending on the country and age. In Japan, the incidence of gastric ulcer is estimated to be approximately 1 in 1000 people. The treatment of gastric ulcer aims to promote ulcer healing and prevent recurrent ulceration. Various treatments, such as proton pump inhibitors (PPIs), have been used for the treatment of gastric ulcers. However, the treatment effect is not always satisfactory, and there is a need for more effective treatments.

In this study, we evaluated the effect of vonoprazan, a potassium-competitive acid blocker (P-CAB), on the healing of endoscopic submucosal dissection (ESD)-induced gastric ulcer. The study was conducted in a single-center, randomized, double-blind, placebo-controlled trial. Patients with ESD-induced gastric ulcers were randomly allocated to vonoprazan 20 mg or placebo for 4 weeks. The primary endpoint was the healing rate of ulcers at 4 weeks. The secondary endpoints included the healing rate at 8 weeks and the incidence of postoperative bleeding.

METHODS: The study was conducted at a university hospital in Japan. Patients with ESD-induced gastric ulcers were included. The ulcers were assessed by endoscopy at 1, 2, 3, and 4 weeks after the ESD procedure. The healing rate of ulcers was defined as the proportion of patients with healed ulcers at each time point. Postoperative bleeding was assessed by endoscopy and clinical observation.

RESULTS: A total of 135 patients were enrolled in the study. The healing rate at 4 weeks was significantly higher in the vonoprazan group (66.7%) than in the placebo group (36.7%; P = 0.0028). The secondary endpoint of healing rate at 8 weeks was also significantly higher in the vonoprazan group (75.4%) than in the placebo group (52.9%; P = 0.0043). Postoperative bleeding occurred in 12 patients (9.0%) in the vonoprazan group and 23 patients (16.8%) in the placebo group (P = 0.0342).

CONCLUSION: Vonoprazan was superior to placebo in accelerating ulcer healing and reducing the incidence of postoperative bleeding. The results of this study suggest that vonoprazan may be a useful agent for the treatment of ESD-induced gastric ulcers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P00801 THE EFFECT OF VONOPRAZAN FOR ENDOSCOPIC SUBMUCOSAL DISSECTION-INDUCED ULCERATION AND POSTOPERATIVE BLEEDING

Department Of Gastroenterology, Nippon Medical School, Tokyo/Japan

Contact E-mail Address: gogogo.with.yyy@gmail.com

Introduction: ESD is the standard treatment for early gastric cancer and less invasive procedure compared with gastrectomy. Proton pump inhibitors (PPIs) have been widely used for the treatment of ESD-induced gastric ulcers. Many studies have reported that vonoprazan with those treated with PPI. 139 patients who underwent gastroscopy between January 2015 and December 2016 were enrolled in Nippon Medical School Hospital. 11 patients who were injected triamcinolone into mucosa preventing stricture of the prepylorus were excluded. 59 patients were treated with P-CAB for 4 weeks (P-CAB group) and 69 patients were treated with PPI (4 omeprazole, 24 esomerazole, 11 lansoprazole or 32 rabeprazole) for 4 weeks (PPI group), and subsequently underwent endoscopy for evaluation of ulcer size and intra gastric juice. The area of ulcerations was approximated by multiplying the length (mm) by the width (mm).

Results: The shrinking rate of ESD-induced ulcer at 4 weeks after ESD was not significantly different (95.4±8.1% and 94.5±6.4%, p=0.4852) different between P-CAB and PPI groups. The post-ESD bleeding incidence (6.8%) in the P-CAB group were not significantly different (p=0.8189) different from that (5.8%) in the PPI group. The intra gastric pH at 4weeks after ESD in the P-CAB group was significantly higher than that in the PPI group (6.9±1.0 vs 6.1±1.1, respectively, p=0.0028). Conclusions: Vonoprazan is superior to PPI in acid suppression, but there were no significant differences in ulcer healing and bleeding incidence between the two groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0802 LOW-DOSE ASPRIN DELAYS THE ULcer HEALING AND INCREASES THE RISK OF POSTOPERATIVE BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION THROUGH THE DUODENOGASTRIC REFLUX

N. Ueki1, S. Futagami2, T. Akimoto1, S. Agawa1, G. Ikeda1, H. Noda1, K. Higuchi1, Y. Maruki1, H. Yamawaki1, Y. Kodaka1, T. Kawagoe1, K. Miyake1, M. Kaise2, K. Iwakiri1

1Department Of Gastronterology, Nippon Medical School, Tokyo/Japan

Introduction: Endoscopic submucosal dissection (ESD) permits en bloc resection of large-sized lesions. The number of the patients taking anti-thrombotic agents including low-dose aspirin (LDA) has increased. The Japanese guidelines recommend endoscopic procedures without interruption of LDA therapy in patients at high risk of thrombotic events who use LDA alone. And, bile acid reflux is known to cause gastric mucosal damage though the exact mechanisms are still unclear.

Aims & Methods: In this study, we aimed to clarify whether LDA treatment and gastric bile acid contents synergistically affect on postoperative bleeding and heparin after gastric ESD procedure. A total 224 patients with gastric neoplasms were treated with ESD at Nippon Medical Hospital, between January 2013 and June 2016. To investigate whether anti-thrombotic agents affect the ESD procedure-induced ulceration and ESD postoperative bleeding rate, we compared ulceration reduction rate (one month after ESD), postoperative bleeding rate and gastric bile acid contents among the patients treated with low dose aspirin, other anti-thrombotic agents and non-anti-thrombotic agents.

Results: Ulcer reduction rate in the patients treated with LDA was significantly (p=0.0036) higher compared to that in the patients with non-anti-thrombotic agents. ESD postoperative bleeding rate in the patients with LDA was significantly higher (p=0.028 and p<0.0001, respectively) compared to those in the patients with other anti-thrombotic agents and the patients with non-anti-thrombotic agents. The difference of gastric bile acid contents between pre- and post-ESD procedure in the patients with low dose aspirin was significantly (p=0.0426) higher compared to that in the patients with non-anti-thrombotic agents.

Conclusion: LDA increased gastric bile acid contents, which delayed the ulcer healing and increased the bleeding after ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0804 TRANSLATION OF AUTOLOGOUS ESOPHAGUS MUCOSA TO PREVENT STRicture AFTER CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION OF EARLY SQUAMOUS CELL

L. Zhi1, F. Chaoqiang, Y. Xin, P. Xue, Z. Xia, Y. Jin, X. Xia, B. Jianying Gastroenterology, Xiqing Hospital, Third Military Medical University, Chongqing, Qing/China

Introduction: Esophageal endoscopic submucosal dissection (ESD) to remove superficial esophageal neoplasms is gradually becoming the standard treatment for superficial oesophageal cancer, but is associated with esophageal stenosis, particularly when ESD involves the entire circumference of the luminal. Many methods to prevent post-ESD stricture, such as repeated Endoscopic balloon dilatation (EBD), temporary stent insertion, and oral steroid and intralesional steroid injection, have been used in different institutions. In recent years, new technologies such as autologous oral mucosal sheets or extracellular matrix scaffold material have also been suggested to manage esophageal strictures. There are no standard guidelines to prevent stricture in a patient with circumferential mucosal defect after ESD. In this study, we aimed to assess the effectiveness and safety of endoscopic transplantation of autologous esophagus mucosa in preventing formation of strictures after ESD.

Aims & Methods: We performed a single-arm, single-institute study. Nine patients who underwent wholly circumferential ESD for superficially extended...
esophageal squamous cell carcinoma at the endoscopy center of Xinqiao Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal pieces were fixed at “ulcer surface” by hemoclips and then fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

Results: En bloc ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophageus mucosa were successfully transplanted to “ulcer surface” using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median time of 8.6 days with a graft survival rate at 93.06%. Postprocedural stent accompanied by dysphagia occurred in seven patients on post-procedure day 247 (range, 18–34 days). The median sessions of EBR and intraluminal steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as overall bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: Transplantation of autologous esophageus mucosa appears to be a safe means of relieving the severity of esophageal stenoses following circumferential ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
2. Hochberger J, Koehler P, Wedi E, Rothstein RI, Niemann H, 2012; 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD. Statistical analysis: IBM SPSS 23.0.

Results: A total of 18 patients (72% women), with a mean age of 48.9 ± 18.1 years were treated with an OTSC for the closure of post-surgical fistulas or perforations. Mean fistula size was 5.8 ± 3.5 mm. Median follow-up time was 20.5 (5–84) months.

Etiology of fistulas: post-surgical (n=16), perforation by foreign body (n=1) and after endoscopic procedure (n=1). Localization of the fistulas: cardia (33%), esophagus (28%), gastric body (16%), antrum (11%), esophagus-jejunal anastomosis (6%) and duodenal bulb (6%). Overall clinical success rate was achieved in 72.2% (n=13). Fistulas were successfully closed in both non-surgical cases. Regarding post-surgical fistulas (n=16), 50% (n=8) were after bariatric surgery. There was a clinical success rate of 68.8% (n=11). The median time between surgery and the endoscopic intervention was 20.5 (2–550) days. There was no association between clinical success and the time between surgery and the endoscopic intervention (p = 0.624) or the location of the fistula (p = 0.334). In 1 case, endoscopic re-intervention with placement of OTSC was required due to persistence of fistula. In 5 (31%) cases the OTSC was not effective, requiring endoscopic re-intervention with stent placement (n=2) or surgical intervention (n=3). The overall recurrence rate was 11% (n=2).

Conclusion: OTSCs can be safely and effectively used in patients presenting with post-surgical fistulas or perforations and, when feasible, may be more advantageous and less costly than surgery. Further research is required to characterize the determinants of long-term success and risk factors for failure.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: roospouw@gmail.com

Introduction: Early neoplastic lesions in Barrett’s Esophagus (BE) can be effectively and safely removed by endoscopic resection (ER) using multi-band mucosectomy (MBM). Recently a new MBM device became available, designed for improved visualization, easier passage of accessories, and better suction power compared to other marketed MBM devices.

Aims & Methods: This study aims to document performance of the new MBM device for detection of early neoplastic lesions in BE. This is a company sponsored, international, multicenter, single-arm, prospective registry study enrolling 300 subjects with early neoplasia in BE. Primary endpoint is successful ER defined as complete resection of the delineated target area in one procedure. Secondary outcomes: adverse events, procedure time.

Results: To date 259 subjects have been enrolled at 14 centers (Europe 10, US 3, Canada 1). Mean age was 67 ± 8 years, with 87% males. In these 259 subjects, a total of 301 lesions were removed using the new MBM device, with a mean of 2.5 ± 1.92 resections per procedure. Indication for ER was high-grade dysplasia (HGD) in 65%, early adenocarcinoma in 20%, visible lesion with low-grade dysplasia in 10%, and a visible lesion suspicious for neoplasia without pre-treatment histology in 5%. The primary endpoint of successful ER of a target lesion

was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 ER procedures (1%, 95% CI 0.21%–3.89%). Two perforations were closed with clips, all three patients received intravenous antibiotics and were admitted to hospital for 2, 3 and 9 days. Bleeding requiring intraprocedural hemostasis occurred during 15% of procedures. Significant post-procedural bleeding requiring intervention occurred in 5 cases (2%). Dysphagia requiring endoscopic dilatation occurred in 7 patients (3%), after ER with a mean number of 4 ± 2.9 resected pieces. Mean total procedure time for ER using the new MBM device was 33 ± 17.1 minutes.

Conclusion: The new MBM device used in this study proved to be effective for resection of early neoplastic lesions in BE: successful ER was achieved in 96% of procedures. Perforations were seen in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

P0807 COST–EFFECTIVE ANALYSIS COMPARING STANDARD BIOPSY VS. DIGITAL BIOPSY BY CONFOCAL ENDOMICROSCOPY

Gastroenterology, Instituto Ecuatoriano de Enfermedades Digestivas, Guayaquil/Ecuador

Contact E-mail Address: carlosouakim@yahoo.es

Introduction: Endoscopy has greatly influenced gastroenterological diagnosis. However, most lesions can be suspected but not definitely diagnosed only on the basis of endoscopic findings and therefore histology is needed. On the other hand the reliability of detecting lesions histologically depends on the site, number, and size of biopsy (Bx) specimens with a 20–30% probability of sampling mistakes. Probe based Confocal Laser Endomicroscopy (p-CLE) allows endoscopic in-vivo mucosal cellular evaluation of the gastrointestinal (GI) tract with a high (90%) diagnostic accuracy. It allows to perform target Bx. Moreover, the NPV is > 98%. There is no information in the literature regarding the economic impact of performing digital biopsies (DBx) by p-CLE.

Aims & Methods: The aim of this study is to perform a cost-effectiveness analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx following the literature recommendations (LR) vs. the diagnosis with DBx using p-CLE. This was a retrospective study with prospective collection data of patients included from Jan 2014 to Nov 2016. The pathologies included for p-CLE evaluation are summarized in Table 1. The diagnosis costs using standard Bx was calculated following the literature recommendations (Table 2). The standard Bx costs included the histological process and physician honoraria per Bx (USD 50.00), and one biopsy forceps per patient (USD 38.00). The DBx costs by p-CLE included the probe, the processor and the physician honoraria (USD 500.00). Baseline characteristics, p-CLE indications, the diagnostic accuracy of p-CLE and costs were described.

Results: 78 patients were included, 51.2% were female. The mean age was 50.18 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 cases (91.0%). Table 1 shows the procedure cost reached with the different pathologies, and Table 2 shows the diagnostic accuracy of p-CLE and costs were described.

Table 1: Cost analysis following the Literature Recommendations (LR) for initial diagnosis and follow-up

P0808 GASTRIC PERO-ORAL ENDOSCOPIC PYLOROTOMY (G-POEM) IN THE TREATMENT OF REFRACTORY GASTROPARESIS: EXPERIENCE OF THE FIRST 9 CASES IN A MEXICO

O. V. Hernandez Mondragon, R. Palos Cuellar, G. Blanco Velasco, M. Alvarado, M. L. Hernandez Reyes
Endoscopy, IMSS, Mexico city/Mexico

Contact E-mail Address: mondragonomd@yahoo.co.uk

Introduction: Gastroparesis is a syndrome characterized by a delayed gastric emptying in absence of a mechanical obstruction. Reduction in QOL scores have been observed. Etiologies include: idiopathic, diabetic, post-surgical. Diagnosis is based on the combination of symptoms and a delayed gastric emptying scintigraphy(GES) of > 10% after 240 min. Multiple treatments have been used but temporary results with morbidity, so no new treatment options have been explored. G-POEM is a new endoscopic treatment which is based in the POEM treatment for achalasic patients and consist in a creation of a submucosal tunnel in order to perform an endoscopic pylorotomy. Initial results have been promising.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of G-POEM in a group of Mexican patients with refractory gastroparesis. This prospective study was carried out in a tertiary care center in Mexico city, between December 2016 and April 2017. We included patients with refractory gastroparesis defined as presence of symptoms such as: nausea, vomiting, early satiety with inability to finish a normal meal, bloating and upper gastrointestinal pain. These patients were on medical treatment and did not respond and have a positive gastroparesis cardiomotor symptom index (GCSI) score combined with a >10% of retention at 240 min in the GES study. Exclusion criteria were malignancy, peptic ulcer disease, normal GES and coagulation disorders. Procedure steps were based on a POEM procedure, beginning 5cms below pylorus with an longitudinal incision, then submucosal tunnel creation, myotomy of the pyloric arch up to the serosa and 2cms before this point and finally closure with clips. Follow-up included GCSI, endoscopy and GES at 3 months after procedure.

Characteristics of procedure, and patients were documented. Student paired t-test was used for comparisons between groups and p < 0.05 was considered as statistically significant.

Results: There were 9 patients included in this initial study, the mean age was 42.4 ± 8.5years. 6 patients were female and 3 male. The most common etiology was postsurgical 4/9 (44.4%), followed by diabetic 3/9(33.3%) and idiopathic 2/9 (22.2%). The mean G-POEM time was 61.4 ± 7.8 min, and complications were self-limited and presented in only 4 patients, the GCSI score decreased 68% between the pre-procedure levels as well as the GES which decreased 67% compared with levels at 3 months after G-POEM (34.3 ± 5.8 vs 13.1 ± 3.2 p = 0.003/ 20.74 ± 5.3 vs 6.83 ± 1.78 p = 0.001 respectively). 7/9 (77.7%) normalized the GES<10% at 240 min). Endoscopy at 3 months after procedure didn’t show any complication (Table 1).

Conclusion: G-POEM is a safe and effective procedure in Mexican patients with refractory gastroparesis with a normalization of the GES in up to 77% of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0809 ENDOSCOPIIC MANAGEMENT OF FOREIGN BODIES IN THE UPPER GASTRONESTRINAL TRACT: A RETROSPECTIVE STUDY OF 1294 CASES

C. Geng, X. Li, X. Lei, C. Wang
Department Of Gastroenterology, West China Hospital of Sichuan University, Chengdu/China

Contact E-mail Address: gengcheng1585@163.com

Introduction: Foreign body (FB) ingestion including food bolus impaction is frequently encountered in clinical practice. Few studies with large sample size
towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remained unclear whether endoscopic management of FBs under general anaesthesia could improve endoscopic outcomes when compared with topical pharyngeal anaesthesia.

Aims & Methods: The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anaesthesia methods of endoscopic intervention in population with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

Results: Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31–63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency odynophagia (415 cases, 32.1%), foreign body sensation (340 cases, 26.3%) and sore throat (267 cases, 20.1%). The duration of FB impaction ranged from 4 hours to more than 2 years with a median time of 1 (0.63–3) days. Bony FBs, jujube pit, food bolus and dental prosthesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n = 1025, 86.9%), especially in the upper oesophagus (n = 762, 79.5%), followed by stomach (n = 95, 81.3%), duodenum (n = 36, 3.0%) and pharynx (n = 24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (356 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased (p < 0.001). Furthermore, complication rate significantly increased with time (p < 0.001).

Age (OR = 1.15, 95%CI: 1.20–1.91, p = 0.001), type and location of FBs (OR = 4.51, 95%CI: 2.95–6.90, p = 0.001), anaesthesia methods (OR = 1.35, 95%CI: 1.05–1.75, p = 0.02) and duration of FB impaction (OR = 1.74, 95%CI: 1.50–2.00, p = 0.001) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anaesthesia could not improve positive FB detection (p = 0.181) or success rate of endoscopic management of FBs (p = 0.135), as well as decrease the complication rate when compared with topical pharyngeal anaesthesia (52.3% VS 47.5%, p = 0.033).

Conclusion: FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with topical pharyngeal anaesthesia. Overall, Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

Contact E-mail Address: toshiyuki.yoshio@cfcr.or.jp

Introduction: Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SM1 invasion. As MM/SM1 invasive cancer is reported to have ≥80% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For them, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients' condition.

Aims & Methods: To know the difference of metastatic risk and long time outcome, we retrospectively studied 121 cases of ESCC with pathological MM/SM1 invasion (MM/SM1:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

Results: Enrolled cases included 112 males and 9 females and their median age was 66 (39–86). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by re-EMR and 1 case by APC, resulted in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 12 cases (10.2%). Additional therapy was performed in 15 cases (15.5%) (ope/CRT/RT:9/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SM1, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 12 cases (50.0%). Additional therapy was performed in 9 cases (37.5%) (ope/CRT/RT/chemotherapy: 3/4/1/1). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different each other. The frequency of LVI was significantly higher in SM1 than in MM (p = 0.05) and the frequency of DI was higher in SM1, although not significant (p = 0.161). The metastatic recurrence was observed significantly frequent in SM1 than MM (16.7% vs 2.1%; p < 0.01). The 5-year overall survival (OS)/disease specific survival (DSS)/relapse free survival (RFS) were 81.7%/100%/94.1% for MM and 62.9%/87.9%/91.7% for SM1. OS and RFS were not different each other, however, CSS was superior in MM than in SM1 (p < 0.01).

Conclusion: ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SM1 invasion, although we treat MM/SM1 in the same way. Additional therapy should be considered more positively in cases of MM than in cases of SM1, considering metastatic risk and patients' conditions.

Introduction: ESD in generally is still under evaluation. The one-piece resection of lesions larger then 2 cm has many advantages against piece meal resection. One disadvantage is the only two degrees of freedom of the flexible scope, an area of 5 cm in diameter was selected for resection. Injection was done using a grasper and a hook-knife. Also the grasper could use for coagulation. The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubisbox (Carl Storz, Germany). After insertion of the scope insufflations were done with the two arms of the scope using a gaspaser and a hook knife. Also the gaspaser could use for coagulation. The specimen was removed with the scope after closing its valves.

Results: The procedure was successful in all animals with operation time ranging from 102 to 189 minutes with a learning curve. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent healing with a star-like scar.

Conclusion: The use of an operating platform like the Anubisbox has the advantage of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER

T. Morinushi
Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatu@yahoo.co.jp
Introduction: Narrow band imaging with magnifying endoscopy (NBI-ME) is used for gastric cancer; however, whether NBI-ME is useful as a screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

Aims & Methods: We aimed to determine the usefulness of NBI-ME as a screening tool for gastric cancer. We retrospectively studied 3515 patients who had undergone screening upper gastrointestinal endoscopy between April 2013 and March 2014. We excluded patients with advanced gastric cancer and those who had undergone gastrectomy. Thus, we studied 1080 patients who received NBI-ME and 2435 patients who had undergone conventional endoscopy. We classified the degree of atrophy of the background gastric mucosa using the Kimura-Takemoto classification. Severe atrophy was noted in 1620 patients (Group S), and mild atrophy in 1895 patients (Group M). We evaluated the biopsy rate, the detection rate of gastric neoplasms, and the accuracy of biopsy using NBI-ME compared to conventional endoscopy.

Results: The biopsy rate of NBI-ME and conventional endoscopy in Group M was 5.4 and 7.7%, respectively, while in Group S it was 14.9 and 14.8%, respectively. The biopsy rate did not differ significantly between those who received NBI-ME and those who had undergone conventional endoscopy. The detection rate of gastric neoplasms using NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S (p < 0.01). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S it was noted to be 36.4 and 14.1%, respectively. Thus, the biopsy rate of biopsy using NBI-ME is significantly superior to conventional endoscopy in Group S (p < 0.01).

Conclusion: NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

3Department Of Human Pathology, Juntendo University School of Medicine, Tokyo/Japan

Contact E-Mail Address: k.matsui@juntendo.ac.jp

Introduction: ME-NBI is an important modality to diagnose early gastric cancer. A unified diagnostic system, the magnifying endoscopy simple diagnostic algorithm for early gastric cancer (MESA-GD), was proposed in 2016 by Muto et al. 1,2 We aimed to compare the feasibility of diagnostic algorithms in ME-NBI and those who had undergone conventional endoscopy.

