Introduction: Liver cirrhosis is associated with an imbalance between vasodilation and vasoconstriction in the sinusoids. Therefore the investigation of the nitric oxide - cyclic guanosine monophosphate (NO-cGMP) pathway, a key regulator of vascular smooth muscle tone, is essential.

Aims & Methods: The rat model of thioacetamide (TAA) was used to induce liver fibrosis/cirrhosis and alterations of the NO-cGMP pathway and subsequent liver damage were assessed. 25 male Wistar rats were studied (11 untreated controls and 14 TAA treated animals [0.03 g TAA/100 ml drinking water for 16 weeks]). TAA dosage was adjusted weekly based on body weight changes. Hepatic gene expression of endothelial and inductive NO synthase (eNOS and iNOS), phosphodiesterase 5 (PDE5) soluble guanylate cyclase subunit a1 and b1 (sGCa1 and sGCb1) was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-amino-transferase (ALT and AST), alkaline phosphatase (AP), albumin and bilirubin). The degree of fibrosis was estimated by histological criteria (i.e. Desmet scores). PDE5-expression was determined by immunohistochemistry. Kruskal-Wallis test was used for statistical analysis of group differences.

Results: 43% (6/14) of TAA-treated rats developed liver fibrosis (Desmet score of 1–3) while 57% (8/14) developed liver cirrhosis (Desmet score of 4). No major differences in ALT, ASAT, and AP serum concentrations were observed in either group. However, bilirubin was significantly elevated in TAA-treated rats, while albumin concentrations were significantly reduced. Gene expression analysis revealed significantly increased expression of eNOS (1.5fold), PDE5 (7.76fold), and sGCb1 (2.1fold) in fibrotic livers compared to controls. cGMP concentrations in fibrotic animals were slightly decreased (34%). Significantly increased expression of eNOS (2.26fold), PDE5 (11.0fold), sGCa1 (1.70fold) and sGCb1 (3.60fold) was observed in cirrhotic livers compared to controls, while cGMP concentrations were significantly decreased (-40%). iNOS expression was only detected in fibrotic and cirrhotic livers, but absent in controls. Immunohistochemistry revealed markedly increased PDE5-expression in cirrhotic livers, which was predominantly localized in hepatic stellate cells.

Conclusion: The analysis of the animal model of TAA-induced liver fibrosis/cirrhosis revealed alterations of the NO-cGMP pathway, characterized by reduced concentrations of cGMP, a key mediator of vasodilation, due to increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to portal hypertension. Thus, administration of PDE5-inhibitors, possibly combined with sGC-activators, should be further studied in clinical trials as a promising therapeutic approach to target portal hypertension.

P0004 THE PROTECTIVE EFFECTS OF GROUP 3 INNATE LYMPHOCYTES ON HEPATITIS B VIRUS RELATED LIVER FIBROSIS COULD BE IMPAIRED BY TH17 CELLS

S. Wang, W. Ma, L. Cheng, W. Jiang
Gastroenterology, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: 15211210012@fudan.edu.cn

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) related liver fibrosis. Group 3 innate lymphoid cells (ILC3s), which have similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s (Lin-CD127+CD117+CD274) and Th17 cells (CD4+IL-17+) were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s co-cultured with hepatic stellate cells (HSCs)-LX2 in contact and non-contact manners. Then Th17 cells, which were induced from naïve CD4+ T cells in vitro, were transferred into Rag1+/− mice with carbon tetrachloride (CCL4) related liver fibrosis. In addition, ILC3s in Rag1+/− mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-α, IFN-γ decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased in both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCL4 administration, even at week 6. Transferring Th17 cells into Rag1+/− CCL4 mice reversed made the ILC3s in spleens and livers decreased significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipients with liver fibrosis and reverse liver fibrosis. Thus, our study suggested the protective role of ILC3s in liver fibrosis, which is through secreting IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice. The relevant mechanisms are currently being investigated.

Aims & Methods: We aimed to investigate the potential relation between the expressions of bile acid receptor and TLR4/NOD2 in intestinal mucosa and its influence on the intestinal mucosal barrier with obstructive jaundice. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NOD2. Sixty male adult Kunming mice were randomly assigned to four groups: SH (sham operation), OJ (obstructive jaundice), ID (internal drainage), ED (external drainage) (n = 15 in each group). On the 7th day from the first operation, the OJ and SH mice were sacrificed and specimens of blood and ileal tissue of groups were collected. ED and ID were reoperated on day 8 for biliary drainage procedure. Blood was drawn from heart for liver function test. The terminal ileum specimen was collected for test of histology using haematoxylin-eosin (HE) staining. Western blot (WB) and real-time polymerase chain reaction (RT-PCR) were used to detect the expression of protein and mRNA of FXR, TGR5, TLR4 and NOD2 in intestinal mucosa.

Results: We have successfully established the animal models. The histopathological examination revealed notable inflammatory infiltration and hyperplasia disruption at terminal ileum in OJ mice; significant alleviation of above injuries by ID while little improvement by ED. FXR-TLR4: After biliary obstruction, the expression of protein and mRNA of FXR were significantly increased, while the expression of protein and mRNA of TLR4 were significantly decreased compared with SH group’s (P < 0.05). After ED, compared with OJ group’s expression of protein of FXR was decreased while TLR4 were increased. The mRNA of both FXR and TLR4 were increased. After ID, the expression of protein and mRNA of FXR were significantly decreased compared with OJ group’s but the changes were still better than that in SH group and were still lower than ED group’s. And the expression of protein and mRNA of TLR4 were significantly increased compared with OJ group’s (P < 0.001), but were still lower than that in SH group and were better than ED group’s. The trend of TLR4 expression was almost the same between vehicle group and no gavage group. After gavage with FXR agonist, the differences of TLR4 expression of four groups disappeared (P > 0.05). TGR5-NOD2: IHC and WB suggested that after OJ surgery, the protein expression of both TGR5 and NOD2 increased obviously compared to that of SH mice; then the level of TGR5 and NOD2 protein fell remarkably after ID surgery close to SH level while in ED group there was only a slightly reduction form OJ level and still with a high expression of TGR5 and NOD2 protein. Detection of RT-PCR found that TGR5 mRNA and NOD2 mRNA level in OJ group increased several times as that of the SH group; after ID surgery, the expression of TGR5 mRNA significantly reduced, NOD2 mRNA level also fell down consistently, but the effect was not observed in ED mice.

Conclusion: The expression of intestinal FXR and TLR4, TGR5 and NOD2 could be one of the critical mechanism why internal drainage is better than external drainage in restore intestinal barrier function of obstructive jaundice mice.

Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestatic injury and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncogenic microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, mice were sacrificed and small intestines were collected, DNA was carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing – metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF-α and IL-1-β mRNA levels increased in the small intestine of BDL-mir-21 KO mice, compared with WT. TLR-4 and TGF-β expression was increased in both sham- and BDL-mir-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Strikingly, mir-21 KO reverted mRNA of tight junction proteins to control levels. BDL-mir-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, mir-21 KO not only show a decreased small intestine permeability through a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased beneficial gut microbiota markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. **Introduction:** Sorafenib is the only approved systemic therapy for advanced hepatocellular carcinoma (HCC). However, the application of Sorafenib in therapy has faced increasing challenges due to drug resistance. Drug resistance is known to be associated with cancer stem cells (CSC). The transcription factor ZBP-89 was reported to be involved in cell growth and apoptosis in tumor and acts as a potential tumor suppressor in HCC. It has shown that high levels of ZBP-89 expression were statistically associated with better survival of HCC patients. Unfortunately, the mechanism of ZBP-89 in modulating sensitivity of Sorafenib in CSC remains unknown.

**Aims & Methods:** In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of HuH7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTT assay. Then we examined the expression pattern of Notch1 and liver CSC markers in HuH7 and Hep3B CSC after the treatment with Sorafenib. MTT assay was also used to measure the effect of ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. The levels of ZBP-89 and CD44 were measured using q-PCR in human HCC tissue samples. The regulatory effects of ZBP-89 on CSC phenotype were explored by various methods including q-PCR, immunoblotting, tumor sphere formation assay, soft agar formation assay and colony formation assay. Gene expression and protein interaction in stemness signaling pathways were analyzed.

**Results:** We found that sphere-forming HCC cells had significant higher resistance to Sorafenib, compared with their parental cells. The expression of Notch1 and EpCAM was increased along with the treatment of low dose of Sorafenib, suggesting that the activation of Notch1 pathway was associated with the drug resistance in liver CSC. Studies further indicated that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib in sphere-forming HCC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor sphere formation of Huh7 was impaired upon the transfection of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed investigation against control cells showed that overexpression of ZBP-89 resulted in reduced expression of CSC markers EpCAM, CD133, Sox2 and e-cmyc at both mRNA and protein levels. In addition, the overexpression of ZBP-89 or silencing of Notch1 reduced the number of colonies formed by sphere-forming HCC cells, demonstrating opposite effects of these two proteins. Mechanistic studies revealed that ZBP-89 was able to repress the expression of Notch1 and reported Notch1 target genes including HES1, HES6, HEY1 and NRP1. Amino acids Δα-180 of ZBP-89 could directly bind to the activated Notch1 in the nucleus, resulting in a negative regulation of CSCs and overcome of Sorafenib resistance.

**Conclusion:** Sphere-forming HCC cells, which contained high levels of Notch1 and EpCAM, were resistant to Sorafenib. The overexpression of ZBP-89 was found to result in the loss of CSC phenotype and improve the sensitivity to Sorafenib in CSC through its interaction with activated Notch1. In conclusion, we believe that targeting ZBP-89 is likely to be a new therapeutic strategy to overcome resistance to Sorafenib in HCC.

**P0008 PROTECTIVE EFFECT OF AKKERMANSIA MUCINIPHILA AGAINST IMMUNE-MEDIATED LIVER INJURY IN A MOUSE MODEL**

**W. Wu, D. Shi, D. Fang, X. He, L. Li**
1State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China, Hangzhou/China
2Department of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China, Hangzhou/China

**Contact E-mail Address:** wuw725@zju.edu.cn

**Introduction:** Accumulating evidence indicates that gut microbiota participates in the pathogenesis and progression of liver diseases. The severity of immune-mediated liver injury is associated with different microbial communities. Akkermansia muciniphila can regulate immunologic and metabolic functions. However, little is known about its effects on gut microbiota structure and function.

**Aims & Methods:** This study investigated the effect of A. muciniphila on immune-mediated hepatitis and potential underlying mechanisms. Twenty-two C57BL/6 mice were assigned to three groups (N = 7–8 per group) and continuously administered with A. muciniphila Muc8 (ATTC BAA-835) or saline suspension daily for 21 days. Mouse feces were collected for gut microbiota analysis on the eleventh day, and acute hepatitis was induced by Concanavalin A (Con A, 15 mg/kg) injection through the tail vein. Samples (blood, liver, ileum, colon) were assessed for liver injury, systemic inflammation and intestinal barrier function.

**Results:** We found that oral administration of A. muciniphila (Akk) decreased serum ALT and AST and alleviated liver histopathological damage induced by Con A. Serum levels of pro-inflammatory cytokines (IL-2, IFN-γ, IL-12p40, TGF-β1, MCP-1, iNOS) were significantly decreased in serum treated mice compared to Con A only group. Further investigation showed that Akk enhanced Ocludin and Tjp-1, two proteins related to strengthened intestinal barriers. Fecal 16S rDNA sequencing analysis indicated that Akk elevated increased microbial diversity. The community structure of the Akk group clustered distinctly from that of the Control and Normal groups. Relative abundance of Firmicutes increased, and Bacteroides abundance decreased. Correlation analysis showed that injury-related factors (IL-12p40, IFN-γ, DR5) were negatively associated with specific genera (Ruminococcaceae_UCG-009, Lachnospiraceae_UCG-001, Akkermansia), which were enriched in mice pretreated with Akk.

**Conclusion:** Our results suggested that A. muciniphila Muc8 (ATTC BAA-835) had beneficial effects on immune-mediated liver injury by alleviating inflammation and hepatocellular death. These effects may be driven by the protective profile of the intestinal community induced by the bacteria. The results provide a new perspective on the immune function of gut microbiota in host diseases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0009 CLINICAL OBSERVATION ON THE TREATMENT OF NONALCOHOLIC FATTY LIVER WITH PROBIOTICS**

**W. Wang**
Gastroenterology, Beijing Hospital, Beijing/China

**Contact E-mail Address:** wangwei-beijing@yahoo.com

**Introduction:** Asian countries, especially China, have the highest prevalence of insulin resistance (IR), hyperlipidemia and diabetes and other metabolic disorders in nonalcoholic fatty liver (NAFLD) in China has increased. NAFLD refers to the factors caused by exclusion of alcohol and other clear liver disease. NAFLD is the leading cause of chronic liver disease in developed countries and China. Chronic liver disease is often accompanied by intestinal micro ecological imbalance; studies have shown that the imbalance of intestinal micro ecology led to the transfer of intestinal endotoxin into the blood, and stimulate the production of inflammatory factors aggravate liver damage, thus chronic liver disease. A series of studies show that intestinal microflora, intestinal bacterial overgrowth (SIBO) and intestinal endotoxemia in the occurrence and development of NAFLD plays an important role, and the recovery of intestinal micro ecological balance may have assisted treatment of NAFLD. A series of studies show that changes of intestinal microflora, intestinal bacterial overgrowth (SIBO) and intestinal endotoxemia in the occurrence and development of NAFLD plays an important role, and the recovery of intestinal micro ecological balance may have assisted treatment of NAFLD.

**Aims & Methods:** We aimed to study the clinical effect of probiotics in the treatment of nonalcoholic fatty liver disease. 200 cases of patients with nonalcoholic fatty liver disease were randomly divided into routine treatment group (A group) and combined treatment 3 groups (B, C, D). All cases were given orally Polyene Phosphatidylcholine Capsules, 456 mg, TID; The combination therapy group D was given orally the Live Bifidobacterium Lactobacillus and Enterococcus Powder, 420 mg, TID; group C, two live combined Bacillus subtilis Enterococcus powder, 420 mg, TID. TID; group D was given orally the probiotics above. The course was 1 month. All patients were respectively examined before treatment and seven days and thirty days after treatment, for cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDL-L), low density lipoprotein cholesterol (LDL-L), alanine aminotransferase (ALT), aspartate aminotransferase (AST), fasting blood glucose (FGG), serum high molecular weight adiponectin (HMW APN) and serum TNF-α. The 4 groups were collected faeces samples, that were tested routine detection, bacterial culture. At the same time all patients were checked with liver ultrasound scan.

**Results:** In terms of blood lipids and blood glucose, each group improved than before, only HDL-Lwas not statistically significant, D group showed significant differences in triglyceride. In liver function, blood ALT, AST were significantly lowered in group D than A, serum TNF-α levels were decreased after treatment in D group. The combined treatment D group was statistically significant; group D more than the group A; serum HMW APN increased after treatment, combined treatment group D comparing with routine treatment group A was significant difference.

**Conclusion:** Intestinal probiotics can regulate the intestinal micro ecological imbalance in NAFLD patients, and reduce the level of serum TNF-α, improve the level of adiponectin, which can further improve the blood glucose, lipid metabolism, and then improve the liver injury of non-alcoholic fatty liver disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
MOUSE MODELS OF NON-ALCOHOLIC FATTY LIVER DISEASE

P0011 GUT MICROBIOTA COMPOSITION IN EXPERIMENTAL MOUSE MODELS OF NON-ALCOHOLIC FATTY LIVER DISEASE

B. Zhang, L. Fan, J. Ren
Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen/China

Introduction: Non-alcoholic fatty liver disease (NAFLD) has become the most common liver disease worldwide, and is thought to be strongly associated with obesity, the microbiota of patients with nonalcoholic fatty liver disease (NAFLD) has not been well characterized. NAFLD is considered a hepatic manifestation of metabolic syndrome and is particularly associated with insulin resistance, obesity, and gut-driven endotoxin.

Aims & Methods: The aim of our study is to assess if there are any differences in the microbiota of patients with biopsy-proven NAFLD and healthy controls (HC). In addition, peripheral blood endotoxin (ET) and gut-permeability were analyzed in NAFLD (mild fibrosis vs severe fibrosis) and HC patients. A total of 201 patients were enrolled in this study: 68 HC and 143 biopsy-proven NAFLD (77 with mild fibrosis and 66 severe fibrosis). One stool sample was collected from each participant. All NAFLD patients included in this study underwent percutaneous liver biopsy. Healthy controls were volunteers. The composition of gut bacterial communities was determined by 16S rDNA sequencing. In addition, peripheral blood ET was determined using endotoxin activity assay (EAA). Gut-permeability was assessed by Lactulose mannitol ratio (LMR).

Results: Among those taxa with greater than 1% representation in any of the diet groups, it was significantly decrease in Bacteroidetes at phylum level in NAFLD compared with HC. At genus level, Faecalibacterium prausnitzii (F.P) was significantly decreased in NAFLD compared with HC. F.P is significantly decreased in NAFLD with severe fibrosis compared with those with mild fibrosis patients. In addition, endotoxin levels were increased in NAFLD with severe fibrosis than those with mild fibrosis. Furthermore, occupation ratio of F.P was reduced in patients with blood ET ≥0.32 (p=0.0001). Additionally, it showed a significant correlation among three items of F.B, EAA and LMR (F.B vs EAA: P < 0.0001, LMR vs EAA: P < 0.0001, LMR vs F.B: P = 0.0025).

Conclusion: Our study indicated that the change of the gut microbiota and pathologic connection were suggested in acknowledgment of the decreased F.P in the NAFLD patients. The decreased abundance of F.B in NASH with severe fibrosis, elevated blood-endotoxin in NAFLD with severe fibrosis patients suggests a role for ET in the pathogenesis of fibrosis. Moreover, our study showed that the mechanism of fibrotic progression via the endotoxin in NAFLD may relate strongly gut-permeability. We postulate that the distinct composition of the gut microbiota among NAFLD and HC could offer a target for intervention or a marker for disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0012 PREVALENCE OF METABOLIC SYNDROME AND LIVER STEATOSIS IN A PROSPECTIVE MULTICENTER STUDY OF PATIENTS REFERRED FOR HYPERFERRITINEMIA

1Gastroenterology, Mendoro Hospital, Mendoro/Spain
2Clinical Epidemiology, Donostia University Hospital, Donostia/Spain
3Gastroenterology, Mondragon Hospital, Mondragon/Spain
4Radiology, Oaske Donostia, Donostia/Spain
5Hematology, Galduko Hospital, Galduko/Spain
6Hematology, Hospital de Cruces, Barakaldo/Spain

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). Liver steatosis is often suspected in patients referred to hyperferritinemia.

Aims & Methods: To study the prevalence of hepatic steatosis determined by MRI in these patients. A prospective study of 312 consecutive with HF (> 200 µg/L; women; 300 µg/L men) and/or TSI > 45%, confirmed in two determinations, was conducted from December 2010 to April 2013. The MS was defined by the presence of three of the following factors: waist circumference ≥94 cm men; ≥80 cm women; Triglycerides ≥150 mg/dL or treatment for this dyslipidemia; HDL < 40 mg/dL or treatment for this dyslipidemia; glucose ≥100 mg/dL or Type 2 diabetes; hypertension: blood pressure ≥130 mmHg≥85 mmHg or treatment for arterial hypertension (1). LIC was determined by MRI 1.5 Tesla system (SIR method) (2). We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis.

Results: 312 patients (272 men/40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729, 6 (SD 449.6); mean TSI 40, 8 (SD 15.8); 276 patients have all the required criteria to determine the MS presence: 115(240 men (48%) and 20/36 with diabetes; 162 patients with MS (51%). In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis. 251 patients with MS criteria and MR for steatosis; NMS group (128): no steatosis 103; steatosis 25; MS group (123): no steatosis 72; steatosis 51 (total: no steatosis 175, steatosis 76). When we study if the presence of liver steatosis was more frequent in the MS group, the results obtained were statistically significant, p = 0.000.

Conclusion: Nearly 50% of the patients referred for hyperferritinemia to the hospitals of our city had MS; the patients with MS had more frequently liver steatosis than the patients without MS.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
patients with HFE mutations and (transferrin saturation index (TSI) values alone. But we did not have C282Y/C282Y patients in the series.

## Aims & Methods
To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque Country. Prospective study of 312 consecutive patients with HF. Group A (C:160) (women), Group B: PM for HH: C282Y/C282Y; C282Y/H63D, H63D/H63D, and C282Y/H63D > 50%; Group C: no PM for HH and normal TSI);Group D: PM and normal TSI. In the Basque Country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

### Results
In all the patients HFE study was available: C282Y/C282Y 14 (4.49%); C282Y/H63D 164 (51.66%); H63D/H63D 99 (31.72%); wt/wt 98 (31.41%); C282Y/S65C 61 (1.98%); C282Y/S65C 0 (%), C282Y/H63D 2 (0.64%); C282Y/C6 16 (5.13%); S65C/S65C 10 (3.21%). LIC was obtained from all the patients by MR. Mean age: 53 ± 13.3, 272 men and 40 women. Group A: 54; Group B: 32 Group C:160; Group D: 54. The mean LIC in all the groups were: Group A: 37.21 ± 27.89, group B: 70.53 ± 56.87, group C: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences (p < 0.0001).

### Conclusion
The LIC in different patients of groups referred for HF are significantly different with different predisposition to HH.

### P0014 LIVER IRON CONCENTRATION IN THE METABOLIC SYNDROME WITH HYPERFERRITINEMIA (DYSMETABOLIC HYPERFERRITINEMIA): RESULTS FROM A PROSPECTIVE COHORT OF 312 PATIENTS

#### Aims & Methods
To study the LIC in patients referred for hyperferritinemia to six different hospitals in the Basque Country (multicenter study), Spain, and determine if there are differences between patients with or without metabolic syndrome. A prospective study of 312 consecutive patients with HF (>200 mg/L women, >300 mg/L men) was conducted from December 2010 to April 2013. The Metabolic syndrome was defined by the presence of three of the following factors: waist circumference >94 cm men/80 cm women; Triglycerides >150 mg/dL or treatment for this dislipidemia; HDL cholesterol <45 mg/dL men/50 mg/dL women; blood pressure >130 mmHg/85 mmHg or treatment for arterial hypertension (1). LIC was determined by MRI (SIRe method) (2).

#### Results
In 276 of 312 patients we have all the data to determine the MS presence: 115/240 men (48%) and 20/36 women (55.6%), 135 patients, presented MS. In all 276 patients MRI for LIC determination (mean ± SD) was performed. (We have LIC in 272/276 patients). The mean LIC was 30.83 ± 19.38 (women) and 38.84 ± 25.50 (men), with 37.66 ± 24.79 (CI 95%) 33, 44 to 41, 88, for all the MS group. In 141 patients MS was not diagnosed (NMS): 125/240 were men (52%), and 16/36 women (44.4%). The mean LIC was 34.88 ± 16.18 in women, and 44.48 ± 38.16 in men, with 43.39 ± 36.83 (CI 95%), 37, to 49, 46, for all the NMS group. We compare the mean values of LIC from both groups (MS vs NMS) by Pearson’s Chi square test and Fisher’s exact test: no significant differences were seen (p = 0.12).

#### Conclusion
Patients with HF and MS (dysmetabolic hyperferritinemia) present a mean LIC near normal values and their values do not differ from those of patients with HF and without MS.

### P0015 INTERLEUKIN-25 PROTECTS AGAINST HIGH-FAT DIET-INDUCED HEPATIC STEATOSIS IN MICE BY INDUCTING IL-25 AND M2 KUPFFER CELL PRODUCTION

#### Aims & Methods
To explore the intracellular signaling pathways of IL-25 to regulate macrophage polarization and direct effects of IL-25 on Kupffer cells. Mouse model of NAFLD was induced by feeding a high-fat diet (HFD); In vitro expansion of mouse Kupffer cells, IL-10 and IL-25 were used to induce M2a Kupffer cells; specific siRNAs were used to knockdown IL-25 receptor mRNA for assessing the direct and specific effect of IL-25 on Kupffer cells. IL-25 induced M2a Kupffer cells were back transfection into the abdomen of NASH mouse to assess the efficacy; Dual-luciferase reporter assays and Chromatin immunoprecipitation assays were used to determine the transcription factor of IL-25 promoter.

#### Results
Exogenous IL-25 induced expression of type 2 cytokine and alternative activation of Kupffer cell in vivo. It could also promote hepatic macrophages to differentiate into M2a Kupffer cells in vitro. Interestingly, IL-25 recovered the expression of IL-25 mRNA in the liver of NAFLD mice. Furthermore, IL-25 could induce the expression of IL-25 in cultured hepatocytes by activation of STAT6, rather than MZF1, API or NF-κB. STAT6 was sufficient and necessary for IL-25 expression. Deletion and site-directed mutagenesis of the IL-25 promoter revealed that IL-25 transcriptional activation depended primarily on a putative STAT-STAT-binding sequence between nucleotides ~682–~674 upstream of the start site. STAT6 binding to this sequence increased in response to IL-25 treatment in vitro and in vivo. Finally, IL-25 induced M2a Kupffer cells could ameliorate HFD-induced hepatic steatosis by reducing lipotoxicity to hepatocytes. Our results elucidate the molecular mechanisms of IL-25 during amelioration of hepatic steatosis and provide the scientific basis of direct IL-25 treatment or macrophage transfection therapy for NAFLD.

#### Conclusion
Our conclusion elucidate the molecular mechanisms of IL-25 during amelioration of hepatic steatosis and provide the scientific basis of direct IL-25 treatment or macrophage transfection therapy for NAFLD.

### P0016 LONG-TERM BENEFIT OF STATINS USED FOR TREATMENT OF NON-ALCOHOLIC STEATOHEPATITIS (NASH)

#### Aims & Methods
To evaluate if statins independently influence the evolution of fibrosis accompanying NASH using the scales of FibroMax, 120 patients with NASH and metabolic syndrome were followed-up for a period of 3 years. We excluded patients taking a series of drugs, with genetic metabolic disorders or impaired intestinal absorption (celiac disease) or alcoholics. Steatosis, fibrosis...
and NASH were quantified by using the FibroMax scales at baseline and after three years of treatment. Patients were randomized to two groups: the active group of 60 patients receiving low-dose hydrophilic statin (rosuvastatin 5mg/day) and the witness group of 60 patients, matched by age, gender and sex, receiving placebo.

Results: 97% of subjects fulfilled the follow-up period. The FibroMax staging at baseline showed the following results in the active group: S1–29%, S2–41% and S3–30%; F1–50%, F2–30%, F3–13% and F4–7% of patients, respectively. N1–31% and N2–69%. The staging according to FibroTest, SteatoTest and NashTest was similar in placebo group. After 2 years of low-dose hydrophilic statin, the mean ALT level from active group decreased from 72.22±1U/L to 32.80±1U/L, p < 0.05 (t); in the witness group no significant ALT decrease was noticed (69.34±1U/L to 58.17±1U/L, p > 0.5). The FibroMax showed an increased amount of steatosis and fibrosis in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–8%, F3–2%, F4–0% of patients. NashTest also showed a positive evolution under statin treatment compared with placebo (N0–36%, N1–40% respectively N2–26%, p < 0.001, ss) After adjusting for age, BMI, diabetes, LDL-cholesterol and triglyceride levels, statin therapy showed a significant correlation with the steatosis, fibrosis and NASH stages improvement in the active group (r = 0.92, r = 0.87, respectively r = 0.95, p < 0.005, ss).

Conclusion: While statins proved to be safe and efficient for the treatment of NASH in our series, larger cohort studies are needed to further demonstrate this potential positive effect on liver fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0017 THE ROLE OF GENETIC FACTORS IN NON-OBSESE NASH PATIENTS

F. Ates
Gastroenterology, Mersin University, Mersin-Turkey

Contact E-mail Address: drfemehatetes@hotmail.com

Introduction: Methylenetetrahydrofolate deplete reductase (MTHFR) is the key enzyme in homocysteine metabolism. It is thought that MTHFR A1298C and C677T gene polymorphisms contribute to etiopathogenesis of NASH because of their effects in homocysteine metabolism.

Aims & Methods: Our aim in this study is to determine the relationship between the NASH and MTHFR C677T and A1298C gene polymorphisms, especially in non-obese NASH patients.

Results: Eighty-eight NASH patients whose diagnoses were confirmed by liver biopsies and 90 healthy volunteers as control group were included in the study. We investigated MTHFR A1298C and C677T gene polymorphisms and compared NASH patients and controls. NASH patients were assigned to two groups according to whether they are obese.

Results: Eighty-eight NASH patients (52M, 36F, mean age 45 years), and 90 healthy controls (55M, 35F, mean age 41 years) were included in the study. All patients were non-obese and 33 patients were obese. There was no statistically significant different between distribution of MTHFR A1298C polymorphism of NASH patients and controls (p > 0.05). The proportion of TT genotype of MTHFR C677T polymorphism of NASH patients was significantly higher than that of controls (p < 0.01). Also the proportion of TT genotype of MTHFR C677T polymorphism of non-obese NASH patients was significantly higher than that of controls (p < 0.01). However, the proportion of TT genotype of MTHFR C677T polymorphism of obese NASH patients was not significantly different than the control group (p > 0.05). MTHFR C677T CC (wild) genotype was significantly lower in non-obese NASH patients than controls (p < 0.05).

Conclusion: This study revealed that TT genotype of MTHFR C677T polymorphism is more frequent, especially in non-obese NASH patients than in healthy controls. This finding shows that genetic factors are particularly more important in non-obese NASH patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0019 INVESTIGATION OF THE RELATIONSHIP BETWEEN THE THICKNESS OF THE INTIMA-MEDIA COMPLEX OF COMMON CAROTID ARTERIES AND PATHOLOGICAL CHANGES IN THE LIVER IN PATIENTS WITH ABDOMINAL OBESITY AND NON-ALCOHOLIC FATTY LIVER DISEASE

E. Chernetcova, N. Denisov, V. Grivevich, V. Kravchuk, K. Ivashkin, L. Kornouchova

Department of Therapy of Improvement of Doctors, The Federal State Medical Educational Institution of Higher Education, Military Medical Academy nam, Saint-Petersburg/Russian Federation

Contact E-mail Address: katemed@list.ru

Introduction: In the last decade, the notion of non-alcoholic fatty liver disease (NAFLD) has undergone noticeable changes. It is shown that in the liver with fatty hepatitis, insulin and glucose utilization is disrupted, conditions are created for the synthesis of atherogenic fractions of cholesterol and triglycerides. This contributes to the development of violations of carbohydrate and lipid metabolism, the early appearance of atherosclerosis and associated cardiovascular complications. Thus, NAFLD can be considered as an independent, additional risk factor of atherosclerosis. Obviously, it is important to clarify the nature of the relationship between NAFLD and the early manifestations of atherosclerotic vascular wall lesions are relevant.

Aims & Methods: Study of changes in the vascular wall of the common carotid artery (IMT CCA) and in patients with abdominal obesity (AO) and different forms of nonalcoholic fatty liver disease (NAFLD). The study involved 60 patients with AO between the ages of 18 to 59 years (waist circumference >80 cm in women and >94 cm in men) and NAFLD, in the absence of clinical manifestations, provided written informed consent to participate in the study.

All patients underwent an ultrasound examination of the abdominal cavity to determine the size of the liver and signs of steatosis. The level of severity of pathological changes in the liver tissue (fibrosis, steatosis and steatofibrosis) was assessed by non-invasive diagnostic method Steatoscreen. (Biopredictive laboratory, France). Measurement of the CCA IMT was performed according to standard procedures on the machine Voluson 730 Expert, equipped with a linear transducer phased array with a frequency of 7.5 MHz. The presence of early signs of atherosclerosis was defined as a local thickening of the IMT CCA more than 0.9 mm in any point of the carotid artery (CCA IMT max). Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steatofibrosis. Depending on the presence or absence of cytology syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all patients, the levels of CRP and GC were studied. Results: Signs of early atherosclerosis, in the form of the IMT CCA, were detected in the majority of the patients (52%) and differed between the observed groups. The average thickness of the IMT CCA was significantly higher in patients with abdominal obesity (AO) and pathological changes in the liver in the form of severe steatofibrosis on the Steatoscreen scale than in groups of patients with less severe changes in hepatic tissue (0.83 mm for the steatosis group, 0.89 and 0.97mm for fibrosis and steatofibrosis groups respectively, p < 0.001).

Conclusion: NAFLD in patients with AO is characterized by the development of a complex of metabolic disorders associated with vascular thickening and atherosclerosis. This fact can influence the risk of developing the pathology of not only the liver, but also atherosclerosis and proves the need for a more thorough examination of patients with AO and NAFLD for the purpose of early detection and correction of existing metabolic disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

complex and pathological changes in the liver, determined by the test SteatoTone (r = 0.76; p < 0.0001). The dependence obtained is confirmed by the equation of simple linear regression.

**Conclusion:** In patients with AO, there is a direct relationship between the presence of pathological changes in the liver and the initial manifestations of atherosclerosis. The results obtained make it possible to evaluate the individual risk of atherosclerosis in this category of patients. Clinical significance of the results is the need for a more thorough examination of patients with AO and suspicion of liver pathology to assess the development of not only the disease of the liver itself, but also cardiovascular complications.

**Introduction:** Insulin resistance is the main pathogenic determinant of both NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver. The overexpression of hepassocin (HPS) increased hepatic lipid accumulation and NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-induced hepatic steatosis and decreased NAS in mice.

**Aims & Methods:** The aim of this study was to explore the relationship between hepassocin and diabetic patients with or without NAFLD. The study included 80 patients that were divided into 4 groups: Group I: included 20 patients who were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who were diagnosed as non alcoholic fatty liver disease, Group III: included 20 patients who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV (control group): included 20 healthy person who were matched in age and sex with patients group.

**Results:** There was stastically significant decrease in mean value of serum hepassocin of group and IV on comparing with group and II. For group H, there was there was significantly significant increase in mean value of serum hepassocin on comparing with other groups. There was a significant serum hepassocin up regulation in patients with type 2 diabetes and non alcoholic fatty liver diseased patients (Group 3) mostly than diabetic patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

**Conclusion:** The present study provides evidence that overexpression of HPS may facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes mellitus.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Individuals with chronic liver diseases may have a mild to moderate iron overload, but the mechanism is not fully understood. Increased contents of iron have been attributed to the progression of liver cirrhosis caused by HCV infection, alcohol-induced fibrosis, or alcoholic liver disease. Serum ferritin concentration can be increased in iron overload and shows hepatic necroinflammation. Recently, raised serum ferritin concentration was shown to predict mortality in patients awaiting liver transplantation in decompensated liver cirrhosis but according to later studies plasma ferritin levels were used to predict the early mortality of patients with alcoholic liver cirrhosis (ALC).

Aims & Methods: The aim of this study was to determine the association between serum ferritin concentration and the outcomes of patients with ALC. The study included 72 patients with ALC. ALC was confirmed by laboratory tests, clinical features, radiological imaging, and percutaneous or tranjugular liver biopsy. Alcohol liver disease was confirmed when daily consumption of alcohol was > 30 g/day for males/females, respectively, as confirmed by at least 1 family member of affected individual. All patients were divided into three groups by serum ferritin concentration: below 200 μg/l, 200–400 μg/l and above 400 μg/l. Statistical analysis was performed using statistical software SPSS version 21. ROC (Receiver operating characteristic) curve was used to assess serum ferritin specificity in predicting early mortality. If the area under the curve (AUC) is greater than 0.5, the test is specific.

Results: The first group consisted of 44 patients, the second group 13 patients, the third group 15 patients. The average age was 57.5 ± 11.7 years. Serum ferritin concentration in first group was 58.2 ± 45.9 μg/l, second 293.5 ± 63.5 μg/l, third –599.5 ± 221.1 μg/l. AST concentration in first group was 90.8 ± 70.2 IU/l, second –96.7 ± 53.1 IU/l, third –133.8 ± 95.1 IU/l. ALT concentration in first group was 64.5 ± 75.5 IU/l, second – 66.8 ± 111.9 IU/l. Significant correlation between RTN4 and AST (p < 0.0001), L/S ratio (r = 0.54), thrombocytes (r = 0.49), S1 (n = 21, p = 0.0001), second degree of portal hypertension (p < 0.01) was found.

Conclusion: Serum ferritin level above 400 μg/l, elevated liver enzymes and bilirubin concentration shows a poor outcome of patients with ALC (p < 0.0001). Serum ferritin level is a specific factor for predicting early mortality in ALC. Disclosure of Interest: All authors have declared no conflicts of interest.

P0026 PLASMA RETICULON 4 PROTEIN IS ASSOCIATED WITH Portal Hypertension in Patients With Liver Cirrhosis
S. Gelman1, V. Salteniene1, A. Pranculis2, L. Kupcinskas3
1Gastroenterology, Lithuanian University of Health Sciences, Medical Academy, Kaunas/Lithuania

3Gastroenterology, Institute for Digestive Research, Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas/Lithuania

Contact E-mail Address: sigita.gelman@gmail.com

Introduction: Reticulon 4 (RTN4) protein was first described as a potent neurite growth inhibitor in the central nervous system1. However, according to recent research, the protein expression is not limited to the cells of nervous system as it is found in various other tissues, including endothelial cells, fibroblasts, muscle cells, hepatocytes2–5. The diverse location of the protein accounts for various functions such as vascular remodeling, inflammation, and oxidant stress6. The function and expression of the protein in liver disease is still not clear.

Aims & Methods: In this study we aimed to evaluate plasma levels of RTN4 protein in cirrhotic patients and associate them with clinical parameters and portal hypertension. The pilot study included 72 patients with hepatitis C or alcoholic liver cirrhosis and 22 healthy controls. Liver cirrhosis was diagnosed by laboratory tests, radiological imaging and/or liver biopsy. Portal pressure was assessed by hepatic venous pressure gradient (HVPG) measurement. Plasma levels of RTN4 were determined by enzyme-linked immunosorbent assay. Association of RTN4 with biochemical parameters, Child-Turcotte-Pugh and Model of End Stage liver disease (MELD) score, transient elastography values, and histological parameters was analyzed. ROC curve analysis was performed to determine a diagnostic cut-off value of RTN4 in cirrhotic patients and associate them with clinical parameters and portal hypertension.

Results: Plasma RTN4 levels were significantly lower in cirrhotic patients than in healthy controls (p < 0.0001). There was observed significant correlation between RTN4 and Child-Pugh score (r = -0.301; p = 0.015), MELD score (r = -0.311; p = 0.026), transient elastography values (r = -0.331; p = 0.006). There was significant correlation between RTN4 and AST (r = -0.307, p = 0.005), ALP (r = -0.396; p = 0.001). Total bilirubin (r = -0.426; p < 0.0001), thrombocytes (r = 0.534, p < 0.0001), INR (r = 0.357, p = 0.002) concentrations. RTN4 correlated with HVPG (r = -0.298; p = 0.011) and predicted CSIP (p < 0.001) as well as SPH (p < 0.001). Using a RTN 4 cut-off value of ≤1.7 ng/ml, the AUC for...
detection of CSPH was 0.71, with positive predictive value of 75% and negative predictive value of 55% not in SBP/PCA vs. specificity 71%. RTN4 value of \( \leq 1.1 \text{ng/ml} \) was associated with esophageal varices (odds ratio [OR] = 3, 63, \( p = 0.022 \)).

**Conclusion:** Low levels of RTN4 are associated with liver cirrhosis and portal hypertension, with RTN4 correlate with liver function. It may be a surrogate marker of CSPH and presence of esophageal varices.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Peritoneal carcinomatosis (PCA) has a prognostic role in patients with gastrointestinal cancers. Despite the low sensitivity, cytology remains the gold standard in differential diagnosis of PCA to peritonitis (for example spontaneous bacterial peritonitis, SBP) or uncomlicated ascites due to portal hypertension (no SBP/PCA). MicroRNAs (miRNAs) are considered as promising biomarkers and are commonly disregulated in cancer.

**Aims & Methods:** In this proof-of-principle study, we systematically evaluated preanalytical factors and potential of miRNAs as ascites biomarkers. We prospectively examined samples from patients with ascites with benign and malignant conditions including: PCA (n = 15), SBP (n = 15) and portal hypertension (no SBP/PCA, n = 15). Various extraction kits were used to compare the total RNA extraction. Furthermore, we systematically evaluated the influence of storage, stability and sample processing (uncentifuged, pelletted etc.) on miRNA expression in ascites. MiRNA expression profiling using Taqman Low Density Array (TLDA) and quantitative RT-PCR (TaqMan/SYBRgreen) were used to evaluate the expression.

**Results:** Systematic analysis of miRNAs stability confirms that miRNAs in ascites are well preserved from degradation with good short-0 (8h, 12h, 24h, and 48h) and long-term stability (30 C, –80 C for 2 years). Several miRNAs that were selected for the proof-of-principle analysis (miR-21 and miR-16) were reproducibly detectable in ascites samples. MiRNA expression profiling in patients with PCA compared to those with uncomlicated portal hypertension revealed miR-21, miR-16, miR-222 and miR-483-5p to be up-regulated and miR-26b to be down-regulated. MiRNA expression validation confirmed higher expression of miR-21 (mean delta CT \( \pm SD \) = ±11.11 ± 1.2 vs. -8.46 ± 3.46 vs. -9.65 ± 2.55 for no SBP/PCA, PCA and SBP, respectively. ANOVA, \( p = 0.026 \); posttest no SBP/PCA vs. PCA \( p = 0.05 \) and miR-16 in patients with PCA compared to no SBP/PCA groups, while miR-223 was significantly upregulated in SBP (mean \( \pm SD \) = ±12.16 ± 1.56 vs. -10.05 ± 3.19 vs. -6.93 ± 3.56 for no SBP/PCA, PCA and SBP, respectively, ANOVA, \( p < 0.001 \); posttest SBP vs no SBP/PCA and vs. PCA \( p < 0.05 \)).

**Conclusion:** Our data provide novel evidence for the differential expression of miRNAs in ascites in patients with PCA and SBP. Evaluation of ascites-miRNAs may offer an alternative approach for diagnosis of peritoneal carcinomatosis and create an avenue for therapeutic application as well.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**INHIBITION OF CYCLOOXYGENASE-2 AMELIORATES SPLENOMEGALY IN CIRRHOTIC RATS**

Gastroenterology, West China Hospital, Sichuan University, Chengdu/China

**Contact E-mail Address:** 812903560@qq.com

**Introduction:** Splenomegaly is a common finding in liver cirrhosis. However, the precise underlying mechanisms behind this phenomenon have not been elucidated, and its effective therapies are limited.

**Aims & Methods:** We aimed to investigate whether cyclooxygenase-2 (COX-2) is involved as a contributing factor in the pathological process of splenomegaly in cirrhosis. Thirty-six male Sprague-Dawley rats were randomized into 3 groups with 12 rats in each group. The control group received intraperitoneal injection of normal saline (1 ml, twice a week); the TAA group received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA + celecoxib group received TAA intraperitoneally and celecoxib via gastric gavage (20 mg/kg/day). The portal pressure was measured by portal venous catheterization. Sections from paraffin-embedded spleens were stained with hematoxylin and eosin and Sirius Red, and immunostained with VEGF and CD31. The protein expressions of COX-2, VEGF, PI3K, p-AKT, and AKT in the spleen were assessed by Western blot. The enzyme-linked immunosorbent assay was performed to evaluate the expression of TNF-a and IL-1b in the spleen.

**Results:** The ratio of splenic weight to body weight increased by 73.9% in TAA group, while in rats treated with celecoxib, the ratio was significantly reduced. While determined by H&E staining, areas of splenic white pulp in the TAA group enlarged by 27.9%. Yet, compared with that in TAA group, celecoxib obviously decreased the area of splenic white pulp by 77.6%. Besides, the portal pressure elevated by 79.1% in the TAA group; while significant reduction of the portal pressure was observed in the TAA + celecoxib group (by 28.8%). In addition, a considerable amount of collagen was visualized with Sirius Red and immunostained with VEGF and CD31. The protein expressions of COX-2, VEGF, PI3K, p-AKT, and AKT in the spleen were assessed by Western blot. The enzyme-linked immunosorbent assay was performed to evaluate the expression of TNF-a and IL-1b in the spleen.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Reference**

with that of the control group, demonstrating that P3K/AKT signal pathway was involved in the development of pathological angiogenesis. However, the treatment with cexebxox strongly decreased the protein expression of VEGF, CD31, P3K and AKT in the spleen of cirrhotic rats.

**Conclusion:** The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by cexebxox could ameliorate portal hypertension and splenomegaly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with *Escherichia coli* (*E. coli*), *Klebsiella pneumoniae* being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiosis.

**Aims & Methods:** With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SBP were explored. These insights might lead to an initiation of antibiosis on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with *E. coli* with different MOI (MOI 0, 1, 5 and 10) for 2 to 4 hours post confluence. Experiments with heat inactivated *E. coli* were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Occludin, E-cadherin and the p53 family including p53 and p73. These changes were dependent on incubation time and bacterial concentration. Following bacterial infection, marginal to no effects were detected on mRNA levels of cellular junctions and p53. Caco-2 cells displayed less reduction of Occludin and E-cadherin protein levels compared to p53-wildtype HCT-116 cells.

**Conclusion:** By using an *in vitro* model, we demonstrate destabilizing effects of *E. coli* on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent mechanisms to protect bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** reiner.wiest@insel.ch

**Introduction:** Pathological bacterial translocation (BPT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to BPT in LC are among others an increased intestinal epithelial permeability.

**Aims & Methods:** Since mucus represents one of the major components of this barrier we hypothesize that i) gut mucus is altered in LC and ii) bile could be a modulator of its production. Two different models of experimental LC - namely bile duct ligation (BDL) and the chronic treatment with carbon tetrachloride (CCl4) - were used. Fuzzy evaluation and TNF-α, as well as excess synthesis in of ECM components such as COL-1, COL-3, COL-4, fibronectin and elastin, were assessed by using thevidual analysis were performed to analyze changes in mRNA and protein levels of Occludin, E-cadherin, p53 and p73. These changes were dependent on incubation time and bacterial concentration. Following bacterial infection, marginal to no effects were detected on mRNA levels of cellular junctions and p53. Caco-2 cells displayed less reduction of Occludin and E-cadherin protein levels compared to p53-wildtype HCT-116 cells.

**Conclusion:** By using an *in vitro* model, we demonstrate destabilizing effects of *E. coli* on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent mechanisms to protect bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

**Results:** We have observed a significant reduction in mucus thickness in ileum and in the proximal colon (Control 54.38 μm ± 12.51 vs BDL 100.74 μm ± 0.6 in proximal colon) and goblet cell numbers in ileum (Control 0.47 GC/100 μm of villus ± 0.07 vs BDL 0.29 GC/100 μm of villus ± 0.04) of mice following BDL but not PPVL (Control 0.27 GC/100 μm of villus ± 0.11 vs BDL 1.5 μm ± 0.1 in ileum; control 154.38 μm ± 12.51 vs BDL 100.74 μm ± 0.6 in proximal colon) and goblet cell numbers in ileum (Control 0.47 GC/100 μm of villus ± 0.07 vs BDL 0.29 GC/100 μm of villus ± 0.04).

**Conclusion:** All these results suggest that a reduced bile production by the cirrhotic liver and not portal hypertension per se interfere in the goblet cell development and/or maturation. In addition, this effect can be, at least partially, be restored by the FXR agonist OCA. Our study opens the possibility to, so far, unknown effect of bile salts in the intestinal epithelium development in the context of liver cirrhosis being a clear candidate for mucus layer regulation and hence protective effect against bacterial translocation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0033 DIAGNOSIS OF GASTRIC VARICES BY ENDOSCOPIC ULTRASONOGRAPHY USING COLOR DOPPLER**

T. Sato

Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenterology, Sapporo/Japan

**Contact E-mail Address:** taka.sato@ja-hokkaidokoukuseiren.or.jp

**Introduction:** Gastric variceal bleeding is common complication, and it is associated with higher morbidity and mortality rates than hemorrhage from esophageal varices. Oesophagogastroduodenoscopy is usually the initial investigation in the portal hypertension for the purpose of the distinction between gastric varices and gastric folds. The aim of this study was to investigate endoscopic color Doppler ultrasonography (ECDUS) findings of gastric varices.

**Aims & Methods:** Two hundred-fifteen patients with gastric varices were evaluated with ECDUS. To begin with, identification of gastric varices was performed with B-mode scanning and then, color flow mapping was done. On B-mode scanning, submucosal gastric varices, and para-gastric collateral veins were obtained as hypoechoic vessels within gastric wall or in the tissue and spaces exterior to the adventitia of gastric wall. ECDUS provides a color display of blood flow and evaluates the flow pattern using fast Fourier transform (FFT) analysis. FFT analysis can indicate the flow pattern and calculate the velocity of blood flow. We monitored the color flow images of gastric varices, and para-gastric or paragastric collateral veins. Endoscopic findings of gastric varices were evaluated according to the grading system outlined in The General Rules for...

**Results:** The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2 ± 6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7 ± 6.2 cm/s (n = 52), while the mean velocity of elongated tortuous (F2) type gastric varices was 16.7 ± 5.0 cm/s (n = 163). The velocities of F3 type gastric varices were significantly higher than those of F2 type (P < 0.0001). Next, we evaluated the wall thickness of submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6 ± 0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2 ± 0.2 mm (n = 42), while the mean thickness of RC or erosion negative varices was 1.7 ± 0.3 mm (n = 173). The thickness of RC or erosion positive varices was significantly thinner than that of the negative cases (P < 0.0001). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow-up bleeding cases (n = 10), and mean thickness of these bleeding cases were 1.2 ± 0.2 mm.

**Conclusion:** ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Liver cirrhosis and portal hypertension are associated with esophageal varices, gastric varices, small and large intestinal entero- pathies.

**Aims & Methods:** We aimed to study the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. The severity of cirrhosis was classified by the Child-Pugh score. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hypertension complications. Esophageal varices were graded as small, moderate and big varices. Portal hypertension gastropathy was classified as absent or present, and, if present, it was sub-classified as mild or severe. Colonoscopy was done up to the terminal ileum in all patients.

**Results:** Our study included sixty chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis (53.33% females) their mean age (±SD) was 54.75 (±13.13) years. Child-Pugh class was A for 2 (3.3%), B for 33 (55.9%) and C for 24 (40.7%). 53 (88.3%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-band ligation and 5 obliterated varices). Gastric varices were present in 3 patients (5%). Portal hypertension gastropathy was noted in 43 patients (71.0 %) and was mild in 38 and severe in 5 patients. Colonoscopy finding up to the terminal ileum revealed that portal hypertensive colopathy was present in 16 patients (26.7%). portal hypertensive ileopathy was noted only in one case (1.7%). No colonic or ileal varices were noted.

**Conclusion:** Portal hypertensive colopathy but not ileopathy is common in Egyptians with liver cirrhosis. Ileal varices and ileopathy are not common in patients with cirrhosis and PHT.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0035 PREDICTIVE FACTORS FOR THE DEVELOPMENT OF ACUTE-ON-CRCHRONIC LIVER FAILURE IN PATIENTS WITH GASTROINTESTINAL BLEEDING**

C. Cojocaru1, S. Chirica2, A. Trifan2, C. Stanciu3

1Gastroenterology, 2Grigore T. Popa University of Medicine and Pharmacy Iasi, Iasi/Romania; 3University of Medicine and Pharmacy Iasi/Romania

**Contact E-mail Address:** stefanmchiriac@yahoo.com

**Introduction:** Acute-on-chronic liver failure (ACLF) is a specific clinical form of liver failure in patients with liver cirrhosis, referred as acute deterioration of liver function associated with an acute specific complication of liver cirrhosis. ACLF is defined by the presence of renal failure or 2 organ failures according to the European Association for the Study of the Liver-International Chronic Liver Failure consortium: 1) circulatory- need for vasopressor support; 2) renal- serum creatinine value ≥2 mg/dL; 3) cerebral- Grade III or IV hepatic encephalopathy; 4) respiratory- SpO₂/FIO₂ ≤ 214.

**Aims & Methods:** We aimed to identify predictive factors for ACLF development in cirrhotic patients admitted for variceal gastrointestinal bleeding. All patients admitted with variceal bleeding in the Institute of Gastroenterology and Hepatology Iasi (consisting of 8 secondary hepatology centers) between June and December 2016 were evaluated for ACLF (we excluded from the study the patients presenting ACLF diagnosis criteria on admission). We compared cirrho- tic patients who developed ACLF after 12 hours of admission with those who did not.

**Results:** 99 cirrhotic patients with gastrointestinal bleeding were evaluated. 45.5% of patients admitted with variceal bleeding developed ACLF. Demographic data were similar in patients with ACLF vs. no ACLF in age (54.2 ± 7.3 vs. 56.6 ± 9.5 years), male sex (54 vs. 45), and diabetes (56 vs. 43) and significant difference was found in alcohol consumption (72 vs. 27). In patients with ACLF, the grade 1 was the most frequent (56.3%); grade 2 (33.3%) and 3 (10.4%) of ACLF were more rare and no significant differences between the ACLF subgroups was observed. The patients with ACLF were more likely to be admitted with infections and alcohol consumption, when compared to patients without ACLF. Independent predictors for ACLF development included a high admission MELD (P < 0.05), presence of infection and alcohol abuse (p < 0.001), hospitalization in the last 6 months (p < 0.05). Inhospital and 30-day mortality were significantly higher in patients with ACLF (P < 0.0001).

**Conclusion:** Patients admitted with variceal bleeding, with alcohol consumption, high MELD on admission, previous admission in < 6 months are more likely to develop ACLF and need to be monitored closely for the development of ACLF. **Disclosure of Interest:** All authors have declared no conflicts of interest.
HEPTEM 57 (50–59), p = 0.05). This finding, together with a decreased concentration of endothelial-MP carrying TM (TM-MP/L: 232 (190–287) vs 377 (218–493), p = 0.002) and endothelial-PC receptor (EPCR/CD65-E-MP/L: 16 (14–25) vs 37 (24–70), p < 0.001), demonstrated a local greater endothelial damage in cirrhotics.

Conclusion: In cirrhotics, venous hypercoagulability and portal site specific endothelial damage, associated with hampered antithrombotic properties, may be important local risk factors in the pathogenesis of PVT along with the documented venous stasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In clinical trials rifaximin-A (RFX) has been shown to reduce recurrence of episodes of overt hepatic encephalopathy (HE) and HE-related hospitalisations. UK real-world data confirmed reductions in hospital admissions and length of stay with RFX use; however, data on use of emergency department (ED; A&E in UK) resources are still scarce. This study assessed the impact of RFX on utilisation of ED resources.

Aims & Methods: Patients from 11 UK hospitals who were prescribed RFX for HE between July 2008 and May 2014 were included in this retrospective observational study. Patient records were reviewed; details of demographic and clinical characteristics, and all-cause ED attendances and admissions were collected in the 6 and 12 months pre- and post-RFX initiation. The analysis included only patients who were alive at the end of the study periods.

Results: Of the 145 patients included, 114 (79%) were alive at 6 months and 102 (70%) at 12 months post-RFX initiation. At RFX start, mean age was 61 years, 63% were male; 67% had alcohol-related liver disease; for patients with available MELD score (70%), the mean was 16; 78% were on lactulose. Use of ED resources in the 6 and 12 months pre- and post-RFX initiation is shown in Table 1. Six patients developed adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE is well-tolerated and associated with significant reductions in ED attendances, with or without admission, both within 6 and 12 months of RFX initiation.

P0038 PREDICTING FACTORS FOR HOSPITAL READMISSION AFTER THE FIRST EPISODE OF HEPATIC ENCEPHALOPATHY

M. Silva1, A. Peixoto2, H. Cardoso2, S. Lopes2, G. Macedo6
1 Gastroenterology, Hospital Sá Joao, Porto/Portugal
2 Centro Hospitalar Sá Joao, Porto Medical School, Porto/Portugal

Contact E-mail Address: marcopeixoto87@gmail.com

Introduction: Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis, with necessity of hospital admission in many cases. The economic burden of HE is substantial. After ascites, HE is the second most common reason for hospitalization of cirrhotic patients. HE is also the most common, possibly preventable, cause for readmission.

Aims & Methods: We aimed to assess the factors associated with the increased likelihood of hospital readmission for HE after the onset episode.