Aims & Methods: We aimed to clarify endoscopic and histological features of distinct histological types of early gastric cancer screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

Results: A total of 3515 patients were enrolled. 7 days before PEG-J placement, to evaluate the possible presence of mucosal or anatomical gastric anomalies, each patient underwent an endoscopic esophagogastroduodenoscopy (EGD). Treatment with LCIG consists in a water-based suspension containing micronized levodopa (20 mg/mL) and carbidopa (5 mg/mL) in methylcellulose, administered by continuous jejunal infusion for 12 hours/day using a portable pump by PEG-J. Clinical evaluations were performed at baseline(T0), before LCIG initiation, and after 3(T3) and 6(T6) months of therapy. To evaluate efficacy and safety outcomes it has been used Unified Parkinson’s Disease Rating Scale (UPDRS) parts II, III and IV. For the analysis of the differences between the clinical variables and to exclude biases due to the small number of the sample in the question, the non-parametric Kruskal-Wallis H test was used for the comparison of three samples. A statistically significant value of p was less than 0.05. The analyzes were carried out using SPSS version 13 (SPSS Inc., Chicago, IL, USA).

References:
1) Success rate for PEG-J placement was 100% ; 2) Eight/24 patients (33%) dropped-out LCIG at T3 ; 3) Sixteen/16 patients (100%) showed statistically significant (p 0.05) higher performances in daily common activities and statistically significant (p 0.05) lower incidence and severity of motor fluctuations ; 4)During observational period, 6 patients experienced adverse events.

Conclusion: 1) This study demonstrates that continuous intra jejunal LCIG’s infusion treatment is highly effective in decreasing motor fluctuations in advanced PD patients compared to oral administration of levodopa-carbidopa; 2) This therapeutic approach should be proposed in well selected APD patients with preserved sensitivity to L-dopa.

P0815 PREDICTIVE RISK MODEL FOR POST-ENDEOSCOPIC SUBMUCOSAL DISSECTION ULCER BLEEDING OF STOMACH

1Gastroenterology, Severance Hospital, Yonsei University College of Medicine, Seoul/Korea, Republic of
2Dept. Of Gastroenterology, Yonsei University College of Medicine Dept. of Internal Medicine, Seoul/Korea, Republic of
3Dept. Of Internal Medicine, Yonsei University, Seoul/Korea, Republic of

Contact E-Mail Address: last_message@yhus.ac

Introduction: Post-endoscopic submucosal dissection (ESD) bleeding is the most common complication of ESD. In previous studies, the post-ESD bleeding occurred from 1.8% to 15.6% of total procedures [1–4]. Recently, many patients who underwent ESD, have been prescribed antiplatelets or anticoagulants, because of various underlying diseases such as cerebrovascular accidents or
cardiovascular diseases [3]. Thus, the verified risk prediction model of post-ESD bleeding may be used to determine preventive therapeutic options and restarting date of antiplatelet agents.

Aims & Methods: The aim of this study is to develop the predictive risk model of post-ESD bleeding. A total of 3574 patients, who were taken ESD from January 2007 to December 2015 in a Korean tertiary hospital, were included in this retrospective study. To avoid overfitting of the prediction model, we divided the patients randomly into two groups, either a derivation group or a validation group. Preoperative and procedural-related variables were selected via univariate and multivariate analysis. A risk score was calculated to assess the bleeding prediction model of a patient in the derivation group and was discriminated in the validation group.

Results: Post-ESD bleeding occurred in 248 patients (6.9%). In the derivation group, the model also showed good discrimination (C-statistic = 0.739; 95% confidence interval [CI] 0.710–0.769). In the validation set, the model also showed good discrimination (C-statistic = 0.697; 95% CI, 0.652–0.741). In the validation set, the model also showed good discrimination (C-statistic = 0.697; 95% CI, 0.652–0.741).

Conclusion: Though our study is preliminary, DRI improves total resection time, the visibility of vessels and demarcation line between the submucosal and muscle layers significantly as previous study showed on colorectal ESD. DRI uses narrow long wavelength light. The light reaches slightly deeper layer than WLI. Therefore, we can see not only clear vessels but intact submucosa with high contrast of submucosal vessels in the mass color image. We named this effect "noise cancelling effect" by DRI. This effect gets better the visibility better, therefore the esophageal and gastric ESD makes easier and safer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0820 USEFULNESS OF LINKED COLOR IMAGING (LCI) FOR RECOGNITION OF EARLY GASTRIC CANCER AND GASTRIC ADENOMA

Introduction
Laser-enhanced white light imaging (LWLI) is a promising method for early detection of gastric lesions. Effective recognition of early gastric cancer and gastric adenoma by LWLI has been reported [1, 2]. However, LWLI lacks color information, which is important for the recognition of early gastric cancer and gastric adenoma. Therefore, we attempted to verify the usefulness of LCI for recognition of early gastric cancer and gastric adenoma. In this study, we evaluated the usefulness of LCI for recognition of early gastric cancer and gastric adenoma by comparing the recognition scores of LCI with those of LWLI, NBI, and CRP.

Methods
We retrospectively analyzed 29 cases with early gastric cancer or gastric adenoma that underwent endoscopic submucosal dissection (ESD) at our hospital between January 2019 and December 2019. The histological diagnosis of early gastric cancer or gastric adenoma was based on the revised Japanese classification of gastritis, gastric cancer, and other gastrointestinal diseases [3]. We assessed the recognition score of each lesion using LCI, LWLI, NBI, and CRP. The recognition score was evaluated by three endoscopists who were blinded to the histological diagnosis. The recognition score was defined as follows: 0 for no lesions, 1 for superficial lesions, 2 for submucosal lesions, 3 for subserosal lesions, and 4 for intraperitoneal lesions.

Results
In this study, we compared the recognition scores of LCI, LWLI, NBI, and CRP for early gastric cancer and gastric adenoma. The recognition scores of LCI were significantly higher than those of LWLI, NBI, and CRP for early gastric cancer and gastric adenoma. Moreover, the recognition scores of LCI were also significantly higher than those of LWLI, NBI, and CRP for early gastric cancer and gastric adenoma.

Conclusion
In this study, we found that LCI could effectively recognize early gastric cancer and gastric adenoma. Therefore, we believe that LCI is a promising method for early detection of gastric lesions.
Introduction: In gastrointestinal stromal tumors (GISTs) without a risk of metastasis to other organs, local resection is acceptable. In small GISTs, however, it is controversial whether surgical resection is necessary because of a risk of recurrence/metastasis in these tumors are considered to be quite low. Laparoscopic endoscopic cooperative surgery (LECS) is a promising surgical technique as one of minimally-invasive, function-preserving surgeries. By using this technique, we are aggressively resecting gastric SMTs including relatively small ones.

Aims & Methods: To investigate necessity of surgical resection for small GISTs, we retrospectively assessed a malignant potential of these tumors which were resected nonexposed endoscopic wall-inversion surgery (NEWS) (nonexposure LECS technique) as well as feasibility and safety of this technique. Between August 2013 and October 2016, NEWS was conducted in 33 consecutive SMTs which met all of following conditions: possible GIST which was preoperatively diagnosed by histology or imaging modalities, less than 3 cm in size and intramurally growing type by the NEWS procedure, a lesion was resected in a following manner: endoscopic mucosal markings, laparoscopic sero-muscular incision and suturing with the lesion inverted toward the inside of the stomach, endoscopic submucosal tunneling and peroral retrieval. Short-term outcomes of NEWS and a potential risk of recurrence/metastasis in each tumor according the Fletcher’s classification were assessed.

Results: Mean age and the size of the lesion were 59.9 ± 13.7 years-old and 23.3 ± 8.4 mm, respectively. The procedure was successfully completed in all cases in a mean procedure duration of 206 ± 43 min. The patients were discharged without severe adverse events 7.3 ± 1.5 days after the procedure. The first endoscopy after the procedure was performed 5.8 months after discharge in 22 cases, which showed no residual food in the remnant stomach in all cases. Neither apparent impairment of food intake nor disease-related death occurred and a body weight loss was 0.9 ± 2.3 kg during the mean observational period of 16 months. GIST was histologically diagnosed in 20 cases. A risk of recurrence/metastasis in these GISTs was classified into high (2), intermediate (1), low (12) and very-low (5), respectively. In a comparison of two groups (high/intermediate and low/very-low), a mean tumor size and existence of delte formation were 31.7 mm and 21.6 mm (p = 0.036), and 67% and 12% (p = 0.028), respectively.

Conclusion: Some small GISTs which could be retrieved transorally had a high malignant potential, NEWS was feasible, safe and therefore recommended for these tumors including ulcerated GISTs as a minimally-invasive surgical option to avoid additional surgical scar for the retrieval of the specimen and a risk of iatrogenic tumor cell seeding into the peritoneum during the procedure.

histological diagnosis to guide management decisions. Western data on ESD for SE is absent. We aimed to analyse the data from our referral centre.

**Aims & Methods:** A prospectively collected ESD database was analysed to identify patients with SMT of the UGI. All lesions were analyzed for the significance of stent insertion. A total of 62 SEMS were inserted; a retrospective observational study was conducted to compare outcomes, using various performance indicators in patients who underwent SEMS for palliation of UGI SMT. The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation of UGI SMT. The histology of the SMT lesions varied, and the percentage of involvement in each group was assessed.

**Results:** Of 24 patients, 11 were male, and the median age was 47 years. The majority of these cancers were incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expandable metallic stents (SEMS) have a well-recognized role in the palliative management of patients with esophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscopically guide in palliative oesophageal stent placement.

**Discussion of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ingestion of caustic substances is relatively frequent and can cause various degrees of harm in the upper gastrointestinal tract, carrying important morbidity and even mortality.

**Aims & Methods:** We aimed to characterize the population assisted for caustic ingestion, the therapeutic approach, complications and risk factors for severe oesophageal lesions. Retrospective cohort of adults presenting due to caustic ingestion between 2000 and 2015. Demographic and clinical data were collected. The endoscopic Zargar classification was applied. We analysed risk factors for severe oesophageal lesions, defined as Zargar 2b-3. Statistical tests: Mann-Whitney, Spearman (significance level 5%).

**Results:** Overall 72 patients were included, with a mean age 53 ± 17 years, 65.3% female. Ingestion was voluntary in 49.3% of the cases, 33.3% had previous suicide attempts. Alkaline substance in 90.4%. Most common symptoms at admission: 60.3% odynophagia, 41.1% epigastric pain, 32.9% vomiting. Orpharyngeal lesions in 41.1%. In 79.5% endoscopy was performed in the first 12 hours. Oesophageal lesions were present in 46.6% of patients (Zargar classification: 1-2.7%, Ha-23.3%, Hb-5.5%, IIIa-6.8%, Hb-8.2%). Gastric lesions in 58.9% and duodenal lesions in 13.7%, 53.4% were hospitalized. 51.3% in intensive/intermediate care units. The mean length of hospital stay was 14.9 days. Medical treatment prescribed: 76.7% proton pump inhibitors, 15.1% corticoids, 15.1% prophylactic antibiotics. Parenteral feeding was initiated in 28.8% of patients. Eight patients required invasive ventilation and two were tracheotomised. Early complications: infections in 12 patients (16.4%), perforations in 2 (2.7%); late complications: stenosis in 7 (9.6%): dilation in 6, surgery in 3. One patient died from gastric perforation after voluntary ingestion of acid. Severe oesophageal lesions were associated with increased inflammatory parameters, tachycardia and/or hypotension at admission and motivated longer hospital stays, requirement of intensive care and further complications (p < 0.002). The ingestion of acidic substances (100% of voluntary intake) was associated with severe oesophageal damage in 3/7 (42.9%) patients, severe gastric lesion in 5/7 (71.4%), acidemia in 5/7 (71.4%), complications in 5/7 (71.4%) and 100% hospitalization.
Conclusion: Early changes in blood tests were seen in severe oesophageal lesions. Severe oesophageal lesions were associated with longer hospitalization and complications (infection/stenosis/perforation). Ingestion of acidic substances was a risk factor for severe digestive lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A value of the combination of magnifying endoscopy of and image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diagnosis for the early gastric neoplasm. That method is useful, but in order to master it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm Co., Tokyo, Japan). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combination of light provides more information about the vasculature and architecture on the mucosal surface than that obtained with typical white-light imaging. When we use acidic acid indigocarmine mixture (AIM) with LCI mode, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects are 120 lesions of 115 patients with gastric neoplasm. We are intended to the endoscopic submucosal dissection (ESD), and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy with the BLI mode and diagnosed using VS classification system. Secondly we observed the lesions by magnifying endoscopy with LCI+AIM method and diagnosed using VS classification system. Furthermore, we classified tumor differentiation into high differentiation, moderately differentiated, and poorly differentiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure, LCI, Visible and Invisible and evaluated it. We carried out ESD and compared the image with the histopathology.

Results: By the results, 92 lesions were gastric cancer and 28 lesions were gastric adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the BLI mode and the LCI+AIM methods. Diagnosis of differentiation of gastric cancer was correct in 87 of 92 cases (94%). In the classification of visualization ability, 32 lesions were Clear, 44 lesions were Visible, 44 lesions were Invisible by BLI mode. On the other hand, 45 lesions were Clear, 64 lesions were Visible, 11 lesions were Invisble by LCI. In the visualization ability of the surface fine structure, LCI+AIM method is significantly clearer than BLI mode (p < 0.001).

Conclusion: When we use AIM, indigocarmine accumulates in pit of the duct, and duct structures become clear by the acidic acid. By LCI mode, we can observe the vascular pattern of the lesion clearly. So by the combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this method, we can compare histopathology with an endoscopic image intuitively, so we believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled even if we do not use various confusing classifications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0030 THE SAFETY AND EFFECTIVENESS OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC NEOPLASMS IN PATIENTS AGED 85 YEARS OR OLDER

Y. Sumida1, T. Kuwai1, K. Tao1, S. Funaki1, Y. Miyasako1, T. Takasago1, H. Kouno1, H. Kohno1, S. Ishig1

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early gastric neoplasms. The advantages of ESD include the ability to control the size and shape of the resection, permitting en bloc resection of large and ulcerated lesions. The frequency of gastric ESD for patients aged 85 years or older has increased along with an increase in the elderly population. However, few studies have reported the short-term and long-term outcomes of gastric ESD in elderly patients.

Aims & Methods: The aims of our study were to evaluate and compare the efficacy, safety, and clinical outcomes of gastric ESD in patients aged 85 years or older, and in younger patients. The subjects were 705 patients who collectively presented with 876 gastric tumors (288 adenomas and 588 early gastric cancers. All patients underwent ESD at our hospital between June 2007 and December 2016. Patients were divided into two groups: elderly (aged ≥85 years, consisting of 59 patients with a collective 71 lesions) and non-elderly (Group B: aged <85 years, consisting of 646 patients with a collective 805 lesions). We evaluated the clinical and pathological findings, resection rates, complications, and long-term outcomes, including the survival rate. The local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection. The 3- and 5-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort.

Results: The patients’ mean ages were 87 (Group A) and 71 years (Group B), and the male-to-female ratios were 30/29 (Group A) and 646/805 (Group B). No significant differences were found in the mean tumor size for Group A (15 mm) and Group B (20 mm). Regarding histopathological findings, the prevalence rates of tubular adenoma were 28.3% (21/71; Group A) and 33.8% (267/805; Group B). Infiltrated mucosal carcinomas, 52.1% (37/71; Group A) and 53.8% (433/805; Group B); shallow submucosal invasive carcinomas (<500 μm), 7.0% (5/71; Group A) and 6.5% (52/805; Group B); and deep submucosal invasive carcinomas (>500 μm), 11.3% (8/71; Group A) and 6.6% (53/805; Group B). Once again, the groups showed no significant differences. The en bloc resection rates were 97.1% (728/782 lesions; Group A) and 97.9% (748/782; Group B), and the curative resection rates were 78.6% (56/71; Group A) and 86.3% (695/805; Group B). Among the non-curative cases, 13 (86.6%) of the 15 patients in Group A and 46.3% of the 110 patients in Group B were given non-curative resection. These results were significantly higher for Group B than for Group A. Concerning complications, the postoperative hemorrhage rates were 2.8% (2/71 patients; Group A) and 2.6% (12/479 patients; Group B), and the perforation rates were 0% (0/71; Group A) and 0.4% (4/805; Group B). Regarding long-term outcomes, analysis of recurrence revealed the local and distant recurrence rates to be 0% for Group A and 0.9% (7/746; local) and 0.1% (1/746; distant) for Group B. Regarding survival analysis, the median overall survival period in Group A and Group B was 839 days and 1156 days, respectively. There were no significant differences observed in the survival rates. 6 (10.0%) of 59 patients in Group A and 54 (9.3%) of 646 patients in Group B died, and disease-specific mortality rates in Groups A and B were 0% (0/59) and 0.8% (5/646), respectively.

Conclusion: Gastric ESD in patients aged 85 years or older can be effectively and safely performed. According to the long-term outcomes, gastric ESD performed as a local resection (total biopsy) in elderly patients may be acceptable, even in non-curative cases.

P0031 RESULTS FROM THE FIRST UK VIRTUAL COMPLEX POLYP MDM

A. Chatterjee, M. Rutter
Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: amit.chatterjee@nhs.net

Introduction: Data from the UK Bowel Cancer Screening Programme (BCSP) has established that the assessment and management of large non pedunculated colorectal polyps (LNPCPs) varies markedly, leading to variable and often suboptimal outcomes, especially for the most complex lesions. A multicentre complex polyp multidisciplinary team meeting was created within the North East of England BCSP with the aim of ensuring more robust decision making and management of complex LNPCPs.

Aims & Methods: A virtual multicentre MDM was conducted via audioconferencing within the North East of England between 2014-6 to discuss complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in the SBCG/ACPGBI guidelines). Non-discussed cases (KPIs) from the BSG/ACPGBI guidelines.2

Results: 61 complex LNPCP cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopies, 2 required surgery due to endotherapy failure leading to a finding of malignancy. 12-month recurrence was 8.7% with no reported complications. The rate of surgical management using the SBCG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection

A430 United European Gastroenterology Journal 5(5S)
rate of complex LNPPCs with features suggestive of increased malignancy risk was 20%. Breakdown of Outcomes (n = 53) *Primary endoscopic therapy, (n = 27) -23 excised with curative intent -21 cases with no recurrence at 1 year 7 cases with recurrence (8.7%) both <1 cm and managed endoscopically -4 required secondary surgery -2 failed endotherapy -2 proved to be malignant *Surgical Management (n = 5) -10/23 malignant lesions (43.5%) -9/23 subject to transanal surgery (39.1%) *Conservative management (n = 3) Breakdown via High risk features of malignancy/SMSA4/SMSA3 (n = 53) *High risk features of malignancy (any SMSA score) (n = 29) -17 endoscopically managed (14.0%); 2 ESD -27 (28.6%) cases (both managed with pEMR) malignant -13 transanal surgical (41.3%); transanal surgery: 9/13 malignant (69.2%); -1 managed conservatively *SMSA 4 (n = 25) -12 managed endoscopically -2 failed endoscopically -2 due to technical considerations) -5/12 malignant (25%); -1 managed conservatively *SMSA3 (n = 7) -4 managed endoscopically -2 management surgically (both lesions originating from within appendix) -1 managed conservatively: Conclusion: 61 complex LNPPC cases were managed via the MDM with 8 excised from analysis (7: managed prior to MDM referral, 1: MDM advice not followed). 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and 2 due to a finding of malignancy. 12 month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSC/APCGBPI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection rate of complex LNPPCs with features suggestive of increased malignancy risk was 71.4%.

Introduction: Patients of endoscopists with high (≥20%) adenoma detection rate (ADR) have less risk for interval cancer than those of low ADR (<20%). Lesion-related-factors, such as size, shape and histology influence the decision-making of physicians with high ADR to detect more flat and serrated adenomas than those with low ADR. Aims & Methods: Our study aim is to investigate the differences of size, shape and serrated histology of adenomas between low- and high-ADR group in our screening cohort. We analyzed 2,534 screening colonoscopies performed by 265 endoscopists between 2007 and March 2017 within the austrain certificate of screening colonoscopy. T-Test was used to assess differences. Results: 39.1% of endoscopists were categorized in the ADR low- and 60.9% in the ADR high-group. Overall, mean ADR was 23.06% (SD 0.55) with a minimum of 0.39% and a maximum of 48.72%. In the low-ADR-group mean ADR was 14.56 (SD 0.42) and 28.51 (SD 0.50) in the high-ADR group. Relating to size, there was a significant difference (p = 0.029) in detection of adenomas of 1–2 cm with a mean of 8.44% (SD 6.02) in low- vs. 10.22% (SD 6.64) of all adenomas in high-ADR group but no differences between adenomas <0.5 cm, 0.5–1 cm and those bigger than 2 cm. Regarding shape, proportion of pedunculated adenomas in low-group-ADR differ significantly higher (p = 0.002), with a mean of 19.36% (SD 14.60) vs. 17.40% (SD 9.55) but there were no differences between flat and sessile adenomas. With a mean proportion of 4.34% (SD 5.61) vs. 6.64% (SD 5.97), the proportion of sessile serrated adenomas (SSA) differ significantly between low-ADR vs. high-ADR group (p < 0.01). There was no significant difference regarding traditional serrated adenomas (p = 0.800).

Introduction: ESD is a complex procedure, mainly in non-Asian countries where the learning process is not well established. Results may be improved in Western countries. Our group, with a careful selection of lesions for ESD and avoiding those with greater chance of technical difficulty. Factors predicting technically difficult ESD when it is performed by non-Asian endoscopists should be clarified. Aims & Methods: We aimed to identify the potential risk factors that are associated with a higher technical difficulty during ESD in a Western European setting where there are no available Asian experts. We prospectively recorded consecutive ESD cases performed by members of the ESD Working Group of the Spanish Society of Digestive Endoscopy. Demographic and clinical characteristics of the patients, location and morphology of the lesions, and technical factors were collected. We defined difficult ESD as those aborted procedures, time-consuming (duration >180 min.) or when changing the technique to piecemeal resection was needed to remove the tumor. Analyses were carried out using IBM SPSS software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous variables are reported as the mean ± standard deviation (SD). A Kolmogorov-Smirnov test was used to evaluate normal distribution. Categorical variables are reported as either frequencies or percentages. Statistical differences between the groups were analyzed using the chi-squared method for categorical data. The meaningful variables with a p value <0.1 in the univariate analysis were included in the logistic regression model. Multivariate analysis was performed using binary logistic regression methods. Odds ratios (ORs) and 95% confidence intervals (CI) were calculated to assess the strength of the influence of each individual variable.

Results: We included 265 lesions in 265 patients (mean age ± SD: 69 ± 10; 150 males (56.6%)). They were recruited in 15 Spanish University Hospitals between January 2016 and March 2017. Location of the lesions were: esophagus (n = 7; 2.6%), cardia (n = 5; 1.8%); stomach (n = 48; 18.1%); duodenal bulb (n = 1; 0.3%); colon (n = 144; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size was 38.6 ± 18.5 mm. Median duration of the procedure was 105 min. (8-375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258; 97.3%) both situations, duration >3h and a piecemeal resection, were noted in 21 (8.1%) patients. Duration >3h in 25 cases (9.7%) and unsuccessful en bloc...
resection in 20 (7.7%) were observed in isolation, respectively. Table 1 shows the univariate and multivariate analysis of factors regarding technically difficult ESD.

Table 1: Univariate and multivariate analysis of possible factors related to technically difficult ESD.

</table>

Conclusion: The factors independently associated with technically difficult ESD (absorbed procedures, time-consuming or finished with a piecemeal resection) were: lesion size >30 mm, poor manoeuvrability, recurrent lesions and intraprocedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curves.

Aims & Methods: The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1376 colorectal tumors in 1341 patients (male: 777; 65.0% mean age, 66.1 years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: 7; 44.6% mean age, 63.5 years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR and is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastases does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be as follows: 1) Intra- mural carcinoma (Tis) and adenoma with high-grade atypia (Vienna Classification:Category 3, 4) accompanied by wide and severe degree fibrosis in the submucosal layer (tumor recurrence after endoscopic and surgical resection); 2) submucosal tumors; 3) Intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia involved appendix or diverticulum. We examined the clinical and pathological outcomes of LECS procedure in 11 cases.

Results: Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The reason why we judged as the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticulum, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. Operative time was an average of 195.8 minutes (127 to 332), and the perioperative bleeding was an average of 8 g/dl (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.7 (6 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10-60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesive ileus, we followed favorable course.

Conclusion: We developed a LECS procedure to overcome the limit of ESD, and completed full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

Reference
Patient experience is increasingly recognised as a key measure of quality of care. Ensuring positive experience is important to patients and fundamental in maximising participation in screening programmes and re-attendance for surveillance procedures. Current measures of patient experience of gastrointestinal (GI) endoscopy are clinician derived. (1) Patient Reported Experience Measures (PREMs) should be patient derived and incorporate pre- and post-procedure experience. We aimed to identify themes considered as important to patients undergoing GI procedures as a basis for developing PREMs.

Aims & Methods: We aimed to identify themes important to patients undergoing GI investigations, to enable questionnaire development. Patients who had undergone upper or lower GI investigations (gastroscopy, colonoscopy and CT pneumocolon) were invited to attend for a semi-structured interview. Thirty-two interviewees were purposefully sampled to ensure diversity. Interviews were conducted by a research fellow trained in qualitative methods and were audio recorded and transcribed verbatim. Recruitment continued until saturation was achieved.

Results: Six over-arching and inter-linking themes emerged across all procedures: anxiety, expectations, choice/ control, communication/information, comfort and embarrassment/dignity. Relation of themes was seen e.g. if the procedure appointment was sooner than expected, patients were anxious about the potential outcome. Choice was important in terms of appointment, endoscopist and choice of pre-medication, however it was highly individualised. Communication prepared patients and managed expectations, with one patient describing poor endoscopist communication affecting the whole experience. Patients described embarrassment related to changing and waiting areas; sensitive nature of the test; exposure and physical reaction. Discomfort during the procedure was attributed to instrument and air insertion.

Conclusion: Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for bowel endoscopy.

P0838 RANDOMIZED CONTROLLED TRIAL OF ABDOMINAL VIBRATION STIMULATION AND WALKING EXERCISE FOR BOWEL CLEANSING PRIOR TO COLONOSCOPY
Gastroenterology, Ajou university School of Medicine, Suwon/Korea, Republic of

Contact E-mail Address: cknoh23@gmail.com

Introduction: Adequate bowel preparation is important to perform colonoscopy for accurate mucosal examination, lesion detection and treatment. Walking exercise is known to be effective for colon cleansing. However, it is difficult for patients with uncomfortable walking to improve the status of bowel cleansing.

Aims & Methods: Therefore, we prospectively evaluated the clinical feasibility and clinical validity of the abdominal vibration stimulation for bowel cleansing.
preparation. In this randomized, prospective, investigator-blind study and single center, 141 inpatients for elective colonoscopy were randomized to two groups. PEG solution was used for bowel cleaning in all patients. The one is walking over 3000 steps and the other is having abdominal vibrator more than 30 minutes before colonoscopy. After examination we recorded procedure results, sedation information, patient's satisfaction and adequacy of bowel preparation by using the Boston Bowel Preparations Scale (BBPS).

Results: There were no significant differences between vibrator group (n=75) and walking group (n=66) in bowel preparation quality (Total BBPS 7.40 vs 7.23, p=0.519), withdrawal time (30.40 vs 30.05 mins, p=0.829), number of polyps (4.09 vs 3.17, p=0.085), patient satisfaction (4.39 vs 4.12, p=0.249) and number of diarrhea after taking PEG (11.49 vs 11.42, p=0.903). Viscosity was superior than walking group in time of first defecation after taking PEG (112.80 vs 123.42 mins, p=0.005) and ecall intubation time (6.23 vs 8.52 mins, p=0.011).

Conclusion: Bowel preparation accompanied with abdominal vibration stimulation showed almost similar results to a walking group which was conventional methods for adequate bowel preparation. The patients with the condition which cause uncomfortable gait such as old age, CVA, Parkinsons, or joint disease, bowel preparation with abdominal vibrator is expected to help in proper bowel cleansing for therapeutic colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rheological properties of the submucosal cushioning solutions are crucial to avoid complications secondary to endoscopic resections. Electrical resistance (R) of a substance is a measure of the difficulty to pass an electric current through that solution. The higher the R, the resection will be quicker, easier and safer, with less temperature increase. Our group has developed a new solution to perform submucosal injection (TriBio).

Aims & Methods: To analyze the electrical (R) and rheological (temperature, viscosity, height and lasting of the cushion) properties of different submucosal solutions in an ex vivo model of porcine stomach. Tested solutions were: Saline (S), Glyceol (GC), Hyaluronic acid (HA), Distilled water (DW), Platelet-rich Plasma (PRP), Glucosated saline 10% (GS), Gelaspan (GP), TriBio (TB) and PRPþTB. Measurements were done at time 0 and 30 minutes.

Results: The solutions that showed the best basal R were: PL, HA, GS, TB and TB+PRP. At 60 minutes, the best R were: PRP, TB, PRP+TB, HA and GS. The best durability at 60 minutes was for TB, PRP, TB+PRP and PL that maintained the height at around 80% of its original in comparison to the other substances with were at around 60%. During the resection the solutions that underwent a lower temperature increase were: TB+PRP, PL, and TB.

Introduction: Patients with chronic diseases, such as inflammatory bowel disease, experience a lower degree of being involved in health care than others. Compared with other countries Swedish patients report lower possibility to be involved in their care and receive less information about care (1).

Aims & Methods: To investigate the perception of written and oral information given before and after a colonoscopy, the perceived knowledge of planned follow-up and preference to be more involved in decisions/participate in their care in different patient groups. Outpatients (≥18 y) undergoing colonoscopy (all indications) were consecutively included (n=862). Before the procedure patients completed questionnaires regarding sociodemographic data and the written information about bowel preparation and examination. After the procedure patients reported their perceptions about the information provided regarding the colonoscopy and the follow-up.

Results: Data from 862 patients were analyzed (447 females) (mean age 52; 18-90 y) A large number of patients (n=740, 87%) rated the written information sent home before the colonoscopy as distinct, while a subset (n=110, 13%) rated it as indistinct/very indistinct. When questions of importance were asked to the medical staff during the colonoscopy most patients were content with the answers from the physician or nurse. A small proportion of patients (n=57, 7%) stated that they received too little information or that they did not understand the information about the colonoscopy results; these patients were mainly younger (<50 y) (p<0.001). The majority of the patients (n=602, 74%) reported thorough knowledge about the follow-up, while 26% (n=207) lacked this knowledge. More than 1/3 (n=275) of the patients wished to be more involved in decisions regarding their care and treatment. Desire for a higher degree of involvement were more pronounced in patients <40 y (p=0.05) and in patients with IBD (p=0.05) compared to patients with other indications for colonoscopy. Patients referred from outpatient clinics in the hospital desires a higher degree of involvement than patients referred from primary care (p<0.01).

Conclusion: The majority of the patients undergoing colonoscopy reported that they received satisfactory information about the procedure and preparation. However, there is room for improvement regarding follow-up information and patients’ involvement in their care and treatment. Specifically, improvements seem warranted for younger patients and patients with chronic diseases, such as IBD.

A SKIRT
NEOPLASIA OF RECTAL LATERALLY SPREADING TUMORS WITH

P0841 THE INCIDENCE OF SYNCHRONOUS ADVANCED
NEOPLASIA OF RECTAL LATERALLY SPREADING TUMORS WITH
A SKIRT

Department Of Gastroenterology, Saku Central Hospital Advanced Care Center, Saku, Nagano Japan

Contact E-mail Address: shou0122@hotmail.com

Introduction: A “skirt” is a slightly elevated flat lesion with wide pits occasionally observed at the margin of laterally spreading tumors (LSTs), and rectal LSTs with a skirt had significantly more skirt lesion in comparison to colonic LSTs. Although the clinicopathological, endoscopic, and molecular characteristics of LSTs with a skirt have been reported [1], there are no reports concerning the incidence of synchronous neoplastic lesions of rectal LSTs with a skirt.

Aims & Methods: The aim of this retrospective study was to clarify the incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt. A total of 13,116 cases underwent colonoscopy in our hospital between January 2012 and June 2016. Of these, 101 consecutive rectal LSTs were examined to assess the incidence of synchronous AN detection rate and the number of AN according to the location of AN lesion; divided into the right colon, left colon and rectum. A skirt was defined on the basis of the following endoscopic findings: spreading across the margins of the LST, consisting of a slightly elevated flat lesion, and containing wide pits. AN was defined as the presence of any of the following features: adenomas larger than 10 mm, adenomas with villous histology or high-grade dysplasia including intra-mucosal carcinoma and invasive cancer.

Results: A skirt was observed in 25 of 101 rectal LSTs (24.8%). Rectal LSTs with a skirt (median age 69 years, 52% female, mean size 51.7 ± 27.1 mm) had 22 high-grade dysplasia and 3 submucosal carcinomas, and rectal LSTs without a skirt (median age 72 years, 34% female, mean size 24.7 ± 16.0 mm) had 8 low-grade dysplasia, 45 high-grade dysplasia, and 23 submucosal carcinomas, respectively. The overall AN detection rate in rectal LSTs with a skirt (20.0%) was significantly lower compared with rectal LSTs without a skirt (46.8%, p = 0.02). As for the analysis of AN detection rate according to the location, there were significant differences in the right colon (8.0% vs 29.9%, p = 0.03) and the left colon (4.0% vs 27.3%, p = 0.01) between LSTs with and without a skirt. In contrast, there was no significant difference with respect to the rectum (6.0% vs 6.5%, p = 0.41). The total number of AN in rectal LSTs with a skirt (n = 7; right colon: 2; left colon: 2 and rectum: 3) was significantly lower than in rectal LSTs without a skirt (n = 74; right colon: 35; left colon: 34 and rectum: 5). There were significant differences in the right colon (p = 0.03) and the left colon (p = 0.04), while, there was no significant difference between these groups with respect to the rectum.

Conclusion: The rectal LSTs with a skirt had significantly lower synchronous advanced neoplasia than rectal LSTs without a skirt, especially in the right and left colon. Our results may suggest that rectal LSTs with a skirt have different characteristics compared with rectal LSTs without a skirt in terms of the incidence of synchronous neoplastic lesion.

Introduction: Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hialuronic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

Aims & Methods: To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomized to receive one of the following shields onto the lesions: PRP + TriBio, PRP and TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Results: Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; p < 0.05). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio

Conclusion: The use of a combination of two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon.

P0843 EFFICACY OF ENDOSCPIC PLACEMENT OF A DRUG-ELUTING PLATFORM WITH DIFFERENT ANTI-TUMORAL AGENTS TO EVALUATE ACUTE NECROSIS IN AN AZOXYMETHANE-INDUCED COLONIC TUMOURS IN RATS

Introduction: Colonic tumors have become massive in the last years since colorectal cancer (CRC) is becoming a prevalent disorder. The next frontier of this technique will be to provide an active substance in a precise site of the colon (targeted therapy). This has many advantages (targeted therapy, dose adjustment, limiting side effects, assessment of mucosal healing, etc.); however, this selective and direct administration of drugs is not possible nowadays, but it is a true challenge. Following these evidences we have developed drug eluting platform to locally treat CRC lesions.

Aims & Methods: To evaluate the efficacy of intratumoral injection of our drug-eluting platform with different combinations of these antitumoral drugs (albumin, etuximab 16 mg/mL, panitumumab 6 mg/mL, irinotecan 3.5 mg/mL and bevacizumab 5 mg/mL) in a rat model of azoxymethane-induced colonic cancer. Rats underwent endoscopic follow-up at 1 and 2 weeks after endoscopic therapy. Afterwards, animals were sacrificed and tumors were excised and macroscopically and histopathologically evaluated.
Results: Intramural injection was feasible in all animals with no adverse events. Biopsy size of tumors ranged from 6 to 8 mm. Approximately 1:2 in comparison with anti-EGF obtained the best results (significantly reduction in size and cell necrosis). However, only albireceptor showed total acute tumoral necrosis.

Conclusion: Intramural injection of anti-VEGF in a drug-eluting platform is able to produce tumoral necrosis in an experimental model of CRC. This technique could open a new way to manage CRC.

P0844 A THREE-DIMENSIONAL IMAGING SYSTEM IMPROVES THE ENDOSCOPIC VISIBILITY OF NON-POLYPOID COLORECTAL NEOPLASMS

T. Matsumura, D. Maruoka, K. Okimoto, N. Akizue, T. Nakagawa, H. Ishigami, M. Ara, N. Kato

Introduction: A three-dimensional (3D) imaging technique has been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colonic lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colorectal neoplasms compared with conventional 2D endoscopy.

We included non-polypoid colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasm was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35 ± 0.58 for 2D endoscopy and 3.75 ± 0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy (p = 0.01). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p < 0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.0 ± 0.53 for 2D endoscopy and 3.87 ± 0.35 for the 3D system, p = 0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Contact E-mail Address: jessica.rylander@vgregion.se

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient’s needs. Colonoscopy is by many patients considered as a painful and strenuous procedure.

Aims & Methods: To investigate congruence and differences between patients’ and caregivers’ report of pain during colonoscopy. Patients (≥ 18 years) undergoing an outpatient colonoscopy (all indications) have consecutively been included (n = 862). Before the procedure the patients completed questionnaires regarding sociodemographic information and anxiety. After the colonoscopy the patients registered their pain experience on a six-grade scale, ranging from “no pain” to “extremely severe pain”. Caregivers (physicians and endoscopy nurses) estimated patient’s pain using the same scale.

Results: From 785 patients has been collected, mean age 52 (18–90) years; 413 women. Approximately 75% of the patients’ reports of pain was underestimated in 25.5% among the group. There was also a difference across gender; physicians underestimated pain in 60% of men who reported “moderate pain” (n = 66) while the nurses underestimated pain in 27% among the same group of men. Women’s pain was overestimated by caregivers in 26% (n = 188) of all cases with mild pain. Patients undergoing colonoscopy for the first time (n = 331), and reporting “moderate pain”, were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety (p < 0.001). Presence of anxiety and a high level of pain was among the group agreeing with nurses’ and the patient’s pain report. The agreement between pain reports from patients and caregivers were poor to fair, with slight differences between nurses (Kappa = 0.37; p < 0.000) and physicians (Kappa = 0.29; p < 0.000) in total, congruent pain reports between patients and caregivers were seen in 36% of all assessments.

Conclusion: Agreement between caregivers’ and patients’ pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients.

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD. The characterization of colonic lesions in IBD remains challenging even by using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]).

Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic lesions, and to validated by international experts (Frankfurt Advanced Chromoendoscopic Ibd LEsions-FACILE Group). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel pattern, signs of inflammation (table). A library of 60 colonic lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariate analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: Of the 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/Ps and 12 (20%) pseudopolyps. Across the experienced academic raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 92%, 91%, 40%, 72%, 93%, 90%, 97%, 46%, 76%, which were significantly more accurate compared with a low confidence of diagnosis (76% vs 65%; p = 0.001). Univariate analysis showed that the non polyoid lesions, irregular and vessel architecture and signs of inflammation within the lesion were predictive of dysplasia. Subsequent multivariate analysis confirmed that of these endoscopic findings non polyoid lesion OR 11.6 (95% CI 6.71–20.2), surface pattern
OR 0.31 (95% CI:0.17–0.54), vessel architecture OR 5.1 (95% CI: 2.7–10.2), sign of inflammation within the lesion OR 0.39 (95% CI: 0.18–0.85) were independent predictors of dysplasia, with vessel architecture and morphology being the best predictors. The sensitivity, specificity, PPV, NPV and accuracy at the multivariate analysis stage were 94% (95% CI: 90–96%), 51% (95% CI: 43–58%), 88% (95% CI: 82–92%), 60% (95% CI:62–75%), 85% (95% CI: 79 –90%), Inter-observer agreement of the raters improved from the pre-test (Kappa = 0.27,95% CI: 0.19–0.38) to post test (Kappa = 0.34,95% CI: 0.23–0.45,P = 0.02) but was moderate.

**Conclusion:** We developed and validated the first endoscopic classification using all imaging modalities (HD, VCE, DCE) to characterize and differentiate dysplastic from non-dysplastic lesions in IBD. Non polypoid lesions, irregular surface and vascular pattern as well as inflammation within the lesions were predictive of dysplasia. The inter-observer variability of the score was moderate. The classification will be further refined based on the multivariate analysis and a prospective study is ongoing.

(continued)
with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Is) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered “pseudopolyps” had a 8 mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

**Conclusion:** This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2Gastroenterology, Dudley Group Hospitals, Birmingham City University, Birmingham/United Kingdom

Contact E-mail Address: toshioki.kawai@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr: Akita Sumitomo Bakedite, Japan) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Aims & Methods: The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥75 years in comparison with those in younger patients. We evaluated 291 lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at King’s College Hospital Endoscopy Centre and Chugoku Cancer Center. The patients were divided into two groups, an elderly group (group A: age ≥75 years; 95 patients, 97 lesions) and a non-elderly group (group B: age <75 years; 176 patients, 194 lesions). We evaluated the en bloc resection rate, complete resection rate, curative resection rate, en bloc tumor size, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

Results: The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.1% (70/194); T1a, 39.2% (38/97) and 44.8% (87/194); T1a, 10.3% (10/97) and 10.3% (20/194); and T1b, 13.4% (13/97) and 8.8% (17/194) in groups A and B, respectively, showing no significant difference. The mean en bloc resection rate was 96.9% (94/97) and 99.0% (192/194); the complete resection rate, 94.8% (92/97) and 94.8% (184/194); and the curative resection rate, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and related death occurred in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period: group A, 523 ± 469 days; group B, 628 ± 582 days), the 3-year overall and disease-specific survival rates were respectively 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of other diseases in group B, while one patient (1.1%, 1/95) died of other diseases in group A.

Conclusion: ESD performed with SB Knife Jr is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms both in elderly and non-elderly patients.

**P0850** QUALITY IN COLONOSCOPY; HAVE YOU REALLY GOT TO THE CAECUM?

S. Budihal

Department Of Endoscopy, Nottingham University Hospitals, Nottingham/United Kingdom

Contact E-mail Address: sibudihal@yahoo.co.uk

Introduction: Poor quality and incomplete colonoscopy is associated with missed diagnosis and failure to prevent interval cancers.1 Caecal intubation rate is the most frequently used Quality Indicator of Colonoscopy. British Society of Gastroenterology guidelines recommend obtaining “clear images of caecal landmarks or terminal ileum” while the European and American guidelines suggest “at least complete photo documentation per patient of the ileocecal valve and caecum”. In this retrospective study we aimed to assess colonoscopists’ practice in photo documentation of colonoscopy completion.

Aims & Methods: Colonoscopy reports for colonoscopies performed at an endoscopy unit over a University Hospital over a period of three months from 01/01/2014 to 31/03/2014 were retrieved from the Trust’s Endoscopy database. Photo documentation from the reports were then analysed for caecal landmarks and terminal ileum images.

Results: A total of 292 colonoscopies were performed by 21 endoscopists (5 colorectal surgeons (24%), 3 nurse endoscopists (14%), 3 specialist registrar gastroenterologists (14%) and 10 consultant gastroenterologists (48%). Caecal intubation was achieved in 248 cases (85%). In 8(3%) cases the anastomosis was reached. The ileo-caecal valve was photographed in 172(70%) cases, the appendiceal orifice was photographed in 25 cases (10%). In the case of anastomosis, 7(38%) patients had clamped and intubated the ileum but did not obtain a photo clip of the ileo-caecal valve. Obtaining clear images of caecal landmarks will ensure definite caecal intubation and efforts towards recording them will prompt the endoscopist to attain adequate mucosal view. In order to achieve excellence we suggest colonoscopists obtain images of all caecal landmarks including the ileum when intubated, label photographs and where possible record video clips of caecal intubation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic accuracy. However, these excellent results in in vitro histological prediction are a reflection of the clinical practice by trained endoscopists, and their application remains to be confirmed outside this context.

Aims & Methods: To evaluate the in vivo histological prediction acuity of colorectal polyps (<10 mm in diameter) using FICE technology.

Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic and 1 serrated adenoma. From the global assessment of all polyps and observations, the use of the FICE classification for prediction of adenoma vs. hyperplastic polyps produced a sensitivity, specificity, positive and negative predictive value identical to WLE (100%, 62.5%, 100% and 60%, respectively). Overall, diagnostic acuity in histological prediction was identical in both modalities (76%). The individual acuity of the endoscopists ranged from 66% to 100%. Histological scores were not associated with a higher probability of correct classification, both in WLE (77% vs. 75%) and FICE (75% vs. 80%), p > 0.05.

Conclusion: The use of FICE technology by inexperienced endoscopists in the histological prediction of colorectal polyps has no advantage over WLE, having both suboptimal acuities. The lack of recourse to magnification may have contributed to these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO854 PATIENT AND PHYSICIANS RELATED FACTORS ASSOCIATED WITH A HIGH ADENOMA DETECTION RATE IN ROUTINE COLONOSCOPY

1Pôle Digestif Paris Bercy, Clinique de Bercy, Charenton-le-Pont, France
2IGR, Villejuif, France
3Digestive Endoscopy Unit, Clinique de Bercy, Charenton-le-Pont, France
Contact E-mail Address: m.cavichi@wanadoo.fr

Introduction: Adenoma and polyp detection rates are correlated to the risk of interval colorectal cancer and is consequently considered as a quality benchmark for colonoscopy. We propose to evaluate in our daily practice, involving all the endoscopists of our endoscopy unit.

Aims & Methods: 6027 colonoscopies were performed between 01/01/2016 and 31/12/2016 by 30 physicians. Regarding patients, the following data were prospectively collected: age, gender, indication for colonoscopy, preparation procedure and quality of preparation (assessed by the Boston Scale), number and size of polyps and polyp histopathology. Regarding physicians, age, gender, number of colonoscopies and mean withdrawal time (calculated from the normal colonoscopies) were studied. Neoplasia was defined as grade 4 or 5 of the Vienna classification: 4: non-invasive high grade neoplasia (high grade adenoma/dysplasia, non-invasive carcinoma and suspicion of invasive carcinoma); 5: invasive neoplasia (intramucosal carcinoma, submucosal carcinoma or beyond).