We completed a retrospective Retrospective analysis of admissions for HE of patients with liver cirrhosis, between October 2010 and October 2015. Only the onset episode was included. Patients were followed for 1 year or until readmission for HE. All patients were discharged under lactulose therapy. Descriptive statistics, uni and multivariate analysis, logistic regression, and ROC curves analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: In this study 119 patients were included: 78% men with a mean age of 59.± 13 years: 8% had hepatocellular carcinoma, and 45% had Child-Pugh C. The most frequent cirrhosis etiologies were alcoholic disease (60%) and HCV infection (12%). The precipitating factors, for the onset episode, more frequently detected were diuretic overdose (36%) and infection (31%). All patients were treated with standard therapy, with an adequate lactulose dose. The readmission rate after the first episode of HE was 72% (75% men). The estimated average time to relapse was 18 weeks. The most frequent causes of readmission were also diuretics overdose (31%) and infection (30%). The patients who were readmitted had a higher MELD score than patients without recurrence (13.9 vs. 11.6 points; p = 0.015). This association was verified in the multivariate analysis (OR = 1.1, p = 0.044).

Conclusion: In this cohort, there was a high rate of readmission for HE after the inaugural episode, which carries a great impact on individual health and high socio-economic costs. A higher MELD score was independently associated with a high probability of readmission for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia and hypoalbuminemia were markers for portal hypertension and hepatic synthetic dysfunction, respectively, have been shown to reduce the likelihood of sustained virological response and to increase the rates of serious adverse events.

Aims & Methods: The aim of this study was to evaluate the impact of thrombocytopenia and hypoalbuminemia on treatment outcome and disease complications. We included in this study 855 HCV-infected cirrhotic patients treated with ombitasvir/paritaprevir/þ-dasabuvir/þ-ribavirin for 12 weeks in 10 university hospitals in Romania. The following groups were studied: 151 patients (17.7%) with albumin <3.5 g/dl, 238 (28%) with thrombocytopenia (a cutoff of 100000/mm² was used) and 71 patients (8.3%) with both hypoalbuminemia and thrombocytopenia. The multivariate analysis showed significant association of hypoalbuminemia with mortality (odds ratio [OR] 1.7; 95% confidence interval [CI] 1.3 to 2.1; P=0.002) and at 30 days post-therapy and complication rate were evaluated using Pearson’s correlation, multivariate analysis and Chi-Square test.

Results: Main patient characteristics were: 100% genotype 1 b, a median age of 60 (27–69), 466 women (54.57%), high rate of previous interferon-based treatment (36.1%). End-of-treatment and sustained virological response rate were both >99% and there was no correlation with the presence of thrombocytopenia or hypoalbuminemia. The rate of adverse events in the whole cohort was 17.5% at 2 weeks reaching 18% at the end of treatment with only 0.8% severe adverse events with no statistical association with the presence of thrombocytopenia and hypoalbuminemia. The multivariate analysis showed significant association of thrombocytopenia (<100000/mm²) with higher (≥1) degree of oesophageal varices (OR 9.5; 95% CI 0.7–135; P=0.011), and prior exposure to interferon based regimens (P=0.025). Low albumin (<3.5 g/dl) also correlated with higher (≥1) degree of oesophageal varices (P<0.001) and onset of upper digestive hemorrhage during treatment (P=0.002).

Conclusion: The efficacy and safety of the ombitasvir/paritaprevir/þ-dasabuvir/þ-ribavirin (as recommended by national regulations) was not different in cirrhotic patients with hypoalbuminemia and thrombocytopenia, but complications rate was higher so close follow-up and proffilactic measures should be recommended, especially if previously exposed to interferon containing regimens.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0040 REAL-WORLD IMPACT OF RIFAXIMIN-A USE IN HEPATIC ENCEPHALOPATHY PATIENTS WITH ADVANCED LIVER DISEASE OR CONTINUED ALCOHOL MISUSE: A POST-HOC ANALYSIS OF THE IMPRESS STUDY
M. Hudson1, P. Di Maggio2, R. Cipiel3, R. Aspinall4
1Freeman Hospital, The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne/United Kingdom
2Uk. Medical, Norgine, Harlefield/United Kingdom
3Ph Associates, Marlow/United Kingdom
4Queen Alexandra Hospital, Portsmouth Hospitals NHS Trust, Portsmouth/United Kingdom

Contact E-mail Address: pdimaggio@norgine.com

Introduction: In the UK multicentre, retrospective, real-world study, IMPRESS, rifaximin-a (RFX) use in patients with hepatic encephalopathy (HE) significantly reduced hospitalisations and length of stay in the 6 and 12 months post-RFX initiation compared to the respective periods pre-RFX initiation. This post-hoc analysis of the IMPRESS data compared hospital resource use pre- and post-RFX initiation in 2 sub-groups of difficult-to-treat HE patients: those with advanced liver disease or continued alcohol misuse.

Aims & Methods: Medical records of patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were retrospectively reviewed; details of demographic and clinical characteristics, and all-cause hospitalisations were collected in the 6 and 12 months pre- and post-RFX initiation. Patients with baseline MELD score ≥15 or not abstinent at the end of the study period were included in this analysis. Statistical significance of the mean change (standard error of the mean, SEM) was calculated using paired t-test or Wilcoxon test.

Results: Only patients alive at the end of the 6 and 12 months RFX-treatment periods were included: 114 and 102, respectively. Amongst these, 33/114 (29%), for the 6 months) and 26/102 (25%, for the 12 months) had baseline MELD ≥15; mean age, 63 years; 70% were male; 66% had alcohol-related liver disease; mean MELD 24. The mean (SEM) number of bed days/patient decreased from 25 (6.0) in the 6 months pre-to 15 (5.5) in the 6 months post-RFX initiation, and from 36 (9.5) in the 12 months pre- to 20 (7.7) in the 12 months post-RFX initiation (p value not significant). At 6 months post-RFX initiation, 15/114 (13%) patients were still actively drinking. At RFX initiation, mean age was 56 years; 73% were male, mean MELD was 19. Despite this, the mean (SEM) number of bed days/patient decreased from 36 (7.9) in the 6 months pre-to 15 (5.4) in the 6 months post-RFX initiation (p=0.048), and the mean of hospitalisations/patient fell from 2.8 (0.5) to 1.2 (0.4) (t-test p=0.059; Wilcoxon test p=0.029). Too few patients with continued alcohol misuse were alive at 12 months to evaluate. Two patients reported adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE for 6 or 12 months suggested trends in reduced hospital length of stay in patients with advanced liver disease and in those with continued alcohol misuse. However, larger studies are needed to strengthen these findings.

P0042 BACTERIAL INFECTION IN PATIENTS WITH DECOMPENESATED CIRRHOSIS - A PREDICTOR OF LONG-TERM MORTALITY INDEPENDENT OF DISEASE SEVERITY
Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: Bacterial infections are common in cirrhotic patients and the pro-inflammatory response superimposed on the hemodynamic dysfunction of portal hypertension predisposes to the development of complications. Some authors suggest that the occurrence of infection should be considered a separate clinical stage, since it alters the natural history of cirrhosis.

Aims & Methods: Retrospective assessment of patients with cirrhosis hospitalized for the first episode of decompensation between 2011-2015. The aim was to evaluate the prognostic significance of bacterial infections regardless of the severity of the underlying liver disease.

Results: Forty-four patients (85% male, mean age 59 years, mean MELD 15, 72% alcoholic cirrhosis) were included with a total of 197 hospitalizations. Hospitals admissions were more frequent due to variceal haemorrhage (42%) and encephalopathy (37%). The incidence of bacterial infection was 25%: 43% respiratory, 31% spontaneous bacterial peritonitis and 24% urinary. Of these, 51% were nosocomial and in 20% an infectious agent was isolated. The survival rates at 30 days, 3 months, 6 months and 1 year were 65%, 55%, 34% and 27% in patients with infection and 97%, 90%, 85% and 78% in those without infection (p<0.001). In the multivariate analysis, survival was independently associated with MELD (ratio hazard at HR 1.073, p=0.012), age (HR 1.032, p=0.012). Bacterial infection remained an independent predictor of mortality, even when excluding patients with in-hospital mortality and all-cause deaths (HR 3.093, p=0.005).

Conclusion: Patients with cirrhosis exposed to a bacterial infection are at increased risk of death. This risk remains in the long term when we exclude patients with in-hospital mortality and at 30 days and regardless of the severity of the underlying disease (MELD).

P0043 A PROPORTIONALLY GREATER ELEVATION IN LIVER TRANSPLANT CANDIDACY IN PATIENTS WITH NAFLD AND PORTAL VEIN THROMBOSIS

M. Basararanolu
Gastroenterology, Bezmi ’Ali Nadir University, Istanbul/Turkey
Contact E-mail Address: metin_basararanolu@yahoo.com

Introduction: NASH progresses to cirrhosis and its complications including hepatocellular carcinoma. It is possible that risk factors for NAFLD-associated cirrhosis are different in Eastern countries than those in the West. Thus, we aimed to document the characteristics of patients with NAFLD-associated cirrhosis from Turkey, a European country sharing 97% of its borders with Asia. Related to other European, the Turkish population exhibits a higher rate of obesity that may be related to that in the Eastern countries.

Aims & Methods: To characterize non-alcoholic fatty liver disease (NAFLD) presentation with esophageal varices. METHODS: We have kept the records of patients at our hepatology unit and affiliated liver center. Data were collected from 2003 to 2014 for esophageal varices at the advanced endoscopy unit. A cohort of patients with esophageal varices from 2003 to 2014 was reviewed. Eligible patients were ≥18 years of age and have had esophageal varices diagnosed by upper gastrointestinal endoscopy examination. They had regular clinical follow-up and endoscopic examinations at our clinic. Efficacy data were based on the last evaluation. Transplanted cases were excluded. The main inclusion criterion was the presence of esophageal varices with or without gastric varices. Only 258 patients with endoscopically defined high-risk varices had reliable data and were included in this study. Each patient was evaluated for fundal varices, PVT, cirrhosis, HCC, and mortality. After the first evaluation, patients were divided into 4 groups: Those with hepatitis B, hepatitis C, NAFLD and others related to autoimmune hepatitis, Wilson Disease, primary biliary cirrhosis, etc.

Results: Primary endpoint of the study was to use this cohort of patients with esophageal varices to evaluate the relationship between this disease and several etiologies, including NAFLD, hepatitis B, hepatitis C or other liver-related diseases. We aimed to draw this conclusion in terms of PVT, HCC, survival and mortality. Of the 258 patients with esophageal varices, NAFLD in 39.0% (101 patients), hepatitis B virus in 29.1% (75 patients) and HCV in 11.2% (29 patients). The mean age of NAFLD was 56.4 ± 16.0 years and 62% of these patients were men. Moreover, 47.5% had PVT, 5.0% had HCC, and 45.5% had fundic varices. The mortality rate was 47.5% during follow-up, but increased to 80% in the presence of HCC. PVT was observed in 47.5% of patients with NAFLD, 29.3% of patients with hepatitis B, 17.2% of patients with hepatitis C, 23.2% of patients with other liver-related diseases (P < 0.001). Of the 111 patients (43%) that died during the study period, 72 patients (64.9%) had no PVT (P = 0.057). HCC was: 5.0% in patients with NAFLD, 26.7% in patients with hepatitis B, 34.5% in patients with hepatitis C, and 5.7% in other diseases (P < 0.001). Of the 38 patients with HCC, 13% had PVT. Moreover, HCC increased the mortality rate in almost all the groups. Of the patients, 50.0% with NAFLD, 33.3% with hepatitis B, 26.3% with hepatitis C, and 58.3% with other diseases were alive at the end of the 5-year period with a significant difference according to the Kaplan-Meier log rank test (P = 0.04). Risk for mortality, measured by risk ratio (RR), did not change per gender (RR: male/ female = 44.8%/28.6%, P = 0.024 in favor of fundic varices development) and RR: 0.05). However, it changed with the existence of fundic varices (RR: 0.49 (95% CI 0.24-0.96)) and in favor of fundic varices development) and RR: 0.0001 in favor of HCC development).

Conclusion: Data revealed a proportionally greater rise in liver transplant candidacy due to NAFLD-associated cirrhosis with portal vein thrombosis. The mortality rate of patients with NAFLD-associated cirrhosis did not differ from that in patients with virally caused cirrhosis. We confirmed that NAFLD was the third leading cause of HCC on the transplantation waiting list. Oldest patients who were responding more cirrhotic HCC and high mortality rate. These findings should constitute a reliable guideline for evaluating patients at the transplant center and for health policy makers to develop better strategic preventive measures against liver diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

This was a retrospective Retrospective study of consecutively evaluated all bacterial infections with confirmed microbiological isolation in patients with decompensated liver cirrhosis admitted to the Gastroenterology ward between January 2009 and May 2016.

Results: There were 308 infections with confirmed microbiological isolates, corresponding to 218 hospitalizations, in a total of 161 patients. The median age of the patients was 63 years (IQR 55–71) and 67% of them were men. Alcoholic liver disease was the major cause of cirrhosis (72%). Among the infections evaluated, 87% were nosocomial and 13% community-acquired. Urinary tract infection was the most common infection (57%). In 27% of patients there were at least two concomitant bacterial infections. Multidrug resistant (MDR) bacteria were isolated in over half of patients. In the multicovariate analysis, prophylaxis for spontaneous bacterial peritonitis (OR 2.3, p = 0.009), MELD score greater than 19 at admission (OR 1.7, p = 0.043), hospitalization in an Intensive/Interimmediate Care in the previous month (OR 2.8, p = 0.001) and antibiotic therapy for infection in the last 6 months (OR 2.4; p = 0.001) were independently associated with MDR infection. From the variables identified in the multivariate analysis, a predictive model of MDR bacterial infection was created. Assuming a sensitivity of 66% and a specificity of 72%, we considered the cut-off of —0.0415 as clinically relevant, regarding likelihood of developing a MDR bacterial infection (AUROC 0.723; 95% CI 0.667–0.780). The occurrence of a MDR infection was associated with a longer duration of hospitalization (p = 0.007). In the multivariate analysis there was no independent association between MDR infection and in-hospital mortality and one month after discharge.

Conclusion: The prevalence of MDR bacterial infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.

Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing of the impact of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients.

Aims & Methods: The aim is to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after 3 months of treatment.

Results: Old chronic hepatitis C patients who were treated achieved primary virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment) with percentage 100% and sustained virological response (end of treatment)

Conclusion: Treatment of chronic hepatitis C in old-aged patients had a significant improvement in work, sleep, rest and recreation and pastimes categories with p-value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and after 3 months of treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Accurate determination of the degree of hepatic-fibrosis is mandatory not only for the diagnosis and prognosis of disease, but also for deciding on the antiviral treatment. Indeed, many studies have been dedicated to the search of non-invasive fibrosis markers capable of providing an accurate information about hepatic fibrosis stage in patients with chronic hepatitis C (CHC). Direct and indirect markers of hepatic fibrosis are useful for prediction of liver cirrhosis but have limited accuracy for the diagnosis of significant fibrosis. Therefore, the development of more advanced scores combining both direct and indirect markers may improve their diagnostic accuracy.

Aims & Methods: This work is concerned with determining the levels of some of fibrosis markers, which are directly involved in deposition and removal of extracellular matrix (ECM), together with other indirect fibrosis markers so as to construct a predictive score capable of identifying the presence of significant fibrosis with a high degree of accuracy. Then, we aimed to estimate its performance against that of the other simple noninvasive tests in chronic hepatitis C patients.

Material and Methods: A total of 148 Egyptian HCV patients were subjected to routine laboratory workup in addition to estimation of serum AFP, hyaluronic acid (HA), platelet-derived growth factor (PDGF), tissue inhibitor of metalloproteinase-1 (TIMP-1) and collagen IV. According to fibroscan, patients were classified into those with non-significant fibrosis (F<2) and significant fibrosis (F2).

Results: Based on univariate analysis, ten variables were significantly higher in patients with significant fibrosis. Patients with F2-F4 had 2.08-fold, 2.14-fold, 1.80-fold and 1.90-fold increase in the concentrations of collagen IV, HA, PDGF and TIMP-1, respectively. Multivariate regression demonstrated that only age, AFP, PDGF, collagen IV and TIMP-1 retained significance. Therefore, a five-marker score named Egypt (EGY) Fibro-mark (FM) was developed. A significant correlation was found between its candidate markers and liver fibrosis progression. AFP was found to have highest correlation (r=0.47, P<0.0001) followed by collagen IV (r=0.46, P<0.0001), age (r=0.43, P<0.0001), TIMP-1 (r=0.40, P<0.0001) and PDGF (r=0.40, P<0.0001). ROC curve was used to estimate and compare the diagnostic accuracy of these candidate variables. As a consequence, these markers were in a decreasing rank: AFP (AUC 0.79), collagen IV (AUC 0.78), age (AUC 0.76), TIMP-1 and PDGF (AUC 0.75). Additionally, Bivariate Spearman’s rank correlation coefficient between EGY-FM and its candidate markers was determined for estimating the magnitude of correlation of each score to hepatic fibrosis progression.

Conclusion: Egypt Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King’s score, APRI, Fibro-score and FibroQ in this group of Egyptian patients.

P0047 EXTRACELLULAR MATRIX PROTEINS CIRCULATING LEVELS SUBSTANTIATE THE EFFECT OF IL-28B RS12979860 T ALLELE ON FIBROSIS STAGE OF CHRONIC HEPATITIS C TYPE 4

Introduction: In patients with chronic hepatitis C, host genetics influence liver fibrosis, particularly modulators in genes controlling the inflammatory and immune response pathways. In this context, interleukin 28B (IL-28B) rs12979860 single-nucleotide polymorphisms (SNP) is considered the most important. Controversial data suggests that IL-28B SNP relate to the severity of hepatic histology. Some studies showed that rs12979860 C allele may be associated with greater hepatic inflammation, higher alanine aminotransferase levels and increased risk of worse clinical outcomes, other studies have not found this association. Furthermore, other studies found that the T allele affects the severity of liver fibrosis and had a mean stage scoring higher than other genotypes. Else, none of the previous studies concerned the association between the IL-28B SNP and signs of fibrosis severity.

Aims & Methods: We aimed to evaluate the cirrhotic development in C/T genotypes using FibroScan, extracellular matrix (ECM) proteins and the model for end-stage liver disease (MELD) in order to resolve conundrum regarding the association between interleukin 28B (IL-28B) rs12979860 and disease severity in chronic hepatitis C (CHC). So, we assessed the allele and genotypic frequencies of IL-28B rs12979860 in 272 HCV-infected Egyptian individuals; investigate serum levels of ECM proteins, including hyaluronic acid (HA), laminin, collagen type IV and the N-terminal pro-peptide of collagen type III (P1P3) as well as its association with liver fibrosis, as assessed by FibroScan, in different IL-28B rs12979860 genotypes. From another view, if C allele has a protective role, we expected the increase in the Fibroscan and extracellular matrix proteins serum levels and increased risk of worse clinical outcomes.

Results: IL-28B rs12979860 CT genotype is the commonest genotype among patients constituting 73% of the studied sample. The CC and TT genotypes constituted 18% and 9% respectively. Liver cirrhosis percentage increased with the increasing number of T alleles as it was 10%, 52% and 96% in CC, CT and TT genotypes, respectively. FibroScan values (kPa) gave a strong positive correlation (r=0.6; P<0.0001) with IL28B polymorphism. Similar to FibroScan, HA, laminin (r=0.3) and P1P3 (r=0.4) serum levels showed significant (P<0.0001) positive associations with IL28B polymorphism. There was stepwise increase in the values of fibroscan and ECM proteins from CC to TT genotypes, so that elevated ECM proteins serum levels were associated with the presence of IL-28B T allele. (Table). In comparison with CC genotype, IL-28B rs12979860 T allele had a significant 2.4-fold increase (in case of CT) and 4.7-fold increase (in case of TT) in Fibroscan score values (kPa). The same was true for ECM proteins serum levels. Interestingly, the characteristics of the cirrhotic patients with TT genotype were completely different from the cirrhotic patients with CT genotype as assessed with FibroScan, ECM proteins and MELD score. Among cirrhotic patients, liver stiffness was 31.13 ± 2.28 kPa in TT genotype vs 20.96 ± 0.74 kPa in CT genotype. MELD was 9.6 ± 0.73 in TT genotype vs 3.9 ± 0.41 in CT genotype and ECM proteins were significantly (P<0.0001) higher in patients with TT than CT genotype. AUC values for FibroScan, HA, laminin, collagen IV and P1P3 serum levels to differentiate CC from other IL-28B genotypes were 0.91, 0.85, 0.84, 0.82 and 0.82, respectively. These values rise to 1.0, 0.97, 0.93, 0.98 and 0.93, respectively, when comparing CC to only TT genotype.

Conclusion: Egy Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King’s score, APRI, Fibro-score and FibroQ in this group of Egyptian patients.
Introduction: Chronic hepatitis C virus (CHCV) patients with persistently normal transaminases represent a category of patients with mild and slowly progressive disease. Proper management of these patients with direct acting antivirals (DAAs) needs to be investigated in real world treatment settings in Egypt to further validate the accumulating data of the achieved high sustained virologic response (SVR) rates with the use of these drugs in clinical trials.

Aims & Methods: We aimed to report the efficacy of 5 different DAAs regimens for treatment of CHCV genotype 4 patients with persistently normal liver enzymes in real-world Egyptian cohort. Data of CHCV genotype 4 patients with normal liver enzymes who started treatment with different DAAs between September and September 2016 in a single specialized viral hepatitis treatment center in Egypt were retrieved. Treatment regimens included: Pegylated interferon alpha 2b/Sofosbuvir/Ribavirin (PEG/SOF/RBV), Sofosbuvir/Daclatasvir (SOF/DCV), Sofosbuvir/Ribavirin (SOF/RBV) and Sofosbuvir/Simeprevir (SOF/SIM). All regimens were given for 12 weeks except SOF/RBV which was given for 24 weeks. HCV RNA was tested at week 4 of treatment, and 12 weeks after treatment cessation to check for SVR 12.

Results: Our cohort included 1149 patients (562 males and 587 females). 158 patients were treatment experienced (13.75%) and 146 patients (12.7%) had liver cirrhosis. Regarding the used treatment regimens; 244 (21%) patients were treated with PEG/SOF/RBV, 382 (33.5%) with SOF/DCV, 152 (13.5%) with SOF/DAC/RBV, 117 (10%) with SOF/RBV and 254 (22%) with SOF/SIM. The overall SVR rate was 97.5% while the SVR rates for different regimens were: 94.7%, 99.7%, 100%, 91.5% and 98% for (PEG/SOF/RBV), (SOF/DCV), (SOF/DAC/RBV), (SOF/RBV) and (SOF/SIM) respectively.

Conclusion: Different DAAs achieved high SVR rates in treating CHCV genotype 4 with normal liver enzymes in a real-world cohort from Egypt. SOF/DCV/RBV combination was the most effective among the studied regimens.

PO050 GENETIC EPIDEMIOLOGY OF HCV INFECTION IN UPPER & LOWER EGYPT: A MULTICENTRE FAMILY-BASED STUDY

M. El-Bendary1, M. Neamatallah1, E. Kamef, H. Elalfy1, T. Besher1, E. Elsayed2, Y. Ellazeik, A. Elmorsy3, M. El-Setouhy4, G. Esmat5, G. mmelbendary@gmail.com

Introduction: Egypt has the highest prevalence of HCV worldwide. Prevalence of HCV was reported to be 13.9% among healthy populations. Adults have higher HCV prevalence (15.7%) than children (4.0%). Geographically, HCV is highly prevalent in the Nile delta (15.8%) than in Upper Egypt (9.0%). The household contacts of HCV seropositive patients had been shown to have a high risk of HCV infection.

Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt. In this Multicentre hospital case control based study a total of 4894 Egyptian individuals were recruited to the hospital from different Egyptian population in Upper & Lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates). The index HCV patients were 1106 cases whereas the families or close household contacts of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders (first and second degree consanguinity, living and sharing usual life activity and having at least 15 years of exposure to the index case). The positive cases (either index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA > 6 months, 2-Adults (above 18 years) of both sexes 3-Age of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC) based on the following criteria: 1) spontaneous ALT normalisation; 2) negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnosis and PCR HCV to confirm HCV infection. Sequencing analysis of the 5’UTR of the HCV was performed using ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were +ve while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among house hold contacts was 17.29% & 19.17% while the SVC was 2.49% & 1.55% in lower & Upper Egypt respectively. When the genotyping of the positive cases were performed it was found that the following pattern was noticed in the upper & lower Egypt respectively: genotype 4a (90.3% & 70.1%), 4m (4.8% & 11.8%), 4n (0.5% & 3.2%) 4o (0.2% & 2.9%) 4i (0.8% & 1.2%) & 1a (2.9% & 8.3%) as shown in the following table.

<table>
<thead>

</tbody>
</table>

Conclusion: The prevalence of HCV was found to be 18.5% among household contacts of Egyptian families. The genotype 4 was predominant in upper Egypt (97.1%) more than lower Egypt (91.7%). On the other hand genotype 1a was higher in lower Egypt (8.3%) more than upper Egypt (2.9%).

PO051 RED BLOOD CELL DISTRIBUTION WIDTH (RDW) AS NON INVASIVE PREDICTOR OF LIVER FIBROSIS IN CHRONIC HEPATITIS C PATIENTS: GENOTYPE 4

M. El-Bendary1, K. Farid1, D. El-Barber2, M. ElNaggar3

1Tropical Medicine And Hepatology, Mansoura Faculty of Medicine- Mansoura University, Mansoura/Egypt
2Genomics and Bioinformatics, Mansoura University, Mansoura/Egypt
3Microbiology Department, Mansoura Faculty of Medicine- Mansoura University, Mansoura/Egypt

Introduction: Red blood cell distribution width (RDW) is a numerical measure of the variability in size of red cell. It reflects variability in the size of circulating red blood cells. RDW can be used as a prognostic marker in heart failure. In hepatic patients it was approved to be an independent predictor of liver fibrosis in patients with chronic HBV infection, and it is higher in patients with alcoholic liver disease and non alcoholic liver cirrhosis. The gold standard for assessing the histological outcome come of liver disease is liver biopsy. This procedure is costly and carries a small risk of complications due to sampling error, invasiveness and requires hospitalization of at least 6-18h. These limitations have stimulated the development of non-invasive techniques for assessing the presence and degree of liver fibrosis. Several laboratory scores composed of routine laboratory markers that are readily available have been proposed for non-invasive prediction of liver fibrosis in chronic hepatitis C (CHC) patients.

Aims & Methods: The aim of this work is to use RDW as a marker for non-invasive prediction of the stage of hepatic fibrosis in patients with chronic hepatitis C genotype4. 100 patients with chronic hepatitis C were subjected to routine laboratory & radiological investigations in addition to using KX-21 Sysmex automated hematology analyzer to measure RDW & RPR (RDW%=Platelet ratio index). Comparing with other parameters liver fibrosis like APRI (AST-to-Platelet ratio index) FIB-4 equation (using platelet count, AST, ALT, age) to perform this test. PCR HCV RNA, genotyping & liver biopsy (using METAVIR scoring system where cases were classified into early fibrosis (F1+F2): 68 patients & late fibrosis (F3+F4): 32 patients were done.

Results: RDW & RPR were significantly higher in patients with late fibrosis > early fibrosis (P < 0.0001) while platelets count was significantly lower in late fibrosis > early fibrosis (p < 0.0001). By applying ROC curve it was found that the cut off value of RDW was 16.5, with sensitivity 86.8% specificity 85.9% & accuracy 86% & the cut off value of the platelets was 196.5 with sensitivity 81.8%, specificity 62.8% accuracy 67%, while RPR cut off value was 0.0897 with sensitivity 90.9%, specificity 85.9% & accuracy 87%. As regard APRI it was found that the cut off value was 0.40 with sensitivity 72.7%, specificity 66.7% & accuracy 68% While FIB-4 equation showed cut off value 1.685 with sensitivity 77.3%, specificity 66.7% and accuracy 69%. In conclusion the area under the ROC curve for. RDW & RPR were excellent but for platelets, APRI & FIB-4 were fair. When applying regression analysis it was found that the RDW (OR:3.903, 95% CI: 1.538–9.904) & Platelets (OR:0.953, 95% CI: 0.913–0.995), so as the level of RDW increase by one unit the risk late fibrosis will increase by 3.9 fold & the other hand when the platelets increase by one unit the risk of late fibrosis will decrease by 0.953.

Conclusion: RDW & RPR may be used as simple, non-invasive predictors of advanced fibrosis in patients with chronic hepatitis C genotype-4.

Contact E-mail Address: e-bun@umin.ac.jp

Introduction: The incidence of liver cancer and its recurrence have been reported frequently at an early stage in patients who underwent interferon (IFN)-free direct-acting antiviral (DAA) therapy [1]. The underlying mechanisms of
cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

**Aims & Methods:** We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as determined by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method and Cox regression analysis. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

**Results:** There was a significant difference in the age and sex of the patients treated with DAs (n = 324, median age: 70, male: 41%) and those treated with IFNs (n = 445, median age: 58, male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 23 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancer cases occurred most frequently in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract/pancreas, lungs, and other organs. The median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0 and 5.0% for the DAA group, and 0.2 and 0.9% for the IFN group, respectively. The difference between the groups was significant (p = 0.02) based on Cox regression analysis using IPTW.

**Table:** Cox regression analysis for cancer incidence other than the liver in IPTW samples

**Conclusion:** Because cancer detection in organs other than the liver can be challenging in management of hepatocellular carcinoma, some cancers found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the post-survey, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Lisboa/Portugal

**Contact E-mail Address:** ebranco,joana@gmail.com

**Introduction:** The impact of the virological cure on the evolution of cirrhosis has been redefined with the introduction of direct-acting antiviral agents (DAA) for HCV. Recently, some papers reported an elevated incidence of recurrence of hepatocellular carcinoma (HCC)[5,6], others a possible rise on the de novo incidence of HCC in the first year after treatment with DAA[5,6,7], but not others[8].

**Aims & Methods:** This is a prospective study of cirrhotic patients treated with DAA between February/2015 and January/2017, under HCC screening with ultrasound and biopsy, according to international guidelines. The main endpoint of the study was to determine the incidence of “de novo” and recurrent HCC. The second endpoint was to search for possible predictive factors associated with the occurrence of HCC. Statistical analysis performed on SPSSv.24.

**Results:** Total 106 cirrhotics (73.5% mean; 34.5± 5.8 years, M/F 72/34, 60% with portal hypertension (n=64) and 22% with decompenesed cirrhosis (n=23, 22 Child-Pugh B)). Two patients with previous HCC, stage Barcelona Clinic Liver Classification (BCLC) A, invasive for loco-regional treatment. The sustained virological response at week 12 was 89.9% (71/79); 4 deaths, 1 relapse, 1 therapeutic failure and 2 losses to follow-up (FU). In 11±4 months of FU, we registered 0 HCC; 4 “de novo” and 1 recurrence, which corresponded to an incidence of 3.8% of “de novo” HCC (13% in decompenesed cirrhosis). The BCLC staging was: 2 stage A, 2 stage B and the one with the recurrence was stage D. A Child-Pugh B class (p=0.004), low platelets level (p=0.001) and hospitalization for decompensation (p=0.005) were associated with the occurrence of HCC; the genotype did not have association. The mean time to HCC development was 7.5 months (2–14).
Conclusion: In this cohort the “de novo” incidence of 3.8% of HCC after the treatment of cirrhosis mainly in patients with decompensated cirrhosis, not eligible for treatment with interferon in the past, and in a short interval of time after treatment. These results alert for an eventual need to increase the frequency of screening in the post-treatment period and carefully evaluate the best timing for liver transplant evaluation. We could not conclude about recurrence due to the small number of patients.

P0055 MiRNA-506 PROMOTES PRIMARY BILIARY CHOLANGITIS-LIKE FEATURES IN CHOLANGIOCYTES AND IMMUNE ACTIVATION

Aim: miRNA-506 is expressed in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

MATERIAL AND METHODS: Aims & Methods: The technical success was 92.4%. Sampling was considered adequate in 92.2% of the cases. Pericupular route included: coagulopathy/anticoagulation (32.2%), thrombophlebitis (31.7%), tumors (9.5%), other (2.5%). Retrograde procedure was used in 79.8%. Sampling was considered adequate in 96.5% of patients. SWE results were reported using three methods: (A) one measurement, (B) the mean of two measurements, (C) three, respectively. Overall, 200 consecutive patients were included. Fibrosis was assessed from 1 to 4 (F1–F4).

RESULTS: In this study, we sought to estimate the most appropriate reporting method for SWE results in practice. Overall, 200 consecutive patients were included. The technical success was 92.4%. Sampling was considered adequate in 96.5% of patients. SWE results were reported using three methods: (A) one measurement, (B) the mean of two measurements, (C) three.

All authors have declared no conflicts of interest.

P0056 CLINICAL EXPERIENCE IN THE USE OF TRANSJUGULAR LIVER BIOPSY WITH TRU-CUT NEEDLE: A RETROSPECTIVE EVALUATION OF 265 CASES

Aim: To evaluate the technical success, diagnostic accuracy, and the impact of the transjugular liver biopsy (TJLB) in patients with chronic hepatitis C infection.

MATERIAL AND METHODS: Aims & Methods: The technical success was 92.4%. Sampling was considered adequate in 96.5% of patients. SWE results were reported using three methods: (A) one measurement, (B) the mean of two measurements, (C) three, respectively. Overall, 200 consecutive patients were included. Fibrosis was assessed from 1 to 4 (F1–F4).

RESULTS: In this study, we sought to estimate the most appropriate reporting method for SWE results in practice. Overall, 200 consecutive patients were included. The technical success was 92.4%. P0057 OPTIMAL NUMBER OF MEASUREMENTS IN REAL-TIME SHEAR WAVE ELASTOGRAPHY TO ASSESS LIVER FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

H. Numako, K. Shimuya, M. Ryoun, S. Igarashi, K. Hasui, K. Kanazawa, M. Murakata, N. Hanabata

Aim: Evaluation of liver stiffness with high diagnostic accuracy, allowing a change in strategy in a high percentage of cases.

MATERIAL AND METHODS: In this study, we sought to estimate the most appropriate reporting method for SWE results in practice. Overall, 200 consecutive patients with hepatitis C virus infection underwent liver biopsy between June 2015 and March 2017 were enrolled. Ten SWE measurements (GE Healthcare, USA) and liver biopsies were performed on the same day. Fibrosis was staged from 1 to 4 (F1–F4).
Area under the curve and receiver operator characteristic (AUROC) compari-
son showed the diagnostic accuracy of the eight methods in the interquar-
tile range (IQR) and median of 10 SWE measurements using body mass
index (BMI) and age were analysed using the Mann-Whitney U test.

Results: The study population consisted of 106 men and 94 women with a mean age of 60.7 ± 13.9 years and a mean BMI of 28.7 ± 5.6 kg/m². F0 was F0/F1/F2/F3/F4 in 70/30/35/32/24 patients, respectively. The median of the 10 SWE (m/s) of 10 measurements in patients with F0, F1, F2, F3, and F4 were 1.33, 1.57, 1.73, 1.95, 1.98, respectively. The median IQR/median was 0.21. Furthermore, we found a significant difference (BMI ≥ 25: 0.24, < 25: 0.20, p = 0.04) and older patients (age ≥ 65: 0.22, < 65: 0.20, p = 0.012) indicated significantly greater IQR/median.

There was no significant difference in the diagnostic accuracy between using the median or mean of three, five, and 10 measurements. The AUROCs to diagnose patients with severe fibrosis (≥F2) ranged from 0.775 (A) to 0.903 (H), respectively. Comparing the AUROC of one measurement to the median or mean of three, five, and 10 measurements using body mass index (BMI) and age were analysed using the Mann-Whitney U test.

No difference was found between reporting mean or median SWE values in each cohort. However, the AUROCs of ten measurements were similar in each cohort.

Conclusion: No differences were found between reporting mean or median SWE values in each cohort. However, the AUROCs of ten measurements were similar in each cohort.

Introduction: To study the effect of NAFLD on the results of shear wave elas-
tography (SWE) in patients with chronic diffuse liver disease.

Aims & Methods: We have performed outcome analysis in 100 patients with liver disease treated from 2015 to 2016. There were 41 male patients (41%), and 59 female patients (59%), age (±) 39 (56), minimal age was 18 years, maximal age was 77 years. All patients were found to have chronic diffuse hepatic diseases and were hospitalized for morphological and elastographic evaluation. All patients had shear wave elastography (SWE) with quantitative measure tissue stiffness, Metavir score staging for received results.

Results: Based on the obtained morphological results, we have formed the fol-
lowing subgroups of patients: F0: F1–31 people, F2: 15 patients, F3–45 patients.

Given that patients with a degree of fibrosis on the scale METAVIR F0 and F1 do not require active conservative therapy, we combined the data of the group into one F0-F1. The obtained results of shear wave elastography are preserved in the form of quantitative variables. Median stiffness with interquar-
tile range (25%-75%) in groups: F0: F1–3, 4 (8, 7, 2) kPa, F2–8, 8 (5, 3, 8, 9)

Kpa, F3–13, 3 (10, 14, 8) kPa and F4–22, 0 (12, 28, 5) kPa. The parameters of liver stiffness (PS) were also significantly greater in patients with F3 and F4 grade fibrosis.

Conclusion: The obtained results of shear wave elastography in patients with chronic liver disease, the absence of correlation with elastometry data.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0060 FEASIBILITY AND REPRODUCIBILITY OF NON-INVASIVE LIVER AND PANCREATIC STIFFNESS ASSESSMENT IN A COHORT OF PATIENTS WITH ALCOHOL-RELATED LIVER DISEASE

C.B. Conti1, N. Weiser2, M. Fracquelli1, G. Casazza2, D. Conte3, M. Colombo3, S. Zuzem2, M. Friedrich-Rust1

Introduction: The estimation of liver stiffness (LS) has recently been evaluated by new elastographic techniques, such as Shear Wave Elastography (SWE), with a potential role in the evaluation of patients with alcoholic liver disease (ALD) by using the elastographic methods. Moreover, exploring the possibility to assess the elasticity of other tissues, few studies evaluated the pancreatic stiffness (PS) by using transabdominal elastographic devices. (2,3), observing that chronic pancreatitis and alcoholic etiology had higher PS values (2).

Aims & Methods: The present study aimed at assessing the feasibility and repro-
ducibility of SHEW at measuring LS and PS in a cohort of patients with alcohol
abuse and known ALD by using the possible correlation between LS and PS with some of the clinical and laboratory data. Over a 6-months period 86 patients undergoing LS and PS measurement by SWE were consecutively enrolled. 66 healthy volunteers (HV) were also examined. SWE was blindly performed by two interventional radiologists, and liver and pancreatic stiffness were performed by a single operator. The comparison of stiffness values between patients and HV was performed. Interobserver agreement for SWE was assessed by intraclass correlation coefficient (ICC). The effect of clinical and imaging data was assessed using linear regression models, with LS or PS as dependent variables.

Results: LS and PS by SWE were obtained in all the patients and HV. No failure was observed. LS and PS were significantly higher in patients than in HV: 22.1 ± 9.5 kPa (95% CI, 16.9–36.2) vs 7.5 ± 4.4 kPa (95% CI 3.1–12.0) for LS and 15.4 ± 7.0 kPa (95% CI 9.9–22.0) vs 12.4 ± 4.0 kPa (95% CI 7.9–16.4) for PS, p < 0.001. ICC for LS was good: 0.96 (95% CI, 0.85–0.99). ICC for PS was fair to good: 0.70 (95% CI, 0.52–0.85).
0.21–0.57). At univariate analysis LS was associated with liver cirrhosis (p < 0.01), while in the multivariate analysis after adjustment for liver cirrhosis, active alcoholic consume (p = 0.015), alcohol consumption/day (p = 0.0134), diabetes (p = 0.0223). At multivariate analysis cirrhosis (p < 0.0001) and steatosis (p = 0.0073) were independently associated with LS. At both univariate and multivariate analysis, PS was significantly correlated only with liver cirrhosis (p = 0.0058).

Conclusion: The present is the first series assessing LS and PS in ALD patients by using SWE. The feasibility of the technique was excellent. The reproducibility was good for LS and fair for PS. SWE was a good predictor of liver fibrosis in the ALD cohort. Liver cirrhosis was the only independent variable correlating with PS, whose estimation could be useful to detect alcohol-related pancreatic damage in patients with severe ALD.

P0061 EXOSOMIC MIR-224 REGULATED TUMOR INVASION AND MIGRATION THROUGH IL-6/STAT3 PATHWAY IN HEPATOCELLULAR CARCINOMA

Aims & Methods: The expression of miR-224, IL-6, and STAT3 was found regulated progression of liver cancer in our previous studies, IL-6/STAT3 pathway play key role, but the precise underlying mechanism remains to be explored. It was found exosomes are the vesicles released by the tumor cells into tumor microenvironment, they are a powerful diagnostic tool due to relative stability and composition covering the whole range of cancer-related biomarkers including proteins, metabolites, DNA, RNA modifications, coding and non-coding RNA. Thus, study the roles of exosomic miRNA could be usefull for therapy and prognosis prediction of hepatocellular carcinomas (HCC).

Results: It was found miR-224, IL-6 and STAT3 were up regulated in the tumor tissues of HCC patients but the SMAD4 showed the down regulated when compared with adjacent tumor tissues. The expression of miR-224 correlated growth, proliferation, migration and invasion capability of HCC cells in vitro. Moreover, the supernatant exosome from HCC cells was isolated and the translocation roles of exosome was studied by confocal. Finally, the expression of miR-224 and genes in STAT3/SMAD4 pathway in the exosome isolated from the supernatant of HCC cells induced by IL-6 were detected.

Conclusion: This study provides the novel mechanism of regulatory roles of miR-224 in HCC, and from the study, exosomic miR-224 showed as the novel target and predictor for HCC prevention and treatment in future clinic.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0062 EXPRESSION ANALYSIS OF LIVER-SPECIFIC CIRCULATING MICRONAS IN HCV-INDUCED HEPATOCELLULAR CARCINOMA IN EGYPTIAN PATIENTS

Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSP (Methylation specific PCR) and BGS (Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was investigated by overexpression or knockdown in HCC cell lines. The effects of MT1G re-expression were also determined by flow cytometry.

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-212 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a (AFP) and des-g-carboxyprothrombin (DCP) were measured using commercial kits.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0063 EPIGENETIC INACTIVATION OF METALLOTHIONEIN IEG IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Introduction: Primary hepatocellular carcinoma (HCC) is one of the most common malignancies all over the world. HCC is associated with poor prognosis. However, the mechanism of HCC initiation and development remains unclear. In our previous work, high-throughput microarray assay in collected clinical HCC samples followed by bioinformatic analysis suggested that Metallothionein IEG (MT1G) might be one of the key factors in HCC. Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSP (Methylation specific PCR) and BGS (Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was investigated by overexpression or knockdown in HCC cell lines. The effects of MT1G re-expression were also determined by flow cytometry.

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-212 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a (AFP) and des-g-carboxyprothrombin (DCP) were measured using commercial kits.

regulated in cancer tissues compared with the adjacent non-tumor tissues (P < 0.05). The expression level of MT1G in the liver cancer tissues was closely correlated to the promoter hypermethylation status. The MT1G expression in silenced HCC cell lines could be restored by demethylating agent. We generated HCC cell lines overexpressed MT1G. Ectopic re-expression of MT1G by stable transfection in SMCC-7721 and HepG2 cells inhibited colony formation (P < 0.001), suppressed cell motility and invasiveness (P < 0.05), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP3 and Vimentin. The in vivo growth of HCC cells in nude mice was also markedly inhibited after a stable expression of MT1G (P < 0.001). MT1G over-expression in HCC cells induced the cell apoptosis (P < 0.01).

Conclusion: Our results demonstrate that MT1G promoter methylated directly mediates the transcription down-regulation and commonly occurs in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, invasion, and induction of cell apoptosis.

Introduction: Hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) may be confused on medical imaging. Both tumours are not connected even though expression is not different, or downstream targets might be influenced. This seemed to account for NTCP (bile salt importer), OATP1B1, OATP1B3, BSEP, CYP7A1, CYP8B1, BAAT, SLC27A5, CYP3A4, CYP2A1 were very strong differently downregulated in HCA, but not in FNH. BAAT was significantly downregulated in HCA. FGFR 4 was heavily downregulated in HCA, but not in FNH. CYP3A4 and CYP2A1 were very strongly downregulated in HCA, but not in FNH. BAAT was significantly downregulated in HCA. MT1G overexpression in HCA cells induced the cell apoptosis (P < 0.01).

Conclusion: Our results demonstrate that MT1G promoter methylated directly mediates the transcription down-regulation and commonly occurs in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, invasion, and induction of cell apoptosis.

P0065 CUX1 CONTROLS ENDOPLOMATIC RETICULUM STRESS AND AUTOPOIETIC-RELATED CELL DEATH

G. Metzger1, P. Di Fazio2, D. Bartisch3, T. M. Gress3, T. T. Wissinowski2

1Department Of Visceral Thoracic And Vascular Surgery, Philipps University Marburg, Marburg/Germany
2Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektiologie, Philipps Universität Marburg, Marburg/Germany

Contact E-mail Address: giulia.metzger@web.de

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze the role exerted by CUX1 during deacetylase inhibitors mediated cell death in liver cancer cells. CUX1, endoplasmic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CUX1 and furthermore treated with deacetylase inhibitors panobinostat, SAHA and trichostatin A. Thapsigargin, an endoplasmic reticulum stress inducer, served as positive control.

Results: CUX1 knock down caused a suppression of ER stress and autophagy markers BIP, CHOP, ATF4, ATF6, Beclin1, MAP1LC3B, UVRAG and TFE2 at early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BIP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CUX1 over-expression after 6 hours of treatment, whereas they show to lose this ability after 24 hours. CUX1 knock-down reduced significantly its protein level after treatment with deacetylase inhibitors. CUX1 knock down counteracts the accumulation of BIP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BIP independently from CUX1.

Conclusion: ER stress and autophagy markers are under the control of CUX1. The cell death induced by deacetylase inhibitors is strictly connected with CUX1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CUX1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0066 CUX1 CONFERRES RESISTANCE TO APOTOTIC CELL DEATH IN LIVER CANCER CELLS

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CUX1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CUX1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL death receptors). The cell death events were analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed. Western blotting was performed for caspase 8 and Fipl detection

Results: Treatment with superkiller TRAIL, at 50 and 100ng/ml, caused cell death in HepG2 and Hep3B cells after 48h proven by an accumulation of 40% of sub-G1 events. CUX1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100ng/ml). CUX1 knock down did not change the expression of TP53, KRT18, CDKN1A and CDKN1B. Interestingly, silencing CUX1 increased the activity of caspase 3/7 after treatment with soluble TRAIL. The effect was neutralized by pan-caspase inhibitor zVAD. Apoptosis array evidenced an increased protein level of un-cleaved caspase 3 after CUX1 knock down. Caspase 8 uncleaved form was down-regulated at protein level after CUX1 knock down and treatment with TRAIL. Its cleaved forms were up-regulated. Fipl decreased in favor of Fipl5 also.

Conclusion: CUX1 mediates the resistance of liver cancer cells to TRAIL signaling. Knock down of CUX1 restores the potential of TRAIL to trigger cell death.

Disclosure of Interest: All authors have declared no conflicts of interest.
Table 1: Results: calibration curve.

- Calibration curves are constructed for each calibrator. The SCC concentrations of patient samples are read from the 405 nm after addition of Stop Solution.

Determination of squamous cell carcinoma antigen (SCC-Ag) Sera from selected patients and controls were used for estimation of SCC-Ag using CanAg SCC EIA. The CanAg SCC EIA is a solid phase, non-competitive immunoassay based on the direct sandwich technique. Calibrators and patient samples are incubated with the target protease.

Recently much attention has been focused on the role of SCCA in HCV cirrhotic patients suggesting that high levels of SCCA can assess HCC development. [5] The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alfa feto protein (AFP).

Aims & Methods: The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alfa feto protein (AFP).

Table 3: Correlation Between AFP and SCCA

Conclusion: In the present study patients with HCC either with or without therapeutic intervention have significantly higher level of AFP in comparison to chronic HCV, cirrhotic and control groups this is in agreement with Awadallah et al.[6] who reported a statistically highly significant elevation in the serum AFP in HCC group when compared with control group. Moreover, the mean serum level of AFP in group A (HCC before intervention) was 263 ng/ml that decreased to 209.4 ng/ml in group B after therapeutic intervention and this agreed with Feng et al.[7] and Molinari et al.[8] Also, at AFP level of 200 ng/ml the sensitivity was 90%, while the specificity was 60%.

Our results showed that SCCA level ranged from 2.5–10 with a mean of 5.53 in HCC patients without interventions, 3.3–7.6 with a mean of 5.3 in patients with HCV and after therapeutic interventions, 1.2–5.6 with a mean of 3.3 in cirrhotic group, 0.6–1.05 with a mean of 0.824 in chronic HCV group while healthy control group had much lower values ranging from 0.3–0.95 with a mean of 0.646. Thus, a highly significant increase in serum SCCA level in patients with HCC before and after therapeutic intervention when compared to cirrhotic, chronic HCV and control groups (P < 0.001). These results were in accordance with Hussein et al. [9] and El Ezawy et al.[10] SCCA was also higher among patients with HCC before intervention compared to patients with HCC after intervention as found by Bin et al.[11]

Applying the ROC curves analysis showed the best cut-off value to differentiate HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielding 80% sensitivity and 90% specificity. These results were in agreement with Trevissi et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion <5 cm in size or 3 lesions <3 cms) so no statistical correlation was done between serum AFP level and tumor size. Our results showed a significant positive correlation between serum SCCA and AFP among patients with HCC before and after therapeutic intervention. Our data are in agreement with that of Hussein et al.[9] and El Ezawy et al.[10] who detected that SCCA were positively significantly correlated with AFP level.

When combined sensitivity of both markers was calculated in our study at the best-cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93%. Matching results were found by Gianluigi et al.[4]

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Hepatocellular carcinoma (HCC) is the first most common primary malignant tumor of the liver, the fifth common cancer and the third most common cause of cancer-related death worldwide. (1) Early detection of HCC provides the best chance for a curative treatment which in turn improves patients survival. However, more than 60% of HCCs are diagnosed at a late stage (2). This could be explained by poor compliance of cirrhotic patients to the surveillance programs and lack of a sensitive and specific tumor marker. Serum AFP – commonly used for HCC diagnosis has a low sensitivity, and specificity for HCC detection (3).

**Aims & Methods:** The aim of this study was to develop Hepatocellular Multidisciplinary clinic – Cairo University (HMC-CU) score and test its accuracy in HCC detection in comparison to the widely used AFP.

In the current study, we reviewed the data of 2363 Egyptian patients with HCV genotype-4 related chronic liver disease CLD; 1291 patients were diagnosed to have HCC while 1072 patients were diagnosed to have HCV related liver cirrhosis with no HCC on top. All the patients were recruited from the HCC multidisciplinary clinic, Cairo University Focal hepatic lesions detected by abdominal ultrasound (US) and/or rising AFP assays were further evaluated by tri-phase multiphase computed tomography (CT) or contrast-enhanced magnetic resonance imaging (MRI). Lesions showing enhancement in the arterial phase were diagnosed as HCC. Diagnosis of HCV related liver cirrhosis was based on clinical, laboratory and imaging evidence of chronic liver disease in addition to detection of HCV antibodies and HCV RNA by PCR technique. Each patient signed an Informed consent and the study was carried out according to the ethical guidelines of 1975 Helsinki Declaration.

**Results:** On bivariate analysis, the HCC patients were significantly older, anemic and showed significant thrombocytopenia, hyper- bilirubinemia, elevated serum AST and AFP serum levels. Serum albumin was significantly lower in HCC patients, consequently, we entered these significant variables in a multivariate regression model that demonstrated that only age, gender, hemoglobin, albumin, AFP and INR were independently associated with HCC development.

**Table:** Multivariate analysis for calculation of the HMC-CU score.

<table>

The best overall formula that could best predict HCC was then constructed: HMC-CU Score = 0.74 x Age + 0.78 x Gender + 0.69 x INR – 1.095 x Alb + 0.022 x AFP + 0.976 x Gender. The diagnostic performance of HMC-CU was then assessed by ROC curve. The area under the ROC curve was 0.997. The cutoff point of 0.56 HMC-CU enabled the discrimination of HCC with 90% sensitivity, 80.6% specificity. AUC was 0.93 and the 95% confidence interval was 0.917–0.94. On comparing the diagnostic performance of HMC-CU to the performance of serum AFP for early diagnosis of HCC, it was found that serum AFP was able to diagnose HCC at cutoff value of 11.9 ng/ml with sensitivity of 68% and specificity 66%. AUC was 0.76 and the 95% confidence interval was 0.74–0.78.

**Conclusion:** The HMC-CU score constructed from routine parameters is accurate in early diagnosis of HCC patients with HCV-related CLD. The advantage of our score is on its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non HCC patients all are Egyptians with a background of HCV type 4 related CLD. A prospective validation study is being planned and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

Introduction: Hepatocellular adenomas (HCA) are rare, benign tumors of pre- sumable epithelial origin, that occur predominantly, but not exclusively, in young women taking oral contraceptives (OC) or using OC medications. The Parisian adenoma tumor markers are a promising method of identifying the high-risk HCA. The Parisian adenoma tumor markers are a promising method of identifying the high-risk HCA of malignant transformation into hepatocellular carcinoma (HCC).

Aims & Methods: Aims: The authors propose to evaluate the demographics, etiology, clinical manifestations and prognosis of HCA. We undertook retrospective analysis of patients with HCA, histologically confirmed by (guided biopsy or surgical resection), between 2008 and 2016, in a tertiary referral centre. When feasible, the subtype classification of HCA proposed by the Parisian group, was performed. Descriptive statistics, univariate and multivariate analysis were performed using IBM SPSS Statistics 22, with p < 0.05 deemed to be statistically significant.

Results: In this study 27 patients were included, 2 men and 25 women, with a median age of 38 ± 11 years, followed for a mean time of 78 ± 36 weeks (lost follow-up in 7 cases). Three cases of hepatic adenomatosis were included. Forty-one percent of the women used OC and 38% of the patients had dyslipidemia. The mean size of the HCA was 70 ± 42 mm; 65% of the patients had abnormal liver tests at diagnosis, 46% were symptomatic and 21% the diagnosis was performed due to ruptured HCA. Surgical resection was performed in 88% of the cases; complete resection was achieved in 75% of the cases. Of the 19 patients who performed abdominal-CT scan or abdominal-MRI before histological confirmation, only 50% had an imagiological diagnosis of HCA. In 12 (44%) cases, immunohistochemical analysis was performed. According to the Bordeaux classification of HCA, 8 (67%) cases were classified as inflammatory, 2 (17%) as HNF-1α-mutated, 1 (8%) as β-catenin mutated and 1 (8%) as unclassified. During follow-up, a hemorrhagic shock related with HCA rupture and in 2 (10%) was necessary surgical revision due to incomplete resection. There were no HCC cases diagnosed during the follow-up. The median size of the HCA that weren’t completely resected and also of those presenting with HCA rupture was significantly higher: (110 vs 55 mm [p = 0.035] and 105 vs 47 mm [p = 0.037]), respectively. The 2 male patients had inflammatory HCA (p = 0.011).

Conclusion: In this cohort, HCA were prevalent in female taking OC and the inflammatory type HCA was the most common. In many cases, abdominal imaging is insufficient for a correct diagnosis, and biopsy specimen or surgical resection should be performed for a correct diagnosis. Lesion size was associated with the risk of rupture and incomplete surgical resection.

Introduction: The standard treatment using transarterial chemo-embolisation (TACE) for patients showing solitary large (>40 mm) hepatocellular carcinoma (HCC) is unsatisfactory with high rate of recurrence. Data from literature suggest the alternative use of thermal ablation.

Aims & Methods: We aimed to evaluate the efficacy and safety of Laser Ablation (LA) in comparison to TACE in patients with large tumor size HCC. Between January 2009 and December 2012, 41 cirrhotic patients (29/12 M/F; median age 72 yrs; range 54-88; Child-Pugh A/B: 18/23) were treated with LA and 24 patients (19/5 M/F; median age 66 yrs, range 40-75) were enrolled in this study. The patients were treated with multifiber technique of LA. The control group consisting of 24 patients (19/5 M/F; mean age 72 yrs, range 49-86; Child-Pugh A/B: 34/1) were treated with TACE. Inclusion criteria were staged according to the BCLC staging system. 11 patients in LA group and 9 patients in TACE group showed a complete response after treatment (p < 0.001). The superior efficacy of LA was confirmed in all categories, also after the stratification of the size of nodule (≥40 mm, ≤50 mm, 40-50 mm, >50 mm). Disease recurrence, during a mean±SD period of follow-up of 37.4±20.7 months, was observed in 13 (24%) LA-treated patients (24%) and in 24 (58.5%) TACE-treated patients (p = 0.00315). Overall survival probability rate at 3 and 5 years was 90.2% and 55.4% in LA group and 85.4 and 48.8. in TACE group.

Conclusion: LA is a more efficacious therapeutic option than TACE in patients with solitary large HCC.

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS- FNA) is one of the alternative methods for tissue sampling of liver solid mass. However, the diagnostic efficacy using cytology alone was limited. Aims & Methods: In this study, we evaluated the feasibility and diagnostic accuracy of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G ProCore needle (PCN) was performed to evaluate the patient with solid liver mass. The primary outcome was the diagnostic accuracy of EUS-FNB for malignancy, and adequacy of the specimen for histology. The secondary outcomes were (1) the proportions of patients in whom immunohistochemical (IHC) stain was possible, and (2) compared diagnostic yield of FNB according to the needle size, and (3) safety of EUS-FNB.

Results: Forty-one patients (13 women; mean age, 67.9±10.3 years [range, 46– 86]) underwent evaluation with EUS and identified hepatic lesions ranging in size from 0.7 cm to 15 cm. EUS-FNB with 20G (n = 10), 22G (n = 24) or 25G PCN (n = 7) was performed (right lobe: n = 10, left lobe: n = 31). The median number of needle passes was 2.4±0.8 (range, 1–5). Technical success rates for tissue acquisition were 97.6%, but both specimen adequacy for histology and available H&E staining (n = 108) was 92.6%. Three (7%) were non-diagnostic (1 was malignant; 2 by smear cytology and 1 after surgical resection). The diagnostic yield, sensitivity and specificity of EUS-FNB for the diagnosis of malignancy were 92.6%, 92.6% and 100%, respectively. The diagnostic yield in 25G PCN and 22G PCN was significantly higher than 20G PCN (p = 0.045). There was one bleeding complication, but controlled with endoscopic hemostasis with endoclips.

Conclusion: EUS-FNB with core biopsy needle may be a safe and useful modality in the management of patients with hepatic solid mass. Moreover, 25G and 22G FNB may be adequate for liver biopsy.

P0073 COMPARISON OF METHODS TO ESTIMATE LIVER FUNCTION IN NEWLY-DIAGNOSED HEPATOCELLULAR CARCINOMA PATIENTS WITH ASCITES

Y. Ko

Internal Medicine, Samsung Medical Center, Seoul/Korea, Republic of Korea

Contact E-mail Address: bs2-32@hanmail.net

Introduction: Liver function is a key element in determining outcome of patients with hepatocellular carcinoma (HCC). For HCC with ascites, estimation of liver function is particularly important, as they already have decreased liver function.

Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly-diagnosed HCC patients with ascites (mean age = 56.0 y, male = 74.8%, hepatitis B virus = 73.2%) were analyzed. We compared Child-Pugh score, Model for End-Stage Liver Disease (MELD) score, mELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival.

Results: During a median 9.0 months of follow-up (range: 0.1-60.8 months), mortality was observed in 79 (17.9%) patients. MELD-Na showed highest time-dependent area under receiver-operating characteristics curves (AUROCs) at 1 year (0.672) that was significantly higher than ALBI grade (0.605), MELD score (0.580), and Child-Pugh score (0.580). The median survival was significantly lower for those with mELD-Na ≥12 than MELD-Na ≥12 (median: 13.6 vs. 37.3 months, p < 0.001). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by radiofrequency ablation (15.7%) and resection (13.4%). Overall survival was significantly different those who received treatment than those who did not (median survival: 13.3 vs. 2.4 months, p < 0.001). When patients were further stratified by mUCC stage and MELD-Na score, treatment was not associated with better outcome for mUCC stage IV patients with MELD-Na ≥12 (median survival: 2.2 vs. 1.8 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups.

Conclusion: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, independently from the stage. Among these patients, MELD-Na showed better performance than MELD, Child-Pugh score and ALBI grade for predicting overall survival.

Introduction: The ideal serological marker in hepatocellular carcinoma (HCC) has not been identified yet since AlphaFetoprotein (AFP) has unsatisfactory characteristics. Squamous Cell Carcinoma Antigen (SCCA) is expressed in tissue and serum samples of HCC patients and when determined immunocomplexed with IgM (SCCA-IgM) has satisfactory diagnostic and prognostic performance.

Aims & Methods: Aim of our study was to evaluate, in HCC patients, the diagnostic and prognostic role of SCCA determination in tissue and in serum samples. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, treatment to response and survival were evaluated.

Results: HCC patients had SCCA-IgM levels significantly higher than cirrhotics (P < 0.0001). Sensitivity, specificity, positive and negative predictive values were 76%, 52%, 60% and 76%, respectively. In comparison, sensitivity and specificity of Alpha-Fetoprotein (AFP), SCCA, SCCA-IgM and SCCA-IgM were 52%, 76%, 99%, and 76%, respectively. In cirrhotics, SCCA-IgM levels were significantly higher than those in HCC patients (p = 0.036 and p = 0.001, respectively). A drop in SCCA-IgM levels after TACE correlated with mRECIST response to treatment. Child-Pugh status was the only independent predictor of survival at Cox multivariate analysis. A better survival trend in HCC with low serum tissue expression was documented (31 vs 24 months, p = ns). No correlation was found between tissue and serum results.

Conclusion: In HCC patients, right before the diagnostic evaluation, SCCA-IgM levels were directly correlated with tumor size and BCLC stage in females and with etiology in males. Conclusion: SCCA-IgM is a sensitive marker of HCC but lacks in specificity. As SCCA-IgM levels were statistically identified as independent predictors of survival, SCCA-IgM levels were directly correlated with tumor size and BCLC stage in females and with etiology in males.

Disclosure: All authors have declared no conflicts of interest.

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients’ survival.

Aims & Methods: We analyzed the region-wide Italian database of Progetto Epatoalcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 regional centers.

Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapy according to BCLC algorithm, while 29.4% underwent different treatments. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP >200 ng/ml, more early stage and monofocal HCC, lower frequency of nodules >2 cm, portal vein thrombosis and metastases were observed. The multivariate analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes B-C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5months, while in patients managed differently was 31.9 months (p < 0.0001).

Conclusion: Adherence to BCLC algorithm in field-practice was high in early and stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required.

P0076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Y. Zhang1, X. Li2, N. Cui3, Y. L. Liu4

1Dept. Of Gastroenterology, Peking University People’s Hospital, Beijing/China
2Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: medicalyuan@qq.com

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common cause are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, et al. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression.

Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People’s Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group...
were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHOQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SPS). The questionnaire scores of the two groups were analyzed.

**Results:** A total of 95 valid questionnaires were collected and divided into cirrhosis group (n = 40) and control group (n = 45). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081, showing no difference from cirrhosis group. WHOQOL includes four domains: physiological domain, psychological domain, social relationship domain, and environment domain. The scores of liver cirrhosis group: physiological field (22.23 ± 3.312), psychological field (19.59 ± 3.925), social relation field (9.64 ± 2.497), environment field (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological field, 19.87 ± 3.152 in psychological field, 10.58 ± 2.061 in social relation field and 28.36 ± 5.091 in environmental field), they had no significant difference between the two groups (P > 0.05). The depression score of liver cirrhosis group (47.86 ± 11.917) was significantly higher than control group (42.61 ± 11.564). Meanwhile, there was no significant difference between the Self-rating Anxiety Scale scores of the cirrhosis group (38.46 ± 11.917) and control group (37.00 ± 12.521) (P > 0.05) (Table 1).

**P0077 THE IMPORTANCE OF INDIVIDUAL CORRECTION OF EATING BEHAVIOR IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE**

Y. Nikiforova

Department For the Study of Diseases of the Liver and Gastrointestinal Tract (from 05.2016 Year - Department Study of Digestive Diseases And Their Comorbidity With Non-communicable Diseases), St.E.T. Mula Therapy Institute of NAMS of Ukraine, Kharkov/Ukraine

Contact E-mail Address: dr.jana@mail.ru

**Introduction:** At the present stage, the treatment of patients with non-alcoholic fatty liver disease has insufficient effectiveness due to the simultaneous availability of a number of recommendations and the lack of an individual approach. Not enough attention is paid to the study of nutritional behavior and the role of nutritions, as additional risk factors for the development of non-alcoholic fatty liver disease. While eating disorders are a modifiable risk factor.

**Aims & Methods:** We aimed to study the dynamics of metabolic parameters in patients with non-alcoholic fatty liver disease (NAFLD) as a result of individual correction of eating behavior (EB).

52 patients (22 men and 30 women) with NAFLD and visceral obesity were examined. All patients studied EB (questionnaire DEBO), physical activity (PHa), were determined: waist circumference (WC), lipid and carbohydrate metabolism studies were performed, a visceral obesity index (VOI) was calculated, the body composition was monitored (determination of visceral adipose tissue (VAT)) and computed tomography of the abdominal cavity (CT AC) with measurement of the area (S, cm2) of VAT and panniculbutton tissue (PAT). Patients were divided into two groups. The control group (n = 40) and experimental group (n = 52) were selected. The patients’ body mass index (BMI) was not different in the two groups, but the depression score was higher in the experimental group (P < 0.05) decrease in VAT/PAT (VAT/PAT = 0.05) was noted to adhere to the recommendations. The percentage of patients improved (p < 0.05) decrease in VAT/PAT (VAT/PAT = 0.05) was noted to adhere to the recommendations. The percentage of patients improved (p < 0.05) decrease in VAT/PAT (VAT/PAT = 0.05) was noted to adhere to the recommendations.

**Conclusion:** Thus, the appointment of an individual correction of eating behavior can increase the adherence of patients to treatment and achieve a reliable positive dynamics of metabolic indicators.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

Introduction: Non-alcoholic fatty liver disease (NAFLD) is liver disease with histological signs of accumulation of cholest erin excessive amount in hepatocyte in the absence of alcohol consumption by the patient (due to causes other than). The search for accessible, non-invasive and effective methods of screening for this pathology, allowing to detect NAFLD at early stages, potentially reversible stages of development is relevant. The purpose of the work was frequency estimation of the prevalence steatosis according to elastometry with controlled attenuation parameter (CAP®) among young people and associated with them specific body composition.

Aims & Methods: 90 volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in research. There were 22 (37.3%) men and 33 (62.7%) women among them without verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the body composition and steatosis and the stage of liver fibrosis was performed with the apparatus FibroScan 502 Touch. The final figures of elasticity of the liver were estimated in kPa (METAIVR). The controlled attenuation parameter (CAP®) in dB/m was used for the severity of steatosis. Moreover, there was the biological impedance analysis of body (BIA), evaluated: body mass index (BMI), body fat.

Results: The signs of violations of the structure of the liver were diagnosed in 15 people out of 59 (25.4%). The signs of steatosis were founded in 12 (20.3%) people. The signs of liver fibrosis were detected in 7 (11.9%) people (E≥5, 5 kPa). At the same time the combination of liver fibrosis and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal in 23 (40.3%); wherein fat body composition above normal values in 19 (33, 4%). Results of binary regression analysis showed that the chance of development of hepatic steatosis in case of excess body weight increase 215 dB/m). The signs of liver fibrosis were detected in 11 patients (19.3%) and unknown CBD stenosis in 31 patients (8.8%).

Conclusion: Based on the results obtained, it can be concluded that there is high enough level of distribution of liver steatosis among young people.Transient elastography (TE) with controlled attenuation parameter (CAP®) is a fast, reliable, repeatable non-invasive method for the assessment of NAFLD. The development of hepatic steatosis among practically healthy young people was reliably associated with the increase the amount of adipose tissue in the body. Confirmed the importance of evaluation of body composition and lack of information of using only BMI when evaluating the chances of development of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: In this systematic review with meta-analysis, alcohol consumption has a dose-dependent negative co-relation with the risk of gallstone disease development.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Introduction: Patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and duct clearance for common bile duct stones (CBDS) should be followed up with an early cholecystectomy to prevent recurrent biliary complications (1, 2) and acute gallstone pancreatitis. Recently the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) recommended that definitive eradication of gallstones by cholecystectomy prevents the risk of a recurrent attack of acute pancreatitis (AP). For patients with an episode of mild acute pancreatitis, early definitive surgery should be undertaken, either during the index admission or within two weeks (3, 4).

Aims & Methods: 1) To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS between 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. All patients were followed up for a minimum period of 2 years following their ERCP.

Results: A total of 273 patients underwent ERCP for CBDS. Out of these 21.2% (n = 58) had previously had CCX and were excluded. Out of the remaining 215 with gall bladder (GB) in situ, 84.7% (188/215) underwent successful duct clearance at index or subsequent ERCP. Of these, 47.3% (89/188) underwent CCX (n = 2/188) patients are currently awaiting CCX and 51.6% (97/188) did not undergo CCX. The outcomes in remaining 13.4% (n = 27) patients whom duct clearance was not achieved are discussed later. In the CCX group, the median time between ERCP/duct clearance and CCX was 123 days (range 0–287 days). In this group, 11 patients had gall stone pancreatitis (GSP) on presentation and the median time between ERCP and CCX in the GSP group was 136 days (range 35–287 days); 12 of these had mild pancreatitis with a median time to CCX of 140 days (range 60–287 days). 4 patients re-presented with CBDS while awaiting CCX after duct clearance; 1 had pancreatitis on readmission. 51.6% (97/188) patients who did not undergo CCX after duct clearance are referred to as non-cholecystectomy (non-CCX) group. This was mainly secondary to high ASA grade. We compared patient demographics and presentation with the CCX group and the results were as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>CCX group (n = 97)</th>
<th>Non-CCX group (n = 90)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Median Age</td>
<td>61 years</td>
<td>79 years</td>
</tr>
<tr>
<td>Median ASA grade</td>

<td>Pancreatitis on presentation</td>
<td>17%</td>
<td>11.4%</td>
</tr>
<tr>
<td>Readmission with CBDS</td>
<td>4.5%</td>
<td>5.4%</td>
</tr>
</tbody>
</table>

In 27 patients duct clearance was not achieved; 26% (7/27) underwent surgical management (CBD exploration on table cholangiogram and CCX). The remaining 74% (20/27) patients were deemed unsuitable for invasive intervention and were either for symptomatic stent change only or conservative management.

Conclusions: The time period between duct clearance and CCX was longer than anticipated, especially in patients with mild acute pancreatitis as none of them underwent CCX during index admission or within 2 weeks of ERCP/duct clearance. Some patients re-presented with CBDS while awaiting CCX. We looked into potential causes of delay in CCX – delayed referral to surgery, long waiting time for elective CCX and patient choice. We propose to develop a local pathway for patients with CBDS and gallstones and institute a robust system for referring patients for CCX following duct clearance. This would help to minimize readmission and potential complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of current study is to develop the multi-layer drug eluting membrane using ultrasonic spray coating method, which have uniform capacity of drug and be able to control the drug-release capacity.

Methods: The drug eluting membrane was made using ultrasonic spray coating machine (MedCoat-2JX). The membrane consists of two kinds of coating material. One is silicone (MED-6640), that was used to basic structure of membrane and the other coating agent is polyurethane (tecofellic, tecothane, Tecoflex and pellethane). The gemcitabine was used as antitumor drug, and coated to membrane by mixed form with polyurethane (gemcitabine, 250ug/ml; polyurethane, 500ug/ml). The thickness of membrane and the capacity of drug in membrane were measured at the proximal and distal end, and mid portion. The drug release capacity and duration was measured by using drug releasing test in vitro for 3 days.

Results: The mean thickness of membrane was 50um. The mean capacity of drug per unit area was 100 ug/cm², and the amount was constant in all tested area (Standard deviation, 5 ug/cm²). In drug release test, the capacity of releasing drug was different depended on the kinds of polyurethane. The total amount of released drug in 24hrs was 919 ug, 836 ug in tecofellic coating, tecothane coating, tecoflex coating, and pellethane coating. The total of released drug amount depended on polyurethane was described in table 1.

<table>

P0087 ADVANCES IN CYTOLOGY FOR THE EARLY DIAGNOSIS OF PANCREATICO-BILIARY MALIGNANCY

C. Meredith, P. Irandoust, P. Baird
1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/ Australia/NSW
2Cytology, Laverty Pathology, Ryde/Australia/NSW

Contact E-mail Address: dcmeredith@gmail.com

Introduction: Liquid-based sample preparations for cytology have improved the cellular yield in pancreatobiliary (PB) malignancy. The SurePath (SP) methodology produces a pellet of concentrated cellular material which enables additional slides for immunohistochemical (IHC) staining for tumour markers Ki67, p53 and C3DX2. The presence of the mitosis-related marker, Ki67, in high concentration in PB tumours with a specific pattern adds a level of confidence in diagnosing malignancy using cytological preparations. The aim of this study was to assess Ki67 staining in biliary epithelium obtained from patients with bile duct obstruction.

Aims & Methods: Brushings were obtained from the common bile duct during endoscopic retrograde cholangiopancreatography (ERCP) in patients presenting with biliary obstruction. After collecting the sample, the brush was placed immediately into a SurePath vial and shaken vigorously to fix and suspend the cells. In the cytopathology laboratory, the vial (with brush included) was agitated on a platform for 10 minutes to shake the cells off the brush into the solution. The high cellular content enabled the preparation of multiple slides for IHC and these slides were reviewed independently by two senior cytopathologists.

Results: Thirty-four (34) consecutive patients with bile duct obstruction were included in the study. The cohort had a mean age of 70.2; 41% were female. Adenocarcinoma was identified in 19 (56%) and atypical/reactive cells in 9 (26%). Ki67 positive nuclei were present in 90-100% of the cells in malignant cell clusters, while sheets of normal cells had positive nuclei in less than 20% of cells. Atypical cells sheets had an intermediate percentage range.

Conclusion: SP is superior to conventional slide-based cytology preparations in the diagnosis of malignant bile duct structures. Advantages include ease of collection, no requirement for a cytology technician, a sizable pellet of intact cells for the cytopathologist to examine and the ability to undertake IHC staining. Ki67 is a marker of cell division and cells stained with Ki67 are increased significantly in adenocarcinoma as confirmed by this study. The presence of a large number of cells stained with Ki67 as well as the pattern of intracellular staining adds a level of confidence for the cytopathologist to diagnose malignancy, particularly when there is no clinical or scan evidence of a tumour mass. Early diagnosis is the key for curative surgery and specific cell tumour markers & or their pattern may impact significantly on the outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0086 THE ANTI-TUMOR EFFECT OF PACLITAXEL, GEMCITABINE AND MITOMYCIN C ELUTING MEMBRANE IN ANIMAL MODEL

J. Park1, D. H. Lee2, S. Jeong1
1Internal Medicine, Inha University School of medicine, Incheon/Korea, Republic of
2Inha University School of medicine, Incheon/Korea, Republic of

Contact E-mail Address: pjshine@naver.com

Introduction: Local treatment of primary bile duct cancer is a challenge and endoscopic stent insertion is widely used to maintain the bile duct patency. Drug eluting stent is currently developed to add the ability of antitumor effect.

Aims & Methods: We aimed to evaluate the antitumor effect of the paclitaxel, gemcitabine, and mitomycin c-eluting polyurethane membrane in a tumor model. Total of 24 mice were used in current study and divided into four groups, each group had six mice. Membranes containing different antitumor drugs (paclitaxel, gemcitabine, mitomycin C, 100ug/disc) were inserted beneath the tumor mass in mouse models. Tumor size and body weight of the tumor model were monitored for 22 days after insertion of the membrane. The results were compared with the tumor model which was inserted only silicone membrane.

Results: Tumor volumes on day 22 of membrane treatment were decreased in all drugs, that were significantly different compared to those of control (paclitaxel, gemcitabine, and mitomycin C, 119.02 mm³, P value ¼ 0.0001; mitomycin C, 119.02 mm³, P value ¼ 0.4116; gemcitabine, 63.38mm³, P value ¼ 0.0001). The thickness of membrane and the capacity of drug in membrane were measured at the proximal and distal end, and mid portion. The drug release capacity and duration was measured by using drug releasing test in vitro for 3 days.

Conclusion: The drug-eluting membrane showed significant antitumor activity. However, the effect was not different according to kinds of the antitumor drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0088 IMPACT OF PALLIATIVE BILIARY DRAINAGE BETWEEN METAL STENT AND PLASTIC STENT ON SURVIVAL RATE IN UNRESECTABLE DISTAL MALIGNANT BILIARY STRICTURE IN SOUTH OF THAILAND

T. Pattarapantakul, B. Ovatlarpon, N. Netinutsanon
Faculty Of Medicine, Prince Of Songkla University, NKC Institute of Gastroenterology and Hepatology, Hatyai/Thailand

Contact E-mail Address: tanawat_kuey@hotmail.com

Introduction: Palliative biliary drainage was used to improving obstructive jaundice, nutritional status, quality of life along with survival rate in unresectable distal malignant biliary stricture patients. The ERCP with biliary drainage with or without systemic chemotherapy are mainstay of treatment in these patients. The benefits of biliary stents were different which are different in cost on survival rate, nutritional status and efficacy of biliary drainage in DMBST patients are still questionable in limit health budget country.

Aims & Methods: We aimed to assess the impact of endoscopic palliative biliary drainage stents on survival rate, nutritional status and efficacy of biliary drainage of patients in distal biliary malignant stricture patients. All of the computerized medical records of distal biliary malignant stricture patients, who were undergoing to endoscopic biliary drainage from January 01, 2012 to December 30, 2015 in Songklanagarind hospital were retrospectively review. ERCP with biliary drainage stents was undertaken at the discretion of attending physicians. The overall survival rate, nutritional status (body weight), efficacy of biliary drainage (level of total bilirubin) after biliary drainage between the metal stent group, plastic stent group and plastic stent followed with metal stent group were compared.

Results: Sixty eight patients (45 males, mean age 63.7 +/- 14.8 years) were enrolled, 35 patients were classified into the plastic stent group, 18 patients were classified into the metal stent group and 15 patients were classified into the plastic stent followed to metal stent group. Demographic data, primary malignancy, tumor staging and ECOG score, initial total bilirubin and stricture length were similar between 3 groups. The median survival time was 5.4 months for 95%CI (3.2-8.5) and overall survival rate was lowest in the metal stent group (median 3.2 months 95%CI 1.8-6.9). Mean weight reduction and the declining of total biliary after biliary drainage were not significantly different between biliary
P0088 PROGNOSTIC VALUE OF EARLY CA19-9 RESPONSE DURING CHEMOTHERAPY IN PATIENTS WITH ADVANCED OR RECURRENT BILIARY TRACT CANCER

Aims & Methods: Between January 2006 and March 2016, a total of 185 advanced or recurrent BTC patients receiving a first line systemic chemotherapy for at least two cycles were retrospectively studied. Serum CA 19-9 was measured at baseline (CA19-9_Pre) and after two cycles of chemotherapy, and patients were categorized into three groups based on CA19-9 response: CA19-9 decrease group (≥30% decrease), stable group (<30% decrease and ≥20% increase) and increase group (≥20% increase). The Cox proportional hazards model was used to analyze the prognostic factors for OS and PFS, using the landmark method.

Results: The primary tumors were located as follows: 68 (37%) in intrahepatic bile duct, 43 (23%) in extrahepatic bile duct, 64 (35%) in gallbladder and 10 (5%) in ampulla. As for chemotherapeutic regimen, single-agent or combination therapy was given in 49 (26%) or 136 (74%), respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median CA 19-9 levels at baseline and after two cycles were 264 IU/mL and 112 (60%), giving response rate of 16% and disease control rate of 76%. The time to treatment failure (TTF) and OS were analyzed for CA19-9 response, and a higher rate of TTF and OS were observed in the decrease group compared to the increase group (p < 0.001). The median OS was 15.2 months in the decrease group and 10.6 months in the increase group (p = 0.01).

Conclusion: CA19-9 response after two cycles of chemotherapy is an independent predictor of OS and PFS in patients with advanced and recurrent BTC on systemic chemotherapy. Disclosure of Interest: All authors have declared no conflicts of interest.

and data on the biliary drainage procedure were collected from medical records. Definitions of failure of drainage or other severe drainage related complications are shown in table 1.

Results: In total, 187 patients were included. Initial drainage was performed in a non-referral center in 125 patients (66.8%). The initial drainage procedure was endoscopic in 158 patients (84.5%) and percutaneous in 29 patients (15.5%). A stent was placed in 91 patients (61.3%) at the initial drainage procedure. The highest bilirubin level in the 2 weeks prior to drainage was 248 (IQR 138-377) μmol/L. Only 14 (8.1%) patients had cholangitis prior to the initial drainage procedure. Failure of drainage or other severe complications related to the initial drainage procedure were noted in 117 (62.6%) patients. Failure of drainage or reintervention was most common and was noted in 85 patients (50.8%). Bile duct injury occurred in 3 (1.6%) patients, acute pancreatitis in 5 (2.7%) patients and cholangitis in 11 (5.9%) patients. Two (1.1%) patients had cardiopulmonary complications and 1 (0.5%) patient had a duodenal perforation. The median period from the initial and second drainage procedure was 13 (5-31) days and the bilirubin level dropped below 50 μmol/L in 27 patients (14.4%). After initial drainage, 20 patients (10.7%) died within 30-days and 66 patients (35.3%) within 90-days. The median OS after initial drainage was 6.6 (95% CI: 2.0-15.2) months.

Conclusion: Patients with unresectable PSC on imaging have a very high failure and complication rate after initial biliary drainage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0091 BRUSH CYTOLOGY GUIDED BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY OF BILIARY STRICTURES

Contact E-mail Address: armandofigp5@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERC) guided brush cytology has become the most widely used method, although with limitations, in the initial diagnostic evaluation of patients with biliary strictures. Aims & Methods: The objective of the study was to evaluate if the systematic use of 10 brush passes improves the diagnostic yield of brush cytology guided by ERCP of bile strictures. ERCPs between 2012 and 2015 involving brush cytology of bile strictures for suspected malignancy were included in the study. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: In total, 62 patients underwent cytology of biliary strictures, with a median age of 69 years (IQ: 55-81). The cytological analysis was compatible with adenocarcinoma in 30.6% of the cases, low grade dysplasia in 3.2%, high grade dysplasia in 1.6% and adenoma in 1.6%. In 26 patients the cytology was negative (41.9%) and in 13 cases it was considered inconclusive (21%). Fifteen patients were subsequently submitted to surgery (24.2%). In 34 cases (54.8%) there was a correlation between the cytology and the final diagnosis. In the univariate analysis, previous history of cholecystectomy (73.7% vs. 26.3%, p = 0.047), cytology suggestive of malignancy/adenocarcinoma (89.5% vs. 10.5%, p < 0.001) and final non-equivocal diagnosis (14.3% vs. 85.7%, p = 0.002) were associated with positive correlation. If the cytology and final diagnosis are coded as "malignant," "benign," or "inconclusive," the correlation increases to 67.7%. In this situation, the univariate analysis showed that the presence of malignancy in cytology (87.5% vs. 10.5%, p = 0.009) and final non-equivocal diagnosis (35.7% vs. 64.3%, p = 0.012) were associated with a positive correlation. If the cases identified as undetermined cytology were excluded, there was no increase in correlation with the final diagnosis (56.5%).

Conclusion: The systematic use of 10 passes in the cytology of the biliary tract modestly increases the accuracy of the detection of malignant versus benign situations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0093 UNILATERAL VERSUS BILATERAL STENT-IN-STENT PLACEMENT OF METAL STENTS FOR MALIGNANT HILAR BILIARY OBSTRUCTION

H. Toyonaga, Y. Taniguchi, T. Inokuma

Contact E-mail Address: toyonaga.pc@gmail.com

Introduction: Endoscopic biliary stenting is widely accepted as effective palliation therapy for unresectable malignant hilar biliary obstruction (MHBO). Although draining more than 50% of liver volume is associated with better outcomes, clinical feasibility and safety are sometimes complicated. Aims & Methods: The aim of this study was to evaluate differences in technical feasibility and clinical efficacy between unilateral and bilateral stent-in-stent (SIS) placement of metal stents for MHBO. We retrospectively reviewed 23 consecutive patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group). In the Uni group, we placed unilateral SEMS. In the Bi group, we placed cross-wired metal stents with the SIS technique. Technical success rates, complication rates and stent patency were compared between groups.

Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups (p = 0.669).

Conclusion: Endoscopic bilateral SIS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0094 CLINICAL ASSESSMENT OF THE SAFETY AND EFFICACY OF A NOVEL BIODEGRADABLE STENT IN PATIENTS WITH BILIARY OBSTRUCTION: A PILOT STUDY

Contact E-mail Address: hairol@gmail.com

Introduction: The commonest indication for biliary stent is for the treatment of obstructive jaundice and for the management of bile leak. The currently available stents are made of either plastic or metal alloy. The stents can be inserted endoscopically to provide internal drainage of the bile into the duodenum. Among the disadvantages of plastic stents are recurrences of jaundice due to biofilms formation, which require a repeat ERCP procedure to remove the stent before 3 months. We have embarked to study the safety and feasibility of a biodegradable plastic stent (BBS), which can treat biliary obstruction without the need to undergo a repeat endoscopic procedure to remove the stents. Aims & Methods: This is a pilot study enrolling 30 subjects with symptomatic jaundice and pruritus caused by either benign or malignant biliary obstructions that were amenable to treatment by ERCP guided stenting. Primary objective was technical success and safety. Procedural and technical successes were assessed during the stenting procedure. Adverse events or complications were monitored throughout the studies. The secondary endpoints were clinical success, which was measured by a reduction of at least 20% of the initial serum bilirubin level at Day 7 post stenting. A simple self-assessment scale from 0 to 10 was used to assess quality of life before and after the stenting.

Results: 30 patients had the Biodegradable Biliary Stent (BBS) implanted. 18 patients (60%) were males, the mean age was 56.9 years. 26 patients (86.7%) had benign biliary duct disease and 4 (13.3%) patients had malignant condition.
9 patients had the fast and medium degradation stents respectively and 12 had the slow degradation stents implanted. All stents were 3-mm in diameter and the length ranges from 60 to 120 mm depending on the level of obstruction. It took an average of 29.6 minutes to complete each procedures, and the mean stent deployment duration was 6.0 minutes. It ranges from 13.5 minutes in the initial phase and improved to 1.5 minutes in the later phase. Biliary sphincterotomy was not necessary for inserting single biodegradable stent, but however, all patients with biliary stone had sphincterotomy to facilitate retrieval of the stones. Serum bilirubin level (SBL) showed reduction of 52% from the mean SBL of 54.9 m mol/L prior to stenting to 26.2 μmol/L at Day 7. Quality of life score improved from 2.0 up to 8.5 after stenting. The BBS ranks high in terms of loadability, track-ability over guide-wire, and pushability with push catheter. There was minimal force required to implant it and it has good visibility by fluorescence. The BBS is as flexible as the conventional plastic stents and can be accurately deployed under fluoroscopy. Technical success or completion of the ERCP and stent deployment was achieved in all 30 patients.

Conclusion: This pilot study has shown encouraging results. It benefit the patient to avoid the burden of a second ERCP procedure for plastic stent removal. However, these results should be interpreted with caution as this is a pilot study to assess the safety and efficacy of the biodegradable stent on limited number of volunteers with symptomatic jaundice. We plan to conduct a phase 2 study involving a larger number of cohorts with a more specific indication of benign and malignant biliary stenosis.

Disclosure of Interest: H. Othman: The Biodegradable Biliary Stents used for this study is sponsored by ang International GmbH, Winsen, Germany. The authors have no financial relationship with the company which could inappropriate influence or bias the content of this presentation.

All other authors have declared no conflicts of interest.

P0095 TOLL-LIKE RECEPTOR 5 IS ESSENTIAL FOR THE ACTIVATION OF LIVER AND PANCREATIC STELLATE CELLS
L. T. Bühm1, D. Bartsch1, T. M. Gross3, M. Buchholz2, T. T. Wisniewski2, P. Di Fazio3

3Contact E-mail Address: alexander.kleger@uni-ulm.de

Introduction: Stellate cells contribute significantly to the development of several diseases. In particular, liver stellate cells are responsible for liver fibrogenesis and further for cirrhosis that culminates into cancer development eventually. In pancreas, it is known that stellate cells sustain the tumor cells via autophagy mechanisms.

Aims & Methods: This study aimed to clarify the involvement of Toll-like receptor 5 (TLR5) in the activation of human stellate cells. LX2 liver stellate cells and HPSC (human pancreatic stellate cells) were treated for 48 hours with 2.5 ng/ml TGF-beta 1 and TLR5 deficient PDEC were used for intracellular Ca²⁺ measurements. Mitochondrial membrane potential (ΔΨm) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

Results: The plateau phase of the agonist-induced Ca²⁺ signal was elevated in TLR5-deficient PDC, which was caused by decreased function of the plasma membrane Ca²⁺-pump (PMCA). The functional inhibition of TLR5 had no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24h treatment of the CF organoids with VX-809 have restored the PMCA function to the control level. Similarly native CFPAC-1 cells and PDEC treated with siRNA to inhibit the expression of CFTR showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained (Ca²⁺) levels decreased ΔΨm and induced cytotoxic α release in CFPAC KO PDEC without significant alterations in mitochondrial morphology.

Conclusion: Dysfunction of PMCA leads to disturbed Ca²⁺ homeostasis in CFTR-deficient PDC and the consequent cellular Ca²⁺ overload impairs mitochondrial function contributing to the pancreatic damage in CF.

Disclose of Interest: All authors have declared no conflicts of interest.
changes in more detail and genome wide expression profiling helped us to under-
stand the role of Eppin in more detail.

Conclusion: Thus, we report a novel signalling molecule playing a critical role
during human pancreas development based on a pluripotent stem cell differen-
tiation platform.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0098 MELATONIN METABOLITE; N1-ACETYL-N2-FORMYL-5-
METHOXYKYNURAMINE STIMULATES PANCREATIC ENZYME
SECRETION VIA CCK RELEASE. STUDY ON THE RATS

J.M. Jaworek
Dept. Of Medical Physiology, Jagiellonian University CM, Krakow/Poland

Contact E-mail Address: jolanta.jaworek@uj.edu.pl

Introduction: N-acetyl-N2-formyl-5-methoxykynuramine (AFMK), melatonin
metabolite, was demonstrated recently as a potent pancreatic secretagogue for
against acute inflammation. AFMK significantly attenuated acute pancreatitis;
however, its effect on pancreatic exocrine function has not been investigated yet.

Aims & Methods: 1. To investigate the effects of intraduodenal (i.d.) application of
AFMK on pancreatic enzyme secretion under basal conditions and following the
stimulation of this secretion with diversion of pancreatic-biliary juice (DPBJ) and
to examine the role of CCK in this process. 2. To assess the effect of AFMK on
CCK receptor in pancreatic acinar cell line AR42J. Material and methods: For in vivo study Wistar rats weighing 300 g were employed. Under pentobarbi-
tane anesthesia the animals were surgically equipped with silicone catheters, inserted into pancreatic-biliary duct, and into duodenum. AFMK (5.10 mg/kg i.d.) was given to the rats under basal conditions or following stimulation of pancreatic secretion with DPBJ. Lorglumide, the CCK1 receptor antagonist (1 mg/kg i.d.) was administered 15 minutes prior to the application of AFMK. Samples of pancreatic-biliary juice were collected to measure the amylase outputs. The blood samples were taken for determination of CCK by ELISA kit. For in vitro study acinar cells AR42J were incubated in presence of AFMK alone or in combination with CCK. The protein signal of CCK receptor was determined by Western blot.

Results: AFMK given i.d. produced the dose-dependent increases of pancreatic
amylase outputs both; unstimulated, as well as that induced by DPBJ. The rises of pancreatic amylase outputs were accompanied by significant increase of CCK plasma levels. Administration of lorglumide, a CCK1 receptor blocker, comple-
tely abolished the stimulation of pancreatic exocrine function induced by
AFMK. This melatonin metabolite failed to affects protein signal for CCK recep-
tor in AR42J cells.

Conclusion: The stimulatory effect of AFMK on pancreatic enzyme secretion in
the rats is indirect and dependent on the release of CCK by this melatonin
metabolite.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0100 INVESTIGATION OF THE PANCREATIC DUCTAL ION
SECRETION IN PANCREATIC DUCTAL ORGANOID CULTURES

Introduction: Pancreatic ductal fluid and HCO3- secretion are crucially impor-
tant in the physiology and pathophysiology of the exocrine pancreas. However,
the role of human pancreatic secretory processes is great challenge due to the
limited access to human pancreatic ductal cells. The recently developed three-
dimensional pancreatic organoid cultures (OC) may help to overcome this lim-
itation. However, the ion secretory processes in pancreatic OC is not known.

Aims & Methods: Our aim was to characterize the ion transport processes in
mouse pancreatic OCs. Mouse pancreatic ductal fragments were isolated by
enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a
week in OC medium. Changes of the intracellular pH was measured to characterize
the ion transporter activities of the epithelial cells in OC.

Results: Basolateral administration of 20 mM NH4Cl in standard HEPES or
CO2/HCO3- buffered solution resulted in rapid intracellular alkalization,
highly dependent on the Na+/H+ exchange. Removal of NH4Cl induced rapid
carbonic acidification followed by regeneration to the resting pH levels. The regeneration
phase was inhibited by the removal of extracellular Na+. The administration of
10 mM CFTRinh172, a selective inhibitor of cystic fibrosis transmembrane con-
ductor regulator decreased the regeneration from alkali load. Basolateral
administration of 20 mM amiloride and 20 mM H2DIDS decreased the intracel-
ular pH suggesting the activity of Na+/H+ exchanger and Na+/HCO3- cotran-
sporter on the basolateral membrane.

Conclusion: The ion transport activities in mouse OC are similar to those
observed in freshly isolated primary tissue. This suggest that OC will be suitable
to study human ductal epithelial ion transport.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0101 INVESTIGATION OF THE ORAI1 MEDIATED CA2+ ENTRY
IN MOUSE PANCREATIC DUCTAL CELLS

M. Görög1, A. Grassalkovich1, A. Balázs1, P. Pallagi1, P. Hegyi1, J. Maleth1

Introduction: Acute pancreatitis (AP) is the most common inflammatory disorder
in the gastrointestinal tract with an overall mortality of 20–30% in severe cases.
The treatment of AP is not resolved yet, urging the identification of novel drug
targets. Toxic cellular Ca2+ overload was highlighted as a key event in pancreatic
acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition
of Orai1 in pancreatic acinar cells markedly decreased the Ca2+ toxicity and the
severity of AP. However, We have no information regarding the role of Orai1
in pancreatic ductal physiology or pathophysiology.

Aims & Methods: Wild type FVB/N mice were used for the isolation of pancreatic
ductal fragments. The intracellular pH and Ca2+ level of the pancreatic ductal
cells (PDC) were measured by microfluorimetry. The effect of selective Orai1
inhibitors provided by CalciMedica was evaluated.

Results: The tested compounds dose-dependently inhibited Ca2+ influx during
the carbachol induced Ca2+ signal in PDC. Inhibition was complete at a con-
centration of 10 μM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reti-
culum Ca2+ stores were depleted with cyclopiazonic acid and the inhibition of
store-operated Ca2+ entry (SOCE) was investigated after the re-addition of
extracellular Ca2+. Under these conditions CM-B and CM-C significantly, but not
different, completely decreased SOCE in PDC (55.96% and 55.03% respectively).
The removal of extracellular Na+ to abolish activity of the Na+/Ca2+ exchanger
had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed that
the inhibition of Orai1 has no effect on the basal secretion of HCO3- by
PDC, which is the main physiological function of these cells.

Conclusion: We showed that Orai1 has a significant role in the Ca2+ signaling of
PDC. In the next step we will evaluate the pathophysiologic relevance of the
channel.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0102 ACUTE PANCREATITIS OF UNKNOWN ORIGIN AND
IDIOPATHIC JUVENILE PANCREATITIS IN SWEDEN

M. Vajasinoski1, F. Lindgren2, S. Haas1, R. Valentie1, S. Ghazi1, N. Kartalis1,
R. Pozzi2, M. Del Chiari3, P. Bauer4, C. Verbeke2, H. Witt1, U. Arnelo1, J-
Löhr2
1Center For Digestive Diseases, Karolinska University Hospital, Stockholm/ Sweden
Acute pancreatitis (AP) is among the most difficult diseases faced by gastroenterologists and surgeons. In some cases it is difficult to understand etiology of AP. Hereditary pancreatitis (HP) is an autosomal dominant genetic disorder characterized by recurrent attacks of acute pancreatitis.

**Aims & Methods:** We analyzed medical records of patients who were diagnosed with juvenile pancreatitis and pancreatitis of unknown etiology (PUE) at the Center for Digestive Diseases at Karolinska University Hospital from January 2008 to December 2016.

**Results:** During the observation period, 44 patients (17 male and 27 females) were registered with the ICD code chronic or relapsing pancreatitis, and onset of symptoms before the age of twenty. At time of first visit, the mean age was 36.7±26.9 years, range 24–75. The average period between the occurrence of first symptoms and diagnosis was 14.0 years (range 1–39 years). All patients (100%) clinically presented with recurrent acute pancreatitis. There were 28 (63.7%) patients with genetic mutations. Five out of 28 genetic positive patients (17.9%) had a definitive diagnosis of genetic etiology of pancreatitis. Seven out of 28 genetic positive patients (25%) had complications in five patients endoscopic treatment due to pancreatic duct stenosis was performed; one patient had pancreatic and bile duct stenosis and one patient, female, age 28, CFFTR heterozygous mutation) a pancreatic tumor (mucinous cystadenoma with high dysplasia that was successfully surgically treated with R0 resection). One patient died due to non-pancreatic related disease (kidney cancer). None of the patients reported alcohol overconsumption. Four out of 28 genetic positive patients (14.3%) were active smokers. Fecal elastase-1 (FE-1) was tested in 28 (63.6%) patients: 16 (57.1%) in genetic positive and 12 (75%) in genetic negative group of patients. Pancreatic exocrine insufficiency (PEI) was found in 5 out of 12 (41.7%) of genetic negative patients and in 5 out of 16 (31.2%) genetic positive patients. Average age at onset of PEI was 38 years (range 27–53). Diabetes mellitus (DM) was diagnosed in one patient in group with genetic alterations and 2 patients in group without genetic alterations.

**Conclusion:** We found high proportion of genetic alterations in patients with juvenile pancreatitis and PUE. In patients in whom pancreatitis remains unexplained after including of the most often etiologies and presence of genetic alteration, hereditary pancreatitis seems as reasonable explanation even in patients with mutations other than PRSS1. Routine follow-up of patients with regular testing on pancreatic exocrine insufficiency and diabetes mellitus and pancreatic cancer surveillance is necessary.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** aries224sin@gmail.com

**Introduction:** Severe acute pancreatitis has high mortality and needs intensive care. However it is difficult to stratify the severity of acute pancreatitis in early stage because revised Atlanta classification requires persistent organ failure lasting at least 48 hours.

**Aims & Methods:** We searched factors to predict hospital mortality in early stage of severe acute pancreatitis. This was a retrospective cohort study of all consecutive patients with severe acute pancreatitis who admitted at 44 institutions between June 1, 2009 and December 31, 2013. We evaluated ten factors which associated with mortality in previous study.

**Results:** The mortality was 12.7% (142/1114 patients). All ten factors were associated with mortality in univariable analysis. In multivariable analysis, four factors: namely "partial pressure of oxygen in blood <60 mmHg (room air) or mechanical ventilation", "age ≥70 years", "blood urea nitrogen ≥40 mg/dL (or creatinine ≥2.0 mg/dL) or oliguria (daily urine output <400 mL even after acute intravenous fluid volume expansion)" and "lactate dehydrogenase ≥2 times upper limit of the normal range" were associated with mortality. The other factors, namely "base excess ≤-3.5 meQ/L", "platelet count ≤100,000/mm³", "serum calcium ≤3.5 mg/dL", "c-reactive protein ≥15 mg/dL", "number of positive measures in systemic inflammatory response syndrome criteria ≥3" and "computed tomography grade" were not associated with mortality.

**Conclusion:** Advanced age, respiratory failure, renal failure and high lactate dehydrogenase could predict mortality in early stage of severe acute pancreatitis. In patients with these factors require transport to a hospital with intensive care unit.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0104 EARLY OR LATE CHOLECYSTECTOMY IN MILD GALLSTONE PANCREATITIS? RESULTS FROM RANDOMIZED TRIAL**

**R. Noël1, U. Arnelo1, L. Enochsson2, G. Sandblom1**

*1Department Of Clinical Science, Intervention And Technology, Karolinska Institute, Stockholm/Sweden*  
*2Department Of Surgical And Perioperative Sciences, Umeå University, Division of Surgery, Luleå/Sweden*

**Contact E-mail Address:** rozh.noel@slu.se

**Introduction:** Cholecystectomy during the index admission may reduce risk of recurrent biliary events but concerns have been raised about complications if surgery is performed to early. The objectives of this study were to compare gallstone- and cholecystectomy-related complications and patient reported quality-of-life and pain during cholecystectomy requiring ERC (23.3% vs. 10.7%, P=0.30). There was no difference in pain measure between the groups at randomization and follow-up.

**Conclusion:** Delaying cholecystectomy in mild gallstone pancreatitis is associated with increased risk for recurrent gallstone-related events. Cholecystectomy performed at the index admission is safe and feasible.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0105 COMPARISON OF PREDICTIVE SYSTEMS TO PREDICT MORTALITY IN SEVERE AND MILD ACUTE PANCREATITIS: ACCORDING TO THE REVISED ATLANTA CLASSIFICATION**

*Aparato Digestivo, Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain*

**Contact E-mail Address:** ruben.pique@salud.madrid.org

**Introduction:** The course of acute pancreatitis (AP) ranges from life threatening to mild disease, so accurately predicting its outcome is important. The revised Atlanta classification breaks the mild/severe dichotomy, so the absence of predictors of severity does not preclude a mild course. Studies designed according to the new classification evaluating existing predictors are still scarce.

**Aims & Methods:** Our study aims at evaluating the diagnostic accuracy of easily available prognostic scores to predict mortality, persistent organ failure (severe AP) and mild AP. We analyzed a single-center retrospective cohort including all adult patients admitted between 2010 and 2015. Patients with a previous episode of AP in the six months before admission, with other primary diagnosis at discharge and those partially attended at other institutions were excluded. Severity and local complications were defined according to the 2012 Atlanta classification. Four different scores (BISP, SIRS, APACHE II and HAPs) and the following predictors: C reactive protein (CRP) at 24 h, hemocrit or BUN at admission.
and their evolution after 24 h were evaluated. Accuracy was measured using discriminative operating characteristic (ROC) analyses.

Results: Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.1–72.7), 57.4% males. Most frequent comorbidities were: diabetes (32.8%), hypertension (36.6%) and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 8.7% and pseudocyst in 16.1%. There were 42 (6.6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1.5–3.9%), 35.7% (23–50.8%) among severe cases. BUN at admission AUC: 0.88 [0.85–0.90], BISAP score (AUC: 0.88 [0.85–0.90]) and APACHE II (AUC: 0.87 [0.83–0.90]) were the two other most powerful predictors of mortality. APACHE II presented the highest sensitivity, 100% (81.6–100%), while the BISAP score presented the highest specificity, 93.1% (90.6–94.8%). BUN at admission (AUC: 0.89 [0.86–0.91]) and the BISAP score (AUC: 0.87 [0.84–0.89]) also presented the best predictive power with a Youden index of 0.91. The BISAP score identified the highest risk of death with a sensitivity of 94.2% (92.2–95.8%), although with a low PPV, 32.1% (21.4–45.2%). On the other hand, diagnostic accuracy for mild AP was poor, as all predictors presented an AUC < 0.7. The HAPS score reached the highest specificity, 87.8% (83.9–91.4%), but presented a very poor sensitivity (28.9% [24.3–33.9%]).

Conclusion: The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 0.9. New scores are needed to predict a mild course, as none of the available indexes presented an AUC > 0.7.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0106 PANCREATIC DUCT ASCARIASIS

P. Somani, M. Sharma
Department Of Gastroenterology, Jaswant Rai Speciality Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Although uncommon in the West, Ascaris lumbricoides is a common cause of acute pancreatitis in developing countries. The mechanism of acute pancreatitis in ascariasis may be due to obstruction of papilla of Vater, invasion of common bile duct (CBD), or pancreatic duct (PD) leading to ductal obstruction. Our aim is to review pancreatic ascariasis.

Methods: A retrospective study of last 10 years of 15 cases of pancreatic ascariasis. The probable reasons are excellent imaging of pancreas by EUS, which can aid in early diagnosis due to its high sensitivity and specificity.

Results: We present our retrospective data of last 10 years of 15 cases of pancreatic ascariasis.

Conclusion: EUS should be used early in the work-up of IAP after the first episode. We consider EUS a standard for diagnosis of biliary ascariasis, should be reserved for therapeutic rather than diagnostic use as papillotomy can lead to reentry of the worm into the common bile duct. EUS should be used early in the work-up of IAP after the first episode. We present our retrospective data of last 10 years of 15 cases of pancreatic ascariasis. 2 patients were managed conservatively with repeat USG showing slow resolution of symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The severity of acute pancreatitis varies widely, from a mild self-limited disease to one with a severe clinical course complicated by multiple organ dysfunction syndrome. No pharmacologic therapy has been shown to improve the prognosis of patients with severe acute pancreatitis, while the quality of supportive care including early fluid resuscitation is critically important. Fluid resuscitation maintains adequate intravascular volume by compensating for fluid shifts to the third space. However, there is lack of consensus regarding the details of optimal fluid administration such as the type of fluid, infusion rate and volume of administration, and the physiologic goals of fluid resuscitation.

Aims & Methods: The aim of this study is to evaluate the association between the type and volume of fluid administration and the occurrence of severe acute pancreatitis. We conducted a secondary analysis of data from a multi-centre retrospective study of patients with severe acute pancreatitis in Japan, which was registered with the University Hospital Medical Information Network Clinical Trials Registry (Registry number 00012220) and approved by the Institutional Review Board or the Medical Ethics Committee at each institution. The diagnosis of severe acute pancreatitis was based on criteria of the Japanese Ministry of Health, Labour and Welfare (Japanese Severity Score). Patients were stratified into two groups according to whether they received >6000 ml or ≤6000 ml in the first 24 hours. We evaluated the association between the two groups and clinical outcomes using multivariable logistic regression analysis. The primary outcome was in-hospital mortality. As a sensitivity analysis, we conducted an identical analysis for subgroup patients with severe acute pancreatitis diagnosed according to the revised Atlanta classification.

Results: We analysed 1097 patients, and the mean fluid volume administered was 5619±3018 ml (mean±standard deviation), with 708 and 389 patients stratified into the fluid >6000 ml and fluid ≤6000 ml groups, respectively. Overall in-hospital mortality was 12.3%. The fluid ≥6000 ml group had significantly higher mortality than the fluid <6000 ml group (15.9% vs. 10.3%, p<0.05). However, in multivariable logistic regression analysis, conversely fluid ≥6000 ml within the first 24 hours was significantly associated with reduced mortality (OR 0.58, 95%CI 0.34–0.98). We performed subgroup analyses for patients diagnosed with severe acute pancreatitis based on the revised Atlanta classification. One hundred and seven patients were classified in the fluid <6000 ml group, and 201 patients classified in the fluid ≥6000 ml group. There were no significant differences between the two groups with regard to in-hospital mortality (fluid <6000 ml: 35.3% vs. fluid ≥6000 ml: 28.4%, p=0.18). In multivariable logistic regression analysis, administration of fluid ≥6000 ml within the first 24 hours was associated with significantly less mortality (OR 0.56, 95%CI 0.32–0.98).

Conclusion: In patients with severe acute pancreatitis, administration of fluid ≥6000 ml within the first 24 hours is associated with decreased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

All 3 patients that died had severe PEP according to Atlanta due to persistent organ failure. Cotton classified them as mild, moderate and severe based on hospitalization. Two patients died within 10 days of early multiple organ failure. No other Cotton criterion for severity was met. Thus, the Cotton criteria did not capture early deaths due to multiple organ failure. The sensitivity and specificity of Cotton and Atlanta for mortality were 100%, 98.4%, 33.6% and 60.7% respectively.

Conclusion: The Cotton criteria for PEP overestimate disease severity, but underestimate mortality. Therefore, the Atlanta criteria should be used for defining PEP severity.

Disclosure of Interest: All authors have declared no conflicts of interest.
according to the revised Atlanta classification. Univariate and multivariate analysis were performed.

**Results:** The median fluid sequestration in the first 48 h after hospitalization was 4.7 liter (2.8–6.8 L). It was 3.2 (1.4–5.1), 6.4 (3.6–9.5) l in those without necrosis and those with necrosis, and 7.5 (4.4–12) l in those with persistent organ failure. The univariate and multivariate analysis showed that alcohol etiology, an increasing number of SIRS criteria and Hematocrit were significantly associated with increased fluid sequestration (Table). Body mass index, APACHE II score, sodium, creatinine and blood urea nitrogen levels did not help predict fluid sequestration. Patients with and without acute fluid collections had a median sequestration of 7.2 and 4.2 L (p < 0.001, respectively). 22 patients died (73.3%); median fluid sequestration in the patients who died was 6.5 L compared to 4.2 L with increased fluid sequestration (Table). Body mass index, APACHE II score, and those with necrosis, and 7.5 l (4.4–12) L in those with persistent organ failure. Among reported prophylactic procedures for PEP, placement of prophylactic pancreatic guidewire during ERCP can be a good candidate for prophylactic pancreatic stent to prevent post-ERCP pancreatitis: a matched propensity analysis. Aim was to investigate clinical features, risk of other organ involvement, risk of relapse and long-term outcomes of AIP type NOS patients. Patients classified by International Consensus Diagnostic Criteria (ICDC) as AIP type 1 and 2, (3, 4) no studies have been focused on AIP type NOS and therefore very little is known about clinical features and long-term outcomes of these patients. Aims & Methods: Aim was to investigate clinical features, risk of other organ involvement, risk of relapse and long-term outcomes of AIP type NOS patients. Patients classified by International Consensus Diagnostic Criteria (ICDC) as AIP type 1 and 2, (3, 4) no studies have been focused on AIP type NOS and therefore very little is known about clinical features and long-term outcomes of these patients.
P0117 698 CASES OF PANCREATIC DISEASES TREATED BY EPDBD (ENDOSCOPIC PANCREATIC DUCT BALLOON DILATION) – ITS USEFULNESS AND SAFETY

T. Tsuji
Gastroenterology, Saitama Kyoudou Hospital, Kagawachih Japan

Contact E-mail Address: t-tsuji@ncp-saitama.or.jp

Introduction: We started our original EPDBD (endoscopic pancreatic duct balloon dilation) therapy for pancreatic diseases in 1996. In these 22 years, 698 cases were treated by this method. We would like to show its usefulness and safety.

Aims & Methods: The balloon (6 mm diameter, 15 mm long -Boston Scientific) was inflated in the stenotic portion of the pancreas duct at 6 atm. pressure for 1 minute several times. Then stone removal or EPS (endoscopic pancreatic stent- ing) was evaluated: Head duct stone: rate and stone relapse rate in 568 pancreatic stone cases treated by EPDBD 2. The proffs of 114 EPS-successful pseudocyst cases treated by EPDBD 3. The prob of 16 EPS-successful divisum cases (complete type 6, incomplete type 10) treated by EPDBD 4. The purpose of making a diagnosis of ampullary/papillary stones and biliary obstruction which can be treated endoscopically.