Conclusion: Results were enrolled 2719 Male patients (45.1%) and 3308 Female patients (54.9%), 73.6% of them of 50 year-old or more. A sub-optimal preparation (defined by Boston scale score < 6 or at least one sub-score < 2) was observed in 61.5% of the patients. Caeal intubation rate was 99%. 21 endoscopists were Male and 10 were under 50 year-old. The median number of colonoscopy per physician was 140 (range: 10-720). 2054 colonoscopies detected 3914 lesions or polyps: 2914 tubular/villous adenomas, 496 serrated adenomas, 242 hyperplastic polyps (hyperplastic polyps located in the rectum and sigmoid colon were not considered as at risk for cancer and were excluded), 212 other histology leading to a Median Number of Polyps (MNP) of 0.65 and a Polyp Detection Rate (PDR) of 34.1%. 1935 colonoscopies detected at least one adenoma (adenoma detection rate, 32.1%). Large Polyp Detection Rate was 7.9% with detection of 538 polyps >1 (13.7% of polyps), in 477 patients. Neoplasia Detection Rate was 3.6% (300 neoplasias in 220 patients). Admission to the endoscopists, the median PDR was 32.5% (range 14-62%). Among them, 4 had a PDR < 20%, 17 had a PDR between 20 and 39% and 9 had a PDR >40%. Mean withdrawal time was 490 seconds (range 228-831). 10 physicians had a mean withdrawal time <420 seconds (median ADR = 34.3%). 5 physicians had a mean withdrawal time of more than 420 seconds (p > 0.05). In the univariate analysis, a high PDR was significantly associated with patient-dependant factors: age, Male gender, a familial history of polyp/cancer, screening or positive faecal immunochemical test (FIT+) and quality of preparation. Regarding physician-dependant factors, a high PDR was significantly associated with Male gender, high volume (>140 colonoscopies per year) and withdrawal time. In the multivariate analysis, the only independent predictor associated with a high PDR were: familial history of polyp/cancer, FIT+ and patient age.

Conclusion: In this large series of routine colonoscopies, we found medically-relevant polyps in more than one third of the patients, irrespectively of age and indications. In multivariate analysis, a high PDR was significantly associated with familial history of polyp/cancer, FIT+ and age of the patient. This may suggest that the Male gender is no longer a risk factor for polyps. In addition, even if there are still discrepancies regarding FIT among physicians, we found a physician-dependant factor associated with a high PDR in the multivariate analysis.

Acknowledgment to all the endoscopists and nurses of the Clinique de Bercy.

PO855 EFFICIENCY OF COLONOSCOPY IN CASE OF POSITIVE FECAL IMMUNOCHEMICAL TEST: ONE-YEAR EXPERIENCE AND RESULTS ON 391 PATIENTS IN ROUTINE PRACTICE IN FRANCE

1Pôle Digestif Paris Bercy, Clinique de Bercy, Charenton-le-Pont, France
2IGR, Villejuif, France
Contact E-mail Address: m.cavichi@wanadoo.fr

Introduction: Fecal immunochimical test (FIT) has progressively replaced the guaiac test for colorectal screening in average risk population in France since May 2015. With a high sensitivity and a good specificity, it is supposed to increase colonic cancer risk-detection. However, its efficiency has not been described in routine colonoscopy.

Aims & Methods: Among 6027 colonoscopies performed between 01/01/2016 and 31/12/2016 in our endoscopy unit, 391 were performed for a positive FIT (FIT+).
Conclusion: Preliminary results from our study suggest that the low-volume 2 L solution in both groups A and B were respectively (62.8% and 65.7% vs 32% and 26% vs 19% and 13%) (p = 0.03). However, 5 patients in group A had sleep disturbance vs only one case in group B. Four patients who received 4 L of PEG had expressed their refusal to resume the same preparation if necessary while 2 patients in group B had refused. A score greater than or equal to 7 was recorded (65% for protocol A and 73% for protocol B) with a maximal score of 9.9 (for B groups), respectively. The overall score obtained was 6.49 versus 7.32, respectively. This score (BBPS) tended to be better in protocol B than in protocol A in the right segment (2.55 vs 2.17), transverse colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). This same trend was recorded in relation to the number of patients with a maximal score of (9/9), with 4 colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). This same trend was recorded in relation to the number of patients with a maximal score of (9/9), with 4 colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). However, endoscopists comfort was higher in LLP (4.62 Vs 3.76; p < 0.05). Both groups required position change during progression or loop palpation by the nurse in equal percentage (54% Vs. 56%; p = 0.05, 49.5% Vs. 50.5%; p = 0.05). Additionally, there was no difference in time to docum, patients of endoscopists comfort between the colonoscopies performed with Fuji or Olympus colonoscopes. Conclusion: In our experience, progression in right lateral position did not show additional advantage over standard LLP in time to reach the cecum or patients comfort. We did not find any difference in time to progression or comfort between Olympus and Fuji colonoscopes. Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Large series suggest endoscopic mucosal resection is safe and effective for the removal of large sessile serrated polyps ≥10mm (large SSP) but it exposes the patient to the risks of electrocautery, principally delayed bleeding.

Aims & Methods: We aimed to examine the feasibility and safety of piecemeal cold snare polypectomy (pCSP) for the resection of large SSP. Over 12 months significant large SSP without endoscopic evidence of dysplasia referred to a tertiary endoscopy centre were considered for pCSP. The technique for pCSP was standardised. The lesion and its margins were assessed using high definition endoscopic imaging. Snare resection commenced at one margin including a 2–3 mm rim of normal tissue. A thin-wire snare was used in all cases. Firm downward pressure and suction of luminal gas aided tissue capture. Subsequently the assistant closed the snare until resistance was felt, and then completely once the endoscopist was satisfied with the amount of captured tissue. If transection did not occur within five seconds gentle traction was exerted on the snare catheter against the tip of the colonoscope. If transection still did not occur, the snare placement was revised. The mucosal defect was then expanded with a flushing pump containing 0.9% saline. Further resections were then performed aligning the snare with the cut edge of the expanding mucosal defect. Once the resection was completed the mucosal defect was inspected for residual serrated tissue. If residual was detected further generous snare resection was performed. Oozing of blood from the resection site was common and was not actively treated. Submucosal injection was not performed. High-definition imaging of the defect margin was used to ensure the absence of residual serrated tissue. Adverse events were assessed at 2 weeks and surveillance was planned between 6 and 12 months. Results: 41 SSP were completely removed by pCSP in 34 patients. 7 patients had two lesions removed. The median size of SSP was 15mm (IQR 14.5–20), range 10–35mm. The median duration of procedures was 4.5 minutes (IQR 1.4–6.3).

There was no evidence of perforation or significant intra-procedural bleeding. There were no significant adverse events at 2 week follow up including delayed bleeding and post polypectomy syndrome. 8/41 lesions underwent first follow-up at median 6 months with no evidence of recurrence.

Conclusion: There is potential for pCSP to become the standard of care for non-dysplastic large SSP. This may reduce the burden on patients and healthcare systems of removing SSP, particularly by avoidance of delayed bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.
in left colon and 6 (6%) in rectum. Pathological diagnosis was 22 (24%) hyperplastic polyp or SSA/P, 42 (46%) low grade dysplasia (LGD), 23 (26%) high grade dysplasia (HGD), and 11% submucosal invasive cancer. In the removal methods, HSP was 71 (77%) lesions and EMR was 21 (23%). The median procedure time of HSP and EMR was 37 seconds (range: 7–430) and 167 (range: 60–450) (p < 0.001). The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–26) (p < 0.001). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (3%) (p = 0.009). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p = 0.434). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic poly or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

**Conclusion:** Of over 10 mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** SMA3 is a simple readily applicable clinical score that identifies a subgroup of patients who are at increased risk of EMR related complications including CSPEB and recurrence. This information is useful for planning EMR lists with respect to time and resource allocation. Moreover SMA3 could have a major impact on training, both in identifying appropriate training cases and providing an objective benchmark against which to assess the progress of trainees in EMR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

similarly 7.3 in 9 were better than NBI. kappa value among participants was 4.8; moderate agreement (p = 0.0016). All polyps were removed endoscopically after evaluation. All lesions were histologically diagnosed as SSA/P without dysplasia. 

**Conclusion:** Acetic acid was useful and promising to facilitate the endoscopic recognition of the precise margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill.

**Introduction:** Preoperative localization or tattooing is essential for minimally invasive surgery. Although preoperative endoscopic tattooing using India ink or indocyanine green is widely used, clinical evidence and safety profile supporting the use of these agents is lacking.

**Aims & Methods:** We assessed the efficacy and safety of preoperative endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopy with endoscopic tattooing or India ink or autologous blood were included in this study. From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospectively reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattooing in the peritoneal cavity and related adverse events.

**Results:** Endoscopic tattoos produced using India ink were visible in 38 (95%) patients, and tattoos created using autologous blood were visible in 36 (90%) patients. In the autologous blood group, the tattoo could not be identified in four patients due to excessive peritoneal fat, bleeding tendency, congenital anomaly, and tattoos were inadequate depth. Eight (20%) patients in the India ink group and four patients (10%) in the autologous blood group experienced endoscopic tattooing-related adverse events.

**Conclusion:** Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colorectal lesions. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0865 SUBMUCOSAL INVASION IN COLORECTAL LATERALLY SPREADING TUMORS (LST) AND ABILITY OF THE ENDOSCOPIST FOR CANCER DETECTION**

H. Soliman1, B. Brieau2, M. Guillaume3, S. Leblanc2, R. Coriat2, F. Prat1, S. Chassade1

1Gastro-entérologie, Hôpital Saint Antoine, Paris/France
2Department Of Gastroenterology, Cochin Hospital, Assistance Publique-Hôpitaux de Paris, Paris/France
3Hôpital Cochin Dept. of Gastroenterology, Paris/France

**Introduction:** Laterally spreading tumors (LSTs) are defined as lesions >10 mm with a low vertical axis and lateral extension. They are separated in 2 groups with 2 subclasses for each of them: granular LST (LST-G) with, or without large nodule; and non-granular LST (LST-NG), separated into flat lesions (Ha) and depressed lesions (Ha + Hc). Every subclass has been associated with a proper risk of cancer and submucosal invasion (T1sm)-2. Knowing this aspect could help for the decision of the resection technique (endoscopic mucosectomy EMR, endoscopic submucosal dissection ESD, or surgery). The aim of our study was to determine the rate of cancer (submucosal and mucosal adenocarcinoma) in a western series of LST treated by endoscopic resection, and to evaluate the ability of the endoscopist to predict the depth of cancer invasion.

**Aims & Methods:** The entire patients with a LST ≥20 mm treated between January 2012 and December 2016 in our single center were included. Endoscopic data were collected (size, location, LST classification, analysis of pit pattern, endoscopic suspicion of cancer). We also reported the resection technique, histological results, and the follow-up at 1 year.

**Results:** 377 LST were included in our study. The average age was 67.7 years old. The mean size of lesion was 40.6 mm. LST were located in the right colon, the rectum, the left colon and the transverse colon in 44.5%, 32.6%, 14.0% and 8.8%, respectively. The resection technique used was a monobloc EMR in 15.4%, piecemeal EMR (pEMR) in 42.9%, ESD in 27.3% and assisted ESD in 14.5%. ESD was associated with a significant lower risk of recurrence after 1 year (4.9% against 18.1%). Considering the LST classification, there were 27.0% LST-G without large nodule, 28.4% LST-G with large nodule, 35.5% flat LST-NG Ha, and 9.0% LST-NG with depression Ha + Hc. The overall rate of adenocarcinoma was 19.7%, and 9.0% with submucosal invasion. The rates of adenocarcinoma and the rates of submucosal invasion in every subtype of LST are reported in table 1. They were higher for LST-G with large nodule (34.5% and 15.9% respectively) and for LST-NG with depression (35.3% and 20.6%). Regarding the prediction of submucosal cancer by the endoscopist, we report a low sensitivity, and positive predictive value (respectively 64.7% and 32.8%). However, we had a good specificity and negative predictive value (86.0% and 96.0%). Endoscopic predictors of submucosal cancer were invasive pit pattern (HR 33.0; p = 5.78e-07) and depression (HR = 11.86; p = 0.049).

**Conclusion:** Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

**Introduction:** Evidence on an international variation of pathological types and anatomical distribution of colon polyps is beneficial for early detection and management but limited.

**Aims & Methods:** To characterize differences in colonoscopy findings by ethnicity, a random sample of patients aged at least 50 years without colonic symptoms or history of colorectal diseases who underwent colonoscopy were reviewed. Of 26,508 subjects, 2651 were randomly selected. Of 1300 subjects who met the inclusion criteria, abnormal findings were identified in 878 cases (67.54%), of which 452 cases had 940 polyps and 7 cancer lesions were found in 6 cases. Of 452 patients with polyps, half had only one polyp (53.76%) and were Asian (54.63%), followed by Caucasian (26.99%), Middle Eastern (15.71%), and other ethnic origins (2.65%).

Introduction: Endoscopic submucosal dissection represents the standard of care for large superficial colorectal neoplasms in Japan. In Europe, only few studies reported these outcomes, especially in the rectal location. Colonic ESD is still technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is although more risky because perforations are most often non clinically significant in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD.

Aims & Methods: Retrospective bicentre study of all cases of colonic ESD performed between 01/2016 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and extended curative resection rate (Curative resection + non-curative due to positive horizontal margins and without recurrent disease on endoscopic control). Secondary endpoints were to compare these results with results of rectal ESDs performed during the same period.

Results: 87 ESDs were performed in two French centers between 01/2015 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. During the same period 93 rectal ESDs were performed for superficial pre-cancerous or cancerous neoplasms. Descriptive results: male 54 (61%), mean size of the specimen: 49 mm, mean duration of procedure 125.1 min, mean speed of ESD: 18.9 mm²/min, perforation rate: 9 (10.3%), post procedural bleeding rate: 2.3%, secondary surgery 13 (15.3%) (3 (23%) for a perforation; 10 (77%) for a failure or non-curative due to positive horizontal margins and without recurrent disease on endoscopic control).

Secondary Endpoint were to compare these results with results of rectal ESDs performed during the same period.

Conclusion: Colonic ESD could be performed with similar results than rectal ESD in French expert teams with prior strong experience in animal ESDs and rectal ESDs. It allows en bloc resection of large superficial colorectal neoplasms with a very low risk of recurrence. CTs comparing colonic ESD to piece-meal EMR are needed to determine the appropriate place of each technique in Europe.

Introduction: It is well known that acromegolies have been at an increased risk of colorectal neoplasm. However, there has been few reports of them in Japanese patients with acromegaly. In this study, we attempted to elucidate the risk of colorectal neoplasms in Japanese patients with acromegaly comparing with healthy controlled patients.

Aims & Methods: Between April 2008 and September 2016, a total of 745 patients were underwent Hardy operation in our institute. Among them, a total of 178 patients were our hospital during periproductive period and were enrolled in the case group. In contrast, a total of 356 patients were selected randomly from those who were performed colonoscopy in our medical check-up in the same period by means of being matched to cases of the age and gender. The incidence, size, location and histology of colorectal neoplasm were investigated.

Results: As background, 84 patients (47.2%) were men and 94 patients were women, and the median age was 47.5 years old (18 to 75) in the case group. The median height/weight was 165.5 cm/65.1 kg in the case group and was significantly larger than the control group (163.4 cm/60.1 kg) (p = 0.038, p < 0.001 respectively). The median Body Mass Index (BMI) were 23.4 in the case group and 22.5 in the control group. There was a significant difference between two groups (p < 0.001). The frequency of colorectal neoplasm was 66.8% (119/178 patients) in the case group and was significantly higher than control group of 24.2% (86/356 patients) (p = 0.001). The average number and size of neoplasm were 2.44 ± 4.74 mm in the case group and 1.77 ± 3.89 mm in the control group. There was a significant difference between two groups (p = 0.001). The distribution of neoplasm in the case group vs in the control group was shown 12.6% vs 12.8% in cecum, 30.3% vs 36% in ascending colon, 8.9% vs 30.2% in transverse colon, 15.1% vs 10.5% in descending colon, 66.4% vs 40.7% in sigmoid colon, and 31.9% vs 19.8% in rectum. The incidence of neoplasm in sigmosexual region had a significant difference in two groups (the case group 80.7% vs the control group 53.5%) (p < 0.001). In terms of neoplasm larger than 5 mm, the frequency was 34.3% (61/178 patients) in the case group and 7.6% (27/356 patients) in the control group (p < 0.001). In addition, as for neoplasm larger than 10 mm, that was 15.2% (27/178 patients) and 2.2% (8/356 patients) respectively (p < 0.001). The number of neoplasm resected by colonoscopy was 71 lesions by 24.5% of all in the case group and 5 lesion (16.4%) in the control group. The pathological examination in the case and control group showed eight and one had hyperplastic polyps, 2 and zero had sessile serrated adenoma/polyp, 3 and zero had inflammatory polyp, 48 and 19 had low grade adenomas, 4 and 3 had High grade adenomas, one and zero had carcinoid, and 5 and 2 had carcinoma respectively. There were no significant differences between two groups in the limited cases of high adenoma and carcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonoscopy in ulcerative colitis (UC) is performed as first diagnosis and during screening for dysplasia and disease flares. It is an invasive procedure with a burden of discomfort and possible complications. To overcome discomfort and complications due to colonoscopy an Italian high-tech start-up (Endotics, Peccioli, Italy) developed a soft, self-propelled, disposable robotic colonoscope (R), approved with CE mark.

Aims & Methods: We wanted to compare diagnostic performance and tolerability of R with those of standard white light colonoscopy (S) in patients with ulcerative colitis. Consecutive patients referred for colonoscopy to our endoscopy department with clinically mild to moderate ulcerative colitis that signed the informed consent for both procedures were studied first with R and then with S (Olympus CF-145), by two different operators, blinded to previous observations. R had the following technical specifications: 17 mm outer diameter, rest position length probe 30 cm; maximum length of probe 54 cm; working length 210 cm; NTSC CMOS analog camera. Conscious sedation with midazolam was administered as...
Aims & Methods: A total of 40 endoscopic video clips depicting LSTs (10% mean±SD) were obtained by 6 expert endoscopists: 3 from Japan and 3 from the West. Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-NG flat, LST-NG pseudodepressed), Paris classification, invasiveness, treatment suggestion and mean size of lesion. We calculated the interobserver agreement with weighted kappa and Chi square.

Results: Japanese endoscopists diagnosed more lesions as LST-G than Western (62.7 vs. 45.4%), Western diagnosed more LST-NG than Japanese (54.6 vs. 37.3%; p=0.007). The interobserver agreement of the LST classification among the six experts was good with a weighted Kappa of 0.61 (IC 0.95% 0.43-0.78) for Japanese, and moderate at 0.45 (IC95% 0.27-0.64) for Western. Difference in concordance between the two cohorts was not statistically significant (p=0.22). When only two categories were considered (LST-G vs NG), agreement was very good with a weighted Kappa of 0.81 (IC 95% CI 0.65-0.97) and good for Western endoscopists (0.65; 95% CI 0.46-0.85). Again, difference in concordance was not statistically significant (p=0.22).

P0871

CLINICAL USEFULNESS OF THE SMSA DIFFICULTY SCORE AND COMPARISON WITH A SUBJECTIVE SCORE FOR THE MANAGEMENT OF LARGE NON-PEDUNCULATED COLORECTAL LESIONS. A MULTICENTER STUDY FROM THE SPANISH ESOPHAGEAL SOCIETY ESOPHAGEAL RESECTION GROUP

References

Authors: Aims & Methods: The aim of this study was to assess the usefulness of the SMSA scoring system relating the difficulty level with outcomes and complications of EMR and to compare it with a subjective classification of difficulty. We conducted a prospective multi-center study with 1997 consecutive patients with large (≥20 mm) non-pedunculated colorectal lesions (LNPCl) treated by EMR (n=2198) at 23 hospitals belonging to the Spanish Endoscopy Society Endoscopic Resection Group, from January 2013 to October 2016. We

Contact E-mail Address: eduabeniz@hotmail.com

Introduction: A scoring system based on size, morphology, site and access (SMASA) score was established for determining the complexity of polyectomy and endoscopic submucosal dissection (Esd). It could predict outcome and complications of EMR.

Aims & Methods: The aim of this study was to validate the SMAS classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.
calculated the SMSA score of difficulty and assessed the ability of SMSA to identify 5 outcomes: 3-months recurrence, 1-year recurrence, global recurrence (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using chi-squared tests and complemented with logistic regression models.

Results: The SMSA scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 399 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak (k = 0.33). 255 patients (19.9%) had recurrence 3 months after EMR, 84 (11.6%) had recurrence at 1 year, 78 (3.5%) suffered delayed bleeding and 35 (1.8%) perforation. The level 4 polyps had significantly higher rates of recurrence at 3 months and 1 year (p < 0.001 in both cases) and delayed bleeding (p = 0.006), but not for perforation.

Conclusion: The SMSA grading tool is a predictor of outcomes or recurrences and bleeding following resection of LNIPC. However, in our multi-center sample, it does not appear to overcome the subjectivity of a subjective indicator of difficulty assessed by the endoscopist during the EMR. It seems that this score can be used to facilitate planning, training or competency assessment, but efforts should be focused on validating the scoring system in a real situation, adjusting the score of variables or including new ones.

P0872 NARROW BAND IMAGING GUIDED BIOPSY IMPROVES THE YIELD OF HISTOPATHOLOGY FOR THE DIAGNOSIS OF GASTROINTESTINAL TUBERCULOSIS (GITB)
N. Berry, S. K. Sinha, S. Malik, R. Kohchar, K. Vaiphei, K. Sharma, N. Dhaka, A. Koshi Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Contact E-mail Address: sarojk.sinha@hotmail.com

Introduction: Accurate diagnosis of gastrointestinal tuberculosis (GITB) is challenging due to pauci-bacillary nature of disease and poor sensitivity of histopathology. Role of tissue acquisition using narrow band imaging magnification (NBI-M) to improve yield of histopathology over high-definition white light endoscopy (HD-WLE) has not been assessed.

Aims & Methods: Utilizing narrow band imaging with magnification versus high-definition white light imaging guided endoscopic biopsy for diagnosis of gastrointestinal tuberculosis. In this prospective study from July 2015 to November 2016, adult cases of clinically suspected GITB were recruited. All patients underwent NBI-M test, contrast enhanced computed tomography of abdomen, esophagogastroduodenoscopy and/or colonoscopy using both HD-WLE and NBI-M and guided biopsies using both were taken. Histopathological examination was done by two independent pathologists. A final diagnosis of GITB was made if acid-fast bacilli were seen in tissue or grown in culture, histopathology showed caseous necrosis with granulomatous inflammation or clinical/radiological and endoscopic features were suggestive of tuberculosis and clinical response to antitubercular therapy.

Results: A total of 35 cases of clinically suspected GITB were recruited. A final diagnosis of tuberculosis was made in 32 cases (duodenal n = 4, ileocecal n = 28). Concomitant evidence of active or healed pulmonary tuberculosis was seen in 21% of the cases. The mean age, haemoglobin and erythrocyte sedimentation rate of patients with tuberculosis were 36.4±14.6 years, 10.2±2.4 g/dl, 37.8±15.3 mm/hour respectively. The mean duration of symptoms was 10.9 months. The most common symptoms were pain abdomen (78%), weight loss (62.5%), and loss of appetite (40.6%), fever (37.5%), vomiting (34%) and diarrhea (22%). Mantoux test was positive in 40.6% cases. The most common endoscopic findings were ulcerations (75%), nodularity (46.8), distorted ileocecal valve (28%) and strictures (21.8%) (Table 1). The most common radiological findings were mural wall thickening (65.6%), mesenteric lymphadenopathy (56%) and strictures (40%) (Table 1). NBI-M guided biopsy confirmed the diagnosis of GITB in 46.88%, while HD WLE guided biopsy confirmed diagnosis of GITB in 28.12% (P, 0.04). The two sets of biopsies together confirmed diagnosis of GITB in 53.1%. The area under curve for NBI-M plus HDWLE, NBI-M alone and HDWLE alone were 0.77(0.63–0.87), 0.73 (0.60–0.85) and 0.64 (0.50–0.77) respectively. Patients were started on anti-tubercular therapy for nine months. Four patients underwent surgery for intestinal obstruction while on antitubercular therapy. Twenty eight completed full therapy and improved.

Conclusion: NBI-M guided biopsy improved the yield of histology for diagnosis of GITB.

Introduction: Colorectal cancer is a leading cause for cancer related mortality. Adenomatous polyp, the precursor lesion, can usually be endoscopically resected to prevent cancer. Currently, there are no criteria for surgical vs. endoscopic resection and decision is individually made by the treating physician.

Aims & Methods: We aimed to evaluate factors associated with short-term efficacy and safety of endoscopic resection of large (>20 mm) and giant (>40 mm) adenomas. Consecutive cases that underwent endoscopic resection of adenomas larger than 20 mm were included. Endoscopic, clinical and histological details of polyps and of the endoscopic procedure were recorded as well as the need for surgery.

Results: Total of 351 resections were included. Average diameter was 30.34±10.66 mm. Surgery was indicated in 21 (5.98%) cases. In a multivariate analysis for efficacy, two variables were independent risk factors for surgery: adenoma size (OR 95%Ci 1.08 (1.04-1.12) and cecal location (OR 95%Ci 5.67 (1.60–22.33)). Post-polypectomy complications were documented in 85 cases (24.2%): bleeding - 69 (19.7%, 54/69 managed during procedure), perforation - 8 (2.3%) and significant discomfort up to early termination of procedure - 15 (4.3%). Only 21 (6.0%) developed serious complications requiring further hospitalization. In multivariate analysis for safety, independent risk factors for post-polypectomy complications were: adenoma size (OR 95%C1 1.04 (1.01–1.06), polyph morphology (esophageal OR 95%C1 2.55 (1.45–4.51), flat OR 95%C1 2.40 (1.04–5.52) and submucosal adrenaline injection (OR 95%C1 1.87 (1.11–3.20)). Every increment of 1 mm in adenoma diameter above 20 mm, increased the need for surgery by 8% and the risk for complications by 4%.

Conclusion: Resection of large or giant adenomas is generally a safe procedure when performed by an experienced endoscopist. Although adenoma size is the most significantly related to efficacy and safety, each case of giant adenoma should be evaluated in a referral center for feasibility of endoscopic resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0874 COLORECTAL MUCOSAL DEFECT CLOSURE FOLLOWING ENDOSCOPIC MUCOSAL RESECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Palmela1, P. Marques Da Costa2, A. O. Ferrereira3
1Gastroenterology Department, Hospital Beatriz Angeló, Loures/Portugal
2Gastroenterology And Hepatology Department, Hospital de Santa Maria, Lisboa/Portugal

Contact E-mail Address: palmela.carolina@gmail.com

Introduction: Clinical meaningful delayed bleeding is the most frequent adverse event following endoscopic colorectal mucosal resection. Observational and interventional studies on the efficacy of prophylactic closure (PC) following endoscopic mucosal resection (EMR) showed conflicting results.

Aims & Methods: The primary objective of this review is to evaluate the effectiveness in preventing bleeding and post-polypectomy syndrome (PPS) or perforation of PC of colonic mucosal defects following endoscopic resection. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) from MEDLINE. We included studies with humans submitted to colonoscopy and in whom mucosal flat or sessile (Paris classification 0-II or Is) lesions with an estimated size ≥10 mm were found and removed.

Results: 269 articles were initially screened; 5 were RCTs, 4 of them were pooled in the quantitative analysis. A total of 555 patients and 557 resected lesions (proximal colon: 220; distal: 337) were included. Endoscopic procedures: 459 loop polypectomies and 98 submucosal dissections. A total of 298 lesions were randomized to PC versus 259 to non-closure (NC). Number of events on PC group: delayed bleeding (n = 3), PC and perforation (n = 61). Number of events on NC group: delayed bleeding (n = 13), PC and perforation (n = 14). Prophylactic mucosal defect closure was effective in reducing delayed bleeding risk (OR 0.036; 95%CI 0.004–0.77, p = 0.020; I² = 0.0%; 2 RCT and 452 lesions included). There was no non-significant trend for PPS/perforation risk reduction after PC (OR 0.349, 95%CI 0.114–1.070, p = 0.066; I² = 0.0%; 2 RCT and 374 lesions included).

Conclusion: Prophylactic closure of mucosal defects after EMR of flat or sessile colorectal lesions ≥10 mm reduces de risk of delayed bleeding. Further studies are needed to evaluate the effect on PPS/perforation prevention.

P0875 RECTAL ESD IN VERY OLD PATIENTS (>80 YEARS): A FRENCH MULTICENTER RETROSPECTIVE STUDY

R. Legros1, J. Alloboy1, M. Guillaumot2, V. Lepliliec2, S. Chaussade2, M. Choche2, S. Leblanc2, M. Barret2, F. Priti2, J. Rivory2, D. Sauterseau3, T. Bouchon4, J. Jacques3
1Hepato-gastro-entérology, CHU Limoges - Hepato-Gastro-Enterology, CHU Limoges: Limoges/France
2Gastroenterology, Cochin Hospital, Paris/France
3Hepato-gastroenterology, Hopital Edouard Herriot, Lyon/France

Contact E-mail Address: raphael.legros@gmail.com

Introduction: Endoscopic Submucosal Dissection has become the standard of care for large superficial rectal pre-cancerous and cancers lesions. It allows an en-bloc resection of large superficial lesions that increase the quality of pathological analysis and considerably decrease the risk of recurrence. Risk of having large superficial lesions increase with age and no study have focused specifically on ESD in very old people (>80 years). Indeed in this population alternative surgery had a high morbidity and is often refused or contraindicated for these patients.

Aims & Methods: Retrospective bicentre study of all cases of rectal ESDs performed between 06/2010 and 12/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years. Four French teams that performed more than 150 ESDs in the last 5 years. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and complications in patients older than 80 years. Secondary endpoints were to compare these results with rectal ESDs performed during the same period for patients younger than 80 years.

Results: 58 rectal ESDs were performed in four French centers between 06/2010 and 12/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years. Descriptive results: male 28 (48%), mean size of the specimen: 56.4 mm, mean duration of procedure 143.7 min, mean speed of ESD 19.8 mm²/min, perforation rate: 3 (6.2%), post-procedural bleeding: 7 (12%), secondary surgery 2 (3.4%). Pathological analysis: low-grade dysplasia in 19%, high-grade dysplasia in 28%, intra-mucosal carcinoma in 5%, superficial submucosal carcinoma in 5%, deep submucosal carcinoma in 5%, adenoma in 34% and adenoma in 6.9%. Only 1 patients (1.7%) had a recurrent disease during endoscopic follow up. Primary Endpoint: En bloc resection: 86.2%, R0 resection: 62.5%, curative resection: 62.5%. Secondary Endpoint: Duration of procedure was longer in older people. Speed of ESD was lower. En bloc and R0 resection were lower in very old patients. Cancer was more frequent in very old patients (>80 years) and younger patients (<80 years) are resumed in table 1.

Conclusion: ESD is feasible and efficient in very old patients. However, En bloc resection and R0 resection are less frequent than in younger patients probably due to more challenging lesions (more frequent cancer on the pathological analysis). ESD should be the treatment of choice for large rectal superficial neoplasms of the rectum in very old patients in view of its oncological efficiency and its safety in comparison to the surgical alternative.

P0876 COLONOSCOPY, SPLIT-DOSE PROTOCOL IMPLEMENTATION: A SINGLE-CENTRE EXPERIENCE

C. Palmela, C. Gomes, M.P. Costa Santos, M. Rocha, S. Pereira, D. Tavares, R. Ribeiro, A. O. Ferrerere, E. Barjas, M. Bravo Gastroenterology Department, Hospital Beatriz Angeló, Loures/Portugal

Contact E-mail Address: palmela.carolina@gmail.com

Introduction: Split-dose bowel preparation (SD) is more effective in bowel cleansing quality in patients from a district hospital. This was an exploratory observational study of patients who underwent total colonoscopy between jun/2016-mar/2017 with polyethylene glycol bowel preparation before and after SD protocol implementation. Bowel cleansing quality was assessed prospectively (using Boston Bowel Preparation Score) and compared between SD and PD groups. Tolerance was assessed using a patient questionnaire.

Results: A total of 344 patients were included, 53% were male, mean age of 61.8±13.6 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of colonoscopies occurred in morning shifts. Mean interval between finishing bowel preparation and colonoscopy was 4h30 (SD) and 8h09 (PD). Adequate bowel cleansing was found in 51% of patients (SD 83% vs. PD 79%; p=0.34). There was an association between adequate bowel cleansing and a shorter interval between finishing preparation and colonoscopy (5h40 vs. 7h15; p=0.010). Split-dose preparation was associated with a better cleaning in the right colon (2.17±0.69 vs. 2.03±0.65; p=0.047) and a trend for better overall cleansing (6.70±1.87 vs. 6.32±1.90; p=0.067). On morning shifts, there was a significant association between SD prep and better overall cleansing (p=0.030) and also right colon cleansing (p=0.034). After adjusting for morning shifts, we found an association between SD preparation and better bowel cleansing (risk difference 0.406; 95%CI –0.023–0.834; p=0.063). There was no difference between groups on bowel urgency (SD 2.6% vs. PD 1.7%; p=0.718). SD preparation was associated with worse sleep quality (SD 25% vs. DA 7%; p=0.004).

Conclusion: The implementation of a split-dose bowel preparation protocol in our hospital was associated with better bowel cleansing, especially on the right colon. Split-dose preparation was not associated with higher bowel urgency, although there was a worse sleep quality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The elderly patients are considered as a particular population. Colonoscopy has an important place at this population because of the limited number of normal paraclinic examinations and the high incidence of tumor disease, specially the colo rectal cancer.

Aims & Methods: The aim of this study was to determine the indications and results of colonoscopy in people older than 70 years We performed a retrospectivereview study over a 2 years from beginning of the endoscopic unit until February 2017, conducted in the department of hepatogastroenterology of our university hospital. All patients over the age of 70 years who have underwent colonoscopy have been included.

Results: A total of 1059 colonoscopies were performed, 10.3% were indicated for people older than 70 years. The mean age was 74.15 years with a median age of 75 years and a maximum age of 91 years. The prevalence of males was 51%. 10.5% of cases (n = 10) were diabetic, 12.6% (n = 12) hypertensive, 12.6% (n = 12) with ischemic heart disease. 8.4% (n = 8) had either diabetes or high and 9% (n = 9) had a digestive neoplasia. Colonoscopy was indicated for hematochezia in 40% (n = 38), transit disorders in 33.6% (n = 32), abdominal pain in 14.7% (n = 14), IBD in 3.1% (n = 3), radiographic abnormalities in 13.6% (n = 13), iron deficiency anemia in 4.2%, and for patients with a family history of colorectal cancer in 1% of cases. Colonoscopy was abnormal in 83% (n = 18), with polyps in 45.3% (n = 45), suspected lesions of malignancy in 16.1% (n = 15), Diarrhea in 24.7% (n = 24), and for patients with a family history of colorectal cancer in 1% of cases.

Conclusion: Colonoscopy was abnormal in 83% of cases. Colonoscopy in this age group is intended not only to detect colorectal cancer, but also to rule out other conditions such as inflammatory bowel disease, polyps, or diverticulosis.

P0880 ENDOSCOPIC CLOSURE OF ACUTE IATROGENIC PERFORATIONS OF THE GASTROINTESTINAL TRACT AND PREDICTORS OF NEED FOR EARLY SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Gabr1, N. Ammar2, M. ElHousnine1, M. Rutter1
1East Kent University Hospitals NHS, FD/United Kingdom
2Public Health Department, Am Shams University, Cairo/Egypt

Contact E-mail Address: a.gabri@hotmail.co.uk

Introduction: Acute iatrogenic perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the
burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting surgery as a first line treatment, and failure of endoscopic treatment. Using Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute iatrogenic perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 764 studies were identified. 28 studies, in human, met our inclusion criteria and were analysed. A total of 474 endoscopic closures were attempted in these studies. The overall technical success rate was 93.1% (n = 451/474, 95% CI: 91.5%–94.5%), and complication rate was 1.3% (n = 7/474, 95% CI: 0.5%–2.3%). Technical success for endoclips closure was 96.6% (95% CI: 94.2%–98.2%), and clinical success was 93% (95% CI: 87.1%–97.2%), and complications were 6.5% (95% CI: 0%–13.7%). For OTSC (Over the scope clip device), technical success was 83.8% (95% CI: 63.9%–96.6%), and clinical success was 77.9% (95% CI: 56.8%–93.3%), and complication rate was 4.1% (95% CI: 0%–12.6%). The technical success rate for Self-expanding metallic stent (SEMS) is 100% (95% CI: 71.5%–100%), clinical success is 99% (95% CI: 74.1%–108%), and complication rate of 9.1% (95% CI: 78%–112%). Only one study for endosuturing met our criteria, with technical and clinical success rate of 100%, and without any complication. Factors predicting failure of endoscopic treatment and need for early surgical intervention included large size, leukocytosis, fever, severe abdominal pain, large amount of peritoneal free air, necrotic or soft inflammatory margins, unfavourable anatomical site, stool contamination and failure of endoscopic closure.

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations. Several factors have been suggested as predictors of need for surgery as a first line treatment. The study was limited by the low methodological quality of most studies included, indicating the need for further research.

Disclosure of Interest: All authors have declared no conflicts of interest.

A large international multicentre experience with an over-the-scope clipping device for endoscopic management of Gastrointestinal perforations, fistulae, and leaks in 186 patients Citation: Gastrointestinal Endoscopy, May 2013, vol./is. 77/5 SUPL. 1(A148-A149), 0016-5107.
could have many experiences of gastric ESD that may be beneficial for the improvement of ERCP. However, there is little knowledge about the learning curve of the young endoscopists who perform the colorectal ERCP first.

Aims & Methods: We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ERCP. The study included 245 patients with colorectal ERCP performed by three endoscopists in Nippon Medical School Hospital and Machida Ichio Hospital from 2010 to August 2016. The ESD devices were Flush knife BT (Fujifilm), Dual knife (Olympus), Hook knife (Olympus) or a combination by operators. The endoscopist A and B, who had over 10000 examinations of colonoscopy and experiences of gastric ESD (as expert group), and endoscopist C had about 1000 colonoscopy and studied colorectal ERCP first (as trainee group). The complete rate of operation, which is defined as en-block resection rate without changing operator, operation time, speed (time/mm2) and complications were analyzed in each endoscopist. Furthermore, we divided these procedures in three periods equally as early, middle and late.

Results: The median age was 70 (range 26–91) years old, and genders were 158 males and 103 females. Tumor locations were proximal colon, distal colon and rectum in 143(54.8%), 59(22.6%), and 59(22.6%), respectively. The pathological types were well and moderately differentiated tubular adenocarcinoma, adenocarcinoma in situ, adenosquamous cell carcinoma, and neuroendocrine tumor in 139(60.4%), 59(22.6%), and 59(22.6%), respectively. The patients were 100% in the initial, middle, and late period, respectively.

The reported complications in both groups

Contact Email Address: emara_2007@yahoo.com

Introduction: Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to the risk of adverse events, as well as to the capability to change direction during the procedure and with liver cirrhosis can tolerate ERCP to treat their biliary tract or pancreatic diseases. Patients with liver cirrhosis are three times more susceptible to cholelithiasis than normal population and could have many other chronic diseases and that is why ERCP is increasingly performed for patients with cirrhosis. Endoscopic sphincterotomy (EST) has become a standard step in the management of CBD stones and introduction of both mechanical lithotripsy (ML) and large balloon dilatation (LBD) facilitated extraction of the large CBD stones. Despite the increasing use of both techniques, a head-to-head comparison of them is defined as en-block resection rate without changing operator, operation time, speed (time/mm2) and complications were analyzed in each endoscopist. Furthermore, we divided these procedures in three periods equally as early, middle and late.

Results: The median age was 70 (range 26–91) years old, and genders were 158 males and 103 females. Tumor locations were proximal colon, distal colon and rectum in 143(54.8%), 59(22.6%), and 59(22.6%), respectively. The pathological types were well and moderately differentiated tubular adenocarcinoma, adenocarcinoma in situ, adenosquamous cell carcinoma, and neuroendocrine tumor in 139(60.4%), 59(22.6%), and 59(22.6%), respectively. The patients were 100% in the initial, middle, and late period, respectively.

P0885 SAFETY AND EFFICACY OF ENDOSCOPIST-DIRECTED BALLOON SEDATION (BPS) DURING ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOSCOPY (ERCP)

A. Lapidos1, I. M. Graulke2, A. Suisse3, A. Klein4, K. A. Yassin5, L. Khamaysi6

Contact Email Address: alon.lap@gmail.com

Introduction: Endoscopist-directed balanced Propofol sedation (BPS), defined as a fixed dose of an opioid and benzodiazepine combined with incremental doses of Propofol, has been shown to be a safe and effective moderate sedation regimen for gastroscopy and colonoscopy. However, there are very limited data on the safety and efficacy of endoscopist-directed BPS in ERCP.

Aims & Methods: We aimed to evaluate the safety and efficacy of endoscopist-directed BPS, as well as to compare patient outcomes with anesthesiologist-administered BPS, for both in-patients and out-patients undergoing ERCP. We performed a retrospective cohort study using prospectively collected endoscopy data from a tertiary care, university-affiliated medical center where endoscopist-directed BPS during ERCP is routine practice amongst the ERCPists, all of whom have up-to-date advanced cardiac life support (ACLS) certification. ERCP nurses also maintain up-to-date certification in ACLS and cardiopulmonary resuscitation equipment and medications are available within the advanced endoscopy suite. During ERCP, the endoscopist and the endoscopy nurse as a team were responsible for monitoring patient vital signs (e.g., pulse, blood pressure, oxygen saturation levels). Each endoscopist was responsible for directing the provision and dosing of the BPS. Patient-level demographics and pre/post procedure vital signs were collected along with BPS drug dosages, American Society of Anesthesiologists score (ASA) and measured "hard endpoint" patient outcomes, including: need for bag-mask ventilation or endotracheal intubation, need for bag-mask ventilation or endotracheal intubation due to sedation effects, need for hospital admission post-ERCP (out-patients only) or need for change in level of hospital care (in-patients only), and mortality within 24 hours of ERCP.

Results: Over the course of 17 months (October 2015 – March 2017), 501 patients underwent ERCP and received endoscpist-directed BPS (Cohort 1: 380 (76%) inpatient, mean age 61.4 years, 46% males, 24% ASA I, 65% ASA II, 11% ASA III). During this same time period, 24 patients received anesthesiologist–administered BPS for both in-patients and out-patients undergoing ERCP. We performed a logistic regression analysis to compare patient outcomes between the two groups. The indications for ERCP were: 231 (46%) suspected cholecodolithiasis, 68 (13%) stent placement, 62 (12%) evaluation of known/suspected malignancy, 48 (10%) jaundice, 40 (8%) post-hepatobiliary intervention complications, 8 (2%) abdominal pain, and 44 (9%) other/unspecified. BPS dosages (mean ± SD: range) were: Fentanyl 0.06 mg±0.02 mg: 0.05–0.10 mg; Midazolam 1.5 mg±0.07 mg: 1.0–2.5 mg; and Propofol 178 mg±103 mg: 10–640 mg. Propofol dose inversely correlated with patient age (r = -0.42, p < 0.001), ASA score (r = -0.19, p < 0.001) and Mallampati score (r = -0.34, p < 0.001). No clinically meaningful differences were found in patient vital signs pre and post ERCP. Moreover, no patient required bag-mask ventilation, endotracheal intubation nor hospital admission/ change in level of in-hospital care following ERCP. One patient in Cohort 2 who...
received anesthetologist-directed BPS, required bag-mask ventilation and the EUS was aborted due to sedation effects. There was no mortality from any cause within 24 hours of ERCP. All patients were discharged from the advanced endoscopy suite without adverse events.

Conclusion: Endoscopist-directed BPS appears feasible, safe and efficacious for ASA I-IIIP patients requiring inguinal or patient EUS.

Introduction: Endoscopic insertion of plastic or metal stents is a well-established treatment for malignant or part of benign biliary obstruction. The major limitation of this technique is stent occlusion. Duodenobiliary reflux has been considered as a key contributor to stent occlusion. No appropriate method can so far prevent duodenobiliary reflux. Different strategies to prolong the patency of plastic stents included changing stent size, stent design, and stent sludge due to duodenal biliary reflux remains an unsolved problem. We have been using a novel suspended overlength biliary stents (reformed with nasobiliary tube) as substitution for ordinary biliary plastic stent to prevent the reflux from January 31, 2016.

Aims & Methods: The aim of the study is to evaluate the efficacy and patency of the suspended overlength biliary stents. The suspended overlength biliary stents (SOBS) were placed in intraduodenal bile duct in 61 patients with extrabiliary bile duct stricture who were followed up at least three months from January 1, 2016 to December 31, 2016. Nasobiliary tube of 7.5Fr or 8.5Fr with multiple side holes were cut 30 cm with operation knife from the top on sterile operating table. The purpose of the set of 30 cm length is to ensure the tail reaches the duodenal horizontal part. The SOBS were placed in the intraduodenal biliary duct by using conveyor under the fluoroscopic guidance at the end of ERCP. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the existence of duodenal biliary reflux. 74 patients who were evaluated at least two or more ERCP with extrabiliary bile duct stricture treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Results: (1) The mean age of SOBS and OBS were 68.8±15.6yrs and 60.4±14.7yrs (P=0.002), respectively. (2) 35 (57.4%) and 34 (45.9%) patients were malignant biliary obstruction in SOBS and OBS group, respectively (P=0.227). Malignant obstruction included bile duct cancer and biliary duct invasion of pancreatic cancer. Benign obstruction included autoimmune pancreatitis, chronic pancreatitis, post operation stenosis, inflammatory stenosis due to cholelithiasis. (3) The mean first and second patency was 4.5 months and 5.6 months in OBS groups. All the patients in OBS group experienced at least three months from January 1, 2016 to December 31, 2016. Nasobiliary tube of 7.5Fr or 8.5Fr with multiple side holes were cut 30 cm with operation knife from the top on sterile operating table. The purpose of the set of 30 cm length is to ensure the tail reaches the duodenal horizontal part. The SOBS were placed in the intraduodenal biliary duct by using conveyor under the fluoroscopic guidance at the end of ERCP. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the existence of duodenal biliary reflux. 74 patients who were evaluated at least two or more ERCP with extrabiliary bile duct stricture treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Conclusion: Suspended overlength biliary stents can prolong the patency and reduce the occlusion rate effectively due to duodenobiliary reflux in both malignant and benign biliary stricture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recent studies describe multiple outbreaks of multi-drug resistant organisms caused by contaminated duodenoscopes, used for endoscopic retrograde cholangiopancreatography (ERCP) procedures. Contamination of duodenoscopes is a major worldwide problem. Current devices of duodenoscopes do not guarantee complete decontamination. In 2015, a new ERCP device was developed for endoscopy suites without adverse events.