Results: The purpose of EPDBD therapy for pancreatic stone was to ease endoscopic procedures in the pancreatic duct and stone removal, and to reduce stone relapse rates. 508 cases of pancreatic stone were treated by EPDBD. They consisted of 90 cases treated by endoscopic method alone, 90 cases treated by endoscopic method and stone extraction (via major papilla 38), and 478 cases treated by ESWL+ endoscopic method (via major papilla 381, minor papilla 97). After EPDBD therapy, the stone free rate was 75.3%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A; 22 y/o male. idiopathic chronic pancreatitis, pancreas stone: After 4th ESWL, small stones remained in the head duct which can’t be removed by basket catheter and severe pain continued, so EPDBD was done under good informed consent. After several dilation of the orifice and the head duct, the stone was easily removed. This is only one case and we think it is a success. In our hospital, EPS and ENPD (endoscopic nasal pancreatic drainage) are the preferred choice for pancreatic pseudocyst therapy after dilation of the stenotic duct. 114 cases were successfully treated without major complications, and their prognoses were good. Case B; 29 y/o female. alcoholic chronic pancreatitis, pancreatic stone: ERP via minor papilla revealed the duct rupture in the body portion and contrast medium flowed out into thoracic and abdominal cavity. After dilation of the stenotic duct in the body, EPS placement was done and she recovered quickly.

Conclusion: By EPDBD therapy, the relase rate of pancreatic stone decreased, and the success rate of endoscopic drainage and stenting in pseudocyst and divisum cases increased with minor complications, and their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

P0118 ENDOSCOPIC ULTRASOUND AS A PREDICTOR AND GUIDE TO SUCCESSFUL ENDOTHERAPY IN CHRONIC PANCREATITIS

M. Sharma, P. Somani
Department Of Gastroenterology, Jawant Rai Specialty Hospital, Meerut/India

Contact E-mail Address: sharmamalay@hotmail.com

Introduction: Pancreatic calculi (PC) are a sequela of chronic pancreatitis (CP) and occur due to chronic ductal hypertension leading to pain, cystic/nodular feature of CP. The rationale for endoscopic treatment of obstructing PC is based on the observation that pain subsides when the stone(s) is removed and drainage of pancreatic secretion is restored. Indications for endotherapy include stones >5 mm size, stones in head of pancreas which are not impacted and absence of downstream strictures. The assessment prior to the procedure is done by MRCP or CT. However, problems are encountered during ERCP clearance which are not anticipated despite MRCP/CT. The problems are, possible impacted stones, head duct stricture, and change in ductal configuration during ERCP. Hence, controversy exists. EUS can help by providing concordance or discordance with MRCP images and may help in further clarification.

Aims & Methods: We aimed to evaluate the role, feasibility and management challenges of EUS-guided ERCP in patients planned for endotherapy in CP. Another objective was to evaluate whether EUS features of pancreatic duct (PD) stones can serve as a predictor of successful removal during ERCP. The data of 412 patients during the study period (2009-2016) with CP was retrospectively analyzed. PD stones were associated with stones in head/papillary region of pancreas. Out of these, 75 were excluded and remaining 68 were evaluated by EUS using a linear/radial echo endoscope prior to ERCP.

Results: Out of 68 cases, 48 were associated with hard stones with acoustic shadowing and 20 were associated with soft stones without acoustic shadowing. In 20 soft stones cases, ERP was successful in 18 patients. In 48 patients with hard stones, there was failure of endotherapy in 40 patients which required ESWL/surgery. The remaining 8 patients required multiple sessions of ERP for successful removal. Three patients had ampullary/papillary stones which were removed with precut sphincterotomy with immediate relief of pain. Four patients had ventral duct obstruction by calculi and hence underwent ERCP through minor papilla with successful removal of stones in 3 patients. In three patients, there were calculus in pancreatic parenchyma and pancreatic duct simultaneously (ducto-parenchymal stones) and hence endotherapy was avoided. Three patients had pancreas divisum diagnosed on EUS and hence underwent minor papillotomy with stone removal. Three patients also had biliary obstruction with CBD stone/slugde and underwent biliary endotherapy. Four patients had pancreatic mass in head and underwent EUS-FNA with two patients diagnosed with pancreatic cancer who were referred for surgery. The remaining two were also referred for surgery. Four patients were found to have strictures on EUS and hence were referred for surgery. The presence of large (>5 mm), hard, incompressible stones were negative predictors of successful endotherapy. Small (<5 mm), ampullary/papillary stones were positive predictors.

Conclusion: Present study suggests that EUS can differentiate "soft PD stones" (without an acoustic shadow) from "hard PD stones"(with an acoustic shadow). A more accurate predicting success rate of endotherapy and hence improves overall prognosis. Hence, EUS is an important tool in the management of pancreatic stones.

Contact E-mail Address: tanoue@m.kufm.kagoshima-u.ac.jp

Introduction: IgG4-related disease (IgG4-RD) is characterized by the infiltration of inflammatory cells, such as plasma cells and macrophages, and fibrosis in tissues. We previously reported that apoptosis inhibitor of macrophage (AIM), which is secreted by macrophages, is related to the progression of hepatic fibrosis in chronic hepatitis C. Some studies have observed a relationship between IgG4-RD and malignancy. IgG4-RD is considered to represent a premalignant state or paraneoplastic condition.

Aims & Methods: To clarify the significance of the serum AIM levels in patients with IgG4-RD, we measured these levels in 22 healthy controls, 32 patients with IgG4-RD, and 36 patients with other pancreatic diseases (chronic pancreatitis [CP], intraductal papillary mucinous neoplasm [IPMN], pancreatic cancer [PC]). We also analyzed the prevalence of malignancy, the relationship between the appearance of malignancy and the diagnosis of 42 IgG4-RD, the type of cancer, and related factors, and we compared the age, gender, laboratory data, and AIM level.

Results: Fifteen malignancies were seen in 12 of 42 patients (28.6%). These diagnoses were made before the diagnosis of IgG4-RD for 10 malignancies in 8 patients (mean 4.8 years earlier, range 1-16 years), and after the diagnosis of IgG4-RD for 3 malignancies in 2 patients (mean 2 years later, range 1-3 years). The prevalence in 2 patients were diagnosed at the same time as the diagnosis of IgG4-RD. The AIM level in IgG4-RD group had significantly higher serum AIM levels than the healthy control or IPMN groups, and the levels tended to be higher than in the PC group.

Conclusion: Macrophages are reportedly related to IgG4 class switching in B cells associated with IgG4-RD. The serum level of AIM in IgG4-RD patients, therefore, is used as a paraneoplastic condition. AIM is considered a useful biomarker for evaluating the pathology and differentiating IgG4-RD and malignant diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest:

negative, repeated EUS after 2–3 months may be useful for detecting an occult pancreatic neoplasm because of cross sectional imaging results, idiopathic acute pancreatitis, weight loss, pancreas hyperenzymemia, painless jaundice and elevated Ca 19-9 values. Cystic pancreatic lesions, pseudocysts and cystic pancreatic cancer were excluded from the analysis. 

Results: Malignant lesions were diagnosed in 98 (45%) patients. 54 patients (24.8%) underwent surgery and 61 patients (28% of all patients) underwent clinical follow-up (16.5 ± 2.73 months, 18 needed surgery). 43 lesions not undergoing surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer (n = 6, 9.8%), neuroendocrine tumor (NET) (n = 10, 16.4%), paradoxe

nal pancreatitis (n = 5, 8.9%), chronic pancreatitis (n = 13, 21.3%), necrosis (n = 3, 4.9%), autoimmune pancreatitis (AIP) (n = 3, 4.9%), microcystic serous neoplasm (n = 2), and pseudocyst (n = 1). Ventral/dorsal split (n = 1), lipomatosis (n = 1). EUS showed sensitivity and specificity for malignancy of 91.4% and 97.7%, respectively, in the non-pancreatitis group (n = 121) and 44% and 87.1% in the pancreatitis group (n = 97). Ca 19-9 elevation, rapid onset jaundice, double duct sign are useful indicators of malignancy both in the setting of normal and inflamed pancreas. Patients without pancreatitis the presence of enlarged lymphnodes or a mass in EUS, weight loss and worsening diabetes are predictor of malignancy. In patients with pancreatitis, a rapid increase in Ca 19-9 sensitivity for malignancy was 95% and specificity was 39%. In the pancreatitis group, Ca 19-9 sensitivity for malignancy (in patients without jaundice) was 45% and specificity was 86%. IgG4 elevation presented a sensitivity of 83.3% and a specificity of 88% for AIP, where one false elevation was seen in a diastel cholangiocarcinoma.

Conclusion: Diagnostic accuracy of EUS is lower in the presence of pancreatitis. Focal autoimmune pancreatitis and paraoduodenal pancreatitis are still confused with each other in the setting of normal inflamed pancreatic parenchyma. EUS in the setting of a normal pancreas is an excellent tool to exclude pancreatic cancer. Tumor markers like Ca 19-9 and IgG4 values should be measured in the evaluation of pancreatic masses, also in the setting of chronic pancreatic disease. In a clinical and imaging follow-up of more than one modality (usually EUS with CT) were necessary for achieving a definitive diagnosis. If there is a high clinical suspicion of pancreatic neoplasm in a patient that does not undergo surgery and if EUS or other available imaging modalities are not repeated EUS after 2–3 months may be useful for detecting an occult pancreatic neoplasm.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic cancer is characterized by a high density of stroma. Interactions between tumor and stromal cells play a critical role in tumor progression and there is increasing evidence that pancreatic stellate cells (PSC), a main component of the stroma, may participate in the development of pancreatic cancer[1]. However, details of the mechanism underlying the interaction between PSCs and pancreatic cancer cells (PCC) are poorly understood. Stomal cell phenotypic changes (SDF-1 or CXCL12) and their receptor CXCR4 belong to the CXC chemokine family and is the ligand of CXCR4 [2]. It has been implicated in promoting the metastatic potential of breast, gastric, ovarian, prostate, lung and pancreatic cancer cells. Although SDF-1 reports of SDF-1 in pancreatic cancer cell lines are rare [3], it is known that carcinoma that metastasizes has homing properties to stromal SDF-1 produced in activated PSCs may be an integral factor in tumor-stromal interactions. Galectin-1 mediates communication between cells by binding to glycol-conjugated proteins on the cell surface. Studies have shown that it is involved in multiple cancer-related processes, including immunosuppression, angiogenesis and metastasis [4]. We previously reported that Galectin-1 was highly expressed in pancreatic cancer tissues; furthermore, the primary source of Galectin-1 was in activated PSCs within the stroma of cancer cells [5]. It has previously been hypothesized that Galectin-1 may also induce activation of PSCs and stimulate secretion of chemokines [6]; however, the biological mechanism and its activities in PCCs are unclear.

Aims & Methods: The purpose of this study was to identify the effect and elucidate the molecular mechanisms of Galectin-1 in PSCs and its role in tumor progression in pancreatic cancer.

Results: By conducting a chemokine antibody array assay and transwell invasion and migration assays we were able to show that Galectin-1 induced secretion of SDF-1 in PSCs that was increased in the presence of NF-κB. Galectin-1 induced SDF-1 activity assay indicated that the mechanism involved activation of NF-κB. These observations were confirmed by qRT-PCR, ELISA and immunofluorescent assays, and were further verified by knockdown of Galectin-1 through lentiviral transfection and by employing inhibitors to block SDF-1, its ligand CXCR4 and NF-κB. In the in vitro findings were supported in an in vivo mouse model. In combination, our results demonstrated that Galectin-1 stimulated production of SDF-1 in PSCs through activation of NF-κB, and that SDF-1 promoted invasion and migration of PCCs.

Conclusion: This study suggested that enhanced expression of Galectin-1 in stromal PSCs promotes metastasis in PDAC, thereby offering a potential target in the treatment of pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The ubiquitously expressed non-receptor protein tyrosine phosphatase SHP2, encoded by *PTPN11*, is involved in the regulation of multiple signaling cascades. SHP2 was the first reported oncogenic tyrosine phosphatase, although more recently demonstrated tumor suppressive properties as well. SHP2 has been proven to be required for proper wild-type RAS activation, yet more recently demonstrated tumor suppressive properties as well. In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumors. All authors have declared no conflicts of interest.

References
Aims & Methods: Twenty concomitant PDAs and IPMNs (39 samples, including concurrent lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMNs was measured after precise pathology mapping. Target amplicon sequencing that covers 18 PDA-associated genes, including RNF43, GNAS, TRPS1, SMAD4, CDKN2A/p16, ATM, PTEN, CTNNB1 and RNFRF4, was performed using Ion PGM™ system (Thermo Fisher Scientific). Protein expression of TP53, SMAD4, p6, b-catenin, and RNF43 was also analyzed immunohistochemically.

Results: KRAS mutations were identified in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. “Adjacent” concomitant PDAs, defined as those that are 5 mm or less away from the IPMN, tended to harbor identical KRAS mutations as the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%). Among cases of contiguous neoplastic lesions via the main pancreatic duct between PDA and IPMNs had identical KRAS mutations. In contrast, 7 of 9 “distant” concomitant PDAs, defined as those further than 5 mm away from the IPMN (n = 11), possessed distinct KRAS mutations from the index IPMNs (74%) and 29 out of 39 (74%) of all IPMNs, but not in PDAs, supporting de novo carcinogenesis rather than progression from the IPMNs. PDAs harboring identical mutations in KRAS as IPMNs were significantly closer to the IPMNs (KRAS identical; n = 16, 35.5 mm, vs. 74.7 mm, P < 0.00397). The KRAS identical group had a better prognosis than the KRAS different group (disease-free survival p < 0.0025, overall survival p < 0.05). Curiously, the molecular signature of 18 PDA-associated genes was not significantly different between two groups.

Conclusion: Multiple clones with distinct KRAS mutations were identified in pancreata during initiation and progression of IPMNs, and a subset of PDAs arising within the field defect share the same KRAS mutation with index IPMN lesions. Interestingly, PDAs adjacent to IPMN tend to have identical KRAS mutations, suggesting PDAs and index IPMNs may arise from a common founder. The KRAS identical group appears to have better prognosis relative to the KRAS different group, implying distinct molecular programs may govern their biological behavior.

Contact E-mail Address: igrigorieva@ngs.ru

Introduction: The pancreatic cancer is a leading cause of death in cancer carriers worldwide.

Aims & Methods: To study the polymorphism of the TP53 gene on the suppressor of apoptosis in patients and to evaluate proinflammatory cytokines in IL-1β, TNF-α, insulin blood serum levels at patients with various pathologies of the pancreas (cancer (PCa), acute and chronic pancreatitis (OP and CP)) with various genotypes and alleles of the TP53 gene by exon (exon 4, Arg72Pro) polymorphism.

Results: The deduced Arg/Arg genotype of the TP53 gene was 65% in patients with PCa, 49% in the control group. In patients with PCa there was no homoyzogotic genotype Pro/Pro, in the comparison group - 13%, p < 0.05. The frequency of Arg/Pro genotype was 35% in patients with PCa and 38% in the comparison group. The frequency of alleles of the TP53 gene in patients with PCa and in the comparison group was: Arg (82.5% and 68%), Pro (17.5% and 32%). The concentration of insulin in different genotypes in patients with PCa did not differ significantly and was 7.5 ± 2.2 μU/ml in Arg/Arg, Arg/Pro – 11.9 ± 2.12 μU/ml, Pro/Pro – 18.0 ± 3.05. In the comparison group, the serum level of insulin was 5.7 ± 1.8 μU/mL. In patients with PCa, the glucose level was significantly higher, compared with patients with OP and CP (8.5 ± 1.4 mMol/l, 5.4 ± 0.3 and 5.1 ± 0.1 mMol/l, respectively, P < 0.05). The level of IL-1β was significantly higher in patients with CP than in patients with PCa (5.1 ± 1.7, 2.0 ± 0.3 and 1.3 ± 0.2 pg/ml, respectively), p < 0.05. The level of TNF-α in the serum of patients with OP was 3.5 ± 0.5 pg/ml, and did not significantly differ from the serum level of patients with CP and PCa – 4.3 ± 0.7 and 1.1 ± 0.2 pg/ml, respectively. In patients with PCa, the level of TNF-α was significantly lower in patients with CP, p < 0.05. The levels of IL-1β in the serum of patients with PCa with different genotypes of the TP53 gene did not differ significantly and amounted to 1.1 ± 0.2 pg/ml in patients with the Arg/Arg genotype, with Arg/Pro genotypes of 1.2 ± 0.3 pg/ml, p > 0.05. The level of TNF-α in the serum of patients with the Arg/Arg genotype was 1.2 ± 0.2 pg/ml, and did not significantly differ from the level in the serum of patients with the Arg/Pro genotype – 1.3 ± 0.1 pg/ml.

Conclusion: The Pro/Pro genotype of the TP53 gene was significantly more common than in the comparison group in patients with PCa. We detected significant differences in serum insulin levels in the comparison group and in patients with heterozygous genotypes, p < 0.05. The level of TNF-α in patients with PCa was significantly lower than in patients with OP, and the level of IL-1β was significantly lower in patients with PCa than in patients with CP.

P0127 VALIDATION OF SERUM/PLASMA METABOLIC BIOMARKERS AGAINST PANCREATIC CANCER BY QUANTITATIVE TARGETED GC/MS/MS

T. Kobayashi1, Y. Hiran1, M. Yoshida1, S. Nishiumi1, K. Honda1

1Gastroenterology, Kobe university, Kobe/Japan
2Division Of Biomarker For Cancer Early Detection, National Cancer Center Research Institute, Tokyo/Japan

Contact E-mail Address: kobataki@med.kobe-u.ac.jp

Introduction: Pancreatic cancer (PC) is one of the most lethal diseases due to the difficulty of early detection. There is no effective blood biomarker for screening. Recently metabolomics is considered to be a promising approach to discover disease biomarkers. We previously reported that the serum/plasma levels of some metabolic biomarkers in PC patients were significantly changed compared with those of healthy individuals.

Aims & Methods: The aim of this study is to confirm and develop our candidate metabolic biomarkers in blood of PC patients. Blood samples from PC patients (n = 11), healthy volunteers (n = 11), and patients with OP (n = 11) were collected by two independent groups consisting of multiple institutions. The 1st set was included 55 PC in stage I and II and 58 HV. The 2nd set was included 16 PC and 16 HV.

Conclusion: Quantitative analysis using GC/MS/MS confirmed the possibility of metabolomics-based screening methods for PC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0128 COMBINED HISTO-CYTOLOGICAL ANALYSIS OF EUS-FNA SAMPLES FROM SOLID LESIONS USING STANDARD FNA NEEDLES GIVES BETTER DIAGNOSTIC YIELD AND ACCURACY

A. K. Banerjee1, A. Cairns2, L. Samii3, B. Paranandi4, M. Huggett1

Introduction: Diagnostic yield from EUS-FNAC (fine needle aspiration cytology) has improved in the past few years with better tissue acquisition techniques. Core biopsy needles are now available but are more expensive than FNAC needles. We assessed the diagnostic yield and accuracy of FNAC samples processed for both cytology and histology.

Results: A total of 211 patients (118 male) were included. Samples were sent to cytology (n = 135; 107 pancreas, 10 biliary, 7 lymph nodes, 11 other), or cytology & histology (n = 76; 56 pancreas, 12 biliary, 5 lymph nodes, 3 other). Sample adequacy was 80.7% and 98.7% (p < 0.0004). Diagnostic yield (64.4%, 94.7%) and accuracy (81.3%, 96.1%) was significantly better in the combined histology & cytology group (p < 0.0001, p = 0.003). Within the combined group, diagnostic yield and accuracy improved by 20.5% (p = 0.007) and 26% (p = 0.0002) respectively when the sample was processed for both cytology and histology.

Conclusion: Our study confirms significant improvement in diagnostic yield and accuracy when samples were sent for both cytology and histology using standard FNAC needles.

Introduction: In the revised international consensus guidelines of 2012 for the management of IPMN of the pancreas, resection is recommended for all main pancreatic duct IPMN. While in branch pancreatic duct IPMN (BD-IPMN), the indications for resection are more conservative. Cyst size >30 mm without “high-risk stigmata” can be observed without immediate resection. And EUS observation is recommended to decide a treatment strategy.

Aims & Methods: The present study was a retrospective investigation of surgical indication for BD-IPMN with worrisome features (WF). 466 patients with IPMN underwent pancreatic resection at 3 high volume centers in Japan between 1996 and 2014. Among them, 156 patients with BD-IPMN were enrolled this study. The investigation of predictors of malignancy was done for 10 factors: age at time of surgery, sex, presence or absence of symptoms, serum amylase, CA19-9, CEA, tumor location, size of mural nodules (MN), diameter of main pancreatic duct (MDP), and cyst size of branch pancreatic duct (BDP). In the selected cases, histological examination, endoscopic ultrasound (EUS) and computed tomography (CT) were considered to be essential. For 8 factors of MN, EUS measurements were used in all cases. For diameter of MDP and cyst size of BDP, the CT measurement value was used. In this study, BD-IPMN was defined as cases with cystic dilatation of BPD and the MDP diameter was considered <5 mm (International Consensus Guidelines 2012). According to the WHO histological classification of IPMN (2000), pathological diagnosis is classified as adenoma (IPMAd), borderline (IPMAB), and noninvasive and invasive carcinoma (IPMCA).

Results: Pathological diagnosis was benign IPMN in 91cases (58%) and malignant in 65 (42%). In univariate analysis CA19-9, MDP diameter, the sizes of MN and BPD cysts were significant factors. In multivariate analyses, size of MN (p <0.0001) and cyst size of BPDs (p=0.004) were independent predictors of malignancy. In the multivariate analysis, the rate of malignancy was significantly higher than that of patients without WF(26%)<p<0.0001). Among 78 WF patients, 54 cases had WF (70%). Among patients with MN was significantly higher than that of WF patients without MN (69% vs 33%). With 7 mm taken as the cutoff value for the size of MN, the diagnosis of malignant IPMN had sensitivity of 76%, specificity of 73% and accuracy of 74%. Cyst size of BPD without MN was present in 8 patients (8/45 = 17%) among 78 WF patients. Pathological findings of these patients were noninvasive carcinoma in 6, invasive carcinoma 2.

Conclusion: Algorithm for the management of BD-IPMN of International Consensus Guidelines 2012 was acceptable. Mural nodules observed with EUS showed high predictive ability in BD-IPMN patients with WF. However, about 15% of carcinoma patients did not have nodules, and the handling of the diag-

P0131 Pancreatic Ductal Cytopathology: An Underused Diagnostic Tool

Centro Hospitalar De Sao Joao, Porto/Portugal

Contact E-mail Address: armandoafp5@gmail.com

Introduction: The diagnosis of pancreatic malignancy can be performed by brush cytology of the common bile duct or main pancreatic duct (MPD) during endoscopic retrograde cholangiopancreatography (ERCP). However, the use of the micro-forceps seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

Aims & Methods: In this work we report our experience in the execution of MPD brush cytology. ERCPs between 2014 and 2015 that involved brush cytology of pancreatic strictures were included. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: Of the 18 patients evaluated, 16 were men and 2 women, with a median age of 62 years (range: 43–89). All patients underwent abdominal computed tomography and 3 patients had magnetic resonance imaging. In addition to pancreatic strictures, abdominal cystic and non-cystic lesions suggestive of chronic pancreatitis in 28%, cancers, or inflammatory features in 6%. The diagnosis of the strictures was: head - 16, head and body - 1, tail - 1. The pancreatic duct was dilated in 16 patients (a median of 6.5 mm). The diagnosis of MPD brush cytology for pancreatic cancer were: sensitivity - 81.8%, specificity - 100%, positive predictive value - 100%, negative predictive value - 77.8%, accuracy - 88.9%. Sixty-one percent (n =11) of the patients had a final diagnosis of pancreatic adenocarcinoma, 5.6% (n =1) of neuroendocrine tumor and 33.3% (n =6) inflammatory stricture. All the adenocarcinomas lead to strictures in the head of the pancreas. The diagnosis of neuroendocrine tumor was made by...
endoscopic ultrasonography fine needle aspiration. One patient developed mild pancreatitis (6.4%).

Conclusion: In patients with suspected cephalopancreatic adenocarcinoma referred for ERCP, MPD brush cytology may be performed beyond biliary cytology, as it may improve cytologic diagnosis of malignancy without increasing complications rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

Aims & Methods: The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 Japanese tertiary referral hospitals between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytologically diagnosed with PM. Kaplan-Meier analysis and Cox’s proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

Results: We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n = 61), followed by lung cancer (24.5%, n = 39), colorectal cancer (11.3%, n = 18), seroma (6.3%, n = 10), breast cancer (6.3%, n = 10), and other cancers (n = 31). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgical resection and no surgical resection was performed in 95 patients (60%). Additional therapies were chemotherapy (n = 69), chemoradiation (n = 4), radiation therapy (n = 3), palliative care, and unclear (n = 2). Eight patients were lost during follow-up and 151 patients were included in the statistical analysis. All patients with PM had a median overall survival of 43.0 months, with 3- and 5-year survival rates of 52.5% and 42.6%, respectively. Among the five frequent primary sites of PM, prognoses of RCC, breast cancer, and colorectal were better than those of lung cancer and seroma. Univariate Cox proportional regression analysis identified four prognostic factors: pancreatic resection (hazard ratio [HR] 0.31, 95% confidence interval [CI] 0.18–0.57, p = 0.001), extra-pancreatic metastases (HR 3.07, 95%CI 1.71–5.51, p = 0.001), tumor-related symptoms at PM diagnosis (HR 3.88, 95%CI 2.29–6.56, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001). Multivariate Cox proportional regression analysis identified three independent prognostic factors: extra-pancreatic metastases (HR 2.13, 95%CI 1.11–4.07, p = 0.02), tumor-related symptoms at diagnosis (HR 5.39, 95%CI 2.92–9.91, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001).

Conclusion: Treatment strategies and prognoses for PM completely differ according to the primary tumor type. A definitive pathologic diagnosis of PM is essential for selecting the appropriate treatment.

Introduction: National Comprehensive Cancer Network (NCCN) guidelines recommend chest x-ray or chest computed tomography (CT) for the staging of potential resectable pancreatic adenocarcinoma (PDA). However, there is limited data supporting these guidelines, and the prevalence of lung metastasis is not well defined on staging CT scans. We report our findings of patients with lung metastasis during initial staging and follow-up of patients with PDA.

Aims & Methods: Data was prospectively collected from May 2013 to September 2016 for PDA patients who were presented at a multidisciplinary pancreas center (MDPC) at a large tertiary care center. All patients were staged with CT pancreatic protocol, CT chest and Endoscopic Ultrasound. Patients with findings of lung lesions on initial staging chest CT were followed prospectively. Metastatic lung lesions were determined based on definite imaging characteristics with clinical consensus or lung biopsy results.

Results: A total 278 PDA patients referred to MDPC were staged with CT chest (Table 1). Out of these, 36 (12.6%) patients were found to have either malignant (N = 6) or indeterminate (N = 30) lung lesions on initial staging CT chest. Out of the six malignant lung lesions, 5 (83.3%) patients had metastatic PDA lesions, and 1 (16.7%) patient had incidental primary lung cancer. On a follow-up of 30 patients with indeterminate lung lesions, 8 patients (26.7%) were later determined to be lung metastasis. The overall prevalence of definite lung metastasis was at least 4.8% (13/278). The prevalence of lung metastasis in pancreatic head cancer was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR = 3.83, CI 1.2–11.8, p = 0.02) compared to head. Overall CT chest resulted in change in management plan in 9 (2.5%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unrespectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic disease in 2 (0.7%) patients. Prevalence of isolated PDA lung metastasis without any other metastasis was 2.8% (8/278).

Conclusion: Our study showed that the prevalence of pulmonary metastasis in PDA was clinically relevant to mandate routine staging with CT chest. Prevalence was significantly higher for pancreatic body and tail cancers compared to the head. Staging CT chest resulted in a change in the stage of PDA and management decisions.

Introduction: New lesions (metachronous pancreatic cancer) and recurrence may develop in pancreas after initial resection for pancreatic cancer and Intraductal Papillary Mucinous Neoplasm (IPMN). Endoscopic ultrasonography (EUS) is proved as a more specific and sensitive method for pancreatic lesion. However, there is no report about EUS after pancreatectomy. If it is possible to observe the remnant pancreas under the EUS, remnant pancreatic cancer may be pointed out an early stage.

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for remnant pancreas. In this retrospective study, 44 patients who underwent EUS for remnant pancreas were enrollment. The definition of observation under the EUS for remnant pancreas was as follows, total observation for remnant pancreas observed from liner white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent pancreatectomy at the JA Onomichi General Hospital between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for remnant pancreas. In the surgical procedure, pancreatectoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of remnant pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIb. The other cases were IPMN. EUS was able to perform EUS-FNA for lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (class III), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by Positron emission tomography (PET). Second pancreatectomy was performed in 4 out of 7 cases. The remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was strongly suspected to recurrence by surgery. In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (P = 0.001).

Conclusion: EUS was able to observe remnant pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be performed for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Introduction: Number of studies reported that patients with intraductal papillary mucinous neoplasms of pancreas (IPMNs) are at the increased risk for occurrence of extrapancreatic malignancies (EPMs). We have conducted a study in the aim to evaluate the prevalence and incidence of EPM in Italian patients with IPMN. In the remnant pancreas after pancreatectomy for PDAC, we have evaluated the presence of new and recurrent cancers.

Methods: A hospital based single-centre study was conducted in hospital Santa Maria della Misericordia, Udine, Italy. Hospital records were screened in the presence of extrapancreatic malignancies (EPMs). We have conducted a study in the presence of extrapancreatic malignancies (EPMs) in 60 patients with intraductal papillary mucinous neoplasms (IPMNs) treated at the University of Udine between December 31st 2015, as well as those seen during the follow-up. Data were collected from the medical records

Results: Among the 60 patients with IPMN, 31 (51.7%) were male and 29 (48.3%) were female. The mean age at diagnosis was 67.4 years (range 26-93). IPMNs were predominantly female (59.1%) and age 70–79 (47.2%). IPMNs were predominantly female (59.1%) and age 70–79 (47.2%). IPMNs were predominantly female (59.1%) and age 70–79 (47.2%). IPMNs were predominantly female (59.1%) and age 70–79 (47.2%). IPMNs were predominantly female (59.1%) and age 70–79 (47.2%).

P0136 CLINICAL CHARACTERISTICS OF SECOND PRIMARY PANCREATIC CANCER

Department Of Internal Medicine And Institute Of Gastroenterology, Yonsei University Health System Dept. of Internal Medicine Dept. of Gastroenterology, Seoul/Korea, Republic of

Contact E-mail Address: woforze@naver.com

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is known to have an extremely poor prognosis. Several studies reported the increased risk of second primary pancreatic ductal adenocarcinoma (2nd PDAC) in cancer survivors. However, data on the characteristics of 2nd PDAC are insufficient. Studies of PDAC in the setting of second primary cancer can provide etiologic clues to understand PDAC.

Aims & Methods: The aim of this study was to investigate the clinical characteristics of the patients with second primary PDAC compared to patients with first primary PDAC. This retrospective cohort study included 1759 patients with PDAC. They were classified as having 2nd PDAC or first primary PDAC (1st PDAC) according to a prior diagnosed cancer that originated from different organ and diagnosed at least 6 months before the diagnosis of PDAC. Comparative analysis and multivariated survival analysis were used to evaluate the characteristics of the 2nd PDAC.

Results: A total of 1759 patients with PDAC were included in the cohort. Forty-three patients were classified as having synchronous 2nd PDAC and excluded from the analysis. There were 110 patients (6.4%) with 2nd PDAC and 1606 (93.6%) patients with 1st PDAC. The median interval between the diagnosis of the 2nd PDAC and the diagnosis of the prior cancer was 8.4 years (range 0.7–31.4 years). The 2nd PDAC group. In the comparison of baseline characteristics between the 1st PDAC and 2nd PDAC groups, patients with 2nd PDAC presented significantly older age at diagnosis (66.5 vs. 62.2 years, p < 0.001), lower rate of alcohol consumption (25.5 vs. 36.8%, p = 0.017), higher rate of resectability of PDAC (26.4 vs. 15.9%, p = 0.004), and higher rate of receiving surgery as initial treatment (26.4 vs. 15.9%, p = 0.018) than patients with 1st PDAC. The most common origin of prior cancers was the stomach (22 of 110, 19.1%), breast (19 of 110, 17.3%), colon (12 of 110, 10.9%), and others. The overall survival (OS) was slightly longer in patients with 2nd PDAC; however, the difference was not significant (11.8 vs. 12.3 months, p = 0.068). Multivariate analysis without resectable status showed that 2nd PDAC (HR 0.73, 95% CI 0.56-0.94, p = 0.016), age at diagnosis (HR 1.02, 95% CI 1.01-1.02, p = 0.001), alcohol consumption (HR 1.25, 95% CI 1.11-1.42, p = 0.001), and resectable status at diagnosis (HR 0.30, 95% CI 0.25-0.36, p < 0.001) were significantly associated with OS. However, 2nd PDAC (HR 0.85, 95% CI 0.66-1.19, p = 0.198) was no longer significantly associated with OS after adjusting for resectable status. This analysis suggested that the association between 2nd PDAC and survival was owing to the higher resectability rate. When subgroups were separately analyzed according to initial treatment modality, the effectiveness of surgery and chemotherapy were similar between 2nd and 1st PDAC. In the subgroup of patients who received curative surgery, the median OS was 28.5 months (95% CI, 23.0-34.1) in the 1st PDAC group compared to 28.5 months (95% CI, 22.3-34.8) in the 2nd PDAC group.
pared with 33.1 months (95% CI, 9.0–27.2) in the 2nd PDAC group (N: 259 vs. 215; p = 0.046). The subgroup of patients who received chemotherapy, the median OS was 10.7 months (95% CI, 10.0–11.4) in 1st PDAC compared with 10.8 months (95% CI, 9.2–12.3) in 2nd PDAC (N: 1094 vs. 66, p = 0.952).

Aim & Methods: This retrospective study was conducted at New Tokyo Hospital. A total of 597 gastric neoplasms (496 with early gastric cancers and 101 with gastric adenomas) in 371 consecutive patients were treated with gastric ESD between January 2010 and October 2016. A total of 102 lesions were excluded from this study: 51 lesions due to anticoagulation therapy; 25 lesions in patients receiving antitape platelet therapy excluding single-LDA and DAPT; and 26 lesions in patients who underwent ESD for more than four operations at the same time. Thus, a total of 495 patients were enrolled in this study. The patients were categorized according to antitape platelet therapy (APT). APT was defined as follows: oral administration of single-LDA (aspirin [100 mg/day]) or DAPT (aspirin [100 mg/day] plus clopidogrel [75 mg/day]). Logistic regression analysis was performed for risk factors of bleeding after gastric ESD.

Results: The patients were categorized into two groups: no APT (n = 370) and APT (n = 125). APT included single-LDA (n = 74) and DAPT (LDA plus clopidogrel; n = 51). Among them, 46 received continuous LDA on single-LDA and 40 received continuous LDA on DAPT. The postoperative bleeding rate in the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; P = 0.001). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group (15.2%) and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≥40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; P < 0.001) was a sole independent risk factor for postoperative bleeding (Table 1). In subgroup univariate analysis among continuous LDA users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding. Multivariate analysis for postoperative bleeding after ESD.

Conclusion: This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. However, patients with continuous LDA on DAPT should be monitored carefully for postoperative bleeding after gastric ESD because the rate of postoperative bleeding in the continuous LDA on DAPT group was higher than that in the other groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

Chronic gastrointestinal ischemia (CGI) results of insufficient blood supply to the gastrointestinal tract. The majority of CGI patients have systemic cardiovascular risk factors. Studies in patients with acute gastrointestinal ischemia have shown that microvascular flow disturbances are associated with organ damage. Sublingual microcirculation visualization may offer a fast non-invasive diagnostic method to assess the risk of gastrointestinal cancer on the basis of several biopsy samples taken from the antrum and corpus.

Aims & Methods: In this study we attempted to evaluate whether gastritis staging using conventional narrow band imaging (NBI) endoscopy is equivalent to that determined by histopathology. Fifty (50) consecutive patients with Helicobacter Pylori (H. Pylori) related gastric atrophy selected according to NBI endoscopic findings were enrolled. The diagnosis of H. Pylori based on detection of the organism by histopathology assessment. The NBI grade of lower gastric atrophy scored from 0 to 3. The histopathological assessment of lower gastric atrophy was based on OLGA scoring system. Furthermore, we assessed the presence or absence of intestinal metaplasia. The NBI and histology stages of gastric atrophy were compared using a combination of scores for the antrum and corpus. These stages further classified into low risk (stage 0, I and II) and high risk (stage III and IV). Finally the degree of correspondence between NBI and histopathology, in prediction of gastric cancer risk, was assessed.

Results: The mean age of included patients was 58.7±15.6 years, they were 21 (42%) males and 29 (58%) females. 38 (76%) and 13 (26%) patients have pseudopyloric and intestinal metaplasia respectively. Overall 41 (82%) and 9 (18%) patients have low and high gastric cancer risk respectively. The sensitivity of NBI in staging of Helicobacter Pylori infection, gastric atrophy and intestinal metaplasia were 96% (n = 48/50), 100% and 61.5% (n = 8/13) respectively. The degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% (n = 43/50) for the antral intestinal metaplasia. The degree of correspondence between the histological risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% (n = 40/50).

Conclusion: NBI is able to approximate histopathological staging of gastritis to a degree. More studies and long-term follow-up will further improve the performance of our suggested new staging method.

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early gastric cancer. Development of the ESD device has been conducted rapidly. Spash-M-Knife® is the only new multifunctional endoscopic device to achieve complete ESD with a simple device. It achieves clear marking, better hemostasis and smoother operation during a procedure without replacing the knife.

Aims & Methods: The aim of this study was to investigate clinical outcome of ESD for early gastric cancer with a new device (Spash-M-knife®). In total, early gastric cancer treated by ESD with a needle-type knife between January 2012 and August 2016 at Kitakyushu Municipal Medical Center were retrospectively reviewed. Lesions treated by ESD with a conventional needle-knife (ESD-C; n = 76) and by ESD with a new device (ESD-N, n = 73) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age (≥75 years vs <75 years), sex (male vs female), underlying disease (none vs with cardiovascular or cirrhosis), antithrombotic drugs (not receiving or discontinuation vs continuation), tumor size (≥21 mm vs <21 mm), lesion location (in the upper or middle third of the stomach vs in the lower stomach), lesion position (in the lesser curvature of the stomach vs others), macroscopic type (flat or depressed vs elevated), prevalence of ulceration (presence vs absence) and operator level (experience of ≥50 vs experience <50). As primary endpoint, the rates of the lesions that need hemostatic forceps was compared
among two groups. As sub-analyses, the cutting time, rate of on-block/complete reversal and rates of adverse events were evaluated among two groups.

**Results:** Propensity score matching analysis created 46 matched pairs. Adjusted comparisons between two groups showed a significantly smaller usage rate of hemostatic forceps in ESD-N than in ESD-C (4.35% vs 84.8%, p < 0.001), and significantly lower rates of adverse events (on-block reversal rate: 100% vs 1; complete reversal rate: 97.8% vs 100%, p = 1; cutting time: 84.6 min vs 63.0 min, p = 0.89; perforation during ESD: 0% in both groups).

**Conclusion:** Splash M-Knife® achieved better hemostasis and safer ESD for early gastric cancer compared to Merocel, contributing to reduce cost for ESD by reducing usage of hemostatic forceps during ESD procedure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Contact E-mail Address: keith@siaa.org

**Introduction:** Intubation failure (IF) when a trained endoscopist is unable to progress into the upper oesophagus via the oropharynx. The incidence is unknown, but estimated at 1–2%.[1] There have been no studies exploring IF and follow-up findings. We aimed to assess the incidence, causes of IF, predictors of pathology in patients with IF, and follow-up findings.

**Aims & Methods:** We retrospectively identified all gastroscopies performed at a district general hospital between August 2010–August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopist status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups: failure to tolerate (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s chi² and Wilcoxon signed rank test.

**Results:** The incidence of IF was 0.95% (28/2963). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, n = 142), CT (21%, n = 50), repeat gastroscopy (29.4%, n = 70) and no further investigations (19.7%, n = 47). Structural pharyngeal abnormalities were diagnosed comprising of Oropharyngeal Hypertrophy (CPH) (49%), Zenker’s diverticulum (ZD) (14.6%), pharyngeal web (12.2%), ZD with CPH (9.8%), cervical spondylosis (7.3%) and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5–0.9, p = 0.007). Within the IF cohort, predictors of structural causes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, p < 0.001), failure to progress (OR 5.2, 95% CI: 2.3–12.0, p < 0.001) and age ≥ 65 (OR 4.0, 95% CI: 1.8–8.9, p < 0.001). Repeat gastroscopy was successful in 65/70 (2 using nasendoscope) after increasing midazolam dosage (mean increase = 1.5 mg, 95% CI: 1.0–2.0 mg, p < 0.001). Diagnostic yield for barium radiology, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of endoscopic indication and pathology on further investigation for IF was 110/192 (57.3%). In patients undergoing barium radiology and repeat gastroscopy, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, p < 0.001). The Kyoto classification is useful for diagnosis of HP infection: Multicenter prospective trial. Digestive Endoscopy 2013; 25: 264–273

**Conclusion:** The Kyoto classification is useful for diagnosis of HP infection: Multicenter prospective trial. Digestive Endoscopy 2013; 25: 508–515

**Aims & Methods:** The aim of this study was therefore to determine the usefulness of the Kyoto classification for diagnosis of HP infection status. A total of 498 subjects were recruited during the period from January to October in 2015 for this study after providing informed consent in writing. HP infection status was determined by the presence of HP-IGb antibody (E-plate II H. pylori antibody, Eiken Chemical Co., Ltd., Tokyo, Japan) and history of eradication therapy. HP infection status was judged to be “eradicated” if there was a definite history of eradication therapy. Without a history of eradication therapy, HP infection status was judged to be “uninfected” if an HP antibody titer of less than 3 U/ml, “eradicated” for an HP antibody titer of 3–10 U/ml and “infected” for an HP antibody titer of more than 10 U/ml. Seven endoscopists (5 well-experienced endoscopists and 2 trainees) who were blinded to history of eradication therapy performed the endoscopies. The following endoscopic findings were recorded according to the Kyoto gastritis classification: diffuse redness, regular arrangement of collecting venules (RAC), fundic gland polyph (FGP), atrophy, xanthoma, hyperplastic polyph, map-like redness, intestinal metaplasia, nodularity, mucosal swelling, white and flat elevated lesion, sticky mucus, depressive erosion, raised erosion, red streak, and enlarged fold. HP infection status was diagnosed on the basis of the findings. An Olympus H260 and Xp260NS were used for endoscopy. The diagnostic accuracy rate of the Kyoto classification and the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic odds ratio (DOR) for endoscopic findings were determined. This study was registered as a clinical trial in UMIN (UMIN000016674) and was conducted with the approval of the ethics committee in our institution.

**Introduction:** Since Helicobacter pylori (HP) eradication therapy is necessary to prevent the development of gastric cancer, evaluation of HP infection status (uninfected, infected, eradicated) by endoscopy has become important. For that purpose, the Japan Gastroenterological Endoscopy Society proposed the Kyoto classification for gastritis. However, the usefulness of the classification in daily clinical practice has not been sufficiently evaluated.

**Results:** The 498 subjects included 376 males and 122 females with a mean age of 53.1 years. HP status was uninfected in 315 subjects, eradicated in 104 subjects and infected in 79 subjects. The diagnostic accuracy rate was 82.9%. The sensitivity, specificity, PPV, NPV and DOR were 88.3%, 92.9%, 95.5%, 82.1% and 99.9%, respectively for uninfected status, 78.8%, 90.0%, 88.9%, 87.3% and 94.2%, respectively, for eradicated status, and 67.1%, 91.4%, 59.6%, 93.6% and 21.7%, respectively, for infected status. High DORs were obtained for the following endoscopic findings: 32.2 for RAC, 7.7 for FGP and 4.7 for red streak in subjects with infected status, 12.0 for erosive redness in subjects with eradicated status, and 26.8 for diffuse redness, 13.3 for mucosal swelling, 10.2 for sticky mucus and 8.6 for enlarged fold in subjects with infected status.

**Conclusion:** The Kyoto classification is useful for diagnosis of HP infection: Multicenter prospective trial. Digestive Endoscopy 2013; 25: 508–515

**P0145 A RETROSPECTIVE AUDIT OF OUTCOMES AND CURRENT CLINICAL PRACTICE POST-BALLOON TAMPODATE FOR ACUTE VARICEAL BLEEDING: HAVE THINGS IMPROVED OVER TIME?**

C. Keung1, A. Jackson2, M. Swan1

1Department Of Gastroenterology And Hepatology, Monash Health, Melbourne/Australia
2Department Of General Medicine, Monash Health, Melbourne/Australia/VIC

Contact E-mail Address: c.keung@gmail.com

**Introduction:** Balloon tamponade has traditionally been the mainstay of management for severe variceal bleeding, but has not been without complications. Data on the current practice surrounding balloon tamponade is needed. A multi-centre and multi-disciplinary survey of balloon tamponade was undertaken to determine balloon tamponade as initial therapy in treating endoscopically uncontrollable variceal bleeding, specialists and trainees feel uncomfortable with SBT insertion [4] given the perceived difficulties and complications [5].

**Aims & Methods:** We aimed to determine the current practice surrounding SBT insertion [4] given the perceived difficulties and complications [5]. The aim of this study was therefore to determine the usefulness of the Kyoto classification for diagnosis of HP infection status. A total of 498 subjects were recruited during the period from January to October in 2015 for this study after providing informed consent in writing. HP infection status was determined by the presence of HP-IGb antibody (E-plate II H. pylori antibody, Eiken Chemical Co., Ltd., Tokyo, Japan) and history of eradication therapy. HP infection status was judged to be “eradicated” if there was a definite history of eradication therapy. Without a history of eradication therapy, HP infection status was judged to be “uninfected” if an HP antibody titer of less than 3 U/ml, “eradicated” for an HP antibody titer of 3–10 U/ml and “infected” for an HP antibody titer of more than 10 U/ml. Seven endoscopists (5 well-experienced endoscopists and 2 trainees) who were blinded to history of eradication therapy performed the endoscopies. The following endoscopic findings were recorded according to the Kyoto gastritis classification: diffuse redness, regular arrangement of collecting venules (RAC), fundic gland polyph (FGP), atrophy, xanthoma, hyperplastic polyph, map-like redness, intestinal metaplasia, nodular-
below. Re-look endoscopy post-SBT insertion was performed in 86% patients at a median of 39 hours after insertion with further endoscopic therapy in 47%. Complications of SBT insertion occurred in 31% and included minor oesophageal ulceration (9%), significant oesophageal ulceration (3), aspiration pneumonia (4) and oesophageal perforation (1).

Current practice surrounding Sengstaken-Blakemore Tube insertion

</tr>
</tbody>
</table>

Rebleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a therapeutic procedure for these still died. The median time of discharge after 7 days was 50% and 41% respectively. The median duration of hospitalisation, intensive care and mechanical ventilation was 13 days (1–56), 6.2 days (0.3–36.2) and 120 hours (1–708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, rebleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and longer-term survival overall has not significantly improved since studies in the 1970s-1980s despite advances in pharmacological therapy. Current practices for SBT insertion vary worldwide and would benefit from further education. Rates of direct visualisation of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

P0147 DIAGNOSTIC ACCURACY OF BLUE LASER IMAGING WITH MAGNIFYING ENDOCOPY FOR INVASION DEPTH OF SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA

Gastroenterology And Hepatology, Kyoto Prefectural University of Medicine, Kyoto,Japan

Contact E-mail Address: tm-ueda@koto.kpu-m.ac.jp

Introduction: Preoperative diagnosis of invasion depth of superficial esophageal squamous cell carcinoma (SESCC) is very important to select appropriate therapeutic procedure. The Japan Esophageal Society (JES) classification using narrow-band imaging with magnification (M-NBI) was effective for predicting invasion depth of SESCC. Blue laser imaging (BLI) is an image enhanced endoscopy consisted of two different lasers with wavelength 410 and 450 nm as light source, which can enhance vascular and surface structure. In previous study, BLI with magnification (M-BLI) was useful for evaluating gastrointestinal neoplasms such as predicting invasion depth or tumor detection.

Aims & Methods: We aim to investigate the diagnostic value of M-BLI by comparing that of M-NBI. Our study was a single center retrospective study and approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. All patients provided informed consent for undergoing both M-BLI and M-NBI. Consecutive 166 patients underwent endoscopic submucosal dissection (ESD) for esophageal tumor at Kyoto Prefectural University of Medicine between April 2014 and March 2016. Endoscopic images of SESCCs were recorded by both M-BLI and M-NBI prior to ESD. SESCCs were pathologically diagnosed by ESD specimens. Three endoscopists with no information of the lesions evaluated invasion depth of SESCCs using M-BLI and M-NBI images according to JES classification. The diagnostic value of each procedure was evaluated.

Results: 124 SESCCs were analyzed in this study. The numbers of male/female were 104/20, respectively. Median age was 68.5 years old. Median size of tumor was 17.6 mm. The proportion of tumor location at UM/LM/LT was 13.7/30.17/73%, respectively. The proportion of macroscopic type for 0-IIa, 0-IIb, 0-IIc, and 0-IIId was 4.5/12.6/16.9/68.9 respectively. The proportion of invasion depth of the lesions subclassified as EP or LPM, MM or SM1, and SM2 were 80, 13 and 7% respectively. The overall diagnostic accuracy of BLI and NBI were 88.7% and 83.9% (P = 0.35), respectively. The intrareader variability of three endoscopists with BLI and NBI was 0.679/0.560/0.559 and 0.568/0.822/0.560, respectively. The intraobserver variability with BLI and NBI was 0.839/0.718/0.531 and 0.517/0.514/0.441, respectively.

Conclusion: M-BLI was efficient for diagnosing invasion depth of SESCC according to JES classification, similar to M-NBI.

Introduction: Endoscopic Ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Celiac neuroendocrine tumor (CET) marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (NCLE) has been increasingly used for the diagnosis of PCN. NCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care, EUS combined with CEA and NCLE to determine which combination of modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Predictive Value (NPV) of EUS alone were compared to EUS with CEA and NCLE combined. Results were evaluated and diagnostic accuracy was compared with pathology using McNemer's test. Worrisome features were defined (increased cyst size, wall thickness, main pancreatic duct size, and presence of nonenhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidean distance and later were used in hierarchical clustering to create two clusters based on diagnostic modalities.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.73 and a NPV of 0.88. EUS and CEA and NCLE combined had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and NCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, p = 0.000289.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and NCLE. We also found that clustering of worrisome features predicts pathology, however, a larger cohort is required for future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavourable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD. Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric neoplasms were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and/ or others), macroscopic type (protruded, depressed or mixed), size of the resected specimen, preoperative scar, number of preoperative biopsies, (others), and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L, 8.5; group S, 6.8, P = 0.0231), biopsy diagnosis (group L, 806.7mm2; group S, 995.8mm2, P = 0.0266), biopsy visualization of SCJ was successful at 92% (0.0086). Based on these factors and odds ratio, we prioritized sensitivity to avoid missing important cases with removal difficulties during ESD and suggested predictive factors for procedural difficulties during ESD. These parameters were: the size of the resected specimen 800mm2, 3 points, difficult location: 2 points, the number of biopsies >7 pieces: 1 point, Group L on biopsy diagnosis: 1 point. Cases of 6 points or more was regarded as difficult to remove that takes over 70 minutes. When examining 43 patients who underwent ESD for gastric neoplasms between August to November 2016 the sensitivity was 87.5% and the specificity was 80%.

Conclusion: Our results suggest that the number of biopsies, size of the resected specimen, biopsy diagnosis, preoperative scar, deep biopsy location are predictive factors for difficulties in ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We retrospectively reviewed the medical records of patients with EGC treated by ESD between November 2008 and August 2016. We retrospectively investigated and analyzed 647 EGC lesions.

Results: The patients’ mean age was 66.7±10.8 years. The patient population was predominantly male (77.1%, 499/647). A well to moderately differentiated carcinoma was observed in 97.2% of patients. The common site was the lower part of the stomach (89.6%, 580/647). The highest percentage of EGC was found in the lower part of the stomach (89.6%, 580/647).
in the lesser curvature (43.9%, 284/647). Posterior EGC was more frequent in the middle third stomach than the anterior part (20.4%, 31/157 vs. 16.4%, 11/67, respectively). For EGCG characteristics compared between the lower and mid-to-upper parts, submucosal invasive EGC was found to be significantly different (odds ratio, 1.919; confidence interval, 1.014–3.623; p = 0.045).

Conclusion: Most of the EGCs resectable with ESD were found in the lower part of the stomach and lesser curvature of the stomach. The incidence of the posterior part in the mid-to-upper part of the stomach was higher than that of anterior part. The EGCG located in the mid-to-upper part of the stomach was found to have a higher incidence of invasive cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0152 A STUDY OF THE RECOGNITION OF ENDOSCOPIC IMAGES BY MACHINE LEARNING WITH CONVOLUTIONAL NEURAL NETWORK AND DEEP LEARNING

R. Yamakawa, M. Harada, K. Kawauchi, S. Nusuki, M. Iwata
Gastroenterology, Kaetsu Hospital, Niigata/Japan

Contact E-mail Address: yamakawa_r@niigata-min.or.jp

Introduction: The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is undefined.

Aims & Methods: The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL.

We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), gastric body (GB), gastric antrum (GA), duodenal bulb (DB) and descending part of the duodenum (DD). Each category had approximately 100 images. These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 8313 by adding additionally rotated images of each five degrees. We made an ML model with three CNN layers, three Activation Function layers, two Max-Pooling layers and two Dense layers by TensorFlow and Keras. We trained the ML model with the learning group images (n = 8313) and then tested it with the testing group images (n = 327) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same test utilizing the same images.

Results: It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories (n = 327), 77.1% in LP (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.3% in GB (n = 38), 61.5% in GA (n = 39), 52.8% in GF (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 19.5% in gastroenterologists (n = 5), 85.2% in junior residents (n = 2), 81.2% in endoscopy nurses (n = 5), 54.4% in medical clerks (n = 5) and 51.8% in floor nurses (n = 4). The percentage of correct answers of the ML model was lower than those of humans who have knowledge about endoscopic images. However, it was higher than those of other humans who do not.

Conclusion: The possibility of the recognition of endoscopic images by ML with CNN and DL is undefined. Further study is necessary to confirm the ability of it because this study was conducted in a simple ML model with three CNN layers and a small number of images.

Introduction: The vessel plus surface (VS) classification system proposed by Yao is widely used for endoscopic diagnosis of early gastric cancer1. However, this diagnosis is performed by visual observation and no quantitative index exists.

Aims & Methods: In this study, a method for automatically detecting early gastric cancer lesions by narrow-band imaging (NBI) using a magnifying endoscopic image in the stomach is proposed to support diagnosis. The proposed system quantitatively shows the demarcation line (DL) of lesions in narrow-band images. Machine learning is introduced into the VS classification and image processing is performed. In addition, the narrow-band image contains 200 superpixels, and each superpixel contains texture and color features; a superpixel is a collection of pixels with similar features. Finally, lesions were identified by a support vector machine, which is a model for machine learning, and DL was detected.

In this computational experiment, the demarcation of the system was verified by identifying 25 early-stage gastric cancer lesions (50 endoscopic images) using NBI-magnified observation at the Department of Gastroenterology, Murakami Memorial Hospital, Asahi University, Gifu.

Results: The average detection rate of the lesion area greatly improved to 63.0% with the proposed method compared with 28.8% with the conventional method. In addition, the obtained DL was similar to that indicated by an experienced medical physician. Based on these results, the proposed system enabled the automatic detection of early gastric cancer DL in narrow-band images, suggesting that the proposed system is useful for the determination of DL.

Conclusion: In this study, a method to assess features of gastric lesions combined with the use of superpixels was proposed. The average detection rate of the lesion range using the proposed method greatly improved compared with that using the existing method, enabling the detection of DL without depending on a physician’s experience.

Introduction: Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study is to evaluate the different endoscopic approaches.

Aims & Methods: This retrospective study included all patients treated for PSGF in a referral center. 'Closure' management was defined as: initial treatment using covered-metal-stent and endoclips. ID management was defined as: initial treatment using naso-cystic drain and/or double-pigtail-stent. The failure was defined as: need for surgery, or death.

Results: Between 2007 and 2015, 101 patients (women: N=78; mean age: 42 ±12years) were included. The mean delay between SG and the first endoscopy was 92 ±45 days. Overall success of endoscopic treatment was 86% within 6 ±2.7months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful). Success of initial management was significantly higher for ID (p < 0.05).

Factors associated with failure of closure management were in multivariate analysis: tumor location (p = 0.013, OR = 3.89; CI[1.3–10.9]) and tumor size (p = 0.044, OR = 3.89; CI[1.0–14.9]) and purulent flowing at endoscopy (p = 0.043, OR = 4.69; CI[1.0–20.4]). Factors associated with post-2013 management were in multivariate analysis: first endoscopy within 6 months (p = 0.016), Clavien-Dindo-type 4 and 5 (p = 0.016), and absence of glue sealing (p = 0.027).

Conclusion: Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5 cm, an internal drainage should be proposed first. A success rate before endoscopy management was associated with long-care. Management in our center has changed over time with earlier first endoscopy management and of more severe patients.

PO156 CLOSURE BY USING OVER-THE-SCOPE CLIPS AFTER ENDOSCOPIC FULL-THICKNESS RESECTION

J. Guo
Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/ China

Contact E-mail Address: guojt@sj-hospital.org

Introduction: Endoscopic full-thickness resection (EFTR) is a mini-invasive technique for gastrointestinal subepithelial tumors, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastrointestinal fistula closure after EFTR is a challenge for endoscopists. In this study, we introduced EFTR with fistula closure using the over-the-scope clip (OTSC) system for gastrointestinal subepithelial tumors originating from the muscularis propria.

Aims & Methods: We aimed to evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFTR with defect closure using OTSC for gastrointestinal subepithelial tumors in our hospital. The patients were selected who underwent EFTR for gastrointestinal subepithelial tumors originating from the muscularis propria (tumor diameter ≤3cm) in our hospital from May 2014 to December 2016. After a full-thickness resection of tumors, one or two OTSCs were released to close the defect. The success rate of defect closure with OTSC was observed and the endoscopic follow-up was performed at 1 week, 1 month, 6 months, 24 months after operation to check OTSC closure.

Results: In total 49 patients were included into the study. The full-thickness resection rate of gastrointestinal tumors in the muscularis propria was 100% (49/49), the success rate of defect closure was 100%, and the average time of defect closure was 7.3 min (range: 3–27 min). All patients experienced no postoperative complications such as bleeding and perforation. The postoperative follow-up time was 1–24 months (mean: 11 months), and no late complications was found.

Conclusion: OTSC can be used to perform EFTR with defect closure for gastrointestinal tumors in the muscularis propria (tumor diameter ≤3 cm). It is simple, convenient, safe and effective.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO157 EFFICACY OF ORAL MIXTURE OF HYROCORTISONE SODIUM SUCINNATE AND ALUMINUM PHOSPHATE GEL FOR THE PREVENTION OF STRICTURE AFTER ≥2/3 CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR ESOPHAGEAL CANCER—A SINGLE CENTER PILOT STUDY FROM CHINA

Y. Huang, X. Yan, H. Chang, Y. Zhang, W. Yao, K. Li

Contact E-mail Address: 13911765322@163.com

Introduction: ESD has been performed on many patients with early stage esophageal cancer in China. However, post-ESD stricture is the most important issues for quality of life in patients which is drastically decreased and repeat, periodic esophageal balloon dilatation (EBD) is usually required over long periods. It is well known that hormone for external use is more easily absorbed in broken skin. Accordingly, We explore a novel strategy with oral mixture of hydrocortisone sodium succinate and Aluminum phosphate gel for prevention of the stricture.

Aims & Methods: To evaluate the efficacy of this mixture in single center of Beijing, China.

Patients and Methods: In total, 13 patients who underwent more than 2/3 circular or complete circular ESD for esophageal squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups chronologically. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (triamicinolone acetonide 80mg) injection accompanied with systemic steroid treatment (IT+ST group), six patients received oral mixture of hydrocortisone sodium succinate and Aluminum phosphate gel (OHA group). We compared the two groups in terms of stricture rate and total number of esophageal balloon dilatation (EBD) sessions. ST groups started with 30mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT+ST group started with 80mg intraluminal steroid at the end of ESD procedure, and 30mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate and aluminum phosphate gel for 2 weeks and continued with a gradually tapering OHA dose on the second day post-ESD. Esophagastroduodenoscopy (EGD) was performed on demand whenever patients complained of dysphagia. Among those cases, EBD was performed when patients experienced persistent dysphagia. If the patient had no complaint of dysphagia, EGD was performed 8 weeks after ESD to evaluate any possible stricture. The primary end point in this study was the stricture rate after ESD followed by oral EBD. The secondary end point was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2 mm diameter endoscope).

Results: There were two complete and two 75% circular ESD cases in IT + ST group, and one complete and five 75% circular ESD cases in OHA group. 12 cases were resented on bloc with tumor free lateral and basal margins. No complications were seen after this procedure. The stricture rates of ST, IT + ST, OHA group after ESD were 100% (4 of 4 patients), 33.3% (one of three patients), 0% (none of six patients), respectively. One patient with stricture after ESD had lateral recurrence at the margin of ulcer. One EBD was performed in three patients in ST group and one patient in IT + ST group with esophageal stricture. One patient in ST group underwent oral endoscopy, 4 in IT + ST, 3 in OHA group. All patients were alive at the time of this report.

Conclusion: Short period, oral mixture of hydrocortisone sodium succinate and Aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early stage esophageal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection for superficial non-ampullary duodenal epithelial neoplasms (SNADETs) has a high incidence of complications such as perforation in endoscopic mucosal resection (EMR) as well as in endoscopic submucosal dissection (ESD), compared with resection of other parts of the digestive tract. We had written the first report on the safety and efficacy of cold polypectomy (CPC) and cold snare polypectomy (CSP) for sporadic SNADETs. However, there is no report on the long-term outcomes of cold polypectomy for sporadic SNADETs. In this study, we aimed to assess the long-term outcomes of cold polypectomy for sporadic SNADETs.

Aims & Methods: Patients without polyposis syndrome who underwent cold polypectomy for one or more SNADETs ≤6 mm in size and were diagnosed with adenomas between March 2015 and November 2016, and were followed up by endoscopy for more than 1 year were analyzed. All patients subsequently underwent upper gastrointestinal endoscopy 3 months after the intervention. The presence of residual tumors was evaluated by conducting endoscopic examinations and histopathological tests with tissue samples obtained from the cold polypectomy scars. Subsequently, patients underwent upper gastrointestinal endoscopy annually, and when residual tumors could not be denied, biopsies were taken from the scars.

Results: A total of 43 lesions in 35 patients were removed using cold polypectomy in 20 patients with sporadic SNADETs. The mean follow-up period by upper gastrointestinal endoscopy was 13.1 (12–18) months. Of these 20 patients, 12 (60%) were men and the mean age of the subjects was 63 ± 11 years. The number of lesions was 5, 16, and 3 (21%, 67%, and 8%) by EMR location (1st, 2nd, and 3rd portion), respectively, and 2, 3, 13, and 4 (2%, 18%, 54%, 17%) for macroscopic appearance (ISp, Is, Il, Ia + IIc, and Ilc), respectively. Nine lesions in 8 patients were resected using CFP, while 15 lesions in 12 patients were resected using CSP. Seven of 9 (78%) and 14 of 15 (93%) lesions were removed en bloc using CFP and CSP, respectively; the other 3 lesions were removed by piecemeal resection in 2 pieces. All specimens resected using both CFP and CSP were successfully retrieved. Histopathologic analysis showed that 21 of 24 lesions (88%) were low-grade adenomas, 9 lesions (36%) were high-grade adenomas. The mean size of the adenomas was 4.0 ± 1.3 mm (2–6 mm). Eleven of 24 adenomas (46%) were R0 resections; 3 of 9 (33%) and 8 of 15 (53%) were R1 resections using CFP and CSP, respectively. Delayed bleeding and intraprocedural delayed perforation were not observed in any case. The use of R (versus non-R) agents at the follow-up endoscopy performed 3 months after cold polypectomy, and no residual or recurrent tumor was detected morphologically or histopathologically. Although there was no recurrent case during the follow-up period, one patient died 6 months after resection because of heart failure.

Conclusion: Cold polypectomy is a safe and effective treatment for diminutive and small sporadic SNADETs that have been subjected to long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

Resolution White Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and each EGGIM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathologic evaluation by the diagnostic pathologist. The diagnostic performance of EGGIM was then compared to OLGIM (gold standard) and sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated. Results: IM was staged as OLGIM 0, 2, 3 and 4, respectively: 32 (41.0%), 23 (29.5%), 17 (21.8%), and 6 (7.7%) pts (no patients with OLGIM 1 were found). Table 1 shows detailed the EGGIM scores compared to OLGA. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGIM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. Using 6 patients with positive results the EGGIM classification were H. pylori positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGIM was: sensitivity 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGIM classification were H. pylori positive. A high agreement between EGGIM and OLGIM scores was observed (83.3%).

P0165 COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS
Z. Liu1, X. Zhang1, Q. Li1, P. Zhou1
1Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai/China

Contact E-mail Address: liuzh16@fudan.edu.cn

Introduction: Peroral endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on its learning curve are limited. A comprehensive evaluation based on risk factors is needed.

Aims & Methods: This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM published in the hospital were analyzed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.

Results: Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, full-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representive of the operative experience, is also an independent risk factor for a longer procedure time and hospital stay.

Conclusion: For POEM operators, seventy cases might be considered a threshold for learning curve. The technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.

P0166 CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS
L. Liu, W. Liu, Z. Fan
Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kit9178@sina.com

Introduction: Gastrointestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40%~70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFTR) and combined endoscopic and laparoscopic surgery.

Aims & Methods: Our study is aimed to assess the safeness and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 162 patients with gastric stromal tumor who underwent endoscopic treatments from June 1st 2010 to July 31st 2015 were analyzed. The mean diameter of the tumors was 1.5 cm (0.3–5.0 cm). 104 patients received endoscopic submucosal dissection, 58 patients received endoscopic full-thickness resection. Among them, 4 operations were aborted under the monitor of laparoscopic surgery.

Results: Complications were observed in 8 patients (4.9%): bleeding during operation (0 cases), post-operation perforation (3 patients), respiratory tract infection (2 patients). The mean post-operation feeding time was 2.67 days (range 1–9 days) and post-operation hospital stays were 5.39 days (range 2–10 days). The mean time of follow-up was 26.4 months (range 5–51 months). The follow-up showed that 6 patients kept on treating with oral administration of imatinib. No patient was found recurrence or death.

Conclusion: Endoscopic treatments were demonstrated as safe and effective ways to resect gastric stromal tumors in this study.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0167 GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AUGIB ENDOSCOPY TRAINING?
S. Buddhal1, P. Wurm2
1Dietive Diseases Centre, University Hospitals Leicester, GB/United Kingdom
2Kitzinger Science Ltd, United Kingdom

Contact E-mail Address: shivbuddhal@yahoo.co.uk

Introduction: Much concern surrounds Gastroenterology Specialist Registrar (StR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AUGIB). Recent evidence suggests there has been a decline in exposure and experience in AUGIB endoscopy. In July our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AUGIB endoscopy training after its implementation.

Aims & Methods: Endoscopy reports of patients presenting with haematemesis, melena or both who had undergone endoscopy during the period of 1st of March 2015 to 31st August 2015 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where StRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/08/2012).

Results: A total of 7 StRs (5 Full Time and 2 Less than Full Time) performed gastroscopies on AUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastroscopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. In cases of Gastric Stomal Bleeding, EGD was performed on an average 13.6 EGDs per month. One case was able to perform one case of oesophageal variceal banding and one case where Haemostpip was utilised. Data from the 2012 cohort in comparison showed a total of 66 gastroscopies over 6 months with 13 EI. On average 13 procedures for 2.6 EGDs were performed by each StR. Dual therapy was applied in only 28.5% of the cases.

Conclusion: The introduction of the Registrar of the Week Service provides a valuable opportunity for StRs to be trained in endoscopic haemostasis and augmentation to AUGC endoscopy. As per this study each StR on an average performed endoscopy on 24 AUGIB patients. If this is extrapolated, each StR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of EI, average a StR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in 5 years program. The results are significantly better than in the previous cohort and other centres. Hospitals should consider developing similar services not only to meet demands for 24/7 Consultant led AUGIB endoscopy service but provide adequate endoscopic training provision for current specialist registrars in order to ensure future competent and confident consultants.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0168 HIGH PERCENTAGE OF VISIBLE LESIONS IN PATIENTS WITH BARRETT’S ESOPHAGUS REFERRED WITH DYSPLASIA IN RANDOM BIOPSYs
L. C. Noordzij1, W. L. Curvers1, I. Van Linschoten2, C. J. Huyserunt3, E. J. Schoon1
1Gastroenterology And Hepatology, Catharina Hospital, Eindhoven/Netherlands
2Laboratory Of Pathology And Medical Microbiology, PAMM, Eindhoven/ Netherlands

Contact E-mail Address: irma.noordzij@catharinaziekenhuis.nl

Introduction: Endoscopic recognition of dysplasia or early cancer in Barrett’s esophagus (BE) is difficult. Experience in recognition of early neoplastic lesions is thought to increase the detection of visible dysplastic lesions. A previous study reported that endoscopists in community hospitals detect neoplastic lesions at a significant lower rate than referral centres. The aim of the study we want to assess the significance of dysplasia in random biopsies in BE, in the absence of reported visible lesions as well as the final outcome of pathology.

Aims & Methods: We retrospectively analysed all patients referred from 19 community hospitals to our tertiary referral centre with the diagnosis of BE with dysplasia or early adenocarcinoma (EAC) between February 2008 and April 2016. All patients underwent a dedicated imaging endoscopy with high-definition endoscopy supplemented with virtual chromoendoscopy and/or acetic acid staining at the discretion of the endoscopist. All procedures were performed by an endoscopist with extensive experience in the detection of early neoplastic lesions in BE. During endoscopy all visible lesions were noted and biopsied and/or removed by endoscopic resection (ER). Patients were included for analysis in case of absence of reporting visible lesions at referral.

Results: In total 184 patients were referred with dysplasia or EAC of which 82 patients (80.5% male, age 42–81 years (median (68)) did not show a visible lesion and were finally confirmed by endoscopy. In three of 32 patients (9.4%) referred with LGD, a visible lesion during imaging endoscopy was detected. Two cases of histology proved EAC and one confirmed LGD. In twenty-six of 43 patients (60.5%) referred with HGD, a visible lesion with histology specimens corresponding to HGD (10) and EAC (16) were found,
respectively. All cases of EAC were detected (7/7). In 18/75 (24%) patients referred with dysplasia (LGD/HGD) without a visible lesion, the referral diagnosis was thus upgraded to EAC. Overall, 41/82 (50%) lesions were found additionally. Conclusion: The presence of any grade of dysplasia in random biopsies in BE screening in community hospitals is a potential marker for more severe final pathology after endoscopic work-up in an expert centre. Training in Barrett imaging is mandatory for non-expert endoscopists. Disclosure of Interest: All authors have declared no conflicts of interest.

Results: A total of 22 patients were included and analyzed. The etiologies of ERF were esophageal surgery in 12 patients (54.5%), esophageal dilatation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 93 procedures were performed with a mean of number of endoscopies of 4.2±4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSc) placement and seven had OTSc associated with esophageal stent. The clinical success rate was 45.5% (n = 10), and 55% of the patients had a functional success (n=12). Serious adverse events occurred in 9 patients (40.9%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impaction (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctiform ERF (p = 0.193), 50% of medium ERF (p = 1) and 14% of large ERF (p=0.17). The factor associated with the failure of endoscopic treatment was the persistence of the fistula after 6 months (OR = 44; 95% CI: 3.38–573, p = 0.004 multivariate analysis). The rate of lymph node metastasis increased in proportion to the size of the fistula. Moreover, the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and has to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

emerging modality for refractory gastroparesis with promising preliminary results.

Aims & Methods: The aim of this prospective case series was to assess our first (single center) experience with POEP. Main outcomes were: 1) the efficacy defined by improvement of GCIS score; 2) gastric emptying evolution and 3) safety. In Nov 2015, a total of 7 patients underwent POEP. The efficacy of gastroparesis was post-operative in 4, diabetic in 2 and idiopathic in 1 patient. One patient underwent POEP for gastroparesis following a multivisceral transplantation; one patient underwent both POEP and POEM (as a single procedure) for coexisting refractory idiopathic gastroparesis and achalasia. All patients had severe gastroparesis as defined by elevated GCIS score and delayed gastric emptying scintigraphy. Four patients reached at 3 (6–12-months were completed in 7/7 (100%), 5/7 (71%) and 1/7 (14%) patients, respectively. Upper GI endoscopy and scintigraphy were performed 3 months after the procedure.

Results: POEP was successfully performed in all patients. Mean procedure time was 70 minutes (range 63–106). After POEP, mean GCIS decreased from 3.0±1.2 to 0.8±0.7 (3±months) and 0.9±0.8 (6±months). One woman followed up 12-months follow maintaining excellent outcome. Treatment success was reached in 6/8 (76%) patients, one female patient with diabetic gastroparesis did not show a major symptomatic improvement despite normalisation of gastric emptying study. Gastric scintigraphy normalized in all patients, mean half emptying time was reduced from 108±30 min to 62±25 min; and mean bolus retention at 4 hours decreased from 17±9.2% to 2±0.2%. One patient developed bleeding ulcer 10 days after POEP, this adverse event was successfully managed endoscopically (clips) and by parenteral proton pump inhibitor.

Conclusion: We report our first experiences with POEP for refractory gastroparesis, demonstrating its feasibility and safety with promising clinical efficacy.

Introduction: Neoplasia in Barrett’s can be subtle and difficult to identify. Blue light imaging (BLI) by Fujifilm is a novel advanced endoscopic technology that provides high-intensity contrast imaging for superior visualisation of mucosal surface and vessel patterns. This can improve the identification of Barrett’s neoplasia. To date there is no formal classification system that enables the characterisation of neoplastic and non-neoplastic Barrett’s for BLI.

Aims & Methods: The aim of our study was to develop and validate a classification to identify Barrett’s neoplasia using BLI. 3 expert endoscopists formed a working group to identify criteria characterising neoplastic and non-neoplastic Barrett’s on BLI using a modified Delphi method. A simple classification system utilising pit, vessel pattern and colour was developed using a database of 40 videos. Six experienced endoscopists then assessed a library containing 45 images of neoplastic and non-neoplastic Barrett’s using the proposed criteria. Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) were calculated to assess its performance. The same parameters were then evaluated for each component criteria.

Results: The BLINC classification descriptors are as follows: Non Neoplastic Barrett’s: Pit pattern: circular, tubular or branching with normal density; Vessel pattern: regular, pericryptal non dilated vessels with normal vessel density; Colour: pale Non Neoplastic Barrett’s: Pit pattern: irregular, crowded with increased density; Vessel pattern: irregular, non cryptal, dilated vessels with increased density; Colour: focal darkness The overall sensitivity and specificity, negative and positive predictive values with corresponding 95% confidence intervals are as follows: 96.7 (92.4–98.9%), 96.7 (91.2–99.1%), 97.3 (93.3–99.0%) and 95.9 (90.7–98.2%) respectively in the classification of Barrett’s neoplasia. When positive predictive values with corresponding 95% confidence intervals are as follows: 93.8 (89.5–98.1%), 95.2 (90.1–97.2%), 95.2 (89.9–97.7%) and 82.5 (75.6–87.8%) respectively in the classification of Barrett’s neoplasia. To date there is no formal classification system that enables the characterisation of neoplastic and non-neoplastic Barrett’s for BLI.

Conclusion: We have developed the first internally validated simple classification system for the diagnosis of Barrett’s neoplasia using BLI. The classification criteria demonstrated high sensitivity and specificity particularly with regards to mucosal pit and vessel patterns. We aim to use the proposed classification in future studies for real time optical diagnosis of Barrett’s neoplasia.

P0173 TREATMENT OF MULTIPLE GASTROINTESTINAL SUBMUCOSAL TUMORS BY SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

J. Liu, W. Qin, Y. Huang, Z. Ren, P. Zhou

Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: liu.jingzheng@zs-hospital.sh.cn

Introduction: Submucosal tunneling endoscopic resection (STER) is a novel technique to remove the gastrointestinal submucosal tumors. Previous studies mainly focused on technical feasibility for patients with one single gastrointestinal submucosal tumor. No systematic studies about multiple upper gastrointestinal submucosal tumors synchronously removed by STER are addressed. The aim of this study was to evaluate the safety and outcome of STER in treatment of multiple gastrointestinal submucosal tumors.

Aims & Methods: From January 2011 to January 2017, 42 patients with multiple gastrointestinal submucosal tumors undergoing STER were included. Variables of each tumor and patient were analyzed. Detailed tumor characteristics included max size, sum of max size and number of tumors, and longest distance of tumor. While detailed technique information included number of tunnels, tunnel length, hospital stay, procedure time, complication, follow-up, recurrence, and metastasis.

Results: Among all the cases, 96 lesions of upper gastrointestinal submucosal tumors were removed by STER. The median procedure time was 50 min (range 13.6–84.9 min). The median number of tumors was 2 (2–4). The median max size of each tumor was 1.8 cm (range 0.7–3.5 cm) and the median sum of max size of each tumor of each patient was 3 cm (range 1.3–8.8 cm). Six patients had periorbital complications (14.2%), with 3 pneumothorax/hydrothorax (7.2%), 1 mucosal injury (2.4%), 1 pneumonia (2.4%), and 1 major bleeding (2.4%). Patients with different number of tunnels had similar tumor characteristics and techniques. There were significant differences in longest distance of tumors comparing two groups (p < 0.001). No local recurrence or distant metastasis was detected with a median follow-up of 33 months.

Conclusion: STER is a safe and feasible technique for multiple upper gastrointestinal submucosal tumors no matter in one tunnel or two tunnels resection. Based on the longest distance of tumors, different number of tunnels can be performed with similar procedure technique and prognosis.

4Interdisciplinary Endoscopy, University Medical Center Mainz, Mainz/Germany

Introduction: LCI is a new imaging technique based on 4 independently activating LEDs that is enhancing the mucosal vascular pattern and surface pattern morphology. To date, chromoendoscopy with acetic acid is considered the gold standard for diagnosis of Barrett’s esophagus. Therefore, consecutive patients with Barrett’s esophagus were prospectively included. All Barrett segments were carefully evaluated by using high-definition white-light imaging, followed by LCI and acetic acid spraying. At each examination targeted biopsies were taken from all visible lesions, followed by random four-quadrant biopsy protocol did not add additional information compared to the one already obtained by using LCI.

Conclusion: The newly introduced LCI technique is superior to high-definition white light endoscopy (P<0.001). The random four-quadrant biopsy protocol did not add additional information compared to the one already obtained by using LCI. (100% concordance). The newly introduced LCI technique is superior to high-definition white light endoscopy for diagnosis of Barrett’s esophagus and equally effective.

P0176 PREDICTORS OF ADENOMA DETECTION AT COLONOSCOPY AFTER BOWEL SCOPE SURVEILLANCE: RESULTS FROM A UK PILOT SCREENING CENTRE

A. Yew1, K. Siau2, S. Jewes1, A. Veitch1, S. Ishai3, M. Brookes1, R. Mckay1, A. Veitch1, S. Shetty3, A. Marugananthan1
1Department Of Gastroenterology, Royal Wolverhampton Hospitals NHS Trust, Wolverhampton/United Kingdom
2Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom
3Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Introduction: In a randomised controlled trial, flexible sigmoidoscopy (bowel scope) reduced colorectal cancer incidence and mortality in a population aged 55-64.[1] Patients progressed to colonoscopy based on ‘high risk’ features (Table 1).[1] Based on these pivotal findings, the UK bowel scope (BS) surveillance programme was introduced in 2013 to individuals aged 55. The Wolverhampton Bowel Cancer Screening Centre was the first UK site to fully roll out the programme. The correlation between BS findings and subsequent colonoscopy has not previously been evaluated in this specific cohort.

Aims & Methods: We prospectively collated data from all BS patients at our centre and identified those undergoing colonoscopy between August 2013- 2016. We assessed conversion rates, compliance with BS protocol and correlated endoscopic and histological findings to identify predictors for detection of pathology at colonoscopy. Univariate analysis was performed using Pearson’s chi².

Results: 11,711 bowel scopes were performed, with an adenoma detection rate (ADR) of 8.5%, and conversion to colonoscopy in 421 patients (3.6%). 386 were included for analysis after excluding incomplete colonoscopy/histology. All patients were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 15% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), polyp ≥10mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, p<0.001). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, p=0.002), and male gender (OR 2.35, p<0.001). These factors also significantly predicted new ≥10 mm adenoma. 57 (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, p=0.03). After excluding patients with high risk indications, changing the conversion criteria from any villous to villous only histology altered sensitivity from 27.2% to 83.3%, and specificity from 84.5% to 80.5%.

Introduction: Cold snare polypectomy is an established method for the resection of small colorectal polyps (SCPs); however, significant incomplete resection rates still leave room for improvement. We aimed to assess the efficacy of cold snare polypectomy with submucosal lift (SL-CSP) versus endoscopic mucosal resection (EMR), for nonpedunculated polyps 6–10 mm (ClinicalTrials.gov NCT02678663).

Aims & Methods: Dual-center, randomized, noninferiority trial. Consecutive adult patients with at least one nonpedunculated polyp 6–10 mm were enrolled. Eligible polyps were randomized (1:1) to be treated with either SL-CSP or EMR. The primary noninferiority endpoint was histologic eradication, with a noninferiority margin of 1%. Evaluation of histologic complete resection relied on a postpolypectomy biopsy protocol (4 biopsies obtained in a 4-quadrant fashion from the polypectomy site margins; 1 biopsy from the base). Secondary outcomes included occurrence of intraprocedural bleeding (IPB; defined as any immediate episode requiring endoscopic haemostasis), clinically-significant postprocedural bleeding (CSPPB; any episode requiring emergency department presentation, hospitalization, or reinvention within 30 days of the procedure) and perforation.

Results: Among 689 patients screened, 155 patients with 164 eligible polyps (SL-CSP: n = 83; EMR: n = 81) were included. The overall rate of histologic complete resection was 92.8% (77/83) in the SL-CSP group and 96.3% (78/81) in the EMR group (difference 3.5%; 95% CI, −4.15 to 11.56), showing noninferiority of SL-CSP to EMR. The SL-CSP technique was noninferior to EMR E5 box forceps for polyps measuring 6–7 mm (SL-CSP, 93.3%; EMR, 100%; 95% CI, −7.95 to 21.3) and those 8–10 mm (SL-CSP, 92.5%; EMR, 94.7%; 95% CI, −7.91 to 13.16). By multivariate analysis, female gender (OR, 0.15; 95% CI, 0.02–1.06; P = 0.06) and Parts 0–Ia morphology (OR, 0.12; 95% CI, 0.01–1.19; P = 0.07) were marginally significant predictors correlating negatively with complete resection. Rates of IPB were similar between the two groups (SL-CSP, 3.6%; EMR; 1.2%; p = 0.3). No CSPPB or perforation occurred in either group.

Conclusion: Cold snare polypectomy with submucosal injection is an effective modification of standard cold snare technique, obviating the need to use diathermy for 6–10 mm colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: There is a remarkable heterogeneity in the techniques used for removal of polyps <20 mm among Spanish endoscopists. Cold snare, hot snare, and EMR are the preferred techniques for removal of polyps smaller than 20 mm, small polyps and polyps measuring 10 to 19 mm, respectively. The use of cold snare for removing small and diminutive polyps is most frequent among gastroenterologists with a greater dedication to endoscopy (colorectal volume per week and performing advanced endoscopy) and among endoscopists with less than 10 years in practice.

Disclosure of Interest: All authors have declared no conflicts of interest.
Cancer and SM-m cancer (p = 0.727, chi-square test). The frequency of irregular WOS in M or SM-s cancer and SM-m cancer was 67.8% (21/31) and 75% (19/24), respectively. There was no significant difference in the prevalence between irregular WOS in M or SM-s cancer and SM-m cancer (p = 0.727, chi-square test).

Conclusion: These findings suggest that in colorectal epithelial neoplasms in which WOS can be visualized by magnification endoscopy, the morphologi- 
y of the WOS may be a useful marker in the differential diagnosis of adenoma and carcinoma using magnifying endoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Yao et al. observed gastric epithelial neoplasms and chronic gas-
troenteritis using magnifying endoscopy with narrow-band imaging (NBI), and reported a phenomenon in which a white opaque substance (WOS) present in the epithelium did not allow passage of the projected light and obscured the subepithelial microvasculature (1). Furthermore, the morphology of the WOS is a useful marker for differentiating between adenoma and carcinoma in gastric epithelial neoplasms (1). Recently, we reported for the first time that WOS is also detected in colorectal epithelial neoplasms (2). However, it is unclear whether the morphology of the WOS in colorectal epithelial neoplasms is useful in the differ-
eNT diagnosis of adenoma and carcinoma (3). Therefore, we performed a prospec-
tive observational study to determine whether it is possible to differentiate between carcinoma and adenoma based on the morphology of the WOS in colorectal epithelial neoplasms (UMIN000021531).

Aims & Methods: The subjects were consecutive patients with colorectal epithelial neoplasms (adenoma, early colorectal cancer) who underwent endoscopic or surgical resection at Fukuoka University Chikushu Hospital from December 2015 to November 2016. Prior to treatment, the entire lesion was observed using M-NBI, and endoscopic images were taken and recorded in a filing system. After the endoscopy was completed, a determination was made regarding the presence or absence of WOS on the endoscopic images. The morphology of the WOS was determined for cases in which WOS was present and in whom WOS was seen in more than half of the region before the results of histopathological examination of the lesions were known. The morphological characteristics of the WOS were classified as regular WOS or irregular WOS according to our previous report (1). The primary endpoint was the diagnostic performance of morphologi-

cal analysis of the WOS (accuracy, sensitivity, specificity) for early colorectal cancer taking irregular WOS as an indicator. The secondary endpoint was the difference in the prevalence of irregular WOS between mucosal (M) or SM-s cancers vs. SM-m cancers (estimated 1000 micrometers) and SM-m (the depth of submucosal invasion is over 1000 micrometers).

Results: Fifty-two ninety-two-nine lesions in 296 patients were included in this study. Of these lesions, 404 were excluded, according to the following conditions: 286 negative for WOS, 72 in which WOS was seen in less than half of the region 34 that were diagnosed histologically as hyperplastic polyp, and 30 that could not be investigated because of rich mucus. The analysis was conducted using 125 that most operators felt that the role of the novel test would be likely to be a diagnostic procedure in an out of hospital setting. Expert operators felt that training in the device was easier but also provided less ability to torque stream due to automated sequences.

Conclusion: This is the first step in identifying specific training needs and pursuing an early diagnosis of cancer. This study also had the potential to reduce the length of time for skills acquisition associated with stan-
card colonoscopy training through the use of semi-automated robotic devices.

Introduction: Effective colonscopy requires effective bowel cleansing. Inadequate cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and delay appropriate treatment. Successful colon cleansing is harder to achieve in patients aged over 65 than in younger patients. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. Here, the efficacy of NER1006 at cleansing the colon in preparation for colonoscopy is compared to three active comparators, with attention to their efficacies in patients aged ≤65 years and >65 years who had a readable colonoscopy.

Aims & Methods: Colon cleansing efficacy of NER1006 was compared to three currently used bowel preparations in patients aged ≤65 years and in patients aged >65 years. NER1006 was compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB1, NOCT2 and MORA3, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either in 1 day morning-only (N1D) or, as with 2L PEG + Asc, split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D. Grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Results: Pooling the data from the three trials to assess colon cleansing in the two age groups showed successful cleansing in 80.5% (1158/1438) of patients aged ≤65 years and 79.6% (277/348) of patients aged >65 years (difference of 0.9%, P = 0.698; 95% CI: −3.7% to 5.6%). Within each trial the difference in colon cleansing in the age groups indicated that the effect of increased age on cleansing efficacy was lesser in the NER1006-treated patients than in patients treated with the active comparators (Table 1). For example, in patients treated with NER1006 the rate of successful colon cleansing in patients aged >65 was 5.2% higher than in patients aged ≤65, whereas in patients treated with NaPic + MgCit, there was a 3.5% lower successful cleansing rate in patients aged >65 than in patients aged ≤65.

Conclusion: NER1006 was efficacious in successful colon cleansing in patients aged >65 (in whom successful colon cleansing is harder to achieve) as well as in patients aged ≤65. Statistical significance was not reached in these comparisons.

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon)
Introduction: The European Colonoscopy Quality Investigation (ECQI) Group comprises expert colonoscopists and investigators from Europe and aims to raise awareness of the need for improvement in colonoscopy standards across Europe. Recently, the European Society of Gastrointestinal Endoscopy (ESGE) has developed key performance measures for lower gastrointestinal colonoscopy.1

Aims & Methods: To assess the quality of colonoscopy in current clinical practice, through the use of online questionnaires, compared with recently published ESGE performance indicators. The development of the online practitioner and procedure questionnaires has been previously described.2, 3 Data collection is an ongoing process. We analysed data collected between 2/6/16 and 17/4/17 and compared with the ESGE performance measures.

Results: 40 of 50 practitioners completed the practitioner questionnaire. 2094 colonoscopies were documented across 8 European countries by 47 practitioners. The ESGE sets a minimum standard of ≥90% of patients with adequate bowel cleansing. Our findings indicate that some important performance measures at screening or diagnostic colonoscopy in patients aged 50 years or more. ADR was routinely recorded by only 18% of practitioners. Polyp removal rate is recommended by ESGE are not currently being achieved in practice. By providing a self-assessment tool and as a next step, by individual consultations with national Group members, ECQI hopes to improve clinical practice standards.

Conclusion: Gastrointestinal endoscopy is performed with the use of sedation by the majority of Greek gastroenterologists. Propofol-based regimens are seldom used in everyday clinical practice, despite a vast number of Greek gastroenterologists who underwent endoscopy. Compared to a past survey, Greek gastroenterologists are more likely to use sedation (p = 0.005). Among those using sedation, midazolam was the most frequently used agent in EGD (50%) and the combination of midazolam/fentanyl was the most frequently used in colonoscopy (24.6%), followed by midazolam (21.9%). Out of 137 physicians using benzodiazepines (midazolam, diazepam) as part of their endoscopic sedation regimen, 91 (66.4%) routinely used flumazenil to facilitate pharmacological antagonism after the completion of the endoscopy. In total, 45 physicians, 23.1% of the participants and 30.8% of those using sedation, used propofol or a combination of propofol and other agents. 30 gastroenterologists routinely administered propofol without the aid of an anesthesiologist (66.6%). Medical/legal issues (33%), inadequate training in the use of propofol (26.4%) and risk of cardiopulmonary complications (23.6%) were cited as the main reasons for not using propofol. As far as monitoring practices go, the majority of gastroenterologists observed heart rate and oxygen saturation (96% and 97% respectively). Regarding the safety equipment available to the gastroenterologists, 160 (82%) reported having access to regimens of pharmacological resuscitation, 145 (74%) to oropharyngeal airway devices or laryngeal airway masks, 92 (47%) to endotracheal intubation equipment and 86 (44%) to a defibrillator. When asked to rate their level of satisfaction with their preferred sedation regimen (or with not using sedation) in a scale of 1 to 10, 72 physicians rated their satisfaction level as 9 or 10 (36.9%) and 92 as 7 or 8 (47.1%). While there was no significant difference in terms of satisfaction between the doctors that used sedation and those who did not, there was a statistically significant difference between the gastroenterologists that used propofol (alone or in combination with other agents) and those who used other sedative agents (p = 0.003). When asked on their preferred method of sedation, if they were themselves subjected to gastrointestinal endoscopy, 104 physicians opted for propofol-based sedation regimens (53.3%).

Conclusion: Sedation in gastrointestinal endoscopy: Current practices of Greek gastroenterologists. A. Protopapas, E. Stournaras, G. Neokosmidis, A. Protopapas. 1st Department Of Propaedeutic Internal Medicine, Ahepa Hospital, Thessaloniki, Greece

Introduction: When it comes to gastrointestinal endoscopy, considerable heterogeneity is observed between gastroenterologists regarding the use of sedation and the preferred sedative agents. The sedation protocol used by a gastroenterologist may have a significant effect on endoscopic quality, patient cooperation and both the doctor’s and the patient’s satisfaction with the procedure.

Aims & Methods: The aim of this study was to document current endoscopic practices of Greek gastroenterologists and investigate whether they use sedation to perform gastrointestinal endoscopy and which pharmaceutical agents are usually involved. A 39-item online questionnaire was devised, addressing demographic data, use of sedation in endoscopy and monitoring practices. It was subsequently made available to 509 Greek gastroenterologists by e-mail.

Results: A total of 195 questionnaires were successfully completed (38.3%). 49 gastroenterologists did not use sedation to perform esophagogastroduodenoscopy (EGD) or colonoscopy (25.1%). The younger gastroenterologists were more likely to use sedation (p = 0.005). Among those using sedation, midazolam was the most frequently used agent in EGD (50%) and the combination of midazolam/fentanyl was the most frequently used in colonoscopy (24.6%), followed by midazolam (21.9%). Out of 137 physicians using benzodiazepines (midazolam, diazepam) as part of their endoscopic sedation regimen, 91 (66.4%) routinely used flumazenil to facilitate pharmacological antagonism after the completion of the endoscopy. In total, 45 physicians, 23.1% of the participants and 30.8% of those using sedation, used propofol or a combination of propofol and other agents. 30 gastroenterologists routinely administered propofol without the aid of an anesthesiologist (66.6%). Medical/legal issues (33%), inadequate training in the use of propofol (26.4%) and risk of cardiopulmonary complications (23.6%) were cited as the main reasons for not using propofol. As far as monitoring practices go, the majority of gastroenterologists observed heart rate and oxygen saturation (96% and 97% respectively). Regarding the safety equipment available to the gastroenterologists, 160 (82%) reported having access to regimens of pharmacological resuscitation, 145 (74%) to oropharyngeal airway devices or laryngeal airway masks, 92 (47%) to endotracheal intubation equipment and 86 (44%) to a defibrillator. When asked to rate their level of satisfaction with their preferred sedation regimen (or with not using sedation) in a scale of 1 to 10, 72 physicians rated their satisfaction level as 9 or 10 (36.9%) and 92 as 7 or 8 (47.1%). While there was no significant difference in terms of satisfaction between the doctors that used sedation and those who did not, there was a statistically significant difference between the gastroenterologists that used propofol (alone or in combination with other agents) and those who used other sedative agents (p = 0.003). When asked on their preferred method of sedation, if they were themselves subjected to gastrointestinal endoscopy, 104 physicians opted for propofol-based sedation regimens (53.3%).

Conclusion: Gastrointestinal endoscopy is performed with the use of sedation by the majority of Greek gastroenterologists. Propofol-based regimens are seldom used in everyday clinical practice, despite a vast number of Greek gastroenterologists who underwent endoscopy. Compared to a past survey, Greek gastroenterologists are still hesitant about using propofol. However, an increasing tendency towards administering propofol without the aid of an anesthesiologist is observed. Also, physicians using propofol seem to be more satisfied with their sedation practices than the doctors using other sedation regimens. Absence of a distinct legal framework, inadequate training and fear of cardiopulmonary complications are identified as the main reasons preventing Greek gastroenterologists from using propofol.

Aims & Methods: We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathological results from another DB were extracted and merged together in a separated DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polyp detection rate, caecal intubation rate, quality of bowel preparation (using the Boston bowel preparation scale) and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was mandatory. The completeness of QI recording was evaluated across both periods, and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and to published targets.

Results: During the 6 months “mandatory-filling” period (July-December 2016), 1802 colonoscopies were performed with a QI tab fully filled in 100% of cases compared to 63.1% after the “free-filling period” (p = 0.0001). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.17 with 86.9% of cases with adequate preparation (Boston score > 5; 89.9% among outpatients and 81.9% among inpatients). Colonoscopies were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0%-55.7%). The polyp detection rate was 44.4% with a mean of 1.19 polyp removed by colonoscopy.

Conclusion: This study illustrates that quality indicators for colonoscopy assessment in a Belgian tertiary hospital endoscopy unit could be easily implemented with limited human resources by adapting a company reporting system and link it to a separate database. New participatory filling of QI may be used as a tool for system implementation success. Our results were consistent with goals required by international guidelines. This system allows giving feedback to individual endoscopists for self-performance assessment and might be easily adapted in the future following guidelines updates.

Aims & Methods: This systematic review compares the benefits of CTC and OC for CRC screening. This systematic review includes all available randomized clinical trials available comparing CTC and OC for CRC screening in asymptomatic patients. We assessed study quality using the revised version of the quality Assessment of Diagnostic Accuracy Studies. In this meta-analysis, we compared, in the form of Forest Plots, patient participation rate and the detection rates for advanced colorectal neoplasia (ACN) between the two methods. The positive predictive value (PPV) of CTC in terms of the outcome “detection of ACN” was also calculated, comparisons were made after considering patients in all included studies.

Results: A total of 386 articles were identified in the initial search. Of these, three studies were included in the systematic review and submitted for meta-analysis. A total of 16,592 patients were invited to undergo screening programs, but only 3881 underwent the procedures. In the analysis of participation rates, only 2333 of 8104 patients invited underwent CTC and only 1486 of the 7310 patients invited underwent OC. The absolute risk difference in participation rate in the two procedures was 0.1% (95% CI, 0.05-0.14) in favor of CTC. In the analysis of ACN detection rates, 2357 patients undergoing CTC and 1524 patients undergoing OC were included. Of these, 135 patients who underwent a CTC and 130 patients who underwent an OC were diagnosed with ACN. The absolute risk difference in ACN detection rate in the two procedure types was −0.02 (with a 95% CI between −0.04 and −0.00) in favor of OC.

Conclusion: CTC is an option for the exercise of CRC screening in asymptomatic patients. However, as a CTC has proved inferior in detecting advanced colorectal neoplasia, the method should not replace a OC, which remains as gold standard.

Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CF-H290i (Olympus Corp., Tokyo, Japan). The current study, two endoscopists (M.M, Y.M.) manually annotated 43 colonoscopy videos with 238 min of 17,993,676 frames. These videos included 75 polyps (48 neoplasms, 27 non-neoplasms), and annotations were made on the presence or absence of polyps in every frame. Forty-three videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion) were used to validate the CAD algorithm. A modified version of Caffe with 3-Dimensional Convolutional Networks (a kind of deep learning) was used for the CAD algorithm. The validation samples were analyzed using the CAD algorithm and its output as the probability of the presence of a lesion in each video. Video-interrater operating characteristic (ROC) analysis was performed to evaluate the efficacy of the CAD algorithm.

Results: The mean probability of a poly-positive video was 62.1±27.9%, whereas that of a poly-negative video was 18.1±24.6% (P < 0.001). The area under the ROC curve was 0.887 for the present CAD algorithm could detect a polyp with 90.9% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions.

P0192 TREATMENT OUTCOMES OF CORE FCOPE POLYPECTOMY FOR PATIENTS WITH DIMINUITE POLYPS: A PROSPECTIVE FOLLOW-UP STUDY
H. Hasegawa, S. Bambu, H. Ban, H. Imaeda, A. Nishida, O. Inatomi, M. Sasaki, M. Sugimoto, A. Andoh,
1Dept. Of Gastroenterology, JCHO Shiga Hospital, Otsu,Japan
Contact E-mail Address: hirohase@belle.shiga-med.ac.jp
Introduction: The results of the National Polyp Study are premised on the removal of all adenomatous lesions. Cold forceps polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (<5 mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated with CFP from June 1st to March 2017. Most CFP were the first colonoscopy of these patients. CFP was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: CFP was performed for total 515 polyps from 277 patients. The size of the polyps was <3 mm/4-5 mm/5 mm was 379/101/35. The rate of one-bite polypectomy for adenoma was <3 mm/4-5 mm/5 mm was 79%/54%/33%. There was no significant difference in the one-bit rate between endoscopists’ experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antplatelet drugs was found in 14% (72/485), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There are no polyps suspecting residual or recurrent lesions. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 13 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rate of newly discovered polyps in the same segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of <5 years/5-9 years/10 years or more than ten years, the rate of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42% (8/18)/37% (11/30), respectively.

Conclusion: The rate of one-bite polypectomy was significantly higher for diminutive polyps especially less than 5 mm. Importantly there are no polyps suspecting residual or recurrent lesions. Cold forceps polypectomy is safe and effective option for diminutive polyps (5 mm). Although the rate of one-bite polypectomy was not related to the endoscopists’ experience, adenoma detection rate is deemed to be low in young endoscopists. Since achievement of “clean colon” is one of the key to reduce colorectal cancer, multiple colorectal examination are necessary to achieve “clean colon” especially if the patients have more than two polyps at the first examination.

Contact E-mail Address: neil.moran@amnch.ie

Introduction: Colorectal cancer (CRC) accounts for up to 11% of all cancers in women and 14% of men in Ireland, and is the second most common cancer across sexes. The adenoma-carcinoma sequence of colorectal carcinogenesis lends itself to screening with the aim of complete excision of polyps. It has been estimated that incomplete resections of polyps are involved in 19–31% of interval cancers. ESGE guidelines state that polyps 5 mm or greater should be removed by snare resection. Non-adherence to guidelines was observed in 17.56% and 17.3% of procedures completed by medical and surgical trainees respectively. Medical (12.3%) and surgical (12.1%) consultants had a lower adherence rate.

Aims & Methods: The study included all patients who underwent colonoscopy in Tallaght Hospital (Dublin, Ireland) between January 2012 and December 2015 for any indication. From this, a list of patients with colonic polyps was compiled. Demographics and other information including number and site of polyps, resection and retrieval rates, method of resection and specialty of endoscopist were included.

Results: 11,400 colonoscopies were performed during the study period. To date, the records of approximately 7000 (61%) procedures have been reviewed. 2337 (22.5%) patients were identified with polyps, with 1027 females (43.4%), 1310 patients were identified with polyps, with 1027 females (43.4%), 1310 males (49.4%) and 120 patients (4.3%) with both female and male patients. The majority of polyps were left-sided, 873 (37.7%) were total dose of propofol, sedation associated complications (bradycardia, hypotension, hypoxia, apnoea), patient cooperation and patient satisfaction. Multivariate analysis was performed to correct confounding factors such as age and BMI.

Conclusion: Women awaken significantly faster compared to men with a time to eye opening of 23.1 ± 1.03 min. (p = 0.005) and time to complete orientation 9.14 ± 3.88 vs. 10.4 ± 3.17 min (p = 0.008) propofol dosage was not significantly different, with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg versus 3.72 ± 1.75 mg, p = 0.232, n.s.).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sedation for colonoscopy by using intravenous propofol has become standard in many Western countries. While gender-specific differences have been shown for general anaesthesia used in dentistry, no such data exist as yet for gastrointestinal endoscopy. In a prospective observational study at an Academic teaching hospital of Hannover Medical School 219 patients (108 women and 111 men) scheduled for colonoscopy were included. Sedation was performed using EEG monitoring during a constant level of sedation depth (D0 to D2) performed by trained nurses or physicians after bodyweight adjusted loading-dose.

Main outcome measures: Primary endpoint was the presence of gender-specific differences in wake-up time (time from end of sedation to eye - opening and the complete orientation of the patient); secondary outcome parameters analysed were total dose of propofol, sedation associated complications (bradycardia, hypotension, hypoxia, apnoea), patient cooperation and patient satisfaction.

Conclusion: Women awaken significantly faster compared to men with a time to eye opening of 23.1 ± 1.03 min. (p = 0.005) and time to complete orientation 9.14 ± 3.88 vs. 10.4 ± 3.17 min (p = 0.008) propofol dosage was not significantly different, with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg versus 3.72 ± 1.75 mg, p = 0.232, n.s.).

P0196 EFFECT OF PREOPERATIVE COLONOSCOPIC TATTOOING USING BOTH SIDE INJECTION OF INDOCYANINE GREEN FOR IMPROVEMENT OF LYMPH NODE HARVEST IN COLORECTAL CANCER

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of Korea

Contact E-mail Address: mkhwook@gmail.com

Introduction: Consensus guidelines suggest to assess at least 12 lymph nodes for adequate staging of colorectal cancer and the correlation between number of lymph nodes retrieved and the patient survival has been formerly reported. To facilitate the retrieval of lymph nodes, preoperative endoscopic tattooing to mark the site of the tumor has been proposed. In this study, we aimed to evaluate the effect of preoperative colonoscopic tattooing (PCT) using indocyanine green (ICG) for lymph node harvest in colorectal cancer. Additionally, we evaluated the effect of both side injection of ICG for improving the rate of adequate lymph node harvest.

Aims & Methods: 1023 patients who underwent curative resection for colorectal cancer between Jan 2012 and Aug 2016 at the Pusan National University Yangsan Hospital in Korea were retrospectively divided into the tattooing group and the non-tattooing group depending on whether PCT using ICG was done. Pathological findings and lymph node harvest were compared between the two groups.

Results: The rate of adequate lymph node harvest (retrieval of more than 12 lymph nodes) was similar in tattooing group and non-tattooing group (91.9% vs. 91.4%). However, when comparing the both side injection group and
nontattooing group, both side injection group was better result (96.2% vs. 91.1%, p = 0.029). Most results did not have statistical association with higher lymph node yield in colorectal cancer. But in T1 cancer, the rate of adequate lymph node harvest was higher in the both side injection group, statistically (94.7% vs. 81.0%, OR 2.435, p = 0.047)

Conclusion: PRP was associated with higher lymph node harvest in colorectal cancer, especially in T1 cancer. And both side injection of ICG increased the rate of adequate lymph node harvest. Further studies and methods are needed to harvest adequate lymph nodes in colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0197 THE EFFICACY OF COLD SNARE POLYPECTOMY IN ACHIEVING COMPLETE RESECTION OF SUBCENTIMETRE RECTAL POLYPS: A MULTICENTRE RANDOMISED CONTROLLED TRIAL (CRESCENT STUDY)

10Waseda University, Tokyo/Japan

Introduction: Cold snare polypectomy (CSP) has grown in popularity worldwide due to its ease and safety with a low incidence of adverse events, such as hemorrhage and post-polypectomy syndrome. However, there are concerns regarding tumor residue with CSP because it does not use electrocautery, thereby eliminating its burning effect. European Society of Gastrointestinal Endoscopy (ESGE) Clinical Guideline suggests CSP for subcentimetre sessile polyps because of the absence of evidence despite lack of evidence for coagulation compared to HSP. The aim of this study was to investigate the success rate of CSP for complete resection of subcentimetre colorectal adenomatous polyps compared to that of HSP.

Aims & Methods: This was a prospective, multicentre, randomised controlled, non-inferiority trial conducted in 12 Japanese endoscopy units. Patients aged ≥20 years, undergoing elective colonoscopy/polypectomy, and who provided written informed consent were included. Patients who were taking anti-thrombotic agent undergoing hemodialysis were excluded, as well as those with inflammatory bowel diseases, polyps, and pregnancy. Endoscopically diagnosed sessile adenomatous polyps, 4–9 mm in size, were randomly assigned to the CSP or HSP group. After complete removal of the polyp using the allocated technique, biopsy specimens from the resection margin after polypectomy were obtained. The primary endpoint was the complete resection rate, defined as no evidence of adenomatous tissue in the biopsied specimens, among all pathologically confirmed adenomatous polyps (full analysis set: FAS). Pre-planned subgroup analyses for the size of polyp were also conducted. The sample size was calculated according to the incomplete resection rate seen in previous articles and the required sample size was estimated at 780 lesions, including drop out cases. The protocol was approved by the institutional review board in each institution.

Results: A total of 796 eligible polyps were detected in 538 of 912 patients screened for eligibility between September 2015 and August 2016. Three hundred and ninety-four lesions were assigned to the CSP group and 402 lesions were assigned to the HSP group. One hundred and nine lesions (56 in the CSP group and 53 in the HSP group) were excluded for FAS analysis. Background characteristics of the lesions (size, location, morphology, and institution) were similar in both groups. The complete resection rate for CSP was 98.2%, compared to 97.4% for HSP. The between group difference in complete resection rate was +0.8%, favouring CSP (90% C.I. of −0.5.2.7; p < 0.0001). Resection time, overall, was significantly shorter with CSP than with HSP (60 versus 83 s, respectively; p < 0.0001). Postoperative bleeding rate, defined as hemostasis occurring within 24 h after the HSP group (5.5%, 2 of 402 cases) subgroup analysis according to the size of the polyp (4–5 mm and 6–9 mm) showed a comparable complete resection rate for CSP and HSP for both subgroups of polyps.

Conclusion: The complete resection rate of CSP is not inferior to that of HSP. CSP can be one of the standard techniques for subcentimetre colorectal polyps. (Study registration: UMIN000018328)

Contact E-mail Address: vlorenzo.germanstrias@gencat.cat

Introduction: Prevention of complications secondary to endoscopic resection techniques (EMR or ESD) requires avoiding deep thermal damage and increase mucosal healing. Platelet-rich plasma (PRP) has demonstrated efficacy in pre-clinical endoscopic resection models [1]. The EndoPRP study was a prospective single-center study to assess the efficacy of PRP on endoscopic resection of large sessile lesions (larger than 35 mm). (Study registered at ClinicalTrials.gov: NCT02931149)

Aims & Methods: In the EndoPRP study 15 patients (males and females, aged 52–80) were assigned to receive PRP (6–15 mL): i) Endoscopic Shielding Technique (EST, n = 4), applying PRP as a shield after standard resection technique, or ii) Submucosal injection (SMI, n = 11), performing a submucosal injection of PRP prior to EMR or ESD. Patients were informed and accepted to participate with a written consent. PRP was obtained from a sample of patient’s blood (18–36 mL) drawn at the time of endoscopy. Patients underwent endoscopic follow-up for 4 weeks. The efficacy of PRP was assessed by the incidence of adverse events (delayed bleeding or perforation). Mucosal healing rate (MHR) was defined as a percentage of mucosal restoration after 4 weeks.

Results: Shielding technique with PRP was performed in 4 lesions at rectum (Æ 53.7 ± 20.6 mm, range 35–80 mm). Submucosal injection of PRP was used in 11 lesions (2 at antrum, 3 at rectum, and 8 at colon) (Æ 41.6 ± 9.6 mm, range 35–70 mm). Delayed bleeding occurred after EMR of 1 lesion (no required blood transfusion or endoscopic treatment; 6.6% of all lesions: 1 patient at EST group, 0 patients at SMI group). MHR was significantly higher in patients treated with SMI than EST (Æ 78.6%; p < 0.05).

Conclusion: PRP applied as a shield over the scar or as submucosal fluid cushion proved clinical efficacy in endoscopic resection of large lesions. Submucosal injection of PRP has showed better mucosal healing rate as comparison with shielding technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

with a defined AE. Treatment options, including none required, were taken from SIVAs- defined lists and responses examined globally. Over 62% of providers were gastroenterologists and anesthesiologists. Local guidelines determined practice in most cases, and propofol and midazolam were the main sedation agents employed. The most common AEs reported were hypotension and bradycardia, with 9% and 4% of respondents, respectively, estimating each to occur during >10% of procedures. Mean provider time required to treat AEs ranged from 1.7 minutes for mild desaturation in Germany to 3.1 minutes for cardiac arrest in the USA. Accounting for interventions and provider time, the mean direct cost per range from EUR 12 for bradycardia in Germany to USD 3, 877 for cardiac arrest in the USA (Table). When costs were “fully loaded” these became EUR 39 and USD 19, 722, respectively. Although of low direct cost, bradycardia in Germany was reported to cause procedure termination or substantial delay in 3.8% of cases. In Euro countries, the median of mean direct costs for an AE was EUR 40 (IQR: 29–67). When costs of outcomes of AEs were included the median “fully loaded” cost reached EUR 301 (IQR: 115–738).