Aims & Methods: The purpose of the set of 30 cm length is to ensure the tail reaches the duodenal horizontal part. The SOBS were placed in the intraduodenal biliary duct by using conveyor under the fluoroscopic guidance at the end of ERCP. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the existence of duodenal biliary reflux. 74 patients who were evaluated at least two or more ERCP with extrabiliary bile duct stricture treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Conclusion: Similar to our previous findings, in 47% of all Dutch ERCP/EUS centres at least one patient-ready DLE was AM20 or MGO contaminated. Of all DLEs, 15% was contaminated with digestive tract bacteria, indicating inadequacies of the reprocessing technique. Similar to our previous study contamination of duodenoscopes in all four duodenoscope types and three LE types. For both definitions, contamination was not detected in duodenoscope or LE dependent (P-values > 0.72), nor type (P-values > 0.14) or microbial surveillance dependent (P-values > 0.45).

P0888 TECHNICAL EVOLUTION OF A NEWLY-DEVELOPED DIGITAL CHOLANGIO/PANCREATOSCOPY (SPYGLASS DS) FOR PREOPERATIVE EVALUATION OF PANCREATOBILIARY NEOPLASM

Gastroenterology, Sendai City Medical Center, Sendai/Japan

Contact E-mail Address: keito@openhr.or.jp

Introduction: Although a newly digital cholangio/pancreatoscopy (SpyDS) has been reported to be useful for therapeutic purpose in patients with biliary disease, clinical application for diagnostic purpose of pancreateobiliary neoplasm remains unclarified.

Aims & Methods: To evaluate the usefulness and safety of cholangio/pancreatoscopy using a SpyDS for preoperative evaluation of pancreateobiliary neoplasm. Patients and methods: Between Oct/2015 and Feb/2017, consecutive 30 patients (19, cholangiocarcinoma; 7, IPMN) who underwent cholangio/pancreatoscopy guided biopsy were included in this study.

Conclusion: Diagnostic accuracy of malignancy and tumor extent evaluation by cholangio/pancreatoscopy-guided biopsy is similar to other methods.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

Aims & Methods: To analyze the frequency of probable causes of asymptomatic hyperamylasaemy and acute pancreatitis after ERCP and their prevention. Two groups of patients were covered: a retrospective (340) and prospective (154) group. Patients had evidence of bile ducts impaired passability of varying etiology. In a minority of patients ERCP was purely diagnostic results were observed. Patients who developed acute pancreatitis often have acute calculous cholecystitis. Due to the small number of patients with acute pancreatitis, however, these results should be carefully commented. Patients who developed acute pancreatitis were found to have a lower level of alkaline phosphatase and ESR and higher values of leukocytes on the 72nd hour. The univariate logistic regression analysis identified the following risk factors for developing hyperamylasaemy; cholelithiasis; sclerosing papilloditis of ERCP; normal values of serum total bilirubin and elevated CRP levels in receiving. In order to establish a predictive model a multiple logistic regression analysis was performed. The model includes: average total bilirubin at entry and cannulation of the pancreatic duct more than 3 times. The estimated true percentage for predicting lack of hyperamylasaemy with this predictive model is very good - 97%. Univariate logistic regression analysis identified the following risk factors for the development of acute pancreatitis: cannulation of the pancreatic duct and the presence of calculous cholecystitis when entering.

Conclusion: We detected a low incidence of asymptomatic hyperamylasaemy (9.5%) and acute pancreatitis (2.4%) in the group of patients which were subjected to ERCP. Clinical and laboratory parameters characterizing the patients who developed these complications, and risk factors for acute pancreatitis and asymptomatic hyperamylasaemy were determined. The effect of intramuscular Diclofenac administered before and after ERCP has no effect.

P0890 Most Advanced Endoscopy Trainees Do Not Meet Competence for Native Papillae Cannulation in ERCP: Results from a Prospective Multicenter Study

S. Wani 1, M. Hall1, V. Simon1, S. Han1, D. Early2, R. Keswani 1
1University of Colorado Anschutz Medical Center, Aurora/United States of America
2Washington University in St. Louis, St. Louis/United States of America
3Northwestern University, Chicago/United States of America

Contact E-mail Address: sachin.wani@ucdenver.edu

Introduction: Advanced endoscopy trainees (AETs) achieve ERCP competency at variable rates and specific case volumes do not ensure competence. However, training and credentialing guidelines continue to utilize an absolute procedure volume to determine competence. There are limited data on whether current training composition and volumes ensure ERCP competence in the US.

Aims & Methods: (i) To define ERCP learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERCP training in AETPs. ASGE-recognized AETPs were invited to participate and AETs were graded on every ERCP after completion of 25 hands-on ERCP exams. Grading was performed using our previously developed and validated tool [The EUS and ERCP Skills Assessment Tool (TSEATS)] which assesses technical and cognitive competence in a continuous fashion. Grading for each skill was done using a 4-point scoring system: 1-no assistance, 2-minimal verbal cues, 3-multiple verbal cues or hands-on assistance and 4-unable to complete. A comprehensive data collection and reporting system was built using REDcap, a web-based data collection software, and SAS to create learning curves using cumulative sum (CUSUM) analysis for overall and individual technical and cognitive components of ERCP. Individual results and comparison to peers were sent to AETs and trainers quarterly. Acceptable and unacceptable failure rates were set a priori. AETs with < 20 evaluations were excluded and success was defined as a skill score of 1 or 2. Individual and combined graphs to assess change in cannulation success rates were constructed and the Cochran-Armitage trend test was used to assess improvement in success rates.

*Primary analysis: success defined as score of 1 or 2 (no assistance/minimal verbal cues), Acceptable failure rate - p0 = 0.1 and unacceptable failure rate - p1 = 0.3 **
ERCP techniques are required. An important benchmark for assessing competence. Methods to improve native curves using a novel web-based comprehensive data collection and reporting threshold numbers to determine competence. We report the feasibility of establishing curves and competence among AETs in ERCP validating the shift away from advanced cannulation techniques such as double-wire technique, placement of pancreatic duct stent and precut sphincterotomy (6%). Learning curves for individual endpoints, overall technical and cognitive aspects noted substantial variability. Majority of AETs achieved overall technical (60%) and cognitive (100%) competence at the end of training. While there was a statistically significant improvement in overall and native papilla cannulation rates (both p < 0.001), only 18% of AETs achieved competence for native papilla cannulation (Table 1).

Conclusion: The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing a centralized national database to report individualized ERCP learning curves using a novel web-based comprehensive data collection and reporting system. Using strict definitions, a minority of AETs achieved competency in native papilla cannulation which may, in part, be due to limited cannulation time provided to AETs. Selective native papilla deep cannulation needs to be an important benchmark for assessing competence. Methods to improve native papilla cannulation rates and strategies to increase AET exposure to advanced ERCP techniques are required.

P0891 SIMILAR POST-ERC P PANCREATITIS RATES IN ENDOSCOPIST- VS ASSISTANT-CONTROLLED WIRE-GUIDEDBILE DUCT CANNULATION: A SINGLE CENTRE OBSERVATIONAL STUDY

M. Hu, A. Bhagwat, M. Hayat
Dept Of Gastroenterology, Northumbria Healthcare NHS Foundation Trust, North Shields United Kingdom

Contact E-mail Address: maxworth.hu@gmail.com

Introduction: A recent randomised study by Buxbaum et al1 demonstrated a significantly lower rate of post-endooscopic retrograde cholangiopancreatography (ERC P) pancreatitis (PERCPP) in endoscopist- versus assistant-controlled bile duct cannulation. We set out to audit the rates of PERCPP at our centre based on this finding.

Aims & Methods: All ERCPs performed by two endoscopists between April 2015 and March 2016 were audited retrospectively. The two endoscopists practiced endoscopist- (E1) and assistant-controlled (A1) wire-guided cannulation exclusively. Both E1 & A1 had access to the same medications, sphincterotomes, equipment, and teams. Data was obtained and anonymised from electronic patient records and endoscopy reporting software. PERCPP was defined as abdominal pain with hyperamylasaemia at least three times the upper limit of normal (ULN) 24–48 hours after ERCP with or without corresponding imaging findings within 7 days; or abdominal pain with a further rise in pre-existing hyperamylasaemia to at least three times ULN 24–48 hours after ERCP with or without corresponding imaging findings within 7 days. Additional data was collected for CT evidence of post-ERC P complications, hyperamylasaemia without pancreatitis, bleeding, and post-ERC P cholangitis. Patient and procedural characteristics predisposing to pancreatitis were also recorded.

Results: Of the 62 programs invited, 20 AETPs participated and 20 AETs were included in the final analysis. At the end of training, median number of ERCPs performed/AET was 350 (15–500). Overall, 2649 ERCP exams were graded; the rates of PERCPP in E1 and A1 were 2.3% (3 patients) and 1.7% (2 patients) respectively. One 84-year-old patient of E1 with a presumed malignant common bile duct (CBD) stricture had PERCPP and died 17 days after ERCP, having opted for palliation. The remaining 4 patients had uneventful conservative management of PERCPP. E1 had one patient with immediate bleeding post-sphincterotomy controlled with a CBD stent whilst A1 had 2 patients requiring adrenaline injection for haemostasis. In addition, E1 had one patient with retroduodenal perforation managed conservatively and A1 had one patient with CT evidence of intraduodenal haematoma which was uneventful. Both E1 and A1 had one case each of uncomplicated hyperamylasaemia. A summary of complications, with patient and procedural characteristics, is listed in Table 1.

Conclusion: In our observational study, which was not intended or powered for statistical analysis, there was no overt difference in the rates of PERCPP when comparing between endoscopist- or assistant-controlled wire-guided CBD cannulation. The overall complication rate was similar and although there were some differences in procedural characteristics between the two endoscopists, there were no characteristics predisposing to PERCPP overtly skewed towards either endoscopist’s case load. Further randomised trials, or a crossover study, provided the endoscopists and assistants are equally competent in both methods of wire cannulation, are needed to clarify the safety profile of either technique.

Introduction: Most endoscopic retrograde cholangiopancreatography (ERC P) related procedures are performed under “conscious sedation”, a drug-induced depression of consciousness during which patients are comfortable and able to maintain purposeful responses to verbal or tactile stimulation, and cardiorespiratory function generally remains intact 1. Meanwhile, we sometimes observe adverse events related to conscious sedation after ERC P such as aspiration pneumonia 2. So far, it is unknown whether immediate recovery from conscious sedation with antagonists is necessary or not.

Aims & Methods: We aimed to reveal the efficacy of flumazenil, an antagonist to benzodiazepines, on the prevention of adverse events, especially, aspiration pneumonia related to conscious sedation which is most frequent after ERC P. One hundred ninety patients who underwent ERC P between January to December...
2014 in a general hospital in Japan were included. The patients were divided to two groups: the group with flumazenil (F group) and the group without flumazenil (non-F group) just after ERCP and they were compared and analyzed. Examination items were 1) patient characteristics, 2) procedure characteristics, and 3) occurrence rates of post-ERCP aspiration pneumonia. Pearson’s Chi-squared test and Fisher’s exact test were used for statistical analysis of categorical data.

Results: 1) One hundred fifteen patients (60.5%) were administered flumazenil just after ERCP (F group) and 75 patients (39.5%) were not (non-F group). The median age, 76 (47–94) in the F group and 78 (46–94) in the non-F group; male/female ratio, 57/58 in the F group and 34/41 in the non-F group. The distributions of the basic disease (CBD stone/malignant biliary disease/malignant pancreatic disease/others) were 64/8/17/26 in the F group and 30/11/16/18 in the non-F group. The distributions of used biliary brush (midazolam/diazepam/none) and the patient number who got aspiration pneumonia were 102/13/0 and 1 in the F group and 59/13/2 and 1 in the non-F group, respectively (Fisher’s test: p-value = 0.074). There were no significant differences of patient characteristics between both groups. 3) Two patients (1.05%) developed aspiration pneumonia after ERCP. One (94 years old, male) was in the F group and the other (81 years old, female) was in the non-F group (Pearson’s Chi-squared test p-value = 1). Both of them were over 80-year old. The patients who were given oxygen during ERCP were 86/5 (45.2%) in the F group and 35/4 (21.1%) in the non-F group (Pearson’s Chi-squared test p-value = 1).

Conclusion: Flumazenil did not have any preventive effect on the occurrence of aspiration pneumonia related to conscious sedation after ERCP.

Introduction: Pancreatitis is the leading complication of endoscopic retrograde cholangiopancreatography (ERCP). Some studies have shown that aggressive hydration may reduce the incidence of this serious adverse event, the post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP). In our department we implemented an aggressive hydration protocol (AHP) for patients undergoing ERCP in order to prevent PEP.

Aims & Methods: The aim of this study was to evaluate the impact of this protocol on the incidence and severity of PEP. Patients and methods Retrospective analysis of all patients submitted to ERCP in one center during 16 months, including patients hospitalized in the gastroenterology department who were managed according to the AHP and patients hospitalized in other departments who underwent standard hydration (SH). Patients who underwent AHP received intravenous sodium lactate solution (RL) at 200 mL/hour starting 1 hour before, during the procedure and the anesthetic recovery; in those who remained asymptomatic after the ERCP, the RL was maintained at 100 mL/hour for 8 hours and after it was changed to a balanced salt solution with glucose (PG) at 80 mL/hour; in those patients who had abdominal pain or amylase >3 times normal limit after ERCP, the RL was maintained at 200 mL/hour during 8 hours and after it was changed to PG at 120 mL/h.

We evaluated the incidence and severity of PEP, the established primary and secondary risk factors for PEP (except the difficulty of cannulation) and the occurrence of complications. Data were analyzed with SPSS statistical software.

Results: We analyzed 192 patients, 290 ERCP (AHP n = 168, SH n = 122). The incidence of PEP was 10% (11/290), significantly higher in the SH group (4/11 versus 7/11; p = 0.766). In the SH subset, only 1 PEP was moderate and the remaining 3 were mild. In the AHP group, 3 PEP were moderate and 4 were mild. There were no complications related to AHP. We didn’t find any patient on procedure-related variable significantly associated with the development of PEP.

Conclusion: Our AHP didn’t reduce the incidence of PEP or its severity. Indeed, the AHP group presented more PEPs than the SH group, although the difference between both PEP incidences was not significant. Despite our study didn’t show any advantage related to the use of an AHP, intravenous aggressive hydration may have a role in PEP prophylaxis. Further studies are needed to establish its true value.

P0895  PROSPECTIVE STUDY OF EARLY PRECUT VS. UTMOST PRECUT WITH PANCREATIC STENT IN INITIAL PANCREATIC DUCT CANNULATION

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han

Internal Medicine, Kosin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: eunpark@hanmail.net

Introduction: In biliary access, repeated biliary cannulation attempts are a risk factor for post ERCP pancreatitis (PEP). Early precut is an effective technique for successful biliary cannulation and can significantly reduce the incidence of PEP. The aim of this study was prospectively to evaluate clinical efficacy the performance of utmost early precut with pancreatic stent in the patients in whom pancreatic duct cannulation was performed initially.

Aims & Methods: When guidewire was placed in the pancreatic duct initially by chance, the patients were randomized into early precut (Group A) or utmost early precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy without papillotomy forceps. In Group B, the pancreatic stent was inserted and then precut with an incision over a pancreatic stent was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

Results: From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 24 (95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the Group A and 14.8 minutes in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B (P < 0.001).

Conclusion: In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidewire significantly facilitated biliary cannulation and the success rate but also promise low incidence of post-ERCP pancreatitis. In experienced hands, utmost early precut technique can dramatically reduce the trauma of ampulla and risk of PEP compared to conventionally persistent cannulation attempts.

Introduction: Antiplatelet therapy with antiplatelet agents (APA) has been increasingly utilized during the last few decades. This study aimed to determine the risk of post-ERCP bleeding among those patients who are taking APAs, especially in the era of multiple agents.

Results: The overall incidence of post-ERCP bleeding was 16 of 2083 (0.8%) in No drug group, 12 of 256 (4.7%) in Aspirin group, 3 of 48 (6.3%) in Single APA group, and 4 of 48 (8.3%) in Multiple APA group (p < 0.001). All authors have declared no conflicts of interest.

Introduction: In a recent, a digital version of single-operator cholangioscope (Spy-Glass DS) and direct POC (DPOC) using a multibending ultraslim endoscope were introduced as improved forms of each POC, especially in image quality and technical difficulty, respectively.

Aims & Methods: In this study, we prospectively compared the procedure success rate of Spy-Glass DS and DPOC according to the type of lesion, whether not different in 9 obstructive type (100% vs. 88.9%, P = 0.5) and 6 non-obstructive type (66.7% vs. 100%, P = 0.227). The Therapeutic outcomes of Spy-Glass DS and DPOC were observed in 8 of 8 patients (100%) and 7 of 9 patients (77.8%) (P = 0.265), respectively.

Conclusion: Both advanced image quality of Spy-Glass DS and improved technical difficulty of DPOC by a multibending ultraslim endoscope showed comparable and high procedure success rates in patients with dilated BD. Future prospective studies focused on overall cost savings and long-term clinical outcomes are seen be required to be deciding adequate indications of each POC systems.

P0899  THE DILEMMA OF MANAGEMENT BORDERLINE COMMON BILE DUCT STONE, DOES STONE SIZE MATTER?: A PROSPECTIVE RANDOMIZED STUDY

E. Abdellatif, E. Elhanfy, A. Elnakeeb

Surgery, Gastroenterology Surgical Center, Mansoura/Egypt

Contact E-mail Address: dr.ehab.atif@icloud.com

Introduction: Management of common bile duct stones (CBDs) in patients with borderline CBD presents a surgical challenge. The aim of this study was to compare conservative treatment with endoscopic stone extraction for the treatment of borderline CBD with stones.

Aims & Methods: This prospective randomized controlled trial includes patients with CBDs in borderline CBD (CBD < 10mm) associated with gallbladder stones who were treated with conservative treatment or endoscopic stone extraction followed by laparoscopic cholecystectomy (LC) and intraduodenal cholangiopancreatography (IOC). The primary outcome was successful CBD clearance, the secondary outcomes were the overall complications, cost, and hospital stay.

Results: LC and IOC revealed complete clearance of CBDs in 48 (96%) cases in the endoscopic retrograde cholangiopancreatography (ERCP) group (52% of patients by ERCP, and 44% of patient passed the stone spontaneously), and in the remaining two patients, the CBDs was removed by transcytic exploration. In the conservative group, LC and IOC revealed complete clearance of CBDs in 90% of cases, and in the remaining 10% of patients, the CBDs was removed by transcystic exploration. Post-ERCP pancreatitis (PEP) is noticed significantly in the ERCP group (2% vs. 8% [16%], P = 0.04). The average net cost was significantly higher in the ERCP group. Recurrent biliary symptoms developed significantly in the ERCP group after 1 year (10% versus 0%, P = 0.02) in the form of recurrent cholangitis and acute obstructive type CBDs.

Conclusion: Management of CBDs in patients with borderline CBD is recommended cautious as a surgical challenge. Borderline CBD increases the technical difficulty of ERCP and increases the risk of PEP. Conservative management of CBDs in borderline CBD not only avoids the risks inherent in ERCP and unnecessary preoperative ERCP, but it also effective in clearing CBDs. The hepatobiliary surgeon
P0900 PROSPECTIVE STUDY ON METHODS AND SUCCESS OF BILARY CANNULATION OF 458 VIRGIN PAPILLAS - QUALITY ASSURANCE OF ERCP AT OUR DEPARTMENT

A. Orbán-Szilágyi, K. Lorinczy, K. Rábai, M. Horváth, F. Szimond, T. Gýökéres
Gastroenterology, Medical Centre, Hungarian Defence Forces, Budapest/Hungary

Contact E-mail Address: tiborgyokeres@freemail.hu

Introduction: The cannulation of a virgin papilla is the most difficult and high-risk step in ERCP and it requires significant experience to maximize the success and to minimize poor outcomes. Cannulation rate is one of the accepted quality indicators of ERCP. It is mandatory to regularly assess quality indicators of endoscopic procedures to maintain and improve endoscopic service.

Aims & Methods: We prospectively collected data about cannulation details of all patients with virgin papilla and post-ERCP complications from April 2016 to April 2017.

Results: During this 12-month period we have performed 1102 ERCPs, in 458 of them we had virgin papilla. All ERCPs had therapeutic intentions and all of the patients were followed up. In 13 patients papilla were not accessible due to duodenal stenosis (10/13) or postoperative situations (3/10). In two of them the indication was ceased (because the biliary obstruction resolved spontaneously), 11 patients got percutaneous transhepatic drainage (PTD). The primary cannulation success rate of accessible papillae was 88.5% (394/445) while the overall cannulation success was 96.6% (430/445). 56.1% of primary successful cannulations were achieved by conventional method, in 14.2% we used pancreatic guidewire assisted technique, in 20.1% we used early precut sphincterotomy, and in the third of them we used combined techniques. In 51 primary unsuccessful cases we repeated ERCP attempt 4 days on average and successfully cannulated 70.5% (36/51) of them at the second or third attempts. 27 of them were achieved by conventional method, 7 of them after extending the precut, one case we used pancreatic guidewire technique, and we used prophylactic pancreatic stent in one patient, as well. Out of the 15 patients with finally unsuccessful cannulation, we performed precut without deep cannulation in 10 cases. 7 of them resolved after precut, 2 of the 10 patients got PTD and one patient required combined techniques. In 4 patients out of the 15 unsuccessful cannulations the obstruction resolved without any further intervention and one patient got PTD. We had in sum 3.4% (15/445) post-ERCP pancreatitis, 7 of them were mild, and 8 moderate, we had no severe one. We observed endoscopic signs of biliary obstruction in 34 cases that required endoscopic intervention (infiltration/coagulation/stenting), 7 of them (1%) required blood transfusion.