Table: Costs of select adverse events by country. FL: Fully-loaded (costs including hospital administration, time, inpatient stays, delays, and cancellations, but excluding legal costs)

Conclusion: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

Introduction: Performing CR-ESD remains challenging in Western countries and surveillance studies in this setting are not fully described. KAR has been advised as a reasonable strategy for non-expert endoscopists and difficult lesions. However, some KAR eventually requires a piecemeal resection (p-KAR). A direct comparison between these two techniques is lacking. Additionally, when the specimen is resected en bloc regardless of what procedure is used, and the only pathological risk factor for recurrence is lateral margin (LM) involvement, its implications concerning the recurrence rate should be assessed.

Aims & Methods: 1) To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD “intention-to-treat” basis, in a Western European setting where CR-ESD is performed by non-experts. 2) To evaluate the impact of LM involvement on local recurrence when neoplasms without risk factors for lymph node metastasis are resected en bloc. We prospectively included 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient’s safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, en bloc resection and R0 resection.

Results: The ER was aborted in 5 cases (perforation n = 3; technical difficulties n = 2). Surgical intervention was needed after ER because of submucosal or linfovascular invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range 10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sm1-Vienna 5. En bloc resections were obtained in 44 cases (58.7%); 33 ESD (48%) and 11 KAR (14.7%). The ER finished as p-KAR in the 31 remaining lesions (41.3%). R0 resections (n = 23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR [OR=8.9 (CI 95%: 2.8–23.3; p < 0.0001]. The median follow-up period was 16 months (1–91). Local recurrence occurred in 11 cases: 9 of the latter throughout the first year (81.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p = 0.03). When results were stratified according to histology and en bloc resections, no significant differences were found in the recurrence rate. When en bloc resections in pT1a/T1b (sm1); (c); (+); pV0M0 lesions (n = 44) were analysed separately, the LM distribution between LM0 (52.3%), 18 LM1 and 3 LMx (6.8). There was a non-significant trend concerning the recurrence rate when LM0 (n = 23) lesions were compared with LM1/LMx (n = 21): 0% vs. 14.8% at 3 years; p = 0.06.

Conclusion: ER R0 resections were 9 times greater than that of KAR on an ESD “intention-to-treat” basis. R0 resections were associated with lower recurrence rates in comparison with R1/Rx resections. LM involvement increased the recurrence rate but without a statistical significance when it was the only pathological risk factor for recurrence and the specimen was resected en bloc.

P0201 ASSOCIATION BETWEEN SIZE, LOCATION AND HISTOLOGICAL CHARACTERISTICS OF COLORECTAL LATERALLY SPREADING TUMORS (LSTs)
F. L. Mota1, J. F. Loureiro1, L. S. V. Da Costa1

1Digestive Endoscopy, Hospital Sírio Libanes, SAO PAULO Brazil
2Digestive Endoscopy Department, Hospital Sírio Libanes, Sao Paulo Brazil

Introduction: LATERALLY SPREADING TUMORS (LSTs) are important precursors of colorectal cancer (CRC)1. The endoscopic characteristics of the LSTs, such as size and location, appear to correlate with the histological findings2, 3, which is an essential data for the decision of the best therapeutic procedure to be carried out1, 4.

Aims & Methods: To determine the association between size, location and the histological characteristics of colorectal LSTs by reviewing of the colonoscopy and histopathological reports of the LSTs endoscopically removed between October 2013 and June 2015 at the digestive endoscopy department of a tertiary hospital. The Vienna revised classification was used for the adenomatous lesions4, and the World Health Organization (WHO) classification for the “sessile serrated adenomas” (SSAs)5. The regions of the colon were referred to
as either “proximal” or “distal” colon. Thereafter the division into six anatomical segments was considered (cecum, ascending, transversal, descending, sigmoid, and rectum).

**Results:** A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.66 cm (range: 0.53-4.0 cm). The most common proximal colon was the most common segment (73.4%) of occurrence of the LSTs, with 34% being at the ascending colon. The most common histological type was the low grade dysplasia adenoma (Vienna 3), followed by the SSA without dysplasia with 21.6%. There was significant correlation between size and histology (p < 0.005), where the adenomas and adenocarcinomas were found to be larger than the other categories. The SSAs, however, did not show this association. We identified association between location and histological type (p < 0.005): the adenomas with low grade dysplasia were most prevalent in the proximal colon. However, when the subdivision of the colon into anatomical segments was considered, the SSA without dysplasia was the most common type at the ascending colon.

**Conclusion:** There is association between the size and the histological characteristics of colorectal LSTs. Adenomas with high grade dysplasia were found to be larger than the other classifications. This association, however, is not observed between SSAs lesions. There is a association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

**Contact E-mail Address:** piero.valli@usz.ch

**Introduction:** Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the novel full-thickness resection device (FTRD®) opens a new dimension of possibilities for endoscopic resection.

**Aims & Methods:** Sixty patients underwent therapeutic endoscopic full-thickness resection (eTFR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD®), Ovesco® Endoscopy AG, Tubingen, Germany, is fused onto a therapeutic endoscope. The endoscope with the FTRD® is advanced to the previously marked lesion. Grasping forceps are used to take hold of the target lesion and carefully pull it into the plastic cap of the FTRD®. Immediately after deployment of the OTSC®, eTFR is performed using the hemoplastic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

**Results:** eTFR was performed for the following indications: 1. Recurrent adenomas (n = 22.3%) with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary non-lifting sign on saline injection (n = 2.3%). 2. Non-lifting base after extensive piecemeal resection of a spreading adenoma (n = 2.3%). 3. Diverticulum (n = 2.3%). 4. Polyps the cecal appendix (4.6%). 5. Submucosal lesions (n = 5.8%). 6. Early carcinoma (n = 7.1%). 7. Follow-up resection of a malignant polyp (n = 1.0%) had. 8. EFTR over endolip preparation (n = 2.3%). In 97% (58/60) of the interventions, the FTRD®-mounted endoscope reached the previously marked lesion and eTFR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up histology was even higher (88%). The following adverse events occurred: Appendicectomy of the residual cecal appendix after eTFR of an appendicular adenoma (1/58.2%). Minor bleeding at the eFTR site (2/58.3%). eTFR performed accidently without proper prior deployment of the OTSC® (1/58.2%). There was no secondary perforation or eTFR-associated mortality.

**Conclusion:** In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eTFR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0203 VASCULAR AND PIT-PATTERN ANALYSIS ACCORDING TO KUDO, SANO AND NICE CLASSIFICATIONS IMPROVES AFTER AN IMAGE-BASED TRAINING PROGRAM**

**Introduction:** Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

**Aims & Methods:** The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopic unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colo-rectal neoplasms, before and after an image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colo-rectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endoscopists. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colonic neoplasms' surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colo-rectal neoplasms' evaluation before and after the training was also calculated using the McNemar test. A value of p < 0.05 was considered statistically significant.

**Results:** A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ± 0.03) and Sano (0.12 ± 0.04), and poor for the NICE classification (0.24 ± 0.05). Diagnostic accuracy was 0.33 ± 0.07, 0.54 ± 0.12 and 0.60 ± 0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification (p < 0.0001) and to good for Sano and NICE classifications (p < 0.0001). Diagnostic accuracy increased significantly, too, with values of 0.60 ± 0.05, 0.76 ± 0.05, 0.80 ± 0.05 for Kudo, Sano and NICE classifications, respectively (p < 0.0001).

**Conclusion:** To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colo-rectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

P0208 SAFETY OF COLD SNARE COLON POLYPECTOMY IN PATIENTS ON ANTIITHROMBOTIC MEDICATION
M. Matsumoto
Dept. Of Gastroenterology, Hokkaido Medical Center, Sapporo/Japan
Contact E-mail Address: miasakura@outlook.jp
Introduction: Cold snare polypectomy (CSP) has been increasingly used in recent years because post-polypectomy bleeding is less common with this technique than with conventional polypectomy. According to the 2012 update of the Japanese guideline for periprocedural management of antithrombotic medications issued by the Japan Gastroenterological Endoscopy Society, procedures with a low risk of hemorrhage may be performed with a short interruption or continuation of antithrombotic medication. However, the guideline does not refer to periprocedural antithrombotic management for CSP.
Aims & Method: The objective of this study was to determine the safety of CSP in patients on antithrombotic medication. The subjects were patients who underwent CSP at this hospital between April 2014 and March 2016. Post-CSP bleeding rates were examined in relation to the use of antithrombotic medication. CSP was indicated for non- pedunculated polyps smaller than 10 mm, excluding lesions with submucosal invasion and suspected of being cancerous at the preprocedural diagnostic evaluation.
Results: CSP was performed to remove 2466 polyps in 1003 patients; cancerous lesions accounted for 0.2% of them, but all had negative margins. There were 549 polyps that had been taken out without interruption or discontinuation of antithrombotic medication before CSP (antithrombotic group), and 1917 (77.7%) in 817 patients not taking antithrombotic medication (non-antithrombotic group). In the antithrombotic group, 106 patients with 283 polyps continued taking the antithrombotic medication; specifically, aspirin in 41 patients with 113 polyps, clopidogrel in 13 patients with 17 polyps, dual antplatelet therapy (DAPT) in 13 patients with 18 polyps, antplatelet agents other than clopidogrel in 17 patients with 68 polyps, anticoagulant agents in 20 patients with 56 polyps, and antplatelet plus anticoagulant combination therapy in 2 patients with 11 polyps. Heparin bridging was used in 13 patients with 38 polyps. Post-CSP bleeding occurred in 0.54% (3/549) of the interventions in the antithrombotic group and in 0.10% (2/1917) of those in the non-antithrombotic group, showing no significant difference (p = 0.08). Endoscopic hemostasis was successful in all cases of bleeding, without requiring blood transfusion. As for the 3 cases of post-CSP bleeding in the antithrombotic group, the specific antithrombotic medication being used was aspirin in 1 patient with 1 polyp (0.88%, 1/113), and aspirin and clopidogrel a patient with 2 polyps (11.1%, 2/18). No post-CSP bleeding occurred in patients on other antplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p < 0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% with clipping vs. 0.34% without clipping; p = 0.55).
Conclusion: CSP is a safe procedure even in patients on antithrombotic medication, provided the rate of bleeding after CSP was not high compared with that after biopsy in patients on antithrombotic medication (post-procedural bleeding rate, 0.09–0.61%), suggesting that CSP can be virtually categorized as a procedure with a low risk for hemorrhage in the guideline for periprocedural antithrombotic management.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0207 OPTICAL ENHANCEMENT FOR THE IN VIVO PREDICTION OF POLYP HISTOLOGY IN PATIENTS ON ANTIITHROMBOTIC MEDICATION
Department Of Medicine 1/University Hospital of Erlangen, Erlangen/Germany
Contact E-mail Address: entcho.klenske@uk-erlangen.de
Introduction: Diminutive polyps are a common finding among surveillance colonoscopies without having high prevalence of advanced histology, making their standardized removal cost-, time- and risk-intensive. Based on these considerations, the American Society of Gastrointestinal Endoscopy (ASGE) proposed the so called PIVI statement, in which diagnostic thresholds are defined that new technologies used for the real-time assessment of colorectal polyp histology should meet. Optical enhancement (OE) is a novel endoscopic pre-processing optical filter technology, in which the spectrum of the emitted wavelengths is reduced, thereby leading to enhanced visualization of the mucosal and vascular pattern.
Aims & Methods: In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIVI criteria. In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIVI criteria.
Methods: In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIVI criteria.
Results: The overall accuracy of OE for real-time prediction of polyp histology was 94.3% with a sensitivity, specificity, positive (PPV) and negative prediction value (NPV) of 100%, 95.3%, 85.4% and 100%, respectively. When including only high confidence (HC) predictions, the accuracy of OE increased to 98.5%. Sensitivity, specificity, PPV and NPV were 100%, 94.5%, 91.2% and 100%, respectively. In distal colorectal polyps the accuracy was 93.3% with sensitivity, specificity, PPV and NPV being 100%, 91.3%, 80% and 100%, respectively. The post-polypectomy colonoscopy surveillance intervals were predicted correctly in >90% of patients with OE.
Conclusion: Optical enhancement allows to accurately predict the histology of diminutive colorectal polyps in vivo in real-time and meets the PIVI thresholds for expanded training and discarding diminutive polyps without histological assessment and for leaving distal diminutive colorectal polyps in place. Hence, optical enhancement can potentially reduce time, risk and costs associated with removal and histopathological assessment of diminutive polyps.
Disclosure of Interest: All authors have declared no conflicts of interest.

A prototype Fiber Brag Grating (FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination.

**Aims & Methods:** The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonoscopy using FBG. In the first part of the study, the FBG sensor was inserted into the working channel of a routine colonoscope in the first 70 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movement in all three dimensions. We evaluated loop formation such as N loop, alpha loop, reverse alpha loop, with the 3D imaging monitor. In the second part of the study, 5 patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. Fluoroscopy was used in all investigations for comparison.

**Results:** In the first part of the study, the results showed that the shape sensor was adequately rotated with the colonoscope configuration. The average tip deviation error was 1.722 ± 1.678 mm, which corresponds to 1.50 ± 1.46% of the total length of the sensor. Scope movement and loops were detected correctly in all cases through the monitor. The prototype used in the second part of the study showed a good correlation and little discrepancy with the comparative findings at fluoroscopy.

**Conclusion:** Scope-guided endoscopy using FBG sensor can be successfully used to display colonoscopy configuration. This flexible, thin and almost weightless FBG sensor would be a novel technique for identification of colonoscopy shape.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
permeability process after IRE by providing the real-time images. Additionally, Morphology assessment for apoptosis assessment method, included Annexin V FITC and PI staining. This MP probe protocol would dramatically increase the accuracy of diagnostic techniques by providing in vivo cell images.

P0211 LARGE (>30MM) POLYP ENDOSCOPIC MUCOSAL RESECTION: OUTCOMES AND PREDICTORS OF SUCCESS
K. Sia1, E. Karunanadase2, A. Kaweisha2, S. Ishag1
1Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom
2Department Of Surgery, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Contact E-mail Address: keithh@sia.org

Introduction: Endoscopic mucosal resection (EMR) is an established therapeutic option for large (>30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

Aims & Methods: We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2008-2016 in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMSA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMSA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

Results: Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colon in 81%, bleeding occurred in 16.5%, all of whom achieved haemostasis. The 30-day complication rate was 1.1% (delayed bleeding in 1 patient), 54 (59%) were fully resected in one session, with overall EMR success in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured advanced adenoma or carcinoma. Of the EMR success group, 4/95 were malignant polyps with R0 endoscopic resection. The overall malignant histology rate in this cohort was 11/91 (12%). In this cohort, the R0 EMR success rates was 4/11 (36%), with no recurrence after 60 months of follow-up. The overall 12-month recurrence rates following complete EMR was 1.5%, with no significant factors affecting EMR durability identified.

Table 1: Predictors of complete resection on first EMR attempt. p-values derived from bivariate regression, with bold values significant if <.05. *Increase in OR for each increase in year. **p-value < 0.05 considered statistically significant.

Introduction: Though numerous research has enabled decreased of the bowel preparation solution volume, it is still a major complaint of patients preparing

colonscopy. There have been studied that additional administration of laxatives could lessen the amount ofavenous formula with prokinetic effect. Prucalopride is a serotonin (5-HT4) receptor agonist which stimulate colonic mass movements and provide main propulsive force for defecation.

Aims & Methods: The aim of this study is to compare 2-L PEG-Asc and 1-L PEG-Asc plus prucalopride while prepe for quality of bowel cleansing while controlled for colonscopy and patient compliance. Two hundred patients were prospectively enrolled. Patients referred for colonscopy were divided into group A (the split dose 2-L PEG-Asc) and group B (1-L PEG-Asc+prucalopride) randomly. During colonscopy, each patient’s bowel preparation quality was evaluated with The Boston Bowl Preparation Scale (BBPS) and Aronchick Preparation Scale (APS). The tolerability and satisfaction of patients was determined based on a questionnaire-based survey.

Results: One hundred patients received either 2-L PEG-Asc or 1-L PEG-Asc with prucalopride. Regarding colon cleansing outcome (BBPS and APS), the 1-L PEG-Asc with prucalopride group showed similar, but non-inferior results compared to the 2-L PEG-Asc group on both BBPS (7.65 ± 1.27 vs 7.52 ± 1.40, p = 0.586) and APS scales (93.8 ± 15.9% vs 95% p = 0.717). Tolerability was similar for both 1-L PEG-Asc with prucalopride and 2-L PEG-Asc.

Conclusion: 1-L PEG-Asc plus prucalopride preparation showed comparable result to traditional 2-L PEG-Asc preparation. 1-L PEG-Asc plus prucalopride preparation method could be an alternative method for bowel preparation which can relieve patient discomfort.

Introduction: Endoscopic mucosal resection (EMR) is an effective and safe treatment for large (>20mm) laterally spreading colorectal lesions. Although colon EMR has been established as a minimally invasive technique for treatment of large colorectal lesions, risk of adenoma recurrence is the main limitation. Current guidelines recommend first follow-up at 3–6 months; however, there are no well-designed prospective-studies published establishing an optimal follow-up. The aim of this study was to conduct a quality improvement initiative aimed at increasing compliance in SC1 by understanding the current screening process and developing strategies to standardize our endoscopy center practices.

Aims & Methods: Single tertiary referral center quality improvement project started in January 2017 and currently still in progress. We present here the interim data. Consecutive patients who had undergone or would have EMR of lesion ≥20mm were eligible for inclusion. The process of following-up patients after EMR was divided at two levels: A dedicated team member generated a monthly report identifying patients who underwent colon EMR using our endoscopy procedure documentation program. The appropriate timeline for SC1 for each patient who underwent colon EMR was identified and orders and scheduling for the colonoscopy follow-up were carried out. Evaluation of follow-up: A dedicated team member reviewed the status of patients who underwent colon EMR six months prior to the start of the QI study. If patient did not show up on their scheduled follow-up, phone calls were placed to contact the patients. Patients who had followed-up with their local gastroenterologists were recorded. All the data in intervention group was compared retrospectively with nonintervention group who were not tracked through quality improvement process. Mean follow-up time and follow-up rate (%) at 6–9 months at SC1 after index EMR was compared between the two groups.

Results: Per-project 25 patients included in intervention group were compared to 60 patients in the nonintervention group. Mean age was 62 years in intervention group and 66 years in non-intervention group (p = 0.04). There were no differences in distribution in size of lesion, gender, EMR site, and polyp histology between two groups (Table 1). The mean follow-up time in intervention group was 8.2 months (IQR 2.6) and nonintervention group was 10.4 months (IQR 9.1). There was increase in rate of 6–9 months follow-up in intervention group when compared to the nonintervention group (88%, 95% CI [0.80%-0.94%] vs 64%, 95% CI [0.54%-0.73%]) (Table 1).

Introduction: Endoscopic treatment of malignant colorectal polyps is often challenging, especially for early rectal cancer (ERC) localized close to the dentate line. Conversely, the surgical approach may result in temporary or definitive stoma and in frequent post-surgical complications [1–2]. Endoscopic Full Thickness resection (EFTR) is a novel technique that, besides having other indications, appears to be promising for wall-thickness excision of intestinal T1 carcinoma following incomplete endoscopic resection [3–4].

Aims & Methods: Follow-up data on patients treated with this device are scarce, particularly for ERC. We enrolled six consecutive patients with T1-ERC. They were treated with the EFTR, after appropriate staging, and their long-term outcomes were evaluated based on a detailed clinical and instrumental assessment. Results: The endoscopic en bloc full-thickness resection was technically feasible in all patients. The histopathologic analysis showed a complete endoscopic resection in all cases, and a full-thickness excision in four. Neither complication, nor disease recurrence was observed during the one-year follow-up performed. Conclusion: EFTR is a promising tool for treating ERC featuring a residual risk of disease recurrence after incomplete endoscopic mucosal resection in patients unfit for surgery or refusing surgical approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0216 UNTUTORED LEARNING CURVE ANALYSIS FOR COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION: PREDICTIVE FACTORS FOR COMPLEX TECHNIQUE.

Servicio de Anestesiología y Reanimación, Hospital Universitario HM Montepríncipe, Boadilla del Monte (Madrid)/Spain

Servicio de Aparato Digestivo, Hospital Universitario HM Puerta del Sur, Móstoles (Madrid)/Spain

Servicio de Aparato Digestivo, Hospital Universitario HM Montepío, Boadilla del Monte (Madrid)/Spain

Facultad de Medicina, Universidad CEU San Pablo, Madrid/Spain

Introduction: Colorectal Endoscopic Submucosal Dissection (CR-ESD) is technically difficult, time-consuming, and has a long learning curve for Western endoscopists. Several factors related with greater difficulty while performing this technique have been described. Generally, during the learning curve phase, we select simple lessions while initiating the technique.

Aims & Methods: Our goal was to assess those factors associated with greater difficulty during untutored DSE-CR without prior selection of less difficult lesions. All patients who attended the complex colorectal polyps consultation were included consecutively. No polyps regardless of their size, morphology, location or any characteristic of greater technical difficulty were ruled out. All CR-ESDs were performed by an endoscopist with previous animal model experience. The demographic and clinic characteristics of the patient, the morphology of the lesion and factors related to the technique were collected. A complex technique

was defined as that dissection that is not done en bloc and/or had complications.

Results: 112 lesions were selected, discarding 4 due to deep invasion. We evaluated in this study 108 DSE-CR, 27 (25%) of which were compatible with our definition of "complex" ESD. In Table 1 you can see the characteristics of each group. Univariate analysis showed that variables such as size over 35 mm [63% vs. 27.2%; OR 4.56 (95% CI: 1.81–11.46); P = 0.001], absence of coffee [55.6% vs. 19.8%; OR 5.08 (95% CI: 1.99–12.94); P < 0.001], presence of serious fibrosis in the submucosa [48.1% vs. 7.4%; OR 11.61 (95% CI: 3.78–35.69); P < 0.001] and presence of fatty tissue in the submucosa [59.3% vs. 22.2%; OR 5.99 (95% CI: 2.01–12.90); P < 0.001] were related to a "complex" ESD. Finally, in the multivariate analysis, those variables were associated with a complex technique with an Odds Ratio of 7.42 for severe fibrosis (p = 0.039), 6.34 for non-CO2 insufflation (p = 0.030), 5.76 in the presence of fatty tissue in the submucosa (p = 0.035) and 5.74 in size greater than 35 mm (p = 0.025). There was no relation with the complexity of the technique the demographic-clinical characteristics of the patient, nor the location-morphology of the lesions. The duration of the technique was an average of 48 minutes longer in cases of a complex technique.

Conclusion: In our series the difficulty of CR-ESD was associated with factors described in other studies such as the size, the non-insufflation of CO2 and the presence of severe fibrosis in the submucosa. Our results describe the presence of fatty tissue in the submucosa as a new predictor of technical difficulty. In our study, we did not select the location to begin the technique, and in our learning curve we did not find significant differences in the performance of ESD in the proximal colon, distal or rectum.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO217 PERSISTENT PAIN AFTER COLONIC ENDOSCOPIC MUCOSAL RESECTION: PREDICTORS, A MANAGEMENT ALGORITHM AND OUTCOMES

L. Desomer, D. J. Tate, H. Awadie, L. Pillay, G. Aldenstiel, M.J. Bourke
Department Of Gastroenterology And Hepatology, Westminster Hospital, Sydney/ Australia/NSW

Contact E-mail Address: lobkedesomer@gmail.com

Introduction: Endoscopic mucosal resection (EMR) of large (>20 mm) laterally spreading colon lesions (LSL) is safe, effective and superior to surgery. This advantage is based on a day stay model of care; however, the most common adverse event is abdominal pain and this is a major impediment to its efficiency. No prospective data exist on the optimal selection of analgesics, the necessary recovery period or the triggers that should alert the practitioner to a more serious complication.

Aims & Methods: We aimed to characterise potential predictors for PP and develop a simple and effective management algorithm for patients with PP based on the need for analgesics in recovery. Data on consecutive patients with a LSL referred for EMR at a single, tertiary referral centre were included. Patient and lesion characteristics and peri-procedural data were prospectively collected. Standard post EMR care included 2 hours in first stage recovery followed by 1 hour in 2nd stage recovery where clear fluids were given and discharge after if the patients were well. Persistent post-procedural pain (PP) was graded from 0 to 10 using a Visual Analogue Scale (VAS). If PP occurred >5 minutes, 1 gram of acetaminophen was administered parenterally and outcomes were monitored. If pain settled the patient was transferred to second stage recovery after medical review. PP >30 minutes lead to clinical review and an upgrade of analgesics to fentanyl, with a starting dose of 25 micrograms (mcg) up to a maximum of 100mcg. Investigations, admission and interventions for PP were recorded.

Results: 166 patients with 166 lesions were included between February and April 2017. 34/166 (20.5%) of patients had PP requiring intervention (median VAS 5, IQR 3–6). 27/34 (79.4%) had resolution of pain with acetaminophen only and 20/34 (20.5%) of patients had PP requiring intervention (median VAS 5, IQR 3–6). 27/34 (79.4%) had resolution of pain with acetaminophen only and 20/34 (20.5%) of patients had PP requiring intervention (median VAS 5, IQR 3–6). 27/34 (79.4%) had resolution of pain with acetaminophen only and 20/34 (20.5%) of patients had PP requiring intervention (median VAS 5, IQR 3–6).

Conclusion: Pain after EMR occurs in 20% of patients and is associated with larger lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the stepped down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO218 QUALITY OF SINGLE-SESSION COLONOSCOPIC EXAMINATIONS INTENDING TO REMOVE ALL NEOPLASTIC POLYPS USING COLD POLYPECTOMY IN OUTPATIENT SETTING: RESULTS FROM CLINICAL PRACTICE DATA OF SINGLE CANCER CENTER HOSPITAL IN JAPAN

Division Of Endoscopy, Shizuoka Cancer Center, Nagaizumi/Japan

Contact E-mail Address: k.hotta@scchr.jp

Introduction: Some high-quality, large-scale cohort studies proved removals of colorectal neoplasms achieved prevention of colorectal cancer incidence and deaths. We introduced a strategy of removing all neoplastic polyps in single session colonoscopic examinations using cold polypectomy was started.

Aims & Methods: The aim of this retrospective study was to investigate about achievement of colorectal polyp remove in our clinical practice setting. Scheduled colonoscopic examinations for 40–79 years outpatients who had at least one colorectal neoplasm between January 2015 and December 2016 were collected from our endoscopic data base. Exclusion criteria were as follows: patients who had colorectal neoplasm larger than 20 mm, pre-examination of colorectal surgery or endoscopic submucosal dissection, inflammatory bowel disease, familial adenomatous polyposis, uncontrolled malignancies, by trainee endoscopists (<500 colonscopies), no agreements of polyp removal, and/or patients with continuation of anti-thrombotic agents. Outcome measurements were polyp removal rate (per-lesion analysis), complete polyp removal rate (per-patient analysis) and complications. Proportions of each endoscopic removal method according to size were also analyzed.

Results: A total of 2527 patients (mean age 66.8 ± 7.99 females) with 8203 colorectal neoplasms (CRNs) (7675 adenomas, 423 serrated polyps and 105 Tis and T1 cancers) who met inclusion and exclusion criteria were analyzed. Mean number of CRNs per patients was 3.2. Mean size was 4.7 (±2.9) mm. Polyp removal rate (per-lesion) and complete polyp removal rate (per-patient) were 97.0% (7955/8203) and 94.7% (2394/2527), respectively. Post-polypectomy bleeding requiring endoscopic hemostasis occurred in 7 patients (0.27%) and all origins of bleeding were endoscopic mucosal resection (EMR) and hot snare polypectomy (HSP). Post electrocoagulation syndrome requiring admission was occurred in one patient (0.04%) after pre-cutting EMR. Mean procedure time was 27.4 (±13.3) min. Proportions of each endoscopic removal method according to size were presented in an attached table. In 1–4 mm CRNs, both cold snare polypectomy (CSP) (51.8%) and cold forces polypectomy (CFP) (45.8%) for 1–4 mm CRNs were main methods. In 5–9mm CRNs, CSP was a leading method (73.8%) and EMR was the second one (24.1%). CRNs larger than 10 mm were almost removed by EMR (94.4%).

Disclosure of Interest: All authors have declared no conflicts of interest.

**Conclusion:** In our clinical practice setting, the polyp removal rates were satisfactory when measured in single session endoscopic examinations using cold polypectomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colonoscopy plays a key role in the prevention and diagnosis of colorectal cancer (CRC), and the quality of its influences intervention cancer. However, we have little information on compliance with quality standards in Spain.

**Aims & Methods:** Knowing quality indicators fulfillment may lead to apply measures to improve the efficiency in the colonoscopy. Hence the aim of this study was to compare the quality indicators of colonoscopy in centers of Spain. A total of 6912 colonoscopies performed between January and November 2016 were prospectively included in the QUALISCOPIA project, an observational, multicenter and prospective study, developed in 12 centers in Spain. The exclusion criteria were patients with diagnosis of colorectal cancer or adenomas in the last 6 months, incomplete excision or post-adenoma excision, treatment of colon stenosis, abdominal or rectal mass, inflammatory bowel disease and hereditary cancer syndrome.

**Results:** 51.9% (3586) patients were men and the median age was 61 years. According to the colonoscopies indications, thirty one percent (2971) of the patients presented gastrointestinal symptoms, 20.3% (1398) were admitted due to post-polypectomy surveillance, 28.3% (1940) presented positive fecal immunochemical test (FIT+), and 8.4% (578) due to direct screening. 70.4% (4869) of the examinations were performed in the morning shift. Respecting the bowel preparation, 48.4% used polyethylene glycol (PEG) 2L, 27.5% (1902) used sodium picosulfate/magnesium citrate, and 19.5% (1347) PEG4L. Digital chromoendoscopy was used for lesion seen in 4.7% (322) and panchroma in 9.1% (7). CO2 was used in 42% (2906) of the procedures. Colon cleansing was good-excellent in 80.1% (4995). The most used drugs for sedation were propofol in 63.9% (4417), midazolam in 44.1% (3045) and fentanyl in 31.1% (2149). In 86.1% (6181) of the examinations the use of sedation was recommended, in 42% (2906) of the procedures. Colon cleansing was good-excellent in 80.1% (4995). 92.8% (6260) of the colonoscopies were performed under sedation, and the gastroenterologist was responsible for it in 80.1% (4995). The most used drugs for sedation were propofol in 63.9% (4417), midazolam in 44.1% (3045) and fentanyl in 31.1% (2149). Olympus was used in 69.2% (4732), Pentax in 21.8% (1492) and Fuji in 8.3% (569). Polyps were found in 50.9% (3515) of the procedures, and CRC was found in 4.1% (281). The total number of adenomas was 6249, and the total number of tissue samples was 224. The adenomas detection rate (ADR) was 39.6%. The sessile and traditional serrated polyps detection rate (SDR) was 2.2%. And for advanced adenomas, detection rate (AADR) was 25.1% and for colorectal cancer 4.1%.

**Conclusion:** In Spain, there is good compliance with the quality indicators of colonoscopies.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
**Results:** According to endoscopic or pathologic judgment resection was complete in 40 or 30 patients, respectively. During hospital follow-up (12–14; median 4 days) abdominal pain, fever or local peritonitis were noted in 6 and bleeding in 3 patients (hypotension in 1) with antibiotics/transfusions/surgery needed in 4/0 patients. There was no hospital mortality. Among those with histologic incomplete resection (n=21), surgery or FTR was performed in 5 patients, endoscopic follow-up is pending in 7 and revealed no residual neoplasia in 9. Among those with cancelled ESD or endoscopic incomplete resection (n=11), surgery or FTR was performed in 5, endoscopic follow-up is pending in 2 and revealed no residual neoplasia.P.

**Conclusion:** After appropriate training, even in low volume European case series ESD in the colorectum appears to be safe and partially effective.

**Contact E-mail Address:** aymeric.histace@enseea.fr

**Introduction:** Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Coloscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration room due to not meeting real-time constraints (40 ms max per image). In this abstract, we present a methodology to adapt and evaluate a real-time still frame-based method [3] to video analysis.

**Aims & Methods:** The still frame detection system used as reference [3] was based on an active learning method. We base the adaptation to video analysis on two aspects: (i) influence of the type of information used for polyp candidate characterization, and (ii) introduction of spatio-temporal coherence. The former studies whether the combination of different types of information may lead to improve system performance whereas the latter fosters stability in the position of the detector output for consecutive frames. The learning stage of the method used a public still-frame database (CVC-Clinic, 612 images) whereas the testing was done on a new set of 18 sequences with a polyp (10,294 images) collected with an Olympus colonoscope CF-H190 at Hospital Clinic, Barcelona. Performance was evaluated using two groups of metrics: (i) standard image/video metrics: Precision, Recall and F1-Score (ii) ad-hoc clinical metrics on an active learning method. We base the adaptation to video analysis on two.

**Table 1** shows the influence of local features on the overall performance and how the combination of both types of features can lead to an overall improvement in Recall and RT, which we interpret as local descriptors complementing each other.

</table>

**Conclusion:** Work presented in this abstract shows how a real-time still-frame-based polyp detection method can be successfully adapted to video analysis. Clinical usability metrics along with a new fully annotated video database were introduced to completely assess method performance. Results show methodology potential regarding clinical deployment as it detects all polyps with a small RT. Results show that the sole use of shape features allows to meet real-time constraints but that a combination with a computationally efficient texture descriptor might improve frame-based performance.

**P0223 RESECTION AND DISCARD/DIAGNOSE AND DISREGARD STRATEGY FOR COLONIC POLYPS: ARE WE READY TO START IT?**

**Gastroenterology, Amostra Lisbom Hospital, Castelo Branco/Portugal**

**Contact E-mail Address:** richardazevedo13@gmail.com

**Introduction:** The use of Narrow Band Imaging (NBI) technology for in vivo histological prediction of colonic polyps presents high accuracy in Referral Centers, particularly for diminutive polyps, which could be managed by the “resect and discard” strategy and, for sigmoid and rectum polyps, the “diagnose and disregard” strategy. However, the applicability of this practice in Community Hospitals still needs to be determined.

**Aims & Methods:** We aimed to determine the accuracy of NBI in predicting histology, according to NICE and WASP classifications, in a Center without previous NBI experience. This was a prospective study including patients submitted to colonoscopy between June 2016 and July 2017. Polyps characteristics: location, size, morphology (Paris Classification), NICE/WASP classification (hyperplastic, sessile serrated, adenoma, invasive carcinoma) and degree of confidence (low: <90% vs. high ≥90%). Comparison between NBI classification and histology SPSS 23.

**Results:** 163 polyps included (71 patients); mean polyp dimension of 6.1 mm (61.3% ≤ 5 mm); 91.4% sessile polyps; 62.6% on the left colon. Polyps classification according to NICE/WASP vs. histology: hyperplastic 49.7% vs. 42.9%, sessile serrated polyps 4.9% vs. 9.8%, adenoma 44.2% vs. 43.6%; carcinoma 1.2% vs. 0%; inflammatory reaction on histology – 3.7%. Adenoma diagnosis using NICE/WASP classification presents an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 78.1%, 84.2%, 85% and 77.1%, respectively. For left lesions ≤5mm (n=61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariate analysis showed that high confidence prediction and ≥3 polyps/exam had a significant association with correct NBI classification (p < 0.05).

**Conclusion:** NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (≥90%). These results justify implementing additional training and monitoring.

Introduction: Cold forceps polypectomy (CFP) is commonly used to remove diminutive colorectal polyps (<5mm). In addition, jumbo biopsy forceps are superior to standard forceps for removing colorectal polyps. However, problems remain for CFP with regard to residual adenomatous tissue on histological evaluation after a complete endoscopic cold forceps polypectomy.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of jumbo forceps biopsy using narrow-band imaging endoscopy in patients with diminutive polyps. In addition, we evaluated the factors related to one-bite resection. This is a multicenter, prospective, single-arm observational study conducted at 11 institutes of the National Hospital Organization between January 2015 and September 2016. Patients aged 20 to 75 years with diminutive polyps were enrolled in this study. When lesions were found, we used magnification endoscopy with narrow-band imaging (NBI) in all the cases. CFP was performed until no polyps were visible under magnified endoscopy with NBI. We evaluated the patients’ characteristics, clinicopathological features of the polyps, adverse events, and complete resection rates of the lesions. Additionally, we studied the factors related to one-bite polypectomy using Cox’s regression model.

Results: A total of 503 patients were prospectively assessed, and 1015 polyps were resected. The median age of the patients was 65 years. The patients comprised 329 men (65%) and 174 women (35%). The polyp morphologies were 0-Is lesions in 886 cases (87.5%), 0-Ia lesions in 65 (6.4%), 0-Ib lesions in 63 (6.2%) and 0-Ip lesions in 1 (0.1%). Polyps were most often resected in the ascending colon (289 lesions) or transverse colon (262 lesions). Of all the polyps, 88% (896 lesions) were adenomas, 10% (100 lesions) were hyperplastic, and 0.3% were adenocarcinomas. The mean procedure and treatment times were 26.5 and 20.4 min, respectively. The complete resection rate was 99.3%. The rate of one-bite polypectomy was 71.8%, which included rates of 100%, 91.5%, 81.8%, 56.9%, and 40.5% for lesions 1, 2, 3, 4, and 5 mm in diameter, respectively. Delayed bleeding that required endoscopic hemostasis occurred in only one case, but no other adverse events occurred. The most important factor related to one-bite polypectomy was polyp size (<3 mm; OR: 5.58), followed by macroscopic type of polyps (non-Ha, OR: 1.95).

Conclusion: In this large-scale multi-center prospective study, 99.3% of all diminutive polyps were completely resected by using jumbo forceps biopsy and magnified endoscopy with NBI. In addition, we were able to do one-bite polypectomy for more smaller polyps (<3 mm). Jumbo forceps biopsy appears to be adequate for resecting diminutive polyps if no residual tissue is visible by using magnified endoscopy with NBI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Heparin bridging therapy (HBT) is recommended for patients administered anticoagulants who have a high thrombotic risk and who undergo a high bleeding risk procedure such as endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR)1-3. However, HBT is actually related to a high frequency of delayed bleeding4,5. Aims & Methods: Our aim is to analyze bleeding and coagulation markers in the perioperative period in patients with HBT during the perioperative periods of ESD and EMR. Patients who underwent ESD or EMR and received warfarin or a direct oral anticoagulant (DOAC) during the period from January 2013 to March 2017 were analyzed. Generally, administration of warfarin was continued within the therapeutic range of the international normalized ratio (INR) during the perioperative periods and DOACs were not administered on the day of the procedure. HBT was conducted only for patients who had a hypercoagulable condition. The rates of delayed bleeding in patients who received warfarin and patients who received DOACs were compared, and coagulation molecular markers including soluble fibrin (SF), thrombin-antithrombin complex (TAT), prothrombin fragment 1 + 2 (F1 + 2) and D-dimer (DD) were compared before and after the procedures in 13 patients.

Results: Among the patients who underwent ESD or EMR during the study period, 5 patients received warfarin and 49 received DOACs. Delayed bleeding occurred in 6 patients (11.8%) in the warfarin group and in 8 patients (16.3%) in the DOAC group, and there was no significant difference. Only one patient with a history of antiplatelet agents had delayed bleeding among the patients in whom administration of warfarin was continued within the therapeutic range (5.3%; 1/19). Six (15%) of the 40 patients in the DOAC group for whom the DOAC was not administered only on the day of the procedure developed delayed bleeding, and 23.8% (5/21) of the patients who received HBT had delayed bleeding. No thrombotic events occurred from one month after the procedures. One patient in whom the DOAC was not administered on the day of the procedure became positive for TAT, F1 + 2 and DD after HBT and had a hypercoagulable condition.

Conclusion: For perioperative management of anticoagulants in patients undergoing ESD or EMR, continuous use of warfarin within the therapeutic range is recommended. DOACs should be carefully managed with attention to hemorrhagic risk and coagulable condition.

Conclusion: SpyGlass cholangioscopy system can be safe and useful for definite diagnosis with high accuracy in patients with indeterminate biliary lesions, and successfully guided stone therapy. Further prospective multicenter trials of the system are warranted in the future.

P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic disorders in pediatric patients.

Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, ERCP interventions performed and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common bile duct obstruction (n = 153, 54.2%), recurrent or chronic pancreatitis (n = 64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was cholecdocholithiasis (n = 146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n = 204), including sphincterotomy (n = 97), stone extraction (n = 55), and stent insertion (n = 29). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS’ EXPERIENCE AT A LARGE CENTER IN CHINA

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy were operated at our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedures related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.5%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagegastrotomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236), including 91.3% (126/138) for Billroth II gastrectomy, 94.5% (52/55) for Billroth I gastrectomy, 89.9% (71/79) for hepaticoduodenostomy, 100% (19/19) for esophagogastrotomy and 61.5% (8/13) for Roux-en-Y reconstruction. The clinical success rate was 88.2% (268/304). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n = 146), sphincterotomy (n = 44), stent placement (n = 57), papillary balloon dilatation (n = 27) and mechanical lithotripsy (n = 25). The adverse event rate was 7.2% (17/236).

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYNDROME RECURRENCE TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESECTION: A PROSPECTIVE SCORE ANALYSIS

1Gastroenterology And Hepatology, Mayo Clinic, Jacksonville, Florida/United States of America/FL
2Biostatistics, Mayo Clinic, Rochester/United States of America/MN

Contact E-mail Address: danieleguerrero@mayo.edu

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size ≥20 mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPR), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to evaluate the efficacy of the newer 190 colonscopes versus standard 180 colonscopes for complete resection of lateral spreading lesions (LSL) ≥20 mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT score) in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscope series from 2010 to 2016. Lesions ≥20 mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p = 0.85). Adenoma size (p = 0.002) and concomitant need for supplemental APC (p < 0.001) were risk factors for recurrence. SERT > 0 lesions had a higher risk of recurrence during follow-up (OR 1.71; 95% CI 1.00-2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest:

and retrieval nets. Normal saline was used for intra-procedural irrigation and subsequently underwent necrosectomy. The conventional technique using a diagnostic approach was the only variable associated with treatment success (OR = 60.4, p = 0.02) when adjusted for patient demographics, lab parameters and disease/WON characteristics.

Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

P0234 WALLED-OFF NECROSIS (WON): OUTCOMES OF AN ALGORITHMIC APPROACH TO NECROSYECTOMY

J.Y. Bang, U. Navaneethan, M. Hasam, R. Hawes, S. Varadarajulu
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Endoscopic necrosectomy (EN) in walled-off necrosis (WON) is a labor intensive, high-risk, non-standardized technique that is associated with significant morbidity and mortality. The aim of this study was to compare the clinical outcomes of patients with WON treated by conventional EN versus an algorithmic approach. We performed a prospective study of 2078 cases under- going diagnostic and therapeutic ERCP at five Japanese institutions between April 2015 and May 2016. Exclusion criteria were active pancreatitis, cholejunctunostomy, inability to approach a papilla, and inspection aimed at only the pancreatic duct (PD). WON associated with RAP underwent endoscopic minor sphincterotomy combined with dorsal duct stenting (Bi-ESCS). Cases with naıve papilla (n=183) were excluded from the analysis of risk factors for PEP because no PEP was observed in these cases. Only cases with native papilla (n=248) were analyzed. Univariate analysis showed that contrast injection into the PD (OR: 4.20, 95%CI:1.64-10.80, p=0.0028) was associated with PEP. Multivariable logistic regression analysis revealed that the algorithmic approach was the only variable associated with treatment success (OR = 60.4, p = 0.02) when adjusted for patient demographics, lab parameters and disease/WON characteristics.

Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0235 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE MANAGEMENT OF PANCREAS DIVISUM ASSOCIATED WITH RECURRENT ACUTE PANCREATITIS IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA

G. Cui, J. Yang, X. Tang, J. Yang, X. Zhang
Gastroenterology And Hepatology, Hangzhou First People’s Hospital, Hangzhou/China

Contact E-mail Address: zyz837@163.com

Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Most PD patients were asymptomatic, but a few may present with symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatic-type pain. It is imperative to treat PD associated with RAP as early as possible to prevent from developing CP. Unfortunately, to date, most of the studies have been concentrated on adults. Researches of PD in children are rare.

Results: A total of 227 pediatric ERCPs were performed for these cases. All procedures were successful with 100% (21/21) of cannulation rate of the minor papilla. The mean interval of ERCPs were performed for these cases. All procedures were successful with 100% (21/21) of cannulation rate of the minor papilla. The mean interval of PD-related studies have been concentrated on adults. Researches of PD in children is rare.

Aims & Methods: To evaluate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERCP) for the treatment of pancreas divisum (PD) associated with recurrent acute pancreatitis (RAP) in children. We retrospectively analyzed patients of PD associated with RAP who were younger than 18 years old from January 2011 to December 2015 in our center. All the patients were diagnosed and treated with ERCP. Patients of complete PD associated with RAP underwent endoscopic minor sphincterotomy combined with dorsal duct stenting (Bi-ESCS). Cases of incomplete PD underwent bi- papilla endoscopic sphincterotomy combined with dorsal duct stenting (Bi-ESCS). ERCP-related data, complications and other relevant data were collected for a mean time follow up of 14.2 ± 4.7 months. The primary outcome was successful endoscopic ductal clearance of the minor papilla. The secondary outcomes were changes in pain scores and pain frequency. The primary outcome was achieved in 100% (21/21) of cases.

Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

P0236 ENDOSCOPIC BILARY SPHINCTEROTOMY IN MALIGNANT BILARY OBSTRUCTION: IS IT INDICATED IN CASE OF STENT PLACEMENT? A META-ANALYSIS

B. Mangiavillano1, A. Montale1, L. Frazzoni2, M. Bianchetti2, A. Repici1, L. Fuccio1,2
1Gastroenterological Endoscopy Unit, Humanitas - Mater Domini, Castellanza (VA)/Italy
2Gastroenterological Endoscopy Unit, Humanitas - Mater Domini, Castellanza (VA)
Aims & Methods: We performed a literature search by using PubMed, SCOPUS, Google Scholar and the Cochrane Central Register of Clinical Trials (up to February 2017) to identify full-text studies evaluating the efficacy and safety of endoscopic biliary sphincterotomy (EBS) in patients with malignant biliary obstruction (MBO), especially if palliative treatment. The role of endoscopic biliary sphincterotomy (EBS) before stent insertion is not clearly defined. The primary outcome of our meta-analysis was to assess the technical success of biliary (plastic or metal) stent insertion. Secondary outcomes included early complications within 30 days from ERCP and late complications which (from 30 days since ERCP).

Results: 14 papers were assessed via full text for eligibility, 8 articles were excluded leaving 6 prospective studies (total of 711 patients). Technical success: The overall rate of biliary stent insertion was not significantly different: 384/392 (97.9%) in the EBS group versus 331/339 (97.6%) in the no-EBS arm (OR: 0.38; 95%CI: 0.17–0.83). Early mortality rate was 0% in the EBS group vs 25/339 (7.4%) in the no-EBS group (OR: 6.29). The mean age and follow-up duration of EST and EPS were 48.4±15.1yrs, 24.1±6.3 months, respectively, (vary from 2months to 115months). (2) The mean episodes of ARP in EST and EPS group before endoscopic therapy were 3.9±3.3 times and 7.9±11.8 times. (3) Four patients in EST group and 6 patients in EPS group suffered PEP after the endoscopic therapy (P=0.418). (4) 15 patients in EST group and 3 in EPS group suffered recurrent pancreatitis. The efficiency in EST group and EPS group is 68.4% and 89.6% respectively (P = 0.039). (5) The incidence of late complications is 18.4% in EST group and 10.3% in EPS group (P=0.567).

Conclusion: EPS combined with pancreatic stent is a promising strategy to prevent recurrence of ARP due to biliary microtholithiasis. Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic biliary stenting is the treatment of choice in presence of malignant biliary obstruction (MBO), especially if palliative treatment. The role of endoscopic biliary sphincterotomy (EBS) before stent insertion is not clearly defined. The primary outcome of our meta-analysis was to assess the technical success of biliary (plastic or metal) stent insertion. Secondary outcomes included early complications within 30 days from ERCP and late complications which (from 30 days since ERCP).
Aims & Methods: In this study, we examined the efficacy and safety of emergency ERC in super-elderly patients with moderate to severe acute cholangitis, according to TG13. We performed 178 emergency ERC procedures in 132 patients during 3 years (June 2014–December 2016). We determined patients ≥ 90 years as “super-elderly” and those < 90 years as “non-super-elderly.” Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERC procedure (examination time, endoscopic biliary sphincterotomy (EST) pre-cut papillotomy, treatment success rate, presence or absence of peripapillary diverticula and papilla after EST, sedation dosage), ERC-related complications (bleeding, perforation, post-ERC pancreatitis, complications within 30 days after ERC procedure), anesthetia-related complications (blood pressure decrease, pulse reduction, respiratory depression).

Results: We examined 69 males (52.3%) and 63 females (47.7%). Women accounted for a larger proportion in the super-elderly group (71% vs 40%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERC procedures (moderate, 32; severe, 22) against 124 ERC procedures (moderate, 104; severe, 20) in non-super-elderly group. When the two groups were compared, the super-elderly group was statistically significant (p < 0.001).

Conclusion: Emergency cholangiography in super-elderly patients was more likely to become severe and the complications were higher than that in non-super-elderly patients. When performing an emergency ERC procedure in super-elderly patients, we should particularly pay attention to developing complications in patients with moderate or higher acute cholangitis, according to TG13.

Introduction: Dysplasia may persist at the termination of the common bile duct (CBD) after endoscopic ampullectomy. Radiofrequency ablation (RFA) could be an interesting alternative to surgery to reduce the risk of invasive cancer with less morbidity and mortality.

Aims & Methods: The aim of the study was to evaluate the efficacy and morbidity of endo-biliary RF for the treatment of residual endo-biliary dysplastic lesions after endoscopic ampullectomy. A prospective open-label multicenter study
P0242 EXPERT VALIDATION OF A NOVEL MECHANICAL CUTTING PAPILLA
S. E. Van Der Wiel1, A.D. Koch2, M.J. Bruno1
1Gastroenterology And Hepatology, Erasmus University Medical Center, Rotterdam/Netherlands
2Erasmus MC Rotterdam Gastroenterology and Hepatology, Rotterdam/Netherlands

Introduction: Simulation-based training has become an important pillar in commissioning training curricula in medical specialties. Effective education is crucial, especially in endoscopic procedures, which are being performed more frequently. The aim of our study was to determine the expert validity of a new cutting papilla for training sphincterotomies,

Methods: A total of 40 ERCP experts were included. All experts were men, originating from 16 different countries with a mean age of 49.6 years (range 37–65). The following factors were evaluated: ampulla shape, number of orifices, angle of opening, and IAC. The following types of IAC were distinguished: IAC with a long protrusion (L), dome (D), and oval (O). IAC was also recognized on magnetic resonance images (MRI) and endoscopic ultrasound (EUS). The eligibility criteria for ERCP were as follows: IAC was present in the CBD, confirmed by a double anatomopathological lecture, in the absence of any technical problems. Intra-operative bleeding and stricture were noted. The current study is a retrospective consecutive case study that is conducted in a single facility, with a mean infiltration height (SD) of 11.2 mm (4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radiopaque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had bile duct stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DHG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients died before the procedure (1 patient died from a peritonitis requiring biliary stent placement, 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At M12, one patient presented with a biliary stricture resolved by dilation and a calibration biliary stent.

Conclusion: Endoscopic RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia era
dication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

P0243 MEDICO-LEGAL CLAIMS IN GASTROINTESTINAL ENDOSCOPY: DOES PROCEDURE RISK RELATE TO SUCCESSFUL OUTCOMES?
S. Budihal, J. F Mayberry
Dietoge Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Introduction: Complications in endoscopy can lead to adverse clinical events. The likelihood of developing a complication depends on the degree of risk associated with a certain procedure. It is generally noted that the riskier the procedure larger is the likelihood of developing a complication. The current study is a retrospective consecutive case study that is conducted in a single facility, with a mean infiltration height (SD) of 11.2 mm (4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radiopaque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had bile duct stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DHG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients died before the procedure (1 patient died from a peritonitis requiring biliary stent placement, 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At M12, one patient presented with a biliary stricture resolved by dilation and a calibration biliary stent.

Conclusion: Endoscopic RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

Results: A total of 291 claims were notified to the NHSLA during this period. 107 (36.7%) of claims still remain ‘open’. Analysing outcomes by procedures reveals a success rate of 44%, 44%, 57%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmodoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used).

Conclusion: A significant number of claims remain open leading to concern and worry among endoscopists. The impact on practitioners after a successful claim is unknown and merits further investigation. Procedures considered as dangerous like ERCP and Colonoscopy have the least successful claims. It is imperative that clinicians remain vigilant. Performing Gastroscopy is dangerous and so is undertaking a Percutaneous Endoscopic Gastrostomy. Endoscopists should tighten their approach to all procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0244 VISUALIZATION OF INTRA-AMPULLARY CHOLEDOCHOCELE WITH CONTRAST MEDIUM FOR EVALUATING TECHNICAL DIFFICULTY IN ERCP
N. Nishino
Gastroenterology Center, Southern Tohoku Hospital, Koriyama/Japan

Introduction: Cholecdochocle has been rarely recognized. It provides a success rate of 44%, 44%, 57%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmodoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used).

**Results:** There were cases of 1223 naïve papilla out of 2226 cases in total. The success rate to access BD with naïve papilla was 97.7% (1195/1223) and overall endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22% respectively. IAC was significantly higher in the L/N (p<0.01) and F (p<0.05) types than in the D type. The choledochocoele shapes of Sh, Oh and Qw were 59.3%, 13.0%, 27.8%, respectively. The average size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were 60% and 40% in Ab; in the Ac was found with L/N shape only. Patients of 53.7% (29/54) required GW placement on PD to access BD. IAC was alternately seen on MRCP in 10% (3/30).

**Conclusion:** Choledochocoele is rarely seen on even cERCP, in addition the visualization of IAC has become rare. IAC may be visualized such as condition. Our results showed the intra-ampullary images. IAC would require refractory pursuit of the axis alignment due to its unexpected pathway within ampulla to access BD. Moreover, 60% prevalence of IAC should not be ignored. IAC can be one of the factor of refractory cannulation. cERCP with focus on ampulla could the difficulty in cannulation. On the other hand, WGC would not do. The previous randomized control trials showed no difference to access BD between WGC and cERCP. However, both procedures still remained cases with refractory cannulation. It has been reported that refractory cannulation might cause PEP1). Therefore careful attention should be paid while passing through IAC to avoid PEP. According to ampula shapes, especially of L/N and F, cERCP would be recommended to identify the presence of IAC. It will be a warrant strategy to choose.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Most appropriate endotherapy of biliary anastomotic strictures (AS) remains to be defined.

**Aims & Methods:** Aim is to retrospectively report the endotherapy for duct-toduct AS in 2013, procedure related complications and medium-term outcome results in Italy. A questionnaire was sent to the Endoscopy Units working with Italian Liver Transplantation Centers (BASALT study group).

**Results:** At present sixteen of the 19 Units (84%) returned the questionnaire. Complete endotherapy data and follow-up are available for 182 pts. One-hundred and two patients have been treated with plastic multistenting (PM), 27 with fully covered SEMS and 53 with single stenting (SS). Radiological success was achieved in 144 pts (79%), i.e. 86% of PM, 89% of fully covered SEMS and 60% of SS (p<0.01 vs PM). Recurrence occurred in 31 pts, i.e. 21% of pts in whom radiological success was achieved: 11% of PM (p<0.0001 vs SEMS and p<0.05 vs SS), 41% of fully covered SEMS and 17% of SS. After failure of first-line endotherapy (36%) or recurrence (31), patients were re-treated with endotherapy (75%), surgery (21%) or percutaneous balloon dilatation (7%), one patient dropped out because of death unrelated to endotherapy. Second-line endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22% of pts and radiological success was achieved in 82% of them (in 86%, 89%, and 66% with PM, SEMS and SS respectively). Procedure-related complications occurred in 7.8% (51/666), i.e. 2.6% pancreatitis (1 severe leading to death), 4.1% cholangitis and 0.9% bleeding. Overall clinical success was achieved in 85% after a median I-SEP of 25 mos and no need of surgery in 92% of patients.

**Conclusion:** Endotherapy is confirmed as the preferred first-line and rescue option for AS. Progressive plastic multi-stenting is most frequently used. Single stenting has suboptimal results and should be abandoned. Use of SEMS is effective, but recurrences seem to be frequent, although a larger patients’ sample needs to be evaluated.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: The aim of our study was to compare conventional suction using a 20mL syringe and capillary suction during EUS-FNA. Patients who required to collect solid mass lesion were prospectively enrolled. We performed EUS-FNA with two needle passes and applied each pass of different techniques which were randomly allocated. The diagnostic accuracy, the quantity of samples (0-5 represents sufficient material for adequate for histological interpretation and sampling, 5 degree of contamination, and the amount of blood (0-2.2 represents significant amount of blood) were compared between conventional suction and capillary suction. Further analysis was carried out in the patients with pancreatic cancer. For patients with negative EUS-FNA, surgical specimen evaluation, results of other diagnostic investigations and/or long term clinical follow-up (6 months) were used to establish the definitive diagnosis. Results: During the study period, 96 patients underwent EUS-FNA were enrolled and 7 patients were excluded due to loss of follow-up. Finally 89 patients (averaged 68.5 y/o, M: F = 47:42) were analyzed. There were 60 pancreatic lesions (42 pancreatic cancer, 6 neuroendocrine tumor, etc.), 17 lymph adenopathy, 6 subcutaneous lesions, 6 other lesions biopsied, with a mean diameter of 28.3 ± 3.5 mm. Although there was no significant difference in the diagnostic accuracy (86.5% vs. 79.8%, p = 0.32), the degree of contamination, the samples obtained by conventional suction contained more blood compared to those obtained by capillary suction (0.17 vs. 0.02, p = 0.05). Moreover, conventional suction showed favorable diagnostic accuracy (83.3% vs. 69.0%, p = 0.20) and significantly higher quality of samples (3.38 vs. 2.74, p < 0.05) than capillary suction, in the patients with pancreatic cancer. Conclusion: Capillary suction was effective in the EUS-FNA sampling and associated with less contamination with blood, but conventional suction is recommended in case of fibrotic pancreatic cancer for obtaining high-quality sample.

P0249 DIAgnostic Efficacy of Endoscopic Ultrasound-Guided Fine-needle aspiration for a Pancreatic Mass using the Cell Block Method without Rapid on-site Cytology

K. Masu1, K. Ito1, Y. Noda1, S. Koshita1, Y. Kanno1, T. Ogawa1, T. Sawai2
1Gastroenterology, Sendai City Medical Center, Sendai/Japan
2Pathology, Sendai City Medical Center, Sendai/Japan

Contact E-mail Address: k-masu@openhp.or.jp

Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) has been shown to be efficient for diagnosis of pancreatic masses. Only with the smear method, however, its diagnostic efficacy may vary greatly depending on the proficiency of the cytopathologist. On the other hand, the cell block (CB) method allows cytological and/or histological evaluation with hematoxylin and eosin (HE) staining and with immunostaining for serial sections if necessary.

Aims & Methods: The aim of this study was to evaluate the diagnostic efficacy of EUS-FNA for a pancreatic mass using the CB method without rapid on-site cytology retrospectively. A total of 206 patients with pancreatic masses (head: 87, body: 86, tail: 33) who underwent EUS-FNA using a GF-UL240® or GF-UL240® (Olympus Medical Systems, Ltd, Tokyo, Japan) between June 2005 and November 2016 were included in this study. The needles used were 22G needles. At least two passes were made during the procedure (mean ± 0.9 passes). Adequate specimens were regarded to be those in which whitish flagging were macroscopically achieved. The samples were immediately fixed in 10% formalin and processed by the cell block method using sodium alginate. Rapid on-site cytology was not performed. All samples were stained by hematoxylin and eosin, periodic acid Schiff and Acidine blue, and immunohistochemical techniques. The final diagnosis was based on histological findings of surgically resected specimen, image diagnosis and clinical course for more than six months.

Results: The final diagnosis was malignancy in 184 patients (pancreatic ductal cancer (PDC), 171; neuroendocrine tumor (NET), 9; malignant lymphoma, 2; metastasis of malignant melanoma, 1; solid pseudopapillary neoplasm, 1), and benignity in 23 patients (autoimmune pancreatitis (AIP), 11; chronic pancreatitis, 7, organizing pancreatic pseudocyst, 4, IPMN, 1). Diagnostic accuracy of on-site cytology showed high for definitive diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO250 A COMPARATIVE STUDY BETWEEN EUS-GUIDED BILARY DRAINAGE AND PERCUTANEOUS BILARY DRAINAGE IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION AND FAILED ERCP

Department Of Gastroenterology, Hangzhou First People’s Hospital, Hangzhou, China

Contact E-mail Address: zacharylu@126.com

Introduction: Patients with malignant biliary obstruction conventionally undergo percutaneous transhepatic biliary drainage (PTBD) after failed endoscopic retrograde cholangiopancreatography (ERCP) (1). While PTBD is effective, it is associated with significant morbidity, such as bile leakage, bleeding, and pneumothorax, and involves uncomfortable external drainage (2). Endoscopic ultrasound-guided biliary drainage (EUS-BD) is a minimally invasive endoscopic treatment increasingly offered in western centers (3). However, data from mainland China is sporadic (4).

Aims & Methods: We aimed to compare efficacy and safety of EUS-BD to PTBD in patients with malignant biliary obstruction after failed ERCP at a single tertiary referral center from mainland China. From November 2011 through December 2015, consecutive patients undergoing EUS-BD or PTBD for malignant biliary obstruction after failed ERCP were included. Demographical, biochemical, and outcome data were registered for each group. The primary outcomes included technical success rate and incidence of complications, the secondary outcomes included clinical success rates and re-intervention rate.

Results: A total of 93 patients (mean age 68 ± 13.5 years, 49 males) were included, 33 in the EUS-BD group and 60 in the PTBD group. Both groups were similar in terms of age, gender, baseline bilirubin and functional status. Technical success was achieved in 32 (97.0%) of 33 patients in the EUS-BD group and in 57 (95.0%) of 60 patients (p > 0.05) in the PTBD group. The clinical success (judged success: reduction in serum bilirubin by 50% within the first month) was achieved in all patients with technical success (32/32, 100% EUS-BD vs. 57/57, 100% PTBD).

Conclusion: Despite similar high technical and clinical success rates compared with PTBD, EUS-BD was associated with reduced rate of re-interventions, UES-BD seems a better alternative than PTBD for malignant biliary obstruction after failed ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0251 A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS-GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOTOLOGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MASSES

P.N. Desai, M. Kabrawala
Endoscopy, Surat Institute Of Digestive Sciences, Surat, India

Contact E-mail Address: drp_desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance is used up till now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for attaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echocodscope, mass identified and FNA performed with a 25 G needle making 2 to 5 passes and material sent for cytology. Same patients subjected to ERCP. A wide papillotomy was performed and over the wire cytology brush was used and brush cytology was obtained. Two passes were made and material taken on a slide and sent for cytology after wet fixation.

Results: Total number of cases 56 Age (range) 57.2±13.6 Male to Female 16:16 Total Number of Biopsies (Bilirubin 9.0 μg/dl) 5.9±6.4 Mean size of the mass 12 mm (7 mm to 30 mm). Mean Number of passes with FNA needle 2.5 (2 to 5 passes). Mean number of passes with cytology brush 2 (2t0 5). Positive diagnosis obtained with FNA 47 (83.9%). Positive Diagnosis obtained by brush 34 (60.7%) of malignancy.

With EUS the tumors were sometimes difficult to locate and identify. But giving some time and instilling water in duodenum were useful techniques to identify the masses. Only a 25 G needle was used as the FNA had to be taken almost always from the duodenum and with difficult angles. But we succeeded in taking FNA from all cases.

Conclusion: EUS FNA is a very effective method for diagnosis of distal bile duct masses with a certain diagnosis in almost 81% and a suspicious diagnosis in around 11% cases. Its efficacy is better than ERCP guided brush cytology. Even small masses are amenable to FNA using EUS guidance. Male over 57 years with jaundice and distal bile duct obstruction has a very likelihood of have a distal CBD cholangiocarcinoma.

P0252 RANDOMIZED TRIAL COMPARING THE LUMEN-APPOISING METAL STENTS (LAMS) AND PLASTIC STENTS FOR EUS-GUIDED DRAINAGE OF WALLEO-FALL NECROSIS (WON)

J.Y. Bang, M. Hasan, U. Navaneethan, R. Hawes, S. Varadarajulu
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Although lumen-apposing metal stents (LAMS) are being increasingly used for drainage of walled-off necrosis (WON), their advantage over plastic stents is unclear.

Aims & Methods: We aimed to compare the efficacy of LAMS and plastic stents for drainage of WON.

Symptomatic patients with WON (>20% necrosis) were randomized to undergo transmural drainage using LAMS (Hot AXIOS, 15 mm x 10 mm) or two double pigtail plastic stents (7Fr x 4 cm). Reintervention in persistently symptomatic patients included additional stent placement, percutaneous drainage and/or endoscopic necrosectomy. Treatment success was defined as symptomatic relief in conjunction with resolution of WON on CT at 6-week follow-up. Main outcome measure was to compare the no. of reinterventions. Secondary outcome measures were to compare treatment success, procedural duration, resolution of systemic inflammatory response syndrome (SIRS), clinical and stent-related adverse events, readmissions and length of hospital stay. Sample size to detect a difference of 1 in the no. of reinterventions performed at 90% power was calculated at 58 patients.

Results: 60 patients were randomized to LAMS (n = 31) or plastic stent (n = 29) placement. While there was no significant difference in the no. of reinterventions (median 1 [IQR 1–2] for both stent types, p = 0.78), the procedural duration was significantly shorter (15 vs. 42.5 mins, p < 0.001) and stent-related adverse event rate was significantly higher with LAMS placement (32.3 vs. 6.9%, p = 0.02). At an interim audit, significant adverse events (delayed bleeding [n = 3], buried stent [n = 2], biliary stricture [n = 3]) were observed in the LAMS cohort after 3 weeks post-intervention. This necessitated an amendment to the study protocol whereby a CT scan was obtained at 3 weeks following by LAMS removal if the WON had resolved. After protocol amendment, no difference in stent-related adverse events was observed between the cohorts (LAMS 8.5 vs. plastic 6.9%, p = 0.94).

Other 9.7 13.8 0.70

No. of reinterventions (n): Median [IQR] 1 (1–2) 1 (1–2) 0.78

Readmissions (%): 29.0 34.5 0.78

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

Results:

We included 42 cases of pancreatic pseudocysts (PP), and 25 walled-off

symptomatic/infected PFCs, who underwent EUSTD. PFCs were drained

EUSTD of PFCs using DPPS and FCSEMSs (Hanarostent BCF and Hot AXIOS system).

Aims & Methods:

pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPPS)

Contact E-mail Address: marcocostais87@gmail.com

Introduction: Ultrasound-guided endoscopic transgastric drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPPS) remains the gold standard even from difficult-to-approach anatomical locations. Comparative studies with comparable results with the new 20G needle were included in the present study. The reference standards for the final diagnosis were histology on surgical specimen or clinical follow-up.

Results: A total of 50 SELs in 50 patients (22 males, mean age 61.5 ± 14.8 years) were included. The mean lesion size was 43.1 ± 17.5 mm. The lesion locations were esophagus (n = 1), stomach (n = 37), distal duodenum (n = 5), rectum (n = 6), and colon (n = 1). The procedure was technically feasible in all patients. Most patients’ number of passes required to reach a diagnosis was 2.2 (range 1–4). Definitive diagnosis with full histological assessment including HIC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36% (7/20) malignant SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinoid, for SEL-like adenocarcinoma), 8 (16%) benign SELs (1 leiomysarcoma, 4 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95%CI 70.2–94.3), 100% (95%CI 58.7–100), 100% (95%CI 85.1–100), and 62.5 (95%CI 27.7–84.8), respectively. No major complications requiring additional care were observed.

Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G core needle is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-approach anatomical locations. Comparative studies with different needle sizes are awaited.

Disclosure of Interest: All authors have declared no conflicts of interest.

between the two groups was applied in order to minimize the effect of selection bias. A success rate of significantly reduced in size (<20% of initial size). The secondary outcomes were the rate of significant growth in size (>10 mm), complete remission rate, and surgical resection rate.

Results: In a propensity matched analysis of 88 pairs, the mean initial cystic size of EUS-guided ethanol ablation group and natural course group was 23.72±10.99, 23.16±13.15 mm and the mean follow-up duration was 75.45±38.12, 82.12±59.06 months respectively. Significant reduction in size was detected in 53 (60.2%) of the EUS-guided ethanol ablation group and 17 (18.8%) of the natural course group (p<0.01). Significance in growth size in was detected in 6 (8.9%) of ablation group and 11 (12.5%) of natural course group. (p=0.202). Seven patients (7.95%) underwent surgical resection in the EUS-guided ethanol ablation group and 17 patients (19.3%) in the natural course group (p=0.028) during follow-up. Overall 28.8% patients (34 of 118) who underwent EUS-guided ethanol ablation had achieved the complete remission.

Conclusion: PCLs that underwent EUS-guided ethanol ablation can be seen the likelihood of getting clinical benefits such as reduction of the cystic size, the chance for surgical resection in comparison to the natural course of them. It is also expected to achieve a certain level of complete remission for PCLs.

Introduction: Fine needle tissue characterization using desmoplastic stroma is required for molecular profile-based personalized chemotherapy in pancreatic cancer. Recently, a three-plane symmetric needle with Fransseen geometry and a Fork-tip biopsy needle have been developed for histological tissue puncture.

Aims & Methods: We aimed to compare tissue acquisition between the 22G Fransseen and 22G Fork-tip needles in patients undergoing EUS-guided sampling of pancreatic masses.

Patients with pancreatic masses were randomized to undergo EUS-guided sampling using the 22G Fransseen and 22G Fork-tip needles. Two dedicated passes were first performed using both needles in individual patients for cell block. Subsequent passes were then performed for rapid onsite evaluation (ROSE) usually both panorama radiology and a VIVA combo generator (TaeWoong Medical, Gimpoo, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-, and 20-mm exposed tips) were used. After the echodescope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at ±4 W for 2–6 min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrant lobe of the gallbladder through the bulb of the duodenum.

Results: All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect were evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

Conclusion: In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver tumors such as hepatocellular carcinoma and liver metastases sometimes occur in positions in which treatment using percutaneous radiofrequency ablation (RFA) is difficult, such as the caudate lobe and surface of the left lobe. EUS-guided RFA can offer an alternative treatment by accessing these tumors through the stomach or duodenum. To the best of our knowledge, only one report has described EUS-RFA of the liver in an animal model, using a 19-gauge EUS-FNA needle with an umbrella-shaped array at the tip. EUS-RFA is expected to obviate the need for ROSE during EUS-guided tissue sampling.

Aims & Methods: We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. EUS-guided 19-gauge needle and a VIVA combo generator (TaeWoong Medical, Gimpoo, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-, and 20-mm exposed tips) were used. After the echodescope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at ±4 W for 2–6 min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrate lobe of the gallbladder through the bulb of the duodenum.

Results: All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect were evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

Conclusion: In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

Contact E-mail Address: albertomurino@yahoo.it

Introduction: Small bowel varices (SBV) occur as a consequence of portal hypertension and may result in life-threatening mid-gut bleeding. First line management usually involves radiological intervention (RI) (e.g. TIPSS, stenting of occluded mesenteric veins +/- embolisation of culprit varices). In cases where RI is impossible, management options become very limited.

Aims & Methods: This case series evaluated the usefulness of DBE facilitated cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV at our institution (December 2015 to August 2016). Demographic, clinical, endoscopic and radiological findings, interventions and follow-up data were analysed.

Results: Seven DBEs were performed in 5 patients (3 women, median age: 73-years). Four patients had previous surgery (hepaticojejunostomy (n=2); SB resection (n=2); one patient had a history of intra-abdominal sepsis in childhood causing portal vein thrombosis. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase CT mesenteric angiography. At DBE, a total of 10 nests of SBV were identified.
and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications as the angulated and was developed to image the submucosa of a congenital jejunal cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route and 1 patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for tending of further patent proximal SBV. At 30-day follow-up post-therapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options have failed.

Introduction: The diagnostic yield of capsule endoscopy (CE) depends on the adequate visualization of the mucosa. As with colonoscopy, cleaning scales should be described in the report in order to better interpret results. In 2009, Broiet al proposed and validated 3 different cleaning scales in 40 patients.

Aims & Methods: A hundred CE videos (Mirocam®) were reviewed by 2 authors at a fixed frame rate of 100 frames per second in quadruple view (Miroview Client). The CE were evaluated according to Brotz scales: (1) Overall adequacy assessment (adequate/inadequate) (2) Qualitative scale (excellent, good, fair, poor) and (3) Quantitative scale (0–10 score, graded from 0–2 visualization of the mucosa, fluids, bubbles, bile and luminosity). The aim of this study was to evaluate the inter-observer variability of this cleaning scales. The kappa coefficient was used to calculate the inter-observer agreement in overall adequacy assessment and the intra-class correlation coefficient was used to evaluate the concordance of the qualitative and quantitative scales.

Results: In overall adequacy assessment, the quality of bowel preparation was classified as adequate by observer 1 in 87% and by observer 2 in 73%, with an inter-observer kappa index of 0.76 (p < 0.001) suggesting strong agreement. In the qualitative scale, most of the bowel preparations were considered inadequate (40% observer 1 vs 36% observer 2), with an intra-class coefficient of 0.89 (p < 0.001). In the quantitative scale, the mean score of the two observers was 6.5 and 6.7, resulting in an intra-class agreement of 0.78 (p < 0.001).

Conclusion: The optimization of quality of bowel preparation and the diagnostic yield of the CE requires first, a well-validated cleaning scale. Brotz’s rating scales have strong inter-observer agreement. The qualitative scale is easier to apply and has better inter-observer agreement, so the authors propose that it should be used routinely in the CE report.

Introduction: Inflammatory bowel diseases (IBD) are chronic inflammatory diseases that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic evaluation of these parts is essential to assess disease extent and severity. The small bowel capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

Aims & Methods: The aim was to evaluate SBC-CE system functionality in suspected or established IBD (Crohn’s disease [CD] and Ulcerative Colitis [UC]) patients. This was a prospective 5 center feasibility study assessing the performance of the SBC capsule and software. Subjects enrolled in the study ingested the new capsule after standard bowel preparation plus boosts. Contraindications for its use included obstruction, dysphagia or swallowing disorders, pacemakers etc. GI patency was assured using the patency capsule. The procedure was successful procedure in terms of video creation and quality generation in accordance to the video reading methodology. Secondary endpoints were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events.

Results: 58 patients, of which 54 were enrolled and 49 ingested the capsule (14 patency failure, 5 withdrew consent). Mean age was 40.1 years, 51% were males. 69% of patients had established CD, 10% UC and 21% suspected. Mean patency was 3.5 (1–7, poor to excellent), and mean frame rate was 3.9 ± 1.4 (1–7, poor to very good) and excellent. Overall cleansing was regarded good or excellent in 96% of patients. All 49 videos met the primary endpoint, i.e. video was created and report generated with all included information and in accordance to the video reading methodology. The study included the rectum to jejunum exploration, mostly while watching video. Gastroenterologists were satisfied with small bowel coverage 6.6 ± 0.6 (mean ± standard deviation) and colon coverage of 6.0 ± 1.2 in a scale of 1–7 (unconfident to confident), image quality 6.1 ± 0.8 (1–7, poor to excellent), and subjective video rating of 3.9 ± 1.4 (1–7, poor to very good). There were 4 patients with small interferences related to video continuity (gaps).

Conclusion: The new SBC capsule is a friendly, minimally invasive capsule allowing complete evaluation of the entire gut of IBD patients. The system may be used to assess disease severity and extent and for follow up of IBD patients.

PO268 THE UTILITY OF A NOVEL TRANSPAPILLARY DILATION TECHNIQUE WITH AN ABLATIVE CATHETER FOR SEVERE MAIN PANCREATIC DUCT STRICTURE DUE TO CHRONIC PANCREATITIS

S. Kato, M. Kuwata1, R. Sugiuha, I. Sano, K. Kawakubo, N. Sakamoto

Gastroenterology And Hepatology, Hokkaido University Hospital, Sapporo/Japan

Contact E-mail Address: shinchan1231@gmail.com

Introduction: Transepipillary biliary drainage for severe main pancreatic duct (MPD) stricture is sometimes difficult and diathermic dilatation is now getting attention as a salvage technique for severe stricture; however its efficacy and safety remains unclear.

Aims & Methods: To evaluate the efficacy and safety of a novel transpapillary dilation technique with a diathermic catheter for severe MPD stricture due to chronic pancreatitis. Between April 2011 and March 2017, 143 patients with chronic pancreatitis underwent endoscopic transpapillary stent placement for MPD. MPD dilatation was indicated in 18 patients, and diathermic dilatation was required in nine patients. We evaluated (1) the patients’ characteristics, (2) procedure characteristics, (3) clinical outcomes, (4) adverse events.

Results: (1) Six patients were men and three were women (mean age, 50.1 years). Alcohol 8, unknown 1. The strictures were in the head of pancreas: 8, body: 1. The mean length of stricture was 20.2 mm (range, 10–30.8). The mean MPD diameter at the distal side of stricture was 6.2 mm (mean 5.56%). Among them had no former procedure for MPD including stenting. (2) A wire-guided 6Fr diathermic catheter with 30 W power was used for all cases. All cases underwent diathermic dilation as salvage procedure subsequent to conventional dilation. One to 7 diathermy procedures (mean 2.9) were done after passage through each stricture. (3) Passage of the diathermic catheter and stent placement was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). Recurrence of stricture was observed in 2 patients (22.2%). One of them needed diathermic dilatation again. (4) Two adverse events (22.2%) were observed and both of them were mild pancreatitis. Multiple diathermy procedures (6 times and 4 times, respectively) and relatively long duration of total diathermy procedure (39 sec. and 25 sec. respectively) were observed in cases with pancreatitis.

Conclusion: Transpapillary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. It should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

Introduction: Endoscopic biliary decomposition is widely used for advanced hilar cholangiocarcinoma. Bilateral stenting has become more feasible with more experienced endoscopists and the development of new devices. However, stent dysfunction develops in 3% to 45% because of tumor ingrowth, overgrowth, or debris as disease progresses. Endoscopic reintervention is difficult and complex with worsening bile duct strictures. The present study aimed to evaluate a suitable reintervention procedure for stent malfunction after stent-in-stent (SIS) deployment for malignant hilar obstruction.

Aims & Methods: From September 2009 to June 2016, a total of 52 patients who underwent failed stenting at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

Results: Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and poor conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

P0271 LONG-TERM OUTCOMES OF ENDOSCOPIC ULTRASOUND GUIDED BILE DRAINAGE WITH TRANSMURAL COVERED METAL STENT

Contact E-mail Address: dhcho81@daum.net

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been regarded as an effective alternative in cases of endoscopic retrograde cholangiopancreatography (ERCP) failure or inaccessible papilla. However, EUS-BD for right intrahepatic duct obstruction (EUS-BD(RIDO)) remains challenging, although recent studies showed promising result. The aim of current study was to evaluate the feasibility and long-term outcomes of EUS-BD with transmural covered metal stents for right intrahepatic duct obstruction.

Aims & Methods: Retrospective study, a total of 24 consecutive patients who underwent EUS-BD after failed ERCP were enrolled. The patients consisted of 12 cases of benign strictures and 12 cases of malignant strictures. The biliary stents used in this study was covered metal stent with anchoring flaps. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and poor conditions.

Conclusion: Technical success of EUS-BD was defined as successful stent deployment for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

Disclosure of Interest: Authors have declared no conflicts of interest.

P0272 OUTCOME OF ENDOSCOPIC REINTERVENTION FOR MALIGNANT HILAR OBSTRUCTION TREATED BY STENT-IN-STENT DEPLOYMENT

Contact E-mail Address: subsulpal@naver.com

Introduction: Endoscopic biliary decompression is widely used for advanced hilar cholangiocarcinoma. Bilateral stenting has become more feasible with more experienced endoscopists and the development of new devices. However, stent dysfunction develops in 3% to 45% because of tumor ingrowth, overgrowth, or debris as disease progresses. Endoscopic reintervention is difficult and complex with worsening bile duct strictures. The present study aimed to evaluate a suitable reintervention procedure for stent malfunction after stent-in-stent (SIS) deployment for malignant hilar obstruction.

Aims & Methods: From September 2009 to June 2016, a total of 52 patients who underwent failed stenting at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

Results: Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and poor conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

Disclosure of Interest: Authors have declared no conflicts of interest.

P0273 EUS-GUIDED GALBLADDER DRAINAGE REDUCES LATE ADVERSE EVENT AND NEED FOR RE-INTERVENTION COMPARED WITH PERCUTANEOUS CHOLECYSTOSTOMY IN PATIENTS WHO ARE NOT ELIGIBLE FOR SURGERY

Contact E-mail Address: dhcho81@daum.net

Introduction: Endoscopic ultrasound guided transmural gall-bladder drainage (EUS-GBD) with covered metal stent has become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-GBD with conventional percutaneous cholecystostomy.

Aims & Methods: Retrospective, comparative analysis of the long-term outcomes of EUS-GBD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-GBD for acute cholecystitis is obtained from prospective collected EUS database and the patient who underwent percutaneous cholecystostomy is obtained from a record of patients who underwent percutaneous cholecystostomy was reviewed and analyzed. Demographics and procedure related outcomes including early, late adverse events and need for re-intervention in each group was compared. Results: A total of 181 patients (74 in EUS-GBD group and 107 in percutaneous cholecystostomy group) were enrolled in this study. The cause of cholecystitis and ASA class were similar in both groups. The technical/clinical success rate was 100%/98.6% in EUS-GBD group and 99.1%/97.2% in percutaneous cholecystostomy group (P=0.591 to Dec 2014). Early adverse events were also similar between two groups (6.8% in EUS-GBD group vs. 15.0% in percutaneous cholecystostomy group, P=0.103). However, late adverse events including migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis was more frequently observed in percutaneous cholecystostomy group (574 in EUS-GBD group and 21/107 in percutaneous cholecystostomy group, P=0.017). Percutaneous cholecystostomy tube was indwelled for
median 20 days (14.0±4.5) after the procedure. A total of 7 patients in EUS-
GID group underwent re-intervention for adverse events and all of them were
correctly conducted. The patients who underwent percutaneous cholecysto-
omy more frequently received re-intervention for adverse event or recurrence of
cholecystitis after removal of cholecystectomy. (7/4 vs. 23/106, P = 0.041).
Conclusion: EUS-GID and percutaneous cholecystectomy were both effective
interventions to urgent drainage for acute cholecystitis. However, EUS-GID
might be beneficial than percutaneous cholecystectomy in long term management
for the patients with acute cholecystitis who are not suitable for cholecystectomy.

P0274 ENDOSCOPIC TREATMENT OF ANASTOMOTIC BILIARY
STRUCTURES IN PATIENTS WITH LIVING DONOR LIVER
TRANSPLANTATION: MULTIPLE PLASTIC STENTS VS FULLY
COVERED SELF-EXPANDABLE METALLIC STENTS
A.T. Eminler, E. Parlak, A. S. Koksal, B. Toka, M. I. Uslan
Gastroenterology, Sakarya University, Sakarya/Turkey
Contact E-mail Address: drrukanparlak@gmail.com
Introduction: The “fully covered self-expandable metallic stents”(fcSEMSs) were
found to be non-inferior to multiple plastic stents (MPSs) for the treatment of
anastomotic biliary strictures after orthotopic liver transplantation (OLT). However,
there is scarce data about their efficacy in the treatment of anastomotic
biliary strictures after living donor liver transplantation (LDLT). We aimed to
compare the efficacy of fcSEMS and MPSs for the treatment of anastomotic
biliary strictures after LDLT.
Aims & Methods: We retrospectively analyzed the data of LDLT patients with
duct-to-duct anastomotic biliary strictures who underwent endoscopic treatment
at our center within the last 3 years. FcSEMSs were inserted in 23 patients (13
male, 10 female, median age: 51±9 years) who were managed with MPS insertion (Group-2). In Group-1, secondary branch ducts were prophylactically drained with insertion of plastic
stent(s) in order to prevent the development of cholangitis due to their occlusion.
FcSEMs and plastic stent(s) were left in place for 2 months. In Group-2, max-
imum number of plastic stents were inserted and replaced every 3 months.
Patients with a follow-up duration of at least 3 months after stenting were
included to the study. Primary end-points were the number of endoscopic pro-
cedures and the time required for structure resolution. The secondary end-point
was the recurrence rate of the stent.
Results: FcSEMSs were successfully deployed in all cases. The diameter of the
Fc-SEMSs were 10mm in 22 patients and 8 mm in 1 patient. The length of the
Fc-SEMSs were 8cm in 13 patients, 10cm in 9, and 8cm in 2 patients. Secondary
branch ducts were prophylactically drained with a single plastic stent in 12
patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The
median number of endoscopic procedures was 2 (2–4) in Group-1 and 4 (2–9)
in Group-2 (p = 0.001). The time required for structure resolution was shorter in
Group-1 (65±7 days) than in Group-2 (240±183.4 days) (p < 0.001). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%)
(p = 0.57) after a follow-up period of 315±290 and 378±36 days, respectively.
Conclusion: FcSEMSs are an effective method for the treatment of anasto-
mosic biliary strictures after LDLT, with a less number of endoscopic sessions
and a shorter stenting duration required for the resolution compared to MPS.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0275 PROSPECTIVE RANDOMIZED STUDY FOR EFFICACY OF
AN DOUBLE BARE STENT COMPARED A DOUBLE COVERED
STENT IN MALIGNANT COLORECTAL OBSTRUCTION

Introduction: Colorectal stenting is a minimally invasive, reliable and effective
intervention in patients with malignant colorectal obstruction, associated with a
low complication rate compared to traditional surgical treatment. One of the actual problems associated with colorectal stenting is the recurrence of
symptoms of obstruction. The most common cause is migration of covered stents
and ingrown of uncovered stents1-3. The aim of our study was to compare the
results of the use of stents of a new design, the development of which was aimed
at preventing these complications.
Aims & Methods: We aimed to evaluate the results of the use of the new design
of double uncovered and dual coated colorectal stents). Between December
2012 and April 2017, 77 patients with colonic malignant obstruction were
implanted 78 stents (39 bare, 39 covered EGIS Colorectal stent, S&G Biotech
Inc., South Korea). A double uncovered stent has a two-layer structure created
by crossing two stents, resulting in a smaller cell size. Such a design theoretically
can prevent the ingrow of the tumor, localization and uncrowed edges prevent the migration of
the stent. All interventions are performed by one operator using endoscopic
and radiological control. Groups of patients using coated and uncovered stents
were comparable in terms of sex, age, duration of symptoms of obstruction,
and stenosis localization. The reasons for the obstruction were primary tumors of the
colon 97.4%. The localization of the tumor is most common in the sigmoid colon
- 54.5% and was provided to 43(55.8%) patients, «bridge to surgery » – 34
(44.7%) patients.
Results: Clinical success was achieved in 74 (96.1%) patients. In two cases, when
using covered stents, the symptoms of obstruction could not be reduced, the
patient died. In one case, 18 hours after stenting with an uncovered stent, was
diagnosed perforation due to obstructive colitis. The average stay in
hospital after the intervention was 3 days; the difference between the groups
was statistically insignificant. 30 day mortality was 5.2%, the difference was statisti-
cally significant. Complications were detected in 3 patients in the group of bare stents
and in 1 patient in the group of covered stents, the difference was statisti-
cally insignificant. One patient with the carcinoma of a sigmoid colon with
invasion in anterior abdominal wall noted the appearance of subcutableus
emphysema without pneumoperitoneum, in 3 (3.5%) patients the occlusion
of the stents. The reasons for obstruction of the stents were occlusion from
the obstruction from stool (fibers) on the 83rd day (the endoscopic recanalization
was performed) and tumor growth over 165 days (endoscopic «sten-in-stent»
placement). In one patient, the cause of occlusion is unknown, operated in
another hospital 34 days after stenting - a transversostomy was performed,
died on the 4th day after the operation.
Conclusion: Double bare and double covered colorectal stents were feasibility
and efficacy for relieving malignant colorectal obstruction. Reobstruction was rare
complication and not different in both groups stent groups. Necessary to con-
tinue to research for the accumulation of material from other centers.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic therapy has been emerged as alternative treatment to
bariatric surgery for reducing weight. We developed a new endoscopic gastro-
inestinal (GI) bypass stent and designed a preclinical study to assess the safety
in a porcine model.
Aims & Methods: The aim of this study is to investigate the feasibility of our GI
bypass device in animal. Before animal study, we performed an experimental
study for durability test under simulated intestinal fluid flow. And next, we
performed an animal study with 10 Yorkshire pigs. The stents were placed on
pylorus with fixation by clippings or on duodenal bulb without fixation. Follow
up endoscopy was done per one week after implantation. After they were sacri-
ficed, gastric, duodenal, and jejunal tissues were harvested and examined for
histologic assessment of any device or procedure-related effects.
Results: Our new GI bypass stent showed a good durability in simulated solution
flow. No breakage or migration of stent occurred under continuous water flow in
simulation system setting. In animal study, the mean starting weight was
30.1±1.5 kg. Delivery of the implant took an average of 19.8 min (range, 11–
32 min) in 5 pigs. The first 2 pigs showed a colostomy stent group and 11.2 min
(range, 6–18 min) duodenal bulb stent group. It required an average clipping time of 10.8 min (range, 8–14 min). Followed for stent migration after implantation, the mean patency duration was
1.5±0.7 weeks. One pig was died due to small bowel perforation and peritonitis
after stenting. In histologic finding, there were moderate degree of mucosal ero-
sions, but no definite ulceration on pylorus and duodenum.
Conclusion: New GI bypass stent has a good physiochemical properties in simu-
lated intestinal system. In animal, all stents were successfully deployed but migra-
tion of stent was seen in this study. Further investigation to known whether such as
eoscopic stuche mechanism and modification of stent would be required.

Introduction: Dysphagia may occur due to benign pharingo-esophageal strictures, often resulting in repeated endoscopic dilations. The aim of the study was to access long-term efficacy of pharingo-esophageal dilations due to anastomotic or post-radiation strictures.

Aims & Methods: Retrospective study of patients suffering of dysphagia due to radiation (Group I) or anastomotic (Group II) induced pharingo-esophageal benign stricture submitted to endoscopic dilation between January 2013 and December 2015. The long-term efficacy (after a minimum follow-up of 12 months) was prospectively assessed by telephone interview by: a) dysphagia improvement or b) resolution (grade 0 or 1 of Mellow-Pinks scale), c) absence of further dilations and d) absence of PEG. Additional therapy (PEG or prosthesis placement, electroincision or surgery) was considered inefficiency criteria and these patients were excluded from the interview. Post-procedure complications were registered. Efficacy predictive factors were assessed.

Results: Forty-eight patients (296 dilations) were evaluated (median of 4 dilations/patient): 85% were male, mean age of 62 years-old, 60% belonging in Group I. Thereforal median interval between consecutive dilations was 2.5 weeks. The median dysphagia Mellow-Pinks score and luminal calibre were 3 ± 1 and 7 ± 2, 8 mm, respectively. Twenty-eight patients (out of 30 live patients not-submitted to additional therapies) answered to the interview: a) 96% had improved; b) 60% had a normal daily life diet; c) 75% did not need further dilations, d) 3 (11.4%) patients developed PEG, with a combined efficacy of 58, 3%. Nine patients required additional therapy (6 PEGs, 2 prosthesis, 1 electroincision). Overall, 17 (out 21 with previous PEG) were able to resume feeding per os. Fifteen and 29% presented Kochen criteria for refractory and recurrent strictures, respectively. There were two post-procedure complications (<1%): one deep laceration and one pharingo-esophageal fistula. Overall mortality was of 20% (10 patients died of non-related procedure causes). Mean follow-up was 29 ± 2, 11 months. Number of dilations and initial lumen calibre were significant predictors of combined efficacy in the univaried analysis; radic strictures predicted a greater final dysphagia in the multivariate model.

Conclusion: Our dilution programme presents relevant benefit to these patients and a low rate of complications. Patients with post-radiation strictures presented a worse prognosis. Even though retrospective we present the longest follow-up and focusing not only in objective measures but also in patient perception of global efficacy.

Introduction: Current guidelines favour the use of bleeding stents over balloon tamponade for controlling esophageal variceal bleeding (EVB). However, data on the efficacy of and outcomes after the placement of an SX-ELLA “Danis-Stent” are limited.

Aims & Methods: Retrospective multicenter study including cirrhotic patients receiving Danis-Stents for massive/refractory EVB at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenanstalt Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic band ligation (EVL) prior to Danis-Stent (D-Stent) procedure. Danis-Stent controlled EVB in 80% (28/35) of patients. In the remaining uncontrolled bleeders (n=7), 3 patients had subsequent EBL, while in 3 patients the stent had to be replaced and 1 patient received a Linton-tube. Among these patients with initial Danis-Stent failure, 4 died of uncontrollable EVB, 2 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control. In total, early-rebleeding within 6 weeks occurred in 14.3% (including n = 1 while Danis-Stent was still in place and n = 5 after Danis-Stent was removed); 3 under- went another EVB related to a subepithelial Danis-Stent, and 1 patient was treated with a Sengstaken tube. Moreover, among n = 14 patients without early rebleeding within 6 weeks, only n = 3 (21.4%) showed rebleeding later during follow-up: n = 2 patients were treated with a Sengstaken-Tube (both experienced bleeding-related death) and n = 1 had another Danis-Stent placed (successful bleeding control). Only n = 11 (31.4%) patients did not experience any rebleeding after Danis-Stent removal, while n = 8 patients died with the Danis-Stent in situ. Notably, “early-TIPS” was performed in this study, but 4 (11.4%) received a NIPS during follow-up (n = 6 patients) (1 patient died due to uncontrollable bleeding (<5days) and n = 10 died within 6 weeks (bleeding-related mortality: 28.6%). Overall, n = 22/35 (62.9%) patients died. The median survival was 10.5 (IQR82) days after Danis-Stent placement. Median Danis-Stents dwell time was 5 (range: 0-13) days. The most common adverse events were stent disloca- tions (n = 13; 37.1%), while ulcers/nercosis of the esophagheal mucosa was seen in only n = 4 (11.4%) patients.

Conclusion: Danis-Stent controlled refractory/massive EVB in 80% of patients but bleeding-related mortality was as high as 45%. While stent dislocations are frequent, ulcers/nercosis of the esophagus were rare with a dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome.

P0279 A NOVEL METHOD WITH SELF-EXPANDABLE METALLIC STENT FASTENED WITH CLIP AND LOOP FOR THE TREATMENT OF ANASTOMOTIC STRICUTURE AFTER SUBTOTAL GASTRECTOMY

J.K. Kang, S.G. Lim, K.M. Lee, S.J. Shin, B.M. Yoo, J. Kim, C. Noh Gastroenterology, Ajou university school of medicine, Suwon/Korea, Republic of

Contact E-mail Address: pterion1@naver.com

Introduction: Benign anastomotic strictures are common adverse events of gastrosintestinal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic stricures are balloon dilatation and bougination. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continuous expending effect for a long period. But, it has problem of frequent stent migration, because of slow stent expanding, 2-3 days. Therefore the new method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stricture. From February 2010 until February 2015, patients with benign anastomotic stricture after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), double-layered, were inserted. We made two nylon thread loops at the proximal bared section of the stents. After stent placement, stent fastening with loop and clip method was performed. Patients’ symptoms and oral intake were assessed once or twice a week with a clinical check-up or telephone interview. After two weeks, the loop and stent removals were done.

Conclusion: The new method with fastening the stent with loop and clip can reduce the risk of stent migration.
Our fastening method can be feasible and useful technique for postoperative anastomosis of submucosal gastrostomy. A large-scale prospective research is needed to validate the clinical effectiveness of our method and to determine the appropriateness.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0280 EFFICACY AND TOLERABILITY OF BIODEGRADABLE STENTS FOR RECURRENT BENIGN OESOPHAGEAL STRICTURES: THE LEEDS EXPERIENCE
N. Rabb, H. Procter, N. Burr, V. Appleby, S. Everett
Leeds Centre For Digestive Diseases, Leeds Teaching Hospitals Trust, Leeds, United Kingdom

Contact Email Address: n.rabb@ahs.net

Introduction: The optimum management of refractory or recurrent oesophageal strictures (RBES) despite repeated attempts at dilation is controversial. An accepted method includes temporary stent placement. Most commonly temporarly fully covered self-expanding metal stents (FC-SEMS) are used but these require removal some 8–12 weeks later. Oesophageal biodegradable stents (EBS) have the advantage that they do not require removal. However, there is a lack of good-quality evidence in support of their use. We aimed to review the safety and efficacy of a large series of single and multiple EBS insertions for benign RBES in a single tertiary referral centre.

Aims & Methods: A retrospective review of insertion of EBS (SX-ELLA) between April 2008 and October 2016 was conducted. Patients with one or more EBS insertions were included. Insertion and follow-up data extracted from the hospital database. 30 day safety and efficacy for all stent insertions and 12 month efficacy and median time to further intervention (MTFI) for first stents were analysed using the Stata package.

Results: 20 patients (13 M, 7 F; age 44–93; Charlson index range 2–8, median 4) with 37 stents were included. Stricture aetiologies included peptic (55%), radiotherapy (20%), post-surgical (20%) and post EMR (5%). Dysphagia score ranged from 2–4(median 3). The total median number of dilations prior to first EBS was 6 (range 0–17). 15(75%) patients had previously had a FC-SEMS placed with subsequent recurrence of symptoms. 30-day technical success and symptom improvement was 100%. 30 day adverse events included 4(11%) stent migrations and 12(32%) with significant pain, 3 patients requiring in-patient pain control (<3 days). There were no significant bleeds or perforations. 12 months following first EBS insertion 18(90%) required further endoscopic intervention due to recurrent symptoms; 5(25%) had further dilation, 9(45%) had either a FC-SEMS (2 patients) or a further EBS (7 patients). 2 patients had NG tube insertion and (5%) patient died of unrelated illness. 3(10%) were symptom free after one stent at 12m. MTFI was 139 days (range 75–517) and was not dependent on aetiology (peptic vs. non-peptic; 135 vs. 127 days, p = 0.54). There was a significant reduction in median number of interventions in the 12m following EBS insertion compared to the preceding 12m (2 vs. 7 respectively, p = 0.0003). 7(35%) patients received multiple EBS (range 2–12). 9 of these (43%) have subsequently required no further intervention, 3(43%) continue to receive intermittent EBS insertions on a symptomatic basis (<3 days). There were no significant bleeds or perforations. There was short-lived pain in a significant number. In this highly selected cohort of patients with severe comorbidity. A drawback to SEMS include their ability to migrate distally, with some studies estimating the rate at around 20%. We report a single-centre, retrospective cohort study on the use if SEMS, and aimed to establish risk factors for stent migration.

Aims & Methods: Case note review was undertaken retrospectively on all patients who had fully covered SEMS inserted at a high-volume tertiary oesophageal cancer centre between Jul 13 to Feb 17. All SEMS were placed under fluoroscopic guidance by experienced endoscopists. Stent migration was confirmed endoscopically or radiologically and was defined as displacement of the stent away from the stomach or cardia. The baseline stent data was recorded. Data on loss of the recanalised lumen. Shapiro-Wilks testing showed non-normal distribution of data. Non-parametric testing by logistic regression was therefore performed.

Results: 188 stents were inserted to palliate malignant strictures. 75% in males. We observed a migration rate of 20% (39) in our cohort. We observed a significant association between predilation (within 7 days of the stent procedure) and subsequent stent migration (31% in dilated vs 13% in undilated SEMS). This also met Bonferroni correction significance. We demonstrate a trend towards shorter strictures being associated with an increased risk of migration [OR 1.14 CI1.122–1.164 (p = 0.0552)]. There were no significant associations between migration with stent type, SEMS performed prior chemo-radiotherapy, or whether the stent crossed the GOJ.

Conclusion: Endoscopic placement of SEMS is a safe and effective procedure in the management of malignant dysphagia with a low risk of complications. Predilation of lesions within 7 days of SEMS insertion carries a risk of subsequent stent slippage – suggesting that a cautious approach to dilation may be prudent. Further, larger studies may demonstrate an association with shorter stent migration rate at our centre is consistent with those found in other studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

SURGERY I - HALL 7
P0281 OUTCOMES OF PATIENTS UNDERGOING PLACEMENT OF FULLY COVERED SELF EXPANDING METAL STENTS FOR MALIGNANT OESOPHAGEAL STRICTURES
Department Of Oesgastroenterology, University College London Hospital, London, United Kingdom

Contact Email Address: martin.everson@uclh.nhs.uk

Introduction: Fully covered self-expanding metallic stents (SEMS) have an established role in the palliation of oesophageal strictures, particularly in those with malignancy. SEMS are advantageous as they reduce the rate of tumour ingrowth, in doing so reduce the need for repeated endoscopic interventions in a cohort of patients with severe comorbidity. A drawback to SEMS include their ability to migrate distally, with some studies estimating the rate at around 20%–30%. We report a single-centre, retrospective cohort study on the use if SEMS, and aimed to establish risk factors for stent migration.

Aims & Methods: Case note review was undertaken retrospectively on all patients who had fully covered SEMS inserted at a high-volume tertiary oesophageal cancer centre between Jul 13 to Feb 17. All SEMS were placed under fluoroscopic guidance by experienced endoscopists. Stent migration was confirmed endoscopically or radiologically and was defined as displacement of the stent away from the stomach or cardia. The baseline stent data was recorded. Data on loss of the recanalised lumen. Shapiro-Wilks testing showed non-normal distribution of data. Non-parametric testing by logistic regression was therefore performed.

Results: 188 stents were inserted to palliate malignant strictures. 75% in males. We observed a migration rate of 20% (39) in our cohort. We observed a significant association between predilation (within 7 days of the stent procedure) and subsequent stent migration (31% in dilated vs 13% in undilated SEMS). This also met Bonferroni correction significance. We demonstrate a trend towards shorter strictures being associated with an increased risk of migration [OR 1.14 CI1.122–1.164 (p = 0.0552)]. There were no significant associations between migration with stent type, SEMS performed prior chemo-radiotherapy, or whether the stent crossed the GOJ.

Conclusion: Endoscopic placement of SEMS is a safe and effective procedure in the management of malignant dysphagia with a low risk of complications. Predilation of lesions within 7 days of SEMS insertion carries a risk of subsequent stent slippage – suggesting that a cautious approach to dilation may be prudent. Further, larger studies may demonstrate an association with shorter stent migration rate at our centre is consistent with those found in other studies.

At pre-operated staging most met advanced form of cancer: T4N1 at 16 (27.1%), T4N2 at 23 (38.9%). Sensitivity in staging of tumor 89.8%. Long-term results: 1-year survival at I group 96.1%, 3-year is 42.3%, 5-year 16.6% II group 1-year survival 6.45%.

Conclusion: The use of 3D-modeling performed using MRI, spiral CT and EUS, allows to planning the optimal surgery and lymph node for locally common form of esophageal cancer, and improve the results of survival.

Contact E-mail Address: horikawa_01@m.e.com

Introduction: Endoscopic submucosal dissection (ESD) was a promising method for the removal of intramucosal gastrointestinal lymphatic agents has increased for first or secondary prevention of cardiovascular or cerebral disease. Continuous administration of low-dose aspirin (LDA) during ESD was recommended in American, British and Japanese guidelines. However, the influence of aspirin for the hemostasis condition during ESD procedure is still unclear. Therefore, we performed this study for addressing intraoperative bleeding risk without cessation of LDA.

Aims & Methods: In this retrospective study, we assessed the hemostasis condition during ESD that were treated for superficial gastric lesions between January 2014 and March 2017. Patients with anti-thrombotic therapy by LDA (n = 42) and those with no anti-thrombotic therapy (n = 187; Control) were compared using propensity score matching. Primary outcome was frequency of intraoperative major bleeding. Secondary outcomes included procedure time, Hb reduction rate, En bloc resection rate, and adverse event rate.

Results: The propensity score analysis yielded 39 matched pairs. Adjusted com-
parison between the two groups showed similar with regards to major bleeding, median (range) (times): 1.0 [0.0–4.0] vs 1.0 [0.0–4.0], p = 0.621. Procedure time was prolonged in Aspirin group by 16.7% without significant differences. Other aspects were the same in both groups with low incidence of adverse events; perforation (0%), thromboembolism (0%).

Conclusion: This study indicated the feasibility of gastric ESD with continuous administration of LDA including little intraoperative bleeding and adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0284 WEEKDAY OF CANCER SURGERY IN RELATION TO PROGNOSIS

P. Lagergren, F. Mattsson, J. Lagergren
Department Of Molecular Medicine And Surgery, Karolinska Institutet, Stockholm,Sweden

Contact E-mail Address: pernilla.lagergren@ki.se

Introduction: Later weekday of surgery seems to reduce the prognosis in oeso-
ophageal cancer, while any such influence on other cancer sites is unknown. This study aimed to test whether weekday of surgery influences prognosis following commonly performed cancer operations.

Aims & Methods: This nationwide Swedish population-based cohort study from 1997-2014 analysed weekday of elective surgery for 10 major cancer groups in relation to disease-specific and all-cause mortality. Cox regression provided hazard ratios with 95% confidence intervals (CI) adjusted for the covariates age, sex, year, cancer stage, vital volume, calendar year, and tumour stage.

Results: Included were 228,927 patients. Later weekday of surgery (Thursdays and even more so Fridays) was associated with increased mortality rates for gastrointestinal cancers. The adjusted hazard ratios for disease-specific mortality comparing surgery on Friday with Monday were 1.57 (95% CI 1.31-1.88) for oesophageal-gastric cancer, 1.49 (95% CI 1.17-1.88) for liver-pancreatic-biliary cancer, and 1.53 (95% CI 1.44-1.63) for colorectal cancer. Excluding mortality during the initial 90 days of surgery made little change to these findings, and the all-cause mortality was similar to the disease-specific mortality. The associations were similar in analyses stratified for covariates. No consistent associations were found between weekday of surgery and prognosis for cancer of the head-and-neck, lung, thyroid, breast, kidney-bladder, prostate, or ovary-uterus.

Conclusion: This study indicates that the type of surgery (Thursdays-Thursday) seems to negatively influence the prognosis for cancer of the gastrointestinal tract, indicating a need for re-scheduling of these operations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0285 IMPACT OF POSTOPERATIVE COMPLICATIONS AND PERIOPERATIVE ONCOLOGICAL TREATMENTS FOR GASTRIC CANCER PATIENTS AFTER GASTRECTOMY

S. Kamiya1, F. Klevebro2, J. Rouvelas3, M. Lindblad4, L. Lundell5, M. Nilsson2
1Surgical Gastroenterology, Karolinska University Hospital, Stockholm/Sweden
2Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: satoxi_ki@hotmail.com

Introduction: Recently, multidisciplinary treatments such as perioperative chemo/ radio-therapies have been introduced to improve the therapeutic impact in gastric cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastric cancer patients.

Aims & Methods: Consequent gastric cancer patients who underwent curative gastrectomy in Karolinska University Hospital between 2006 and 2016 were enrolled. Patients’ characteristics, surgical data, postoperative courses and prognosis were examined retrospectively. Complications were evaluated according to Clavien-Dindo classification. The significance of postoperative severe complications and perioperative oncological treatment for overall survival (OS) was evaluated by the Cox proportional hazard model.

Results: Six hundred-forty-nine-sixty-nine patients were examined in this study. 89 (52.7%) and 66 (39.1%) patients had neoadjuvant and adjuvant treatment, 85 (50.3%) and 84 (49.7%) underwent distal and total gastrosectomy, respectively. 24 (14.2%), 16 (9.5%) and 5 (3.0%) were diagnosed as grade III, IV, V complications. The prognosis of the patients with grade III or higher complication was significantly worse (3-year OS: 66.6% vs 47.3%, P = 0.001). Subgroup analysis by pathologi-
cal stage showed that the prognosis of pStage III/IV patients with postoperative high complications was significantly poor compared to the patients with out grade III or higher complications (3-year OS: 45.3% vs 7.5%, P = 0.001). For the patients who had either neoadjuvant or adjuvant treatment, however, no obvious prognostic worsening was seen by the existence of complications (3-year OS: grade I/II vs 52.9%, P = 0.13). Multivariate analysis identified that severe com-
plication was independent risk factor for OS (hazard ratio 1.82; 95% confidence interval 1.08-3.05), especially in pStage III/IV gastric cancer (hazard ratio 3.00; 95% confidence interval 1.53-5.86).

Postoperative severe complications had considerable impact on the OS, especially for pStage III/IV gastric cancer patients. Perioperative oncological treatment may be able to prevent the prognosis from deteriorating due to post-operative complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0286 ENDOSCOPIC PAPILLECTOMY OF DUODENAL PAPILLARY TUMOR: A REPORT OF 75 CASES

Z. Wang1, E. Linghu2, F. Cai1, Y. Yang2, G. Sun1, M. Li1, S. Li1, X. Wang2, J. Meng1, H. Du1, J. Zhu1, W. Liu1

Introduction: Duodenal papillary tumor as rare gastrointestinal neoplasm is essential for curative therapy due to its malignant potential. Endoscopic papillectomy as the treatment of duodenal papillary tumor has been developed and is accepted as an alternative approach to surgery in select cases. Endoscopic papillectomy as a relatively difficult endoscopic technique mainly performed by experienced endoscopists. Studied standard endoscopic procedures for endoscopic papillectomy have not been established.

Aims & Methods: We aimed to investigate the clinical value of endoscopic papillectomy for duodenal papillary tumor based on the endoscopic and clinic characteristics. Between 2006 and 2017, seventy-five patients with duode-
nal papillary tumor under endoscopic papillectomy in the gastrointestinal endoscopic center of Chinese PLA General Hospital were included. These patients were diagnosed of duodenal papillary tumor by the clinical manifes-
tation, laboratory tests, CT, MRCO, endoscope, EUS, ERCP along with biopsies and histopathologic tests. During the detailed clinical assessment combined with patients’ wishes, endoscopic papillectomy and followed ERCP procedures were performed successfully, and the clinical data of these patients were retrospectively summarized.

Results: 75 patients (50 males and 25 females) with a median age of 58.6 yrs (range 27 to 82 yrs) were evaluated. The main clinical symptoms were predomi-
nated by abdominal pain followed by cholestasis and cholangitis, but nine cases had no abdominal symptoms. Endoscopic papillectomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists. The majority of excised tumors were exogenous (90.7%, 68/75), and the tumor size ranged between 8 and 55 mm. The final histopathological diagnosis included intraductal papillary mucinous neoplasm (37.3%, 28/75), high-grade intraepithelial neoplasia (18.7%, 14/75), adenoma with high-grade intraepithelial neoplasia (26.7%, 20/ 75), adenoma combined with local carcinoma (16%, 12/75), and neuroendocrine tumor (1.3%, 1/75). In total resection was achieved in 53 cases (70.7%) and the partial resection was performed in 22 cases (29.3%). After endoscopic papillectomy, the ERCP procedures were performed in 70 cases (93.3%). The pro-
phyllactic pancreatic duct stent was placed in 30 cases (40%) for preventing pancreatic fistula, the biliary plastic stent or nasobiliary drainage tube in 16% (12/ 75), the combined of both in 17.3% (13/75), and no stent placement in 28.7% (20/75). Moreover, intraoperative hemostasis was performed in 47 cases (62.7%), including pure endoscopic clip placement, followed by injection therapy, thermal therapy or in combination. Regarding to the postoperative adverse events,
hemorrhage was identified in 11 patients (14.6%) but mainly cured by endoscopic hemorrhoidectomy, followed by percutaneous (9.3%, 7.75%) but cured with medical treatment.

Conclusion: Endoscopic papillotomy can be considered as a feasible and reasonable treatment option for suitable patients with tumors of duodenal papilla.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0207 PROPHYLACTIC COLECTOMY WITH EXTENDED INDICATION OF RECTAL PRESERVATION IN RELATED ABC FAMILIAL ADENOMATOUS POLYPOSY-SYSTEMIC SYNDROME: ADENOMA TREATMENT DRAMATICALLY CHANGES THE NATURAL HISTORY OF POLYPOSY

A. Pasquer1, G. Poncelet1, M. Pioche2, J. Rivory2, O. Vinet2, N. Benech2, J.C. Saurin2

Introduction: Prophylactic surgery of familial adenomatous polyposis (FAP) ranges from total colectomy with ileorectal anastomosis (IRA) to proctocolectomy with ileoanal anastomosis and J pouch (IAA). Rectal preservation is based on studies that did not include systematic endoscopic treatment that we perform. The objective was to compare IRA to IAA in terms of oncological safety and quality-of-life.