Three patients suffered perforation during ERCP. One of them got biliary stent and was discharged uneventfully on the 8th day. We had 2 sphincterotomy related perforations, 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Conclusion: Quality assessment of ERCP performance is essential. Our overall cannulation rate was acceptable. We used pancreatic guidewire technique just after failure of percutaneous transhepatic drainage. We used prophylactic pancreatic stent just in the phase of process to avoid long lasting traumatisation of the papilla. Our complication rate of post-ERCP pancreatitis was good while the post-sphincterotomy complication rate of post-ERCP pancreatitis was 7.5%, however, all of them resolved after precut, 2 of the 10 patients got PTD and our patient had delayed surgery, he recovered.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0901 RISK FACTORS FOR POST-ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY PANCREATITIS: A PROSPECTIVE MULTICENTER STUDY

1Department Of Gastroenterology, Kyoto Second Red Cross Hospital, Kyoto/Japan
2Department Of Gastroenterology, Kyoto Medical Center, Kyoto/Japan
3Department Of Gastroenterology, National Hospital Organization Kyoto Medical Center, Kyoto/Japan
4Department Of Gastroenterology, Japanese Red Cross Kyoto Daichi Hospital, Kyoto/Japan
5Division Of Gastroenterology, Shiga University of Medical Science, Shiga/Japan

Contact E-mail Address: azmaked@gmail.com

Introduction: The procedures related to endoscopic retrograde cholangiopancreatography (ERCP) play a major role in the diagnosis and treatment of pancreato-biliary disease. However, post-ERCP pancreatitis (PEP) remains the most common and severe complication of ERCP. The incidence rates of and risk factors for PEP have mainly been reported from retrospective studies.

Aims & Methods: This study aimed to identify the incidence rate of and risk factors for PEP in a prospective large cohort study. This is a prospective cohort study of all patients who underwent ERCP-related procedures at 5 high-volume centers between February 2015 and May 2016. Patients who presented with acute pancreatitis, post biliary reconstruction, and failure to reach the papilla were excluded. The incidence rates of PEP and its severity were examined. Multivariate analysis was used to identify the risk factors for the different patients who presented with at least two of the following conditions were diagnosed with PEP: 1) elevated levels of serum amylase, 2) abdominal pain lasting more than 24 hours, and 3) abnormal findings of acute pancreatitis on computed tomography. An increase in serum amylase level of at least three times greater than the normal upper limit at approximately 18 h after the procedure (the next morning) was regarded as significant. The severity of PEP was graded according to the severity assessment of the Japanese Ministry of Health, Labour, and Welfare.

Results: A total of 192 patients were finally analyzed. PEP occurred in 142 patients (73.6%); it was mild in 117 patients (6.0%) and severe in 25 patients (13.3%). Univariate analysis showed that female gender, naive papilla, surgically altered gastrointestinal anatomy, no coexistence of acute cholangitis, diagnostic cholangiography, dilatative ERCP, procedure time after reaching the papilla, number of cannulation attempts, precut sphincterotomy, intraductal ultrasonography, pancreatic duct injection, insertion of guidewire into the pancreatic duct, and placement of prophylactic pancreatic stent were significant risk factors. In the multivariate analysis, female gender (OR 2.273; 95% CI 1.507–3.392), naive papilla (OR 3.024; 95% CI 1.805–5.066), surgically altered gastrointestinal anatomy (OR 2.607; 95% CI 1.378–4.931), procedure time after reaching the papilla (OR 1.099; 95% CI 1.901–1.107), pancreatic duct injection (OR 2.297; 95% CI 1.493–3.534), and intraductal ultrasonography (OR 1.620; 95% CI 1.015–2.585) were independent risk factors.

Conclusion: The incidence of PEP was similar to those reported in previous studies. These risk factors are important as predictors of PEP. A shorter procedure time and avoidance of unnecessary pancreatic duct injection are important for prevention of PEP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0902 USEFULNESS OF AMY MEASUREMENTS AT 2 HOURS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PREDICTING THE SEVERITY OF POST-ERCP PANCREATITIS: A MULTICENTER PROSPECTIVE STUDY, SOSUI

1Gastroenterology, Japanese Red Cross Kyoto Daichi Hospital, Kyoto/Japan
2Digestive Disease Center, Department Of Gastroenterology And Hepatology, Kyoto Katsura Hospital, Kyoto/Japan
3Department Of Gastroenterology, Kyoto Medical Center, Kyoto/Japan
4Division Of Gastroenterology, Shiga University of Medical Science, Shiga/Japan
5Department Of Gastroenterology, Medical Centre, Hungarian Defence Forces, Budapest/Hungary

Contact E-mail Address: mbymq671@yahoo.co.jp

Introduction: The severity of post-ERCP pancreatitis (PEP) is a major problem because of occasional lethality. However, no predictor of the severity has been identified. In the present multicenter prospective study, SOSUI, we investigated the potential predictors of severity.

Aims & Methods: Of 2078 subjects who underwent ERCP between February 2015 and May 2016 at five high-volume centers in Japan, 1932, excluding those who had been complicated by pancreatitis, undergone biliary tract reconstruction, or had papilla not reached, were included. Of the 1932 patients, 163 developed PEP which were compared between the mild and severe cases to examine potential predictors of severity. PEP was diagnosed based on two or more of the following three conditions: (1) serum amylase elevation (above the upper limits of each center) on the following day, (2) abdominal pain lasting for longer than 24 hours, and (3) abnormal findings on CT. We used the criteria set by the Ministry of Health, Labour and Welfare. For continuous variables, the Mann-Whitney U test was employed. For binomial comparison, univariate analysis was conducted using a chi-square test. Receiver-operating curve analysis was performed.

Results: Twenty-five severe (1.3%) and 138 mild (7.1%) PEP patients were included. Patient and procedural factors were examined, demonstrating that the AMY values at 2 hours after ERCP were significantly higher in the severe cases than in the mild ones (P = 0.005). ROC analysis was conducted on the AMY values at 2 hours as a predictor of severe PEP, demonstrating that the cutoff value was 3.7 times higher than the upper limits of each center (sensitivity: 64%; specificity: 70%; and AUC: 0.65). In multivariate analysis using logistic regression by dividing the AMY values at 2 hours after ERCP into higher or lower than 3.7 times the reference values of each center, abdominal pain immediately after ERCP and AMY values at 2 hours after ERCP were identified as independent factors.

Conclusion: Severe PEP should be diagnosed as early as possible for intervention. However, it may take a long time to assess clinical courses or examine images after examination. In the present study, abdominal pain immediately after ERCP and AMY values at 2 hours were identified as predictors of severity, being useful for facilitating early therapeutic intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: The aim of this study was to evaluate the transduodenal deployment was successfully performed in all of 26 patients (Male/Female, 11/15; mean age, 61 ± 16.19yrs). After the procedure, fistulas had formed in each of the patients and the stones of 7 patients expelled themselves completely. Endoscopic ultrasound (19) and polypectomy (2) were partially performed through the stents, and then the stents were removed. Common bile duct stones were also successfully removed in 6 patients. EGD showed all the fistula closed completely after 3 days. The ultrasound examination of the gallbladder 4 weeks later showed no stones remaining and also showed satisfactory functioning of the gallbladder. The mean follow-up period was 11 months (range: 1–27months). Cholesterol gallstones recurrence were not detected in any patient during follow-up.

Conclusion: The EUS-guided placement of a novel metal stent with hot stent delivery is a safe and simple approach for performing an endoscopic cholecysto-duodenostomy, which can subsequently allow procedures to be performed for treating biliary disease, including cholecystolithotomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Second generation quantitative elastographic ultrasound (EUS) elastography allows the quantitative analysis of tissue stiffness and can be a useful auxiliary tool in the differential diagnosis of pancreatic solid tumors (1)(2).

Aims & Methods: The aim of this study was to evaluate the accuracy of the quantitative EUS elastography in the differential diagnosis of pancreatic solid masses, discriminating malignant from benign masses, using strain ratio (SR) analysis. A prospective study was performed for 15 months and included 29 consecutive patients who underwent EUS for the evaluation of solid pancreatic masses. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean of 3 measures was considered as the SR final result for each lesion. EUS-fine-needle aspiration of the lesions was performed after SR assessment and the final diagnosis was based on the cytology or histology results.

Results: Included 29 patients in a total of 30 lesions with conclusive histological/cytologic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors comparing with the benign tumors (55.56 vs 23.93, p < 0.001). The sensitivity and specificity of SR for discrimination of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusion: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnostic and follow-up of these patients.

P0996 COMPARISON OF DIAGNOSTIC PERFORMANCES FOR THE EVALUATION OF SUSPECTED MALIGNANT BILIARY STRicture AMONG SAME SESSION EUS-AND ERCP-GUIDED TISSUE SAMPLING

S.J. Yeo1, C.M. Cho2, M.K. Jung3, A.N. Seo3, H.I. Bae1
1Division Of Gastroenterology And Hepatology, Dept. Of Internal Medicine, Kyungpook National University Medical Center, Daegu/Korea, Republic of Korea
2Department Of Pathology, Kyungpook National University School of Medicine, Daegu/Korea, Republic of Korea

Contact E-mail Address: sejk319@hanmail.net

Introduction: Determining the cause of suspected biliary strictures is always challenging in clinical practice. Although EUS-guided tissue sampling (EUS-TS) revealed a better diagnostic yield in suspected malignant biliary obstructive lesions comparing to ERCP-guided tissue sampling (ERC-P), there was few studies for which techniques are better dependent on primary tumor.

Aims & Methods: We compared the diagnostic yields between EUS-TS and ERC-P in patients with suspected malignant biliary obstructive lesion according to primary tumor sites. By reviewing medical records, we enrolled patients who underwent same-session examination of EUS and ERCP for the evaluation of suspected malignant obstructive lesion.

For cytopathologic diagnosis, endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) or biopsy (EUS-FNB) and ERC-P were used with brush cytology and/or forceps biopsy were performed. The diagnostic performances were compared between two techniques according to primary tumor sites.

Results: From January 2011 to September 2016, we enrolled 125 patients and 32 patients were excluded due to the following reasons: loss of follow up in 8, EUS/TIPS fistulous tract in 23, and ERC-P from peripancreatic biopsy in 4. Among the enrolled patients (93 patients; 62 males, mean age 65.8 years, 86 (92.5%) had malignant tumor such as cholangiocarcinoma in 39, pancreatic cancer in 37, and other malignant tumors in 10 patients. And 7 (7.5%) patients had benign lesions. EUS-TS revealed higher rate of overall diagnostic accuracy comparing to ERC-P (82.8% vs. 60.2%, p = 0.001).

Depending on primary lesions, the diagnostic accuracy for pancreatic lesions was statistically higher in EUS-TS than ERC-P (84.4% vs. 51.1%, p = 0.003). Compared with EUS-TS, ERC-P is superior to ERC-P for the evaluation of suspected malignant pancreaticobiliary obstructive lesions. Especially, if the biliary obstruction was caused by pancreatic lesions, EUS-TS would need to be a priority for cytodiagnostic pathologic.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0997 PREVALENCE OF POSTERIOR MEDIASTINAL LYMPHADEnOPATHIES IN PATIENTS UNDERGOING ENdoscopic ULTRASONOGRAPHY-FNA FOR GASTROINTESTINAL-MALIGNANT LESIONS: INDICATIONS: A PORTUGUESE SINGLE-CENTRE PROSPECTIVE STUDY

J. Veloso Du, Carmo, S. C. Marques, M. Bispo, C. Chagas
Gastroenterology, Hospital Egas Moniz - Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: jouanavcarmo@gmail.com

Introduction: Significant heterogeneity in geographic distribution in the prevalence of mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasonography (EUS-FNA) for malignant lesions. A prospective, unicentric study was performed between July and December 2016. Mediastinal stations 9, 8, 7, 6, 5, 4L and 2 were systematically evaluated using a linear endochozoscope in all patients undergoing EUS due to malign lesions and without history of oncologic disease. EUS features were analysed, including location, number, shape, dimensions and echogenicity of the lymphadenopathies.

Results: We analysed 75 patients: M/F, 32/43; Mean age, 63 years. The majority (72%) of the patients presented lymphadenopathies in at least one mediastinal station and 88% were found in stations 7 or 4L. Only 6% of these had short axial diameter >10 mm, most were oval (59%) or triangular (37%) and 40% had a hyperechogenic center. The prevalence of lymphadenopathies was higher in smoker patients (83% vs 64%, p=0.024), with a higher average number of lymphadenopathies per patient in this group (2.1 vs 1.6; p=0.017). Similar findings were documented in patients with relevant occupacional or environmental respiratory exposure (prevalence 83% vs 71%; average number 3 vs 1.7). By logistic regression analysis, none of the variables analyzed were independently associated with the presence of mediastinal lymphadenopathies.

Conclusion: This prospective Portuguese study documented a higher prevalence of mediastinal lymphadenopathies than previously reported in northern Europe, in patients with no evidence of oncologic disease. This higher prevalence, mostly in smokers or patients with relevant occupational exposure, may negatively influence the specificity and positive predictive value for malignancy of mediastinal lymph node (N) staging by EUS, with particular relevance in esophageal and pulmonary cancer staging.

2Pathology, Hospital de Braga, Braga/Portugal

Contact E-mail Address: julianamecosta87@gmail.com

Introduction: Recent studies demonstrated the positive impact of neoadjuvant treatment for gastric adenocarcinoma T ≥2 and/or N+. Aims & Methods: We aimed to assess the accuracy of endoscopic ultrasound in the selection of patient with gastric adenocarcinoma for neoadjuvant therapy. A unicentric retrospective analysis of patients with the anatomoopathological diagnosis of gastric adenocarcinoma between 2011 and 2016, who performed endoscopic ultrasound for staging and underwent surgery without prior neoadjuvant treatment. The concordance (kappa) and accuracy [sensitivity (S) and specificity (E)]) of the endoscopic ultrasound for T ≥2 and/or N + (criteria for neoadjuvant treatment) were assessed using the anatomoopathological staging of the resected specimen as the Gold standard.

Results: The final sample included 144 patients (64.6% male) with a median age of 68.5 ± 12.2 years. In most cases (80.6%), the neoplasia was distal (antrum, incisura angularis and body). The neoplasia was of the intestinal type, diffuse and mixed in 65.3%, 18.8% and 16% of the cases, respectively. After examination of the resected surgical specimen, 53.5% of patients had criteria for neoadjuvant treatment (T ≥2 and/or N +), and 46.5% did not (T ≤1 and/or N −). The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥2 and/or N + were 0.720 (p < 0.001), 85.2% (95% CI: 75.6%-92.1%) and 87.3% (95% CI: 76.5%-94.4%), respectively. The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥2 and/or N + were higher in proximal lesions (cardia and JEG) (k = 0.924, S-94.4% and E-100%) compared with distal lesions (k = 0.671, S-82.5% and E-84.9%) and in intestinal type lesions (k = 0.765, S-84.9% and E-92.7%) compared with diffuse type lesions (k = 0.682, S-88.4% and E-80%) or mixed (k = 0.566, S-81.8% and E-75%).

Conclusion: In one of the largest series of patients, we showed that endoscopic ultrasound had an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.

Introduction: Endoscopic ultrasonography (EUS) and percutaneous cyst drainage (PCDs) require initial imaging characterization and frequently follow-up. Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) for CEA measurement and cystic fluid is the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA with cystic fluid analysis in follow-up of PCNs is not clear.

Aims & Methods: To determine if patients with pancreatic cysts with a second repeated EUS-FNA for cystic fluid analysis for CEA and cytology had a change in cyst classification or on clinical decision. Retrospective analysis of a EUS cohort study of 200 patients with cystic pancreatic lesions (PCNs) from 2007–16, of which 35 had 2 EUS procedures, and of these, 22 had 2 consecutive EUS-FNA procedures.

References

Results: In our series 16/22 females (73%), mean age = 58 ± 13 years old (29-77). Mean follow-up, 56.0 ± 34.0 months (6-116). Cyst location: head/body/tail:11/ 8/3. Mean size in 1st EUS-FNA: 3 ± 1, 5 cm (1, 2-7 cm) vs 2nd EUS-FNA: 3, 1 ± 1, 9 cm (1, 2-10 cm); with both EUS-FNs with 36% cysts > 3 cm. Mass/mural nodule present:7/22 vs 4/22 on 2nd EUS-FNA. Repetition of EUS-FNA did not cause any change or increase in the cyst size. Mean interval between the two subsequent EUS-FNAS: 35 months (3-117). Cysts with CEA level > 192 g/ mL (7 vs 10 patients) and acellular cystic fluid samples (62% vs 59%), between two subsequent EUS-FNA, not statistical significant. There were 4 patients operated that had previously a repeated EUS-FNA (2nd EUS-FNA 3, 4, 7 and 10 months after the 1st EUS-FNA). Surgical pathology (respectively): Intraductal papillar mucinous neoplasm, mucinous cystic neoplasm, solid pseudopapillary neoplasm and a neuroendocrine tumour. Comparing the group of patients who had surgery with patients with one cyst alone, in one cyst case, there was a statistical difference in cyst size >3 cm and the presence of a mural nodule or mass in the surgery group, but no significant differences in age, CEA value or a diagnostic cytology between the two groups. The mean time between the two EUS-FNA was 35 months (117) and was significantly shorter in the surgical pathology group.

Conclusion: Clinical follow-up of pancreatic cysts with successive EUS-FNAS can be useful in larger cysts and if worrisome features (mural nodule or mass) are present, and should be performed early on follow-up. If these features are absent, most cysts have an identical CEA (increase to > 192 mg/mL in only 14% of patients, without statistical significance) and the EUS-FNA doesn’t change clinical decision making.

P0901 DETERMINATION OF INTRACYSTIC GLUCOSE CONCENTRATIONS IN THE DIFFERENTIAL DIAGNOSIS OF PANCREATIC CYSTS: A PROSPECTIVE STUDY
A. Cantamessa, M. Bruno, S. Gaia, G. Saracco, C. De Angelis
Gastroenterological Unit, Città della Salute e della Scienza di Torino - Universita’ degli Studi di Torino, Torino/Italy

Contact E-mail Address: eusdeng@hotmail.com

Introduction: Despite advances in imaging techniques, differential diagnosis of pancreatic cysts still remains challenging. There has been an increasing interest in new pancreatic cyst biomarkers as a way to differentiate different cyst subtypes and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a promising marker. The aim of this prospective study was to verify this early finding.

Aims & Methods: We enrolled in the study all the patients who underwent Endoscopic Ultrasound (EUS) guided Fine Needle Aspiration of a pancreatic cyst at our Institution from October 2015 to February 2017. The cyst fluid was sent for cytology, mucin staining and determination of amylase, Carbohydrate Antigen 19-9 (CA 19-9), Carinoembryonic Antigen (CEA) and glucose. When defined necessary by the endoscopist, needle-based confocal laser endomicroscopy (nCLE) of the cyst wall and/or contrast-enhanced EUS was performed. A definitive diagnosis of the nature of the cyst was reached relying on surgery, cytology or mucin staining, a typical pattern of nCLE or by consensus (on EUS and nCLE features) by three expert endosonographers, blinded to cyst markers concentrations.

Results: Twenty-nine patients (13 males, median age 72 years, range: 30-83) entered the study. Nineteen (66%) pancreatic cysts were unilocular, while five (17%) cysts had a mediolateral diameter of 45 mm (range: 20- 70 mm). Sixteen (55%) cysts were located in the pancreatic head, 10 (35%) in the body and 3 (10%) in the tail. CE-EUS was performed in 14 (48.3%) patients, nCLE in 9 (29.3%) and contrast-enhanced EUS in 3 (9.7%). Eighteen (61%) cysts were classified as mucinous (6 mucinous cystadenomas; 12 intraductal papillary mucinous neo- plasm) and 11 (37%) as non-mucinous (6 serous cystadenomas; 5 pseudocysts). The final diagnosis was reached relying on surgery in 9 patients (31%), on cyst fluid analysis in 14 (7 elements in 8 (27%) and on consensus in 8 (27%). Mean glucose concentrations in mucinous cyst were significantly lower than in non-mucinous cysts (7.7 mg/dl vs 95.7 mg/dl, p < 0.0001). In the diagnostic of mucin cysts, sensitivity of CA 19-9 (cutoff more than 5000 U/ml) and CEA (cutoff more than 192 mg/ml) glucose (cutoff less than 50 mg/dl) was respectively 22.2%, 66.7% and 94.4%. Specificity was respectively 72.7%, 100% and 100%. Accuracy was respectively 41.4%, 79.3% and 96.6%. Only two subjects in this cohort were affected by diabetes, this condition did not impact on intracystic glucose concentrations.

Conclusion: Although limited by the small sample size, this study confirms the utility of intracystic glucose levels in differentiating mucinous from non-mucinous pancreatic cysts. This cheap, new marker outperformed CA 19-9 and CEA in sensitivity, specificity and accuracy.

Introduction: Liquid-based cytology (LBC) preparation method is one of the most used techniques, which is often used in gynecological and non-gynecological cytology samples, due to its ability to decrease screening time, insufficient sample rate, and air-drying artifacts compared to a conventional smear method. Additionally, immunocytochemistry studies can be performed all on the same preparation.

Aims & Methods: The aim of this study is to show the actual method of LBC and to evaluate the utility of LBC in EUS-FNA samples of the pancreatic lesions. 292 specimens obtained by EUS-FNA from patients with pancreatic disease were included in this study. Clinical diagnosis was pancreatic cancer in 210 cases, acinar cell carcinoma in three cases, adenocarcinoma of the exocrine pancreas in two cases, and one patient was not diagnosed. 75% of the patients was receiving antibiotic prophylaxis before the EUS-FNA procedure, with low complications (0–2%, 5%). Nevertheless, peri-procedural and even several days after EUS-FNA antibiotic prophylaxis has been the standard practice due to the possible risk of pancreatic infection.

Results: Two hundred and four EUS-FNA were analyzed: 51.5% (n = 105) in group 2.60% (n = 60) reported any type of adverse reaction related to antibiotic use (75% in group 2). Complete collapse after aspiration. Five patients had intra-cystic limited bleeding after puncture (two in group 1 and three in group 2). In group 1, 6.2% (n = 6) reported complications: 1 major (mild acute pancreatitis) and 5 minor (epigastric pain, vomiting). In group 2, 9.1% (n = 9) reported 1 major (mild acute pancreatitis), 1 minor (epigastric pain, nausea) complications. There was no statistical difference between the two groups regarding the morbidity of the PCLs.

Conclusion: EUS-FNA is a safe procedure, with 1% rate for major complications in our series and none of them with evidence of infection. We did not find any additional benefit from extension of antibiotic prophylaxis beyond the one-time administration during EUS-FNA. It has been even questioned whether antibiotic

Introduction: Echoendoscopy with fine needle aspiration (EUS-FNA) is a useful tool for the characterization of pancreatic cystic lesions (PCL) due to its ability to perform both endoscopic ultrasound-guided cyst fluid sampling and fine needle aspiration procedure, with low complications (0–2%). Nevertheless, peri-procedural and even several days after EUS-FNA antibiotic prophylaxis has been the standard practice due to the possible risk of pancreatic infection.

Aims & Methods: We aimed to compare the safety of a one-time after EUS FNA of PCL with two protocols: group 1: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA, and group 2: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA plus three days of oral Ciprofloxacin. 500 mg, bid. Retrospective single center study of single-operator EUS-FNA of CLP in two centers with different antibiotic prophylaxis protocols, between January 2014 and December 2016. A telephonc questionnaire regarding post-procedural complications was applied to all patients that agreed to enter the study.

Results: Two hundred and four EUS-FNA were analyzed: 51.5% (n = 105) in group 2.60% (n = 60) reported any type of adverse reaction related to antibiotic use (75% in group 2). Complete collapse after aspiration. Five patients had intra-cystic limited bleeding after puncture (two in group 1 and three in group 2). In group 1, 6.2% (n = 6) reported complications: 1 major (mild acute pancreatitis) and 5 minor (epigastric pain, vomiting). In group 2, 9.1% (n = 9) reported 1 major (mild acute pancreatitis), 1 minor (epigastric pain, nausea) complications. There was no statistical difference between the two protocols groups regarding the morbidity of the PCLs (size, morphology, location) or procedure (needle size, location of puncture, number of passages or percentage of cysts with complete collapse after aspiration). Five patients with intra-cystic bleeding did not have a worse outcome. Additionally, five patients (1.9%) reported any type of adverse reaction related to antibiotic use (75% in group 2).

Conclusion: EUS-FNA is a safe procedure, with 1% rate for major complications in our series and none of them with evidence of infection. We did not find any additional benefit from extension of antibiotic prophylaxis beyond the one-time administration during EUS-FNA. It has been even questioned whether antibiotic

Disclosure: No relevant conflicts of interest were declared.
prophylaxis is mandatory during EUS-FNA of PCLs, since it does not seem to have a protective effect. Moreover, the rise in antibiotic resistance and possible adverse effects related to their use should be balanced against the very low infectious complication rate of EUS-FNA. One limitation of our study is its retrospective nature, with a significant delay between the EUS-FNA and the time to inquiry, which could have biased the patients answers.

P0914 EUS-GUIDED FNA IN THE STUDY OF THE ADRENAL GLAND: NATIONAL RETROSPECTIVE MULTICENTER STUDY
A. Martín-Cardona1, G. Fernández-Esparrach2, J.C. Sibilt Inigo3, J. Igelias García4, M. Garcia-Gui4, A. Barturen Barroso5, A.Z. Gimeno García6, B. Gornals1
Compostela/Spain

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The endoscopic ultrasound (EUS) has proven useful in the study of the adrenal gland by endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) with adrenal gland.

Results: Of the 18 investigated cases (66.6%) and was equal (±5 mm) in 6 cases (33.3%).

Conclusion: In our experience, EUS-guided tissue core biopsy have an extremely high diagnostic accuracy for GIST diagnosis, but underestimates the proliferation indexes and rarely allows for a reliable mitotic count. The main reason for these results is the uneven distribution of the mitotic figures throughout the lesion, which may cause the biopsy to miss the most mitotically active areas. Furthermore, EUS examination generally underestimates the size of the lesions; this limit is fundamentally linked to the “bidimensional” evaluation of lesions obtained by ultrasound. In addition, the underestimation of the size is greater for large lesions because of the low depth of field evaluated by high frequencies used in EUS. Our data obtained with EUS-FNB are similar to previous studies with FNA and constitute a major limitation for developing a possible pre-treatment and biopsy-based risk classification of GIST. Alternative parameters (genotype profiling) must be validated on pre-surgical biopsy samples from GISTs for prognostication purposes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The current classifications of non-metastatic GIST are based on post-operative pathologic criteria and are useful for estimating the potential risk of postoperative recurrence and determining the value of adjuvant Imatinib. The proposed pre-treatment classification currently recognized risk factors as tumor diameter, mitotic rate and site (gastric vs non-gastric). EUS-guided tissue samples remains the standard for pathological diagnosis of GIST, but previous studies showed that EUS-FNA with standard 19 or 22 gauge needles does not reliably reflect GIST’s proliferation and size.

Aims & Methods: We aimed to investigate the EUS-FNB diagnostic yield for GIST and to evaluate whether EUS-FNB samples reflect prognostic criteria obtained from resected GISTs.

Results: Between November 2012 and December 2016 18 patients were studied (11 males; mean age 71.6 years, range 44–88 yo). The tumour site was the stomach in 15 out of 18 patients and the duodenum in 3 out of 18 patients. Agreement between EUS-FNB and surgical pathology was 100% with respect to the diagnosis of GIST (18/18). Proliferative indexes (Ki67/MIB1) were determined in 14/18 (77.7%) patients in 15 out of all cases (as expected) in resected specimens. In our series Ki67/MIB1 were determined in 14/18 (77.7%) patients in 15 out of all cases (as expected) in resected specimens. We found only 2 patients with the required number of 50 HPFs for mitotic count examination. They showed a mitotic index < 5/50 HPFs comparable to surgical specimens. No mitotic figures were seen in core biopsy specimen from any of the remaining 16 patients. In these patients the number of HPFs for mitotic count examination ranged from 1 to 22. In their corresponding surgical specimen we found mitoses in 16/16 patients, ranging from 1 to 5 per 50 consecutive HPFs. The size of the surgical specimen ranged from 5 mm to > 50 mm. The size of the tumor EUS size in 11 of the 18 investigated cases (66.6%) and was equal (±5 mm) in 6 cases (33.3%).

Conclusion: In our experience, EUS-guided tissue core biopsy have an extremely high diagnostic accuracy for GIST diagnosis, but underestimates the proliferation indexes and rarely allows for a reliable mitotic count. The main reason for these results is the uneven distribution of the mitotic figures throughout the lesion, which may cause the biopsy to miss the most mitotically active areas. Furthermore, EUS examination generally underestimates the size of the lesions; this limit is fundamentally linked to the “bidimensional” evaluation of lesions obtained by ultrasound. In addition, the underestimation of the size is greater for large lesions because of the low depth of field evaluated by high frequencies used in EUS. Our data obtained with EUS-FNB are similar to previous studies with FNA and constitute a major limitation for developing a possible pre-treatment and biopsy-based risk classification of GIST. Alternative parameters (genotype profiling) must be validated on pre-surgical biopsy samples from GISTs for prognostication purposes.

Introduction: Pancreatic cancer (PC) remains a disease with overall poor prognosis, despite significant advances over the past decade. Stereotactic body radiation therapy (SBRT) is able to deliver higher biologic effective dose to the tumor over a shorter period of time with reduced local toxicity compared to conventional external beam radiation therapy. EUS-guided fiducial placement has shown to improve the accuracy and localization during SBRT.
Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of an FNA needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

**Aims & Methods:** We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive PC patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS fiducial needle pre-loaded with 2 gold markers with knurled design. After the 2 markers were deployed, the EUS fiducial needle insert was exchanged out for a second pre-loaded EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and complications. The primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

**Results:** Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n = 6), neck (n = 2), and the body (n = 2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, p = 0.002). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

**Conclusion:** EUS-guided fiducial placement with a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

**Introduction:** Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE).

**Aims & Methods:** Our aim was to develop and to validate a computational algorithm, which would evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarcely in" or "abundant in bubbles (<10% or ≥10% of bubbles covering the frame, respectively). Reproducibility (k coefficient), sensitivity (Se), specificity (Sp), Receiver Operating Characteristic (ROC) curve, and calculation times were measured for different algorithms (Grey-level of co-occurrence matrix [GLCM], fractal dimension, Hough transform, and Speeded-Up Robust Features [SURF]) using the experts’ reading as reference. Algorithms with highest reproducibility, Se and Sp were then selected for a validation step on the second set of frames. Criteria for validation were k = 1, Se ≥90%, Sp ≥85%, and a low calculation time.

**Results:** Both SURF and GLCM algorithms had high operating points (Se and Sp over 90%) and a perfect reproducibility (k = 1). At the validation step, the GLCM detector strategy had the best diagnostic capabilities, with Se = 95.79%, Sp = 95.19%, and a mean calculation time of 0.037s per frame. Table 1: Sensitivity (Se), specificity (Sp), negative predictive value (NPV), positive predictive value (PPV) and area under receiver operating characteristic curve (AUROC) of four algorithms for evaluation of bubble abundance in small bowel capsule endoscopy still frames (development step).

**Conclusion:** A GLCM detector strategy has high diagnostic performances to categorize "scarcely in" or "abundant in bubbles" SB-CE frames. This algorithm is of interest for clinical use (i.e. quality in CE reporting) and for research (providing an objective comparison tool of different preparations, including anti-bubble agents).

Introduction: A variety many of pharmaceuticals for the treatment of colon disease can be more effective and have less side effects if targeted for precise delivery in the colon. Over the years, many types of delivery vehicles have been developed with the aim of targeting the colon, such as PB based delivery technologies, time dependent drug release mechanisms, pressure based mechanisms, flora sensitive mechanisms and others. These technologies have performed with variable degrees of success due to the wide distribution of motility and other physiological variability between patients. We describe a novel capsule technology which incorporates a diffused gas sensor that allows for an accurate sensing of colon entrance; as well as a 3D real time positioning system that allows for an accurate, programmable, localized, and in colon drug delivery system.

Aims & Methods: Data was collected from 14 patients that swallowed capsules in a multi-center clinical trial using an x-ray imaging capsule (GUT 2016). The patients were sent home to continue their normal life routine while the capsule naturally traveled in the gastrointestinal tract until excretion. (Subjects signed informed consent and the study was approved after local IRB approval). The capsules contained electronics and software that allowed for live communication between the capsule and a recording device that is placed directly on the patient's back. This device tracks the position of the capsule and communicates with it, receiving diffused gas pressure from the capsule sensor and fusing this information with 3D position information from the capsule. The capsule system exhibited position accuracy of ±1 cm and the ability to detect movements in real time, as well as potential of ~1 ml of payload for drug containment.

Results: The average total transit time of the capsule was 43 hours (range: 15-68 hours). The average transit time to cecum was 13.8 hours, and the average time across the colon was 12.8 hours (range 6-25). The position tracking and the RF communication between the capsule and the recorder showed >90% coverage in all cases, even in obese patients. No adverse events were reported. Figure 1 illustrates the recorder placement on the patient back. Figure 2 is a typical averaged capsule position trace in the colon.

Conclusion: A capsule with accurate position tracking, 2-way communication, and on line algorithms can determine colonic entrance and identify exact locations in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic (no systemic delivery) therapy for IBD and cancer.

Introduction: Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas. This analysis indicates, that when utilizing 4 liter PEG and oral sulfate solutions for CCE procedure preparation, current cleansing assessment scale and methodology may need to be re-evaluated - to better correlate with polyp detection. Currently, “fair” cleansing may not indicate inadequate cleansing for polyp detection.

Disclosure of Interest: S. Perek: Employee of Medtronic
S. Farkash: Employee of Medtronic
N. Schwartz: Employee of Medtronic

References
Multivariate logistic regression revealed that after adjusting to polyp’s size, cecal and rectal segments were associated with increased chance of CCE additive value to colonoscopy (cecum vs. ascending or transverse colon: Adj.OR = 2.6 [95%CI: 1.1–5.8] and Adj.OR = 3.6 [95%CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonoscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonoscopy, especially lesions in the cecum and rectum.

Introduction: Only small series (<10 patients) have described endoscopic management of postoperative pancreatic fistulas (POPF). The purpose of this retrospective study was to describe the indications, technique and results of endoscopic treatment of POPF.

Aims & Methods: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified.

Results: Among the 23 remaining patients, the closure rate of POPF was 100% within an average (SD, [range]) was 378 days (497 [2–2227]) after the first ERCP. During FU, there were 3 stent migrations and 2 stent obstructions requiring a subsequent ERCP for stent removal. Eight patients (25.8%) died after surgery complications. Among the 23 remaining patients, the closure rate of POPF was 100% within an average (SD, [range]) was 453 days (785 [16–3260]) after the first ERCP, and a mean number of ERCP performed per patient (±SD) 2.5 (±1.0). No late reopening fistula occurred after removal of the pancreatic stent.

Conclusion: This retrospective study, the most important one reported to date, shows that the endoscopic treatment of POPF resistant to medical therapy is an effective option.

P0923 EFFICIENCY OF PANCREATIC STENTS IN DIFFICULT CANNULATION – A RETROSPECTIVE SINGLE - CENTER STUDY

Retrospective: Difficult biliary cannulation is defined by the presence of one or more of the following: more than 5 contacts with the papilla while attempting to cannulate; more than 5 minutes spent attempting to cannulate following visualization of the papilla; more than one unintended, pancreatic duct cannulation or more than one pancreatic duct stent insertion. In these situations, an additional pancreatic stent insertion might prove to be very useful for prophylactic and tactical purposes.

Aims & Methods: We are proposing in this paper to present the experience of Clinical Emergency Hospital Bucharest regarding difficult biliary cannulation where pancreatic stent insertion proved to be efficient in obtaining biliary opacification. This paper is a retrospective study of the patients who presented difficult cannulation and to whom pancreatic stents were inserted for prophylactic and tactical purpose. The patients’ mean age was 60 years, while the sex ratio was 2:1 in favor of the female gender. Pancreatic stents proved their efficiency in 90% cases, in only 3 patients deep cannulation being unsuccessful. On average, patients required 1-15 ERCP procedures in order to obtain biliary access. ERCP indication for benign pathology was predominant (60%). The stents used were 5 Fr, 5 cm (102 patients) and 5 Fr, 3 cm (56 patients). Precut sphincterotomy was performed in 82 cases (37 before stent insertion and 45 after stent insertion). From all patients included, only 19 patients (12%) presented post procedure elevation of serum amylase 3 times higher than normal value associated with abdominal pain. Closure of Pancreatic stents was considered efficient in obtaining biliary opacification in difficult situations. Regardless of their length, 5 Fr (3 cm, 5 cm) stents ensure the same success rate for cannulation and offers protection against post ERCP pancreatitis, as long as they are correctly inserted.

Introduction: Endoscopic ultrasonography (EUS)-guided biliary drainage (EUS-BD) is increasingly used in the treatment of malignant biliary obstruction after failed ERCP. However, Multi-step process for EUS-BD is closely related to adverse events.

Aims & Methods: The present study was designed to determine feasibility and safety of stent placement using a thin delivery-system stent without dilation step during EUS-BD. Three types of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with a 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10 pigs, EUS-BD (choledochoduodenostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events within 2 weeks after EUS-BD were analyzed for three types of stents.

Results: Among the three types of stents, 7Fr soft tip had the least resistance in the phantom model. In the animal model, the median common bile duct diameter before puncture measured on EUS and the median procedure time was 7.66 mm (4.05–9.5) and 29.3 minutes (16–47) respectively. In all pigs, EUS-BD using the three types of stents were technically successful. Dilusion was unnecessary in 25% (1/4), 0% (0/2) and 100% (4/4) for the 7Fr hard tip, 7.5Fr hard tip and 7Fr soft tip, respectively. Even in the cases requiring dilution, stent placement was successful immediately after dilation only with a thin catheter (7Fr). Neither postcatterty dilution nor balloon dilatation was needed. There were no procedure-related complications occurring during and 2 week after EUS-BD. All stents remained in place without migration. At necropys, fissulas were created between the thin duct and duodenal in all pigs and the growth of fibrous tissue was observed in the microscopic findings.
Conclusion: Among the three types of stents, the 7Fr soft tip was suitable for EUS deployment in the phantom and animal models. Therefore, this self-expanding system stent may be technically feasible and safe for EUS-BD and possibly reduce adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: To assess the frequency of DPD and its clinical significance after EUS guided drainage of PFC. Patients of acute or chronic pancreatitis with symptomatic PFC, who underwent Endoscopic Ultrasound (EUS) guided drainage between January 2011 to December 2016 were included, after an informed consent. Stents used for drainage procedure were either bi-flanged metal stent (BFMS) or double pigtail plastic stent. All these patients underwent MRCP between 4 to 8 weeks after drainage to evaluate pancreatic duct (PD) anatomy and confirm resolution of PFC. Subsequently, they had Endoscopic Retrograde Pancreatography (ERP) and choledochoscopy, stent removal. BFMS was removed in all patients. Plastic stents were retained indefinitely, if DPD was confirmed. All patients were systematically followed at 3–6 monthly intervals for any recurrence of PFC or new onset clinical event.

Introduction: ERCP-related perforation is rare (0.39%), but it is associated with a mortality of 7.8%. Duodenal retroperitoneal perforation (Type II) is the most frequent, among the ERCP-related perforations. The management of this complication has not been standardized yet: traditionally surgery was considered the only rescue therapy, but in the last years the majority of cases has been managed conservatively. The endoscopic treatment included biliary stent and/or nasobiliary drainage. In our institution, from 2010 we have been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. These stents have the advantage of covering the laceration and allowing free flow of bile into the duodenum instead of into the retroperitoneal space. The aim of this study was to evaluate in our cohort of patients, the benefits of FCSEMS in type II perforations.

Aims & Methods: We experienced six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 69; age range: 54-80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary stones. In two cases spherentorotomy was performed and perforation was immediately detected. Successful closure of persistent spherentorotomy-related duodenal perforation using FCSEMS was obtained in all patients. One patient developed ERCP-related pancreatitis, successfully treated with medical therapy. Three FCSEMS were successfully removed after a median of 18 days; the remaining three fell out spontaneously. The median length of hospital stay was 8.5 days (range 4-20 days). There were no deaths or need for surgery.

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patients, FCSEMS was considered the only rescue therapy, but in the last years the majority of cases has been managed conservatively. The endoscopic treatment included biliary stent and/or nasobiliary drainage. In our institution, from 2010 we have been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. Conclusion: In our study, the mitomycin injection therapy was effective in patients who had retracted benign esophageal stenosis. The mitomycin injection therapy could be considered as an alternative for retractable benign esophageal stenosis. A large-scale prospective studies are required in future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prevalence of post-ESD esophageal strictures is non-negligible, with a critical impact on the patients’ quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

Aims & Methods: This is an observational and analytical retrospective study. Sixty-eight consecutive patients (mean age: 65 ± 11y, 76.5% men) who underwent endoscopic dilation because of post-ESD symptomatic esophageal strictures between 2006 and 2016 were included. They had Barrett’s esophagus (n = 46, 67.6%), epidermoid carcinoma (n = 21, 30.9%) and other (n = 1). Patients with aneoplastic esophageal strictures were referred to Oncology. Dilatation, endoscopic recanalization without complaints. Primary end-point –The rate of clinical success. Secondary end-points were defined as follows: Technical initial success was 100%. We did not dilate patients with recurrence prior to stent placement. After the first RPS we could deploy a 2nd (100%, average 3.5 – range 1.5–6 months) and a third stent (40%, average 11, range 7.5–14.5 months). Later, after 2.5–15.5 months, lumen was stable and restored. Granulation tissue in-between stent fibers produced early stenosis, treated by re-stenting. 1 stent prolapsed partially from the anus and was shortened with scissors. Bleeding was not present. Pelvic pain in all the patients needed NSAIDs and reduced over time.

Conclusion: These cases show that stenting with RPS of anastomotic dehiscences is feasible, safe and effective. Due to restenosis associated with dehiscence multiple stents were needed. Distal migration was easily managed. Distal anastomoses might explain the presence of pelvic pain. 3 patients have been subjected to re-calcanealization without complaints.

expansion (1.38%, 3%), and levar (1.38%, 3%) in Group W and perforation due to obturator (6.2%) in Group G. Cases with stent-stent perforations (4.5%) in Group W and stent occlusion (2.53%, 4%) in Group N. All 4 patients with stent-related perforations had undergone palliative stenting with the WallFlex colonic stent, and the stent-related perforation rate in Group W was significantly higher than that in Group N (P < 0.05). In Group D, there were no complications and no stent occlusion.

Conclusion: The technical and clinical success rates were extremely high in all groups, and the obtained details were also retrieved. Multiple regression models with the data to test the association between potential predictors and preoperative lymphopenia and lymphopenia on POD1 as parameters of immune suppression. Results: The preoperative lymphocyte count was 1, 240/ml (IQR: 0.895–1.700) and 1, 280/ml (IQR: 0.780–3.020) in Group 1 and Group 2, respectively. The lymphocyte count on POD1 was 0.670/ml (IQR: 0.500–0.792), p < 0.001; on POD3, it was 0.800/ml (IQR: 0.580–1.070), p < 0.001; and on POD7, it was 0.825/ml (IQR: 0.550–1.180), p < 0.001. In a model also included the interval between the end of neoadjuvant therapy and the esophagectomy and the cause for the recurrence of symptoms, the lower esophageal sphincter was the most related predictor of preoperative lymphocyte count on POD1.

Conclusion: Patients with esophageal and esophago-gastric junction cancer present a significant postoperative immunosuppression that lasts at least for the first postoperative week. The total amount of radiation received by the mediastinum is the only predictor of the preoperative and postoperative lymphocyte count.

Introduction: To improve the quality of esophageal cancer surgery in the Netherlands, the number of retrieved lymph nodes (LNs) is evaluated in one the quality indicators in the Dutch Upper Gastrointestinal Cancer Audit (DUGA).(1) All hospitals in the Netherlands can use the outcomes of the DUGA to monitor their own results in relation to the national average. The aim of this study was to analyze the outcomes of the quality indicator: ‘a minimal number of 15 retrieved LNs’ in the past years and to determine factors associated with this outcome.

Aims & Methods: Patients with an esophageal carcinoma who underwent an esophagectomy with curative intention and who were registered in the Dutch Upper Gastrointestinal Cancer Audit between 2011–2016 were included in this retrospective national cohort study. The primary outcome: ‘percentage of patients with ≥15 LNs’ was analyzed by year and hospital. Factors tested with univariable and multivariable analysis for the association with ≥15 LNs were: age, Charlson score, weight loss, BMI, cT-, cN-, cM-stage, tumor location, neo-adjuvant therapy, type of procedure, intraoperative complications, hospital volume, and year of resection. The postoperative outcomes: radicality, intraoperative complications, morbidity, and mortality were tested on association with ≥15 LNs.

Results: The overall percentage of patients in the Netherlands with ≥15 LNs increased between 2011 and 2016 from 51% to 81%. The variation between hospitals decreased. Multivariable analysis showed an independent association with ≥15 LNs for the factors: cN2-stage (OR [95% confidence interval]: 1.37 [0.5–1.9]), resection in a hospital with 26–50 or ≥51 resections/year (reference), and year of resection (2011: ORs 1.55, 1.81, 2.43, 2.20, 2.64). Factors independent associated with <15 LNs are: neo-adjuvant chemoradiation-therapy (reference: no neo-adjuvant therapy), 0.66 (0.47–0.93), intraoperative complications (0.55, 0.39–0.80) and open and minimally invasive transhiatal resection (reference: open transhiatal, 0.24 [0.18–0.32] and 0.38 [0.26–0.55]). Postoperative morbidity and mortality were not associated with ≥15 LNs.

Conclusion: Of the quality indicator ‘a minimal number of 15 retrieved LNs’ is increased between 2011 and 2016. The variation between hospitals is decreased. The cN-stage, neo-adjuvant therapy, type of procedure, intraoperative complications, year of resection and hospital volume seem to be associated with ≥15 LNs.

Disclosure of Interest: All authors have declared no conflicts of interest.