Aims & Methods: Between January 1965 and November 2015, all consecutive patients undergoing prophylactic surgery for FAP with advanced endoscopic follow up in our unit: systemic endoscopic treatment of adenomas (argon, mucosectomy), were prospectively included. MYH-related polyposes and patients who underwent abdominoperineal resection were excluded from analysis.

Results: 296 patients included: 92 proctocolectomy with IAA (31.1%), 197 IRA group (66.1%) and 1 patient with colorectal cancer were excluded. Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of lower endoscopies was 3.4 (2.5) in the IRA group vs. 3.4 (2.5) in IAA group (p = 0.09) and 3.1% (n = 9). Mean (SD) number of lower endoscopies was 24.7 (33.9) in the IRA group vs. 3.4 (2.5) in IAA group (p = 0.09) and 98.9% vs. 98.8% (p = 0.82).

Conclusion: Combination of aggressive endoscopic treatment and extended rectal preservation appears to be a safe alternative to ileoanal anastomosis and J pouch.

P0208 ANAL PROBLEMS DURING PREGNANCY AND POSTPARTUM: A PROSPECTIVE COHORT STUDY

K. Ferdinande, Y. Dorreman, K. Roelens, W. Ceelen, D. De Looze

University of Ghent, Ghent/Belgium

Contact Email Address: kymenite.ferdinande@ugent.be

Introduction: Many pregnant women have anal symptoms during pregnancy and postpartum. The most common proctological problems reported are haemorrhoids, anal fissures and anal incontinence. Literature about this problem is scarce.

Aims & Methods: The aim of this study is to determine the prevalence of anal problems and consitipation during the second and third trimester of pregnancy, in the immediate postpartum and up to three months after childbirth. We want to identify the risk factors for the development of anal symptoms. This is a prospective cohort study.

Women between their 19th and 25th week of pregnancy are included. High-risk pregnancy and non-Dutch speaking are exclusion criteria. Nineteen questions were formulated in a symptom questionnaire in the second and third trimester, in the immediate postpartum (within 3 days) and three months postpartum. Descriptive data were obtained from the patient files. A specific proctological diagnosis was presumed on the basis of combined symptoms (rectal bleeding, anal pain and swelling). Consitipation was defined by the Rome III criteria. Statistical analysis was performed with SPSS and risk factors were identified using multivariate analysis with binary logistic regression.

Results: Sixty-eight percent of the women developed anal symptoms during the whole study period. Anal symptoms occurred in 50% of the women during pregnancy, in 56.2% in the immediate postpartum and in 62.9% during the three months postpartum.

Conclusion: The most prevalent symptom was anal pain. Consitipation was reported by 60.7% during the whole study period. Most prevalent risk factors for the development of anal complaints were: pregnancy, use of anal faeces, personal (obstetrician or dietician) advice, illness, anal fissure or haemorrhoidal prolapse (3rd trimester and immediate postpartum) and anal fissure (not episode-related). Anal incontinence was only reported in 2% during the postpartum.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0209 SURGICAL TREATMENT OF DIVERTICULITIS AND ITS COMPLICATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROL TRIALS

Introduction: Diverticulitis is a common gastrointestinal disease in developed countries, especially among elders. It is classified into five stages according to the severity of the inflammation with stage 3 involving peritonitis as a consequence. Therefore, perforation and peritonitis in stage 3 occurs with 30-50% chance and mortality reaching 32%. This indicates that acute diverticulitis is an emergency case requiring rapid management. However, the surgical interventions of diverticulitis vary according to its grade and severity, there is a controversy about the preferable surgical approach and treatment in this clinical condition.

Aims & Methods: We aimed to systematically review and meta-analyze randomized controlled trials (RCTs) comparing outcomes and complications between different surgical approaches for acute diverticulitis and its complications. Nine databases, including PubMed, Scopus, Google Scholar, ISI Web of Science, WHO Global health library (GHL), POPLINE, Virtual health library (VHL), NYAM (New York Academy of Medicine), and SIGLE (System for Information on grey literature international) were searched for RCTs comparing different surgical procedures for different grades of diverticulitis. Out of 1378 articles, we included 14 studies with 1076 patients. The primarily assessed outcomes were post-surgical mortality rate besides short- and long-term post-surgery complications. The risk of bias was assessed using the Cochrane Collaboration tool. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated in the meta-analysis using the RevMan platform. The protocol was registered in PROSPERO (CRD42015032290).

Conclusion: Two-thirds of pregnant women deal with anal symptoms during the second or third trimester, in the immediate postpartum (within 3 days) and three months postpartum. The most common proctological problems reported are haemor- rhage was identified in 11 patients (14.6%) but mainly cured by endoscopic hemorrhoidectomy, followed by percutaneous (9.3%, 7.75%) but cured with medical treatment.

Conclusion: Endoscopic papillotomy can be considered as a feasible and reasonable treatment option for suitable patients with tumors of duodenal papilla.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0209 NLR AND PLR IN DIAGNOSING SYNCHRONOUS LIVER AND LYMPH NODE METASTASES IN PATIENTS WITH CRC

M. Stojkovic1, V. Markovic2, I. Dimitrijevic2, M. Stojkovic3, S. Krizkovic2

3School of medicine, Belgrade/Serbia

Contact Email Address: drmilicastojkovic@gmail.com

Introduction: There has been enormous progress in diagnosing and treatment of colorectal cancer (CRC), however a great number of patients is nevertheless diagnosed in an advanced diseased stage, which is of great importance, to determine the most effective, inexpensive, prognostic, diagnostic, and treatment predicting biomarkers in early diagnostics of CRC considering its incidence worldwide. There are studies suggesting that the systemic inflammation play an important role in CRC tumor stage development, which can be reflected by the levels of neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR).

Aims & Methods: This study was designed to investigate the efficiency of preoperative NLR, PLR as a tool for the assessment of synchronous lymph nodes
and liver metastases in newly diagnosed patients with CRC. Three hundred patients with CRC undergoing primary resection were included in this cross-sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and PLR was estimated by ROC curve.

Results: Our results suggest that there was high statistically significant difference between NLR (p = 0.003), PLR (p = 0.002) and tumor stages (I to IV). ROC curve analysis showed high diagnostic efficiency of NLR (AUC 0.774, 95%CI = 0.683–0.790) and PLR (AUC 0.698, 95%CI = 0.636–0.742) for synchronous lymph node and liver metastases. Also combination of NLR and PLR improved diagnostic efficacy (AUC 0.841, 95%CI = 0.811–0.863) for synchronous liver and lymph node metastases.

Conclusion: Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential use in early recognition of different stages of CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Section For Clinical Epidemiology And Biostatistics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/Thailand

Contact E-mail Address: chumphon.wil@mahidol.ac.th

Introduction: Diagnosis of appendicitis is still clinically challenging where resource is limited. The purpose of this study is to develop and externally validate Ramathibodi Appendicitis Score (RAMA-AS) in aiding diagnosis appendicitis. Aims & Methods: Two-phase cross-sectional study (i.e., derive and validation) was conducted at Ramathibodi Hospital (for derive, Thammasat University Hospital and Chaiprayam Hospital (for validation). Patients with abdominal pain and suspected of having appendicitis were enrolled. Multiple logistic regression was applied to develop parsimonious model. Calibration and discrimination performances were assessed. In addition, our RAMA-AS was compared with Alvarezado’s score performances using ROC curve analysis. The study was conducted and reported according to Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis Or Diagnosis (TRIPOD) statement.

Results: The RAMA-AS consisted of 3 domains 7 predictors including symptoms (i.e. progression of pain, aggravation of pain, and migration of pain), signs (i.e. fever and rebound tenderness), and laboratory (i.e. white blood cell count (WBC) and neutrophil). The model fitted well with data and it performed better discrim inate than the Alvarezado score with C-statistic of 0.842 (95% CI: 0.804, 0.881) versus 0.760 (0.710, 0.810). Internal validation by bootstrap yielded Somer’s D of 0.686 (0.608, 0.763) and C-statistics of 0.848 (0.846, 0.849). The C-statistics of two external validations were 0.853 (0.791) and 0.813 (0.736, 0.892) with fair calibrations.

Discrimination: RAMA-AS is a useful tool for diagnosis of appendicitis. It has good discrimination performance and good calibration performance after revision.

P0923 EARLY VERSUS DELAYED CLOSURE OF TEMPORARY LOOP ILEOSTOMY AFTER COLORECTAL SURGERIES: A PROSPECTIVE RANDOMIZED STUDY

S. Gavini, V. Vutukuru, D. Annareddy, C. Chandramaliteeswaran, V. Dasari, N. Pongsupala

Gi Surgery, SVIMS, Tirupathi/India

Contact E-mail Address: srkgavini@gmail.com

Introduction: Temporary loop ileostomies are commonly performed to protect a distal anastomosis in colorectal surgeries. Although they have been shown to reduce the number of leaks requiring surgery, they remain a source of complications and have an adverse effect on the quality of life. A few non-randomized studies have shown the feasibility of early stoma closure.

Aims & Methods: To compare the outcomes of early and delayed closure of temporary loop ileostomy in terms of operative parameters, morbidity, mortality, and quality of life. The study was conducted from May 2014 to September 2015. Following creation of loop ileostomy after colorectal surgeries, distal loop cont stast study was done on POD 7. Patients who had no leak were randomized to either early closure (8-13 days) or delayed closure (after 6 weeks) group. Patient demographics, operative parameters, morbidity, mortality and quality of life data were recorded in both groups.

Results: There were 24 patients in each group. Both groups were comparable in terms of demographic data except for age, which was significantly higher (p = 0.012) in the early closure group. Incidence of stoma related complications (p = 0.01) and Pittman ostomy complication severity index (p < 0.01) were significantly higher in the delayed group. Operative time (p = 0.033) and Surgeons assessment score (p = 0.0012) for the stoma closure surgery were significantly lower for the early closure group. There was no significant difference in the duration of hospital stay and the incidence of postoperative complications in the two groups. Quality of life as calculated by the Ostomy Adjustment Index score (OAI 23) was better in the early closure group (p = 0.014).

Conclusion: Early closure of a temporary loop ileostomy is feasible with the advantages of decreased stoma related morbidity, operative difficulties without increased morbidity and mortality when compared with conventional delayed ileostomy closure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0294 FULL-SCALE INTRODUCTION OF RADICAL LAPAROSCOPIC SURGERY FOR INGUINAL HERNIA EMPLOYING THE TRANSABDOMINAL PREPERITONEAL (TAPP) REPAIR AND EARLY OUTCOMES

Gastroenterological Surgery, Aichi Medical University, nagakute/Japan

Contact E-mail Address: tsaito0726@gmail.com

Introduction: Ger reported the first laparoscopic hernia repair in 1982 by approximating the hernia orifice with stainless steel and using a laparoscopic transabdominal preperitoneal (TAPP) repair as a revolutionary concept in hernia surgery and was introduced by Arregui and Dion in the early 1990s. Institutions performing radical laparoscopic surgery for inguinal hernia have been rapidly increasing since the NIH point was amended in Japan. However, in the 12th JAPAN SOCIETY FOR ENDOSCOPIC SURGERY questionnaire survey, the recurrence rate after surgery employing the TAPP method was reported to be 4%, posing a problem regarding the thoughtfulness of introduction of the TAPP method. Our hospital started using the TAPP method only occasionally until April 2015, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia in our department as follows. Symptomatic inguinal hernia treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone emergency surgery for acute complicated Hinchey 3 diverticulitis from January 2012 to December 2016 was retrospectively evaluated. All patients were treated by pure laparoscopic left colectomy with primary colorectal anastomosis and temporary loop ileostomy. All the procedures were performed by the same surgeons (IS, ADL, FR). Perioperative care plan, operative steps and surgical instruments were standardized. We collected patients-, surgery- and hospital stay-related data, as well as short-term outcomes. Complications were classified using the Clavien-Dindo classification system.

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m². No conversion to open surgery was registered. The mean operative time and estimated blood loss were 184.3 ± 32.7 minutes and 81.2 ± 7.2 ml respectively. All complications were treated by percutaneous drainage or sutures. There were 8 complications (6.8%, 5 according to the Clavien-Dindo classification system). There were no postoperative deaths. The median hospital stay was 7.8 ± 2.8 days and we have not recorded any readmissions in patients discharged within 60 days after surgery. The rates of postoperative complications were classified as grade 3 or higher in 2.5% of the cases. The 30-day readmission rate was 0%.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0295 EFFECTIVENESS OF PURE LAPAROSCOPIC LEFT COLECTOMY WITH PRIMARY ANASTOMOSIS AND LOOP ILEOSTOMY FOR THE TREATMENT OF COMPLICATED HINCHHEY 3 DIVERTICULITIS

F. Roscia, A. De Luca, I. Scandroglio
Galmariuni Hospital, ASST Sette Laghi, Tradate/Italy

Contact E-mail Address: francesco_roscio@yahoo.it

Introduction: Due to the effectiveness of laparoscopic left colectomy with primary anastomosis and loop ileostomy in the treatment of complicated acute diverticulitis with diffuse purulent peritonitis (Hinchey 3), also considering the lack of evidence about this topic due to the difficulty of carrying out comparative trials with the laparoscopic washing/drainage technique, we carried out this study. A consecutive unselected series of 44 patients underwent emergency surgery for acute complicated Hinchey 3 diverticulitis from January 2012 to December 2016 was retrospectively evaluated. All patients were treated by pure laparoscopic left colectomy with primary colorectal anastomosis and temporary loop ileostomy. All the procedures were performed by the same surgeons (IS, ADL, FR). Perioperative care plan, operative steps and surgical instruments were standardized. We collected patients-, surgery- and hospital stay-related data, as well as short-term outcomes. Complications were classified using the Clavien-Dindo classification system. The 30-day readmission rate was 0%.

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m². No conversion to open surgery was registered. The mean operative time and estimated blood loss were 184.3 ± 32.7 minutes and 81.2 ± 7.2 ml respectively. All complications were treated by percutaneous drainage or sutures. P0296 LAPAROSCOPIC COMPLETE LATERAL LYMPH NODE DISSECTION FOR LOW RECTAL CANCER

T. Kinoshita, K. Komori, T. Oshiro, A. Ouchi, Y. Shimizu
Gastroenterological Surgery, Aichi Cancer Center Hospital, NAGOYA/Japan

Contact E-mail Address: t.kinoshita@aiich.cc.jp

Introduction: Total mesorectal excision (TME) with lateral pelvic lymph node dissection (LLND) is a standard procedure for low rectal cancer in Japan. However, ME alone is the international standard surgical procedure for rectal cancer. Complete LLND is controversial because of the limited field, which requires more pelvic exposure than TME. In expert hands it represents an effective technique for the treatment of acute diverticulitis complicated by diffuse purulent peritonitis.

Aims & Methods: After laparoscopic ME, the external iliac artery was exposed and the external iliac nodes were completely removed from inguinal ligament. Obrurator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall, bladder wall and scatic nerve. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccygeal muscle (Alcock’s canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were separated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.

Results: Between 2015 and 2016, we performed laparoscopic ME with LLND for 10 patients with cT2 or deeper low rectal cancer. The median operative time was 502 min (420–679 min), and the median blood loss was 90 ml (5–500 ml). Postoperative complications developed in 4 (40%) patients, and the most frequent one was temporary urinary disorder in 2 (20%) patients. The median number of harvested lateral lymph node was 20 (14–23). So far there are no long-term outcomes.

Introduction: Natural orifice translumenal endoscopic surgery (NOTES) proposed advantages should be established by comparison with standard procedures. Using a single side transluminal access, the feasibility of performing advanced surgical procedures is still limited, especially for a single endoscope. We used the ANUBIS-system for sigmoid resection with a transgastric access reached by needle-knife incision and balloon dilatation. CO₂ pneumonueum was achieved by insufflation via a working channel. By steering the colonoscope, the colon was manoeuvred endoluminally and the colic mesentery was exposed. Bowel-close preparation was performed with a coagulation needle-knife with simultaneous assistance by a grasper via the Anubiscope. Both instruments have the possibility of two-directional movements. The access angle for preparation and visualisation could be altered during the procedure by manoeuvring the colonoscope and the movements of the flexible endoscopic instruments. To prepare anastomosis, circular stapler anvil was introduced transmurally and penetration of the colon wall was carried out. Subsequently, proximal resection of the sigmoid colon was performed using a linear stapler inserted through a trocar at the left
lower abdomen. The bowel extraction was performed by invagination transre- 
cecum and the intermesenterial distal linear stapling of the sigmoid, the colorectal 
anastomosis was completed by applying a circular stapling device transrectally, 
asisted by a transcutaneous inserted grasper. Function testing was performed by 
the colonoscope. Gastric access closure was performed by OTSC clip.

**Results:** The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic heal-

ing with a stenosis and consecutive prestenotic dilation in one case. These anastomotic or peritoneal abscess beside the anastomosis. Gastric closure 
was healed and the OTSC clip still in situ in all animals. In one case we used two 
OTSC clips for gastric closure, there were severe adhesions with two peri gastric 
abscesses.

**Conclusion:** The use of an operating platform like the Anubisoscope has the 
advantage of flexible preparation in opposite position of the instruments. The 
disadvantages are the only two degrees of freedom of the flexible instruments 
and the rotation-like movements. Flexible colonoscopy provided a fixed reference 
frame that enabled preparation and dissection. For resection and anastomosis an 
additional transcantage access was necessary.

**Contact E-mail Address:** sondajardak1@gmail.com

**Introduction:** Peritoneal tuberculosis (TB) is an advanced ovarian cancer, two 
conditions with different management and prognosis, have many similarities: 
ascesis, complex adnexal mass, peritoneal deposits, and raised CA-125 level. 
Symptoms such as weight loss, reduced appetite, and dull abdominal pain are 
also common to these two entities.

**Aims & Methods:** The aim of this study was to analyze patients’ characteristics, 
laboratory investigations, radiological and surgical findings in post-menopausal 
women with pelvic TB who were diagnosed after laparotomy or laparoscopy 
for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB 
in post-menopausal women who presented with mimicking miliary ovarian 
malignancy from 2004 to 2014 in a Tunisian center.

**Results:** The mean age was 59.8 (46–87 years). Three patients have personal 
or family history of TB. All women presented with abdominal pain and distension 
in two. A laparoscopic evaluation with biopsies was performed in 16 patients 
fluid showing lymphocytic predominance and no malignant cells and 
in 100% and ascites in 90.4%. Ascitic fluid analysis was done in 19 patients 
and an exploratory laparotomy in 4 women for suspected ovarian cancer.

**Conclusion:** Intraoperative findings of tubercles on the pelvic organs and peritoneal surfaces 
and elevated CA-125 levels in patients who presented with features mimicking ovarian malig-

P0300 REGULATORY B CELLS CONTRIBUTE TO THE ALLEVIATION OF COLITIS INDUCED BY DEXTRAN SULPHATE SODIUM AFTER H. PYLORI INFECTION

X. Li1, N. Wang1, Q. Xu6, J. Tan1, J. Wang1
1Department Of Gastroenterology, Peking University, People’s Hospital, Beijing/China

**Contact E-mail Address:** lixialiy@163.com

**Introduction:** Epidemiological studies have showed that there was an inverse association between H. pylori infection (H pylori) and the incidence of 
ulcerative colitis (UC) and Crohn’s disease (CD). At the same time, IL-8 is one of 
the critical inflammatory cytokines in the colitis induced by DSS. A C57BL/6 mice model of acute and chronic colitis was 
used to investigate the cellular composition of the inflammatory infiltrate in the 
CM of patients with active UC. Through the period of the clinical remission 
development (an average of 8 weeks) the IFI-1 levels increased up to 9.25±2.81 
mol/l (P<0.05), yet have not reached the control value (P<0.05 to control). Induction of the clinical remission was associated with a 
decrease to the level of the control values for spontaneous and LPS-induced IL-8 production, regardless of UC activity.

**Conclusion:** The intensity of the inflammatory process in the CM depends on the 
level of IL-8 produced by respective cells. Evidently, IL-8 has a capacity of 
inhibiting the production of IFI-1 at the peak of inflammation (acute UC). 
Further synthesis of IFI-1 and reduced IL-8 in remission facilitates regenera-

tion of the damaged mucosa.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0299 INSULINLIKE GROWTH FACTOR IGF-I AND INFLAMMATORY RESPONSE IN THE COLONIC MUCOSA IN ULCERATIVE COLITIS

V. Pavlenko, F. Urasova, G. Esenueva, A. Pavlenko, N. Korabina
Starvropol State Medical University, Starvropol Russian Federation

**Contact E-mail Address:** pavlenkovv@yandex.ru

**Introduction:** Peptide growth factors including the IGF family are expressed in the 
mucosa and play a role in the proliferative activity of the intestinal epithelium in 
ulcerative colitis (UC) and Crohn’s disease (CD). At the same time, IL-8 is one of the 
main triggers behind the immunoinflammatory process in the colonic mucosa 
(CM) in UC, and its level may be of prognostic value in determining the illness 
course.

**Aims & Methods:** The aim of the study was to identify the role that IGF-I plays in 
colon inflammation in 35 patients with different clinical (Rahmlehiv index) and 
endoscopic (Mayo index) activity of UC. The treatment was administered in 
view of the severity of UC. 20 healthy volunteers were the control group. IGF-I 
levels in peripheral blood were determined by ELISA (Mediagnost, Germany).

The results were expressed as pmol/l. The spontaneous and E. Coli LPS-induced 
synthesis of IL-8 in rectal bioptic samples were studied via ELISA. The results 
were expressed as picograms per 1 mg of wet tissue (pg/mg). The severity of the 
illness was determined using the method of activity index. The percentage of 
patients with inflammatory infiltrate (in %) in the lamina propria. The study implied 
investigating the cellular composition of the inflammatory infiltrate in the 

alimentary tract. Depending on the density of the inflammatory infiltrate, 

the patients were divided into three groups (Group 1: 1–4%, Group 2: 5–9%, 

and Group 3: 10–25%). The results were expressed as nmol/l. The spontaneous and E. Coli LPS-induced 

production of IL-8 chemokine in rectal bioptic samples went up (300.0±6.0 pmol/l, P<0.05). In case of the LPS stimulation the production of 

IL-8 in the blood plasma decreased (15.1±1.35 nmol/l (P<0.05)), while spontaneous 

production of IL-8 chemokine in rectal biopic samples went up (300.0±6.0 pmol/l, P<0.05). There 

was significant inverse correlation (r) detected between the IGF-I levels in the 

blood plasma, on one hand, and indicators of the UC clinical, endoscopic activity 

and the intensity of the inflammatory infiltrate in the CM, on the other. Direct 

result of this was found between levels of spontaneously stimulated produc-

tion of the IL-8 chemokine and the density of the inflammatory infiltrate in 

the CM of patients with active UC. Through the period of the clinical remission 
development (an average of 8 weeks) the IGF-I levels increased up to 9.25±2.81 
mol/l (P<0.05), yet have not reached the control value (P<0.05 to control). Induction of the clinical remission was associated with a 
decrease to the level of the control values for spontaneous and LPS-induced IL-8 production, regardless of UC activity.

**Conclusion:** The intensity of the inflammatory process in the CM depends on the 
level of IL-8 produced by respective cells. Evidently, IL-8 has a capacity of 
inhibiting the production of IGF-I at the peak of inflammation (acute UC). 
Further synthesis of IGF-I and reduced IL-8 in remission facilitates regenera-

tion of the damaged mucosa.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
CD19 may through the expansion and function of CD19 analysis of bacteria-biomarkers correlation, we found bacteria such as IL-22, IL-8 and MCP-1, and treatment altered microbiota-biomarkers correlation in inflamed mucosa of Antiinflammation. Additionally, we inflamed mucosa of Immunosuppression, but only correlated to A. asterotremella.

Conclusion: (1) H. pylori infection can alleviate the acute and chronic colitis induced by DSS in 19-10 Breg cells expanded significantly in H. pylori/DSS co-treated acute colitis mice. (3) CD19-10 Breg cells expanded while CD4+CD25+Foxp3+ Treg cells reduced significantly in H. pylori/DSS co-treated chronic colitis mice. The potential protective effect on acute and chronic colitis induced by DSS may take through the expansion and function of CD19-10 Breg cells.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD was unclear. The aim of our study was to clarify the gut fungal composition in IBD patients with different treatment strategies.

Aims & Methods: 73 IBD patients were divided into three groups, Untreatment (n = 21), Antiinflammation (n = 43) and Immunosuppression (n = 9). Antiinflammation was defined as treatment with 5-aminosalicylic acid (5-ASA), salazaoulsalicylic acid (SASP) and Immunosuppression as treatment with Glucocorticoid (GC), azathioprine (AZA), biologics and thalidomide. Noninflamed and inflamed mucosa were acquired for 16S and ITS sequencing and fungal community was analyzed. Inflamed mucosa was used for RNA extraction and real-time PCR to detect the expression of IBD-associated biomarkers, such as TNF-alpha, etc. Notably, there were different correlation patterns in different treatment strategies.

Results: Compared with noninflamed mucosa, lower diversity and evenness were observed in inflamed mucosa in all IBD patients, but no significance in noninflamed (or inflamed) mucosa of different treatment strategies. Beta diversity showed a treatment-dependent clustering in inflamed mucosa. Fungal microbiota was constituted by fungi from Ascomycota, Basidomycota and Zygomycota. There was a higher proportion of Zygomycota in inflamed mucosa than both noninflamed mucosa in untreated IBD patients, and Antiinflammation and Immunosuppression significantly altered its abundance in unclassified fungi from Zygomycota. E. coli was the richest fungi in both inflamed and noninflamed mucosa of all patients. To analyze the effects of treatment strategies on fungal microbiota in IBD patients, we found Immunosuppression decreased abundance of Ascomycota and increased Basidomycota. There was a trend of increased relative abundance of Akkermansia muciniphila in noninflamed mucosa but decreased it in inflamed mucosa. Both Antiinflammation and Immunosuppression increased Zygomycota in inflamed mucosa, but not in noninflamed mucosa. Fungi-bacteria correlations analysis showed a weak correlation in noninflamed mucosa of untreated IBD patients, and Antiinflammation and Immunosuppression didn't significantly alter fungi-bacteria correlation patterns in noninflamed mucosa. However, after Immunosuppression, fungi including Candida, Chaetomium, Cladosporium and Cryptococcus were positively correlated to CD4+CD25+Foxp3+ Treg cells in the CD19-10 Breg cells. Notably, different correlation patterns in different treatment strategies, especially, IL-17A was extensively correlated to bacteria such as Enterococcus, Cuprococcus, Fusobacterium and Klebsiella in inflamed mucosa of Immunosuppression, but only correlated to Faecalibacterium in Antiinflammation. Additionally, we found a weak fungi-biomarkers correlation in IBD patients, but fungi such as A. asterotremella and Verruclitili were correlated to biomarkers such as IL-17A, IL-22, IL-8 and MCP-1, and treatment altered microbiota-biomarkers correlations patterns.

Conclusion: Treatment strategies affect fungal composition. To some extent, immunosuppression may aggravate gut fungal dysbiosis in IBD patients, but antiinflammation partially ameliorate it. The bacteria-fungi and microbiota-biomarkers correlations analysis on acute and chronic colitis and treatment change these correlation patterns. Additionally, IL-17A tended to be the main mediator for bacteria to induce inflammation in IBD.

Introduction: Cronh’s Disease (CD) and Ulcerative Colitis (UC) are inflammatory Bowel Diseases (IBD) with a complex ecology, including an immune response against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments. Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments (1).

Conclusion: (1) H. pylori infection can alleviate the acute and chronic colitis induced by DSS in 19-10 Breg cells expanded significantly in H. pylori/DSS co-treated acute colitis mice. (3) CD19-10 Breg cells expanded while CD4+CD25+Foxp3+ Treg cells reduced significantly in H. pylori/DSS co-treated chronic colitis mice. The potential protective effect on acute and chronic colitis induced by DSS may take through the expansion and function of CD19-10 Breg cells.

Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD was unclear. The aim of our study was to clarify the gut fungal composition in IBD patients with different treatment strategies.

Aims & Methods: 73 IBD patients were divided into three groups, Untreatment (n = 21), Antiinflammation (n = 43) and Immunosuppression (n = 9). Antiinflammation was defined as treatment with 5-aminosalicylic acid (5-ASA), salazaoulsalicylic acid (SASP) and Immunosuppression as treatment with Glucocorticoid (GC), azathioprine (AZA), biologics and thalidomide. Noninflamed and inflamed mucosa were acquired for 16S and ITS sequencing and fungal community was analyzed. Inflamed mucosa was used for RNA extraction and real-time PCR to detect the expression of IBD-associated biomarkers, such as TNF-alpha, etc. Notably, there were different correlation patterns in different treatment strategies.

Results: Compared with placebo-treated patients, those who received andecaliximab trended towards decreased alpha diversity (p = 0.06) at 36 days post-treatment. These changes in alpha diversity were not dose related. At Day 36, a trend towards a significant difference in community beta-diversity was observed between the andecaliximab-treated group relative to placebo (p = 0.07). Andecaliximab treatment was also associated with differences in bacterial taxonomy relative to placebo (p = 0.07). Specifically, the genera Clostridia and Akkermansia represented some of the top organisms enriched post andecaliximab treatment relative to placebo. Andecaliximab treatment exhibited a non-significant expansion of Akkermansia from Basaline to Day 36 (p = 0.15). Amongst the fungal microbiome, treatment effects were not useful in parsed in relation to andecaliximab treatment effects, but may be beneficial as a reference for future trials in inflammatory bowel disease.

Aims & Methods: This work was designed to investigate the pattern of cytokines that regulate the mucosal immune response occurring in different intestinal compartments of IBD patients, using LCM technology (1). Frozen sections of colonic biopsies were obtained from 5 patients with active CD, 5 patients with active UC and 5 controls. None of the patients with CD or UC had been ever undergone local antibiotic therapy. RNA extraction from the mucosa of CD and UC patients was carried out using kit RNeasy FFPE. LCM samples were prepared and interrogated by GenePix Pro 4.0 software. RNA expression of canonical and non-canonical Wnt ligands was significantly higher in the surface EP of both CD and UC patients, when compared to controls.

Results: Our data show that the LP compartment play a key role in the mucosal immune response in IBD patients. In particular, UC seems to be prominently different from that of the HS. Alterations in gut fungal composition might be associated with mucosal inflammation and pathogenesis of UC. Further studies are needed to define the fungal composition in detail and identify the role of different fungi in the gut, and determine the mechanism of the host-fungal interaction underlying the development of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: quxinyun2812@126.com

Introduction: The gut microbiota play important roles in the development of the ulcerative colitis (UC). Our previous study has indicated that mucosal immune-regulatory mechanisms could be impaired. This work underlines the importance of LCM as a valuable tool to determine potential inflammatory components involved in IBD pathogenesis.

Results: We observed a significant increase in gene expression level of IL-17 in the lamina propria of UC patients as compared to controls (p < 0.05). TNF-α, IFN-γ, IL-10 and TGF-β were determined by quantitative PCR, using glyceraldehyde 3-phosphate dehydrogenase (GAPDH) as reference gene.

Conclusion: In the present study we observed that the LP compartment play a key role in the mucosal immune response in IBD patients. In particular, UC seems to be prominently different from that of the HS. Alterations in gut fungal composition might be associated with mucosal inflammation and pathogenesis of UC. Further studies are needed to define the fungal composition in detail and identify the role of different fungi in the gut, and determine the mechanism of the host-fungal interaction underlying the development of UC.

Introduction: Although the etiology of ulcerative colitis (UC) has yet to be characterized, it is increasingly accepted that the cause of UC might be related to commensal enteric bacteria in a genetically susceptible patient. Anti-inflammation agents and immunosuppressive drugs are usually prescribed for UC treatment, and we previously demonstrated that triple antibiotic combination therapy with oral amoxicillin (1500 mg/day), tetracycline (1500 mg/day) or fosfomycin (3000 mg/day), and metronidazole (750 mg/day) (ATM/AFM), for two weeks, induces remission in more than 72% of patients with active UC including those with steroid-refractory or dependent disease, suggesting ATM/AFM may be possibly effective for achieving UC remission.

Aims & Methods: Thirty-two patients with UC given ATM/AFM therapy for two weeks on average were enrolled in this study. The clinical conditions of these UC patients were evaluated prior to, after therapy and at three months after treatment completion. Gut microbiota were compared employing metagenomic analysis of fecal samples.

Results: Of the 32 patients, 17 and eight, respectively, experienced complete and partial remission over three months in response to ATM/AFM therapy, whereas ATM/AFM showed no efficacy in seven patients. The metagenomic analysis revealed abundant human DNA to correlate positively with the disease activity index indicated by the Mayo score. Furthermore, drastic gut microbiota changes were observed at an early stage, i.e. just two weeks after starting ATM/AFM therapy. Comparison of the metagenomic data suggested that the dysbiosis through the expression of Wnt ligands (Mucosal Immunology, 2016). We have recently reported that STAT6 deficiency favours fibrosis in a murine model of TNBS colitis (P031, ECCO 2016).

Aims & Methods: We aim to characterize here the functional relevance of the macrophage phenotype in fibrosis development. WT or STAT6 (-/-) mice were given TNBS (0.5, 0.5, 0.75, 0.75, 1, and 1 mg, intrarectally) or saline weekly and they were sacrificed 3, 5 or 7 weeks after the first TNBS administration. The percentage of CD206+ cells isolated from the mucosa was 7 weeks after the first TNBS administration and results are expressed as fold induction vs vehicle-treated mice. The mRNA expression of CD16 and fibrosis markers were evaluated in the colonic mucosa. The mRNA expression of CD16 was significantly increased in ATM/AFM treated mice. The percentage of CD206+ cells was similar between TNBS-WT and TNBS-STAT6 (-/-) mice. In CD16+ macrophages isolated from TNBS-STAT6 (-/-) mice the mRNA expression of canonical and non-canonical Wnt ligands was significantly increased compared with cells isolated from TNBS-WT mice (Table). A positive and significant correlation between CD16 and Vimentin (p = 0.0088*, r = 0.51), a-SMA (p = 0.0044*, r = 0.55) and MMP2 (p = 0.0022*, r = 0.67) was detected in TNBS-STAT6 (-/-) mice but not in WT animals.

Conclusion: The expression of Wnt ligands from CD16 positive cells, which are accumulated in the mucosa, may be involved in murine intestinal fibrosis.
before treatment in the active stage to possibly be associated with increased prevalence of Bacteroides, Parabacteroides, Rickenella, Clostridium, Flavonifractor, Pelagibacter, Bordetella, Massilia and Piscicicketta species. In responders after treatment, populations of Bifidobacterium and Lactobacillus species were significantly increased. In this study, there was an especially strong negative correlation between Bacteroides and Bifidobacterium before and after treatment.

Conclusion: These results suggested metagenomic analysis results to be associated with a remarkable change in gut microbiota after antibiotic combination treatment. In comparison to responders in association with increases in Bacteroides and Lactobacillus species and a decrease in Bacteroides.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Classically, enteroeendoctrine cells (EEC) are regulated for regulating gastrointestinal motility, secretion, and insulin levels by release of peptide hormones. Via receptors and transporters, EEC are capable of sensing the lumina properia and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin horion hormone glucagon-like peptide 1 (GLP-1) is increasingly recognized to exert direct effects on immune cells and to orchestrate a metabolic-inflammatory response. In mone glucagon-like peptide 1 (GLP-1) or GLP-1 receptor antagonists (DPP-4 inhibitors) are used in clinical practice to treat type 2 diabetes, yet, via receptors and transporters, EEC are capable of sensing the lumina properia and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin hormone glucagon-like peptide 1 (GLP-1) is increasingly recognized to exert direct effects on immune cells and to orchestrate a metabolic-inflammatory response. Inflammatory bowel disease (IBD), a role for EEC in disease pathogenesis is indicated by a risk-associated SNP and autoantibodies affecting EEC function as well as general disease symptoms like insulin resistance and altered intestinal motility. However, the total number of studies investigating EEC number and function in IBD and mouse models of intestinal inflammation is limited and results are conflicting.

Aims & Methods: To characterize alterations in GLP-1-expressing EEC numbers under intestinal inflammatory conditions, immunoassays for GLP-1 and Chga as well as mRNA expression analysis was performed in intestinal tissue samples. Mouse models of intestinal inflammation used include genetic models, IL-10-/-, Apc-/- mice (colitis), an adoptive transfer model, Rag2-/- mice reconstituted with CD4+ T cells, chemically (DSS)-induced colitis and an infection model (Citrobacter rodentium).

Results: Numbers of GLP-1+ and Chga+ cells were consistently reduced in all mouse models of intestinal inflammation. These changes were confined to the site of intestinal inflammation. Neither absence of mature B and T cells in Rag2-/- mice alone was associated with reduced numbers of EEC, nor adoptive transfer of CD4+ T cells per se, since transfer of non-colonitic CD4+CD45R- T cells did not lead to changes in Chga+ cell numbers in the colon. The reduction of GLP-1+ and Chga+ cells observed by immunohistochemistry was reflected by diminished levels of Gcg and Chga mRNA expression, whereby mRNA levels of the L-cell-derived hormone Pty remained unaltered.

Conclusion: To our knowledge, this work provides the first comprehensive study of GLP-1+ and Chga+ cell numbers in different mouse models of intestinal inflammation. A reduction of GLP-1-expressing EEC seems to be a general feature of small as well as large intestinal inflammation. Further research will clarify if these alterations represent a consequence or causatively contribute to intestinal inflammation and elucidate the functional consequences on immune responses.

Introduction: The intestinal stem cell layer is a multicellular interface that is completely renewed every 3–5 days. Pluripotent stem cells reside at the crypt bottom giving rise to transient amplifying cells and subsequently differentiated intestinal epithelial cells (IEC) of all subtypes. Phases of cellular and functional transitions are characterized by distinct metabolic identities, reflected by changes in mitochondrial activity. Alterations in mitochondrial function and mitochondrial unfolded protein response (MT-UPR) activation are associated with various chronic pathologies including inflammatory bowel diseases (IBD) and cancer. We have previously shown that MT-UPR and mitochondrial function itself is involved in the regulation of cell cycle progression and intestinal stemness. Here, we present evidence that impaired mitochondrial proteostasis is sufficient to drive differentiation of Lgr5+ stem cells (ISC) into Paneth cells.

Aims & Methods: To depict the impact of imbalances in mitochondrial proteostasis on ISC, we used mice with a tamoxifen-inducible ISC or IEC-specific conditional knockout allele for the mitochondrial chaperone Hsp60 and the mitochondrial protease ClpP. Molecular consequences of the gene deletions in the different models were further characterized ex vivo using intestinal organoid culture. In situ hybridization, IHC and combinations of both as well as cross-talk of both as well as IF were performed to illustrate alterations of ISC subtypes. Readouts were complemented by mRNA expression analysis and biochemical approaches to further characterize the ISC refractory to netosis. The main outcome of our study is that ISC and Paneth cell populations are alternatively regulated by mitochondrial proteostasis. Under conditions of impaired mitochondrial function, ISC populations shift towards the differentiation into Paneth cells.

References
Concomitantly, these cells were positive for the WNT ligand WNT10A and autophagy/mitophagy- associated LC3, suggesting autoregulatory mechanisms for the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

Conclusion: Our results indicate that mitochondrial function not only reflects IEC phenotypic changes but seems to be the driving force in differentiation processes. Mitochondrial function might therefore represent a key player at the edge of intestinal tissue homeostasis and repair/healing processes in the context of disease.

Introduction: Previous studies have shown differences in disease phenotype of ulcerative colitc (UC) in South Asian (SA) migrants compared to Caucasians with pan-colonic phenotype predominat. The gut microbiota differs in Caucasian and SA patients with UC however, there is limited evidence on how this translates to the metabolome.

Aims & Methods: We aimed to examine the metabolic profile in a newly diag- 
nosed cohort of UC patients recruited from St. Marks Hospital, London, UK. Patients were stratified by ethnicity (SA, Caucasian, Other), treatment (None, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and further time points over one year (time point 2; months 4–8, time point 3; months 9–12) Metabonomics approach was applied using two different UPLC-MS profiling methods; for small metabolites (hydrophilic liquid chromatography, HILIC) and for bile acids (BA) platforms. Univariate (UV) and multivariate (MV) data analysis was implemented to build models using principle component analysis (PCA) and orthogonal partial least squares -discriminant analysis (OPLS-DA) to find metabolites that were expressed in significantly different amounts between the two populations, time points (1 vs 3) and treatment groups.

Results: Fifty patients with UC of SA and Caucasian backgrounds were recruited. A total of 309 samples were collected. Sample collection was completed for all time points for 18 SA (11 UC and 7 HC) and 21 Caucasians (9 UC and 12 HC). There was no significant difference between SA and Caucasian at time points 1, 2 and 3 and treatment groups. Significant differences were observed between HC vs. disease, SA HC vs. Caucasian HC and SA UC vs. Caucasian UC. For the UC cohort, robust models were obtained by OPLS-DA between SAs and Caucasians; Faecal HILIC (R² 0.869, Q² 0.451, p < 0.0003) and urine HILIC (R² 0.783, Q² 0.526, p < 0.0001) and serum BA (R² 0.702, Q² 0.517, p < 0.0001) and faecal BA (R² 0.832, Q² 0.395, p < 0.0001). Combined analysis revealed 1611 significant features (faecal HILIC 60, urine HILIC 189, serum BA 489 and faecal BA 873). The assigned features are shown in Table 1. Faecal HILIC showed significantly higher essential amino acids (Adenine, L-phenylalanine, L-tryptophan) levels on UV and higher L-cysteine and creatinine levels on MV analysis for SAs. Urine HILIC showed lower creatine, L-phenylalanine and hippuric acid levels. Serum primary (Cholic and chenodeoxycholic acid) and secondary bile acids (BA modified by the gut) were significantly reduced in SAs. Table 1: Significant metabolites in OPLS-DA model between South Asian (SA) and Caucasians with UC. *compound is increased or decreased in SA compared with Caucasians respectively.

Conclusion: This study highlights the promise of UPLC-MS profiling to differ- 
entiate between SA and Caucasian groups. There are several possible reasons but two important factors are differing microbial metabolism and diet between the two groups. We are conducting further studies incorporating dietary data and 16S microbial analysis in this cohort. In combination with matching disease extent (left-sided vs colonic disease) may help to identify possible explanations for the different disease phenotype in this group.

Introduction: Patients with active inflammatory bowel disease have elevated mye-
loid lineage leucocytes1 including the CD14 +CD16 + DR+ e phenotype known as proinflammatory monocytes, and a major source of tumour necrosis factor-a. Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) is expected to promote remission or enhance drug efficacy. However, studies in ulcerative colitis (UC) patients have reported contrasting efficacy outcomes, ranging from an 85%3 to statistically insignificant level.4 Patients’ baseline demographic features may guide to selecting responder patients.
Aims & Methods: In a retrospective and single-centre setting we aimed to under-
stand if patients’ baseline clinical and endoscopic features were relevant guide for identifying likely responders and non-responders to adsortive GMA. The sub-
jects were 145 consecutive UC patients who had undergone GMA with the Adacolumn as remission induction therapy between 2012 and 2016. Seventy-
three percent patients were steroid naive, 70 were steroid dependent, and 2 patients were steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index was defined as remission. Biopsies from endoscopically detectable inflamed large intestinal mucosa were processed to see the impact of GMA on leukocytes within the mucosal tissue.

Results: At entry, the average CAI was 12.8, range 10–17. Ninety-three patients (65.1%) had the ability to induce regulatory T cells (Treg) play an important role in maintaining immune tolerance and has been proposed for treatment of inflammatory bowel disease (IBD). In this study, we report on the use of glic-
derived neurotrophic factor (GDNF) produced by enteric glial cells (EGCs) as a therapeutic action of DCGDNF were examined. Diverse clinical signs of the dis-

**P0314 A COMBINED ADMINISTRATION OF AMPICILLIN AND VANCOUPIXAN MILDLY REDUCES IBD, DIVERSITY OF GUT MICROBIOTA AND PERTURBATION OF GLUTAMINE AND SHORT CHAIN FATTY ACID METABOLISMS**

**Introduction:** Antibiotics sometimes have an influence on colitis negatively. Although it is well known that dysbiosis is one of the major disturbances to the gut environment, the molecular mechanisms underlying the pathogenesis remains unclear.

**Aims & Methods:** We aimed to clarify how antibiotics affect the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin (VCM), kanamycin, or a combination of ABPC and VCM (AV) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Metabolites and short chain fatty acid (SCFA) in the feces were measured by a chromatography-tandem mass spectrometry. Fecal microbiota was characterized by 16S rDNA sequencing.

**Results:** AV treatment in the A-V mice. Moreover, Glu metabolites and SCFA including butyric acid were significantly increased. The caecums were enlarged and dun-colored MIP-1α were significantly increased. The caecums were enlarged and dun-colored.

**Conclusion:** AV treatment improved the antibiotics—negative impact on colitis negatively. Interestingly, Glu treatment improved the microbiota—SCFA composition.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0316 THE MECHANISM OF PROTECTIVE ROLE OF D3 DOPAMINE RECEPTORS IN PATHOGENESIS OF ULCERATIVE COLITIS**

A. Prysiazhnik, T. Dovbynych, Y. Holota, I. Vareniuk, L. Garmanchuk, G. Tolstanova

**Introduction:** The role of D3-dopamine receptors in the ulcerative colitis pathogenesis was studied in a recent literature. The hypothesis that activation of D3R improves colonic mucus secretion during experimental colitis. Study was done on male Wistar rats (180-230). Experimental colitis was induced by 6% dextran sodium colitis (0.5 ml, s.c.) in IA enema. Rats were euthanized 0, 5, and 2 h after IA enema. During the autopsy 7 cm from the anus has been removed. Surface mucosa layer was separated from epithelial cells with N-acetyl-L-cysteine and glycopolysaccharides were measured by periodic acid-Schiff (PAS) staining or by the reaction with Folin reagent. The content of hexose, fucose and hexosamine were determined by standard biochemical assays. Morphometric analysis was performed to evaluate the histological changes of colonic epithelium and Goblet cells. Oxidative metabolism and arginase activity (analyzed by colorimetric method) in peripheral macrophages were investigated.

**Results:** Pre-treatment with 7-OH-DPAT did not affect the glycoprotein levels in normal mucosa, but significantly increased total levels of glycopolysaccharide (1, 6-fold, p < 0.05) and hexose (1, 1-fold, p < 0.05) during IA-colitis. Furthermore, 7-OH-DPAT significantly increased total levels of peripheral macrophages in 0.5 h (1, 6-fold, p < 0.05) and in 2 h (1, 3-fold, p < 0.05) after IA enema. Pre-treatment with 7-OH-DPAT decreased the mucosal layer thickness, 1, 1-fold (p < 0.05), crypt depth 1, 1-fold (p < 0.05) and Goblet cell villous thickness 1, 1-fold (p < 0.05) in 0.5 h and 2 h after IA enema.

**Conclusion:** Pre-treatment with D3R-agonist increased levels of mucus secretion and activated natural immune response by macrophage activation during experimental colitis, which could indicate about the protective role of D3R.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Results: Of 104 ileocecal resections, 30 (29%) and 15 (14%) had inflammation at the proximal and distal resection margins, respectively. After a median follow-up of 8.6 years, clinical recurrence was seen in 57%, and surgical recurrence in 26%. A significantly increased recurrence rate was seen in patients with active inflammation at the distal resection margin whereas recurrence rates were comparable for inflammation at the proximal site and radical resections (87%, 61%, and 50% resp., \(p < 0.001\)). Active inflammation at the distal resection margin (HR: 3.189 (1.635–6.220); \(p = 0.001\) and smoking (HR: 2.502 (1.311–4.703); \(p = 0.004\) were the only independent predictors for clinical recurrence. The incidence of surgical recurrence was small to perform AIEC screening.

Conclusion: Inflammation at the distal (colon) resection margin, and not the proximal ileum, after ileocecal resection was associated with significantly increased risk of clinical recurrence. This unexpected finding suggests that radiological symptoms in correctly diagnosed terminal ileitis (L1 disease), while it is of crucial importance to exclude colonic L3 disease. As this phenotype is unlikely to benefit from more extensive surgery, pathological finding of positive distal resection margin should be regarded as a risk factor, warranting prophylactic drugs or close monitoring.

P0319 LIPOSOMAL FORMULATION AS A NEW DRUG DELIVERY SYSTEM FOR CROHN’S DISEASE - VALIDATION IN THE MOUSE MODEL OF TNBS-INDUCED COLITIS

J. B. Krajewska, P. Pietrusza, D. Tomczyk, J. Fichna
Department Of Biochemistry, Medical University of Lodz, Lodz; Poland

Contact E-mail Address: julia.krajewska@stud.uned.lodz.pl

Introduction: C. jejuni infections are associated with an increased occurrence of inflammatory bowel disease (IBD), constitutes a significant healthcare burden, especially in the developed societies. Current methods of treatment are only partially effective and/or associated with major adverse effects. New therapeutic solutions are therefore required to ameliorate the side-effects of medical therapy, reducing complications and improving patients’ quality of life.

Aims & Methods: The objective of the study was to assess the effectiveness of delivery of anti-inflammatory drugs encapsulated in the liposomal formulation. Liposomes were prepared using thin-liquid hydration method. 0.9% sodium chloride was used as a solvent. The hydration solutions contained an aminosalicylate mesalazine (5-ASA), two recently validated plant-derived anti-inflammatories with low bioavailability, chlorogenic acid (CGA) and berberine, and pure solvent as negative control. Colitis was induced in male BALB/c mice by a single intracolic (i.c.) administration of 2, 4, 6-trinitrobenzene sulphonic acid (TNBS) on Day 0. Liposomal suspensions containing 5-ASA (5mg/kg), CGA (20mg/kg), berberine (5mg/kg) and the solvent were administered i.c. twice daily from Day 3 to Day 6. Mice were sacrificed on Day 7 and colonic damage was evaluated.

Results: The macroscopic scoring system included the evaluation of the colon length and bowel thickness as well as the presence of ulcers, haemorrhage, faecal blood and diarrhoea. Additionally, tissue myeloperoxidase (MPO) activity was determined and body weight was measured. The obtained results indicate that the best anti-inflammatory effect was obtained when liposomal suspension with berberine was used, while the treatment with 5-ASA was less effective.

Conclusion: CGA administration caused a detrimental effect as demonstrated by higher macroscopic score and increased MPO activity.

Background: Extragastrointestinal manifestations (EIM) at diagnosis of ulcerative colitis (UC) are rarely reported. The aims of this study were to determine the frequency of EIM at diagnosis and its association with a more severe disease outcome in paediatric-onset (≤17 years) and elderly-onset UC (> 60 years). Methods: A population-based study (Registre Epimad, France) of UC included 158 paediatric-onset and 470 elderly-onset patients. Results: The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset UC). Conclusion: EIM at diagnosis of UC are associated with a more severe disease outcome in paediatric-onset UC. The association was independent of other risk factors such as disease activity or age at diagnosis.

P0322 LONG-TERM NATURAL HISTORY OF MICROSCOPIC COLITIS: A POPULATION-BASED STUDY

6CHU, Amiens, France, Amiens/France
7Gastroenterology Unit, Epimad Registry, CHU Amiens Sud, Avenue Laennec-Salouel, Amiens University Hospital, Amiens/France

Background: The aim of this study was to determine the incidence of microscopic colitis (MC) in France, to observe its natural history, and to compare it to the incidence observed in the United States. Methods: MC diagnostic criteria were used to identify patients with MC in the population-based cohort of UC patients of the Epimad registry. Results: A total of 13031 lower GI endoscopy procedures were undertaken between January 1st 2006 and December 31th 2017. The incidence of MC at diagnosis was 9.74 per 100,000 and increased with age at diagnosis. Conclusion: The incidence of MC at diagnosis appears low in France and was stable over time. The current incidence rate of MC is twice that observed in the United States.

Introduction: The aim of this study was to develop an updated self-questionnaire to assess patients’ level of knowledge of IBD. Methods: The IBD-INFO questionnaire included 3 parts: a original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohn’s and Colitis Knowledge score (CCKNOW) (Q2) and Crohn’s and Colitis Pregnancy Knowledge score (CCPKNOW) (Q3). Results: The score for each part of the questionnaire was calculated and associated with a risk of relapse. Conclusion: The questionnaire-based study showed that after diagnosis, two thirds of patients with MC observed long-term clinical remission. Age at diagnosis and exposure were associated with a risk of relapse.

Introduction: Primary sclerosing cholangitis (PSC) is a disorder predominantly affecting the bile ducts and comprising Crohn’s disease (CD) and ulcerative colitis (UC), which are characterized by chronic remitting-intestinal inflammation and carry the risk for extraintestinal manifestations including primary sclerosing cholangitis (PSC). Available data on the impact of PSC in the disease course in IBD patients is scarce. In this study, we assessed the impact of coincidental PSC on the disease course in a large IBD patient cohort.
Aims & Methods: In total 1814 patients with histologically confirmed IBD were evaluated. Medical records from 705 UC and 1022 CD patients as well as from 77 UC-PSC and 10 CD-PSC patients were assessed. Data were evaluated using standard statistical methods. In matched-pair analyses, IBD patients with and without PSC were matched at the ratio of 3:1 by sex, disease entity, age at diagnosis, time from diagnosis to first presentation, and duration of follow-up. Time to event analysis was performed using survival analytic methods including Kaplan-Meier method and log-rank test.
Results: PSC was diagnosed in 77 and 10 patients out of 781 UC (9.8%) and 1022 CD patients (1.0%), respectively. Of note, at UC onset was significantly lower in UC-PSC patients than in patients without PSC (23.3 vs. 29.3 years; p < 0.001). Extensive disease manifestation was observed in 46% of UC patients, whereas pancolitis was more frequently diagnosed in UC-PSC patients (75% vs. p < 0.001). Concerning CD, all patients with coincidental PSC showed colonic involvement, while only 69% of the CD patients without PSC had colonic manifestation (p = 0.044). Interestingly, IBD patients without PSC presented more frequently with active disease, as compared to IBD-PSC patients (14% vs. 11% in year 1; p = 0.055). Convenantli, average disease activity assessed by complete Mayo score, was significantly higher in UC patients with acute flare as compared to UC-PSC patients (7.3 vs. 6.2; p < 0.001). Investigation of the average disease activity in 5-year-intervals in UC patients revealed a stronger disease activity in UC patients without PSC, especially within the first 10 years after UC onset. Furthermore, biological therapy including vedolizumab and anti-TNF antibodies was initiated more frequently (30% vs. 22% p = 0.043) and earlier (20.4 vs. 26.8 years after onset, p = 0.087) in UC without PSC than in those with coincidental PSC. Colorectal high grade intraepithelial neoplasia (HGIEN) and CRC were detected in 25 IBD-PSC patients without PSC and in 7 IBD-PSC (4 UC and 3 CD) patients (1.45% vs. 8.05%). Of note, in IBD-PSC patients, HGIEN/CRC occurred significantly earlier than in IBD patients without PSC (20-year-risk: 9.6% vs. 5.6%; p = 0.003).
Conclusion: In our large cohort study, IBD patients with coincidental PSC showed a distinct disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The EpiCom-cohort is a European prospective population-based cohort of uniformly diagnosed patients with inflammatory bowel disease (IBD) diagnosed in 2010 in centres from Western and Eastern European countries. The cohort aims at describing differences in occurrence, treatment strategies, disease course and prognosis within Europe.
Aims & Methods: Patients were followed each 3rd month for the first year after diagnosis and then according to the treating physician for the 2-5th year of follow-up. Clinical data on surgery, hospitalizations and medical treatment included biological therapy were captured prospectively throughout the follow-up period and entered in a validated web-based database. The aim of the study was to investigate differences in disease outcome and the use of biologicals between Eastern and Western Europe, from diagnosis and during the first 5 years of follow-up. Associations between outcomes and multiple covariates were analysed by Cox regression methods.
Results: A total of 1289 patients aged 15 years or older from 29 centres in 13 Western and 8 Eastern European countries were followed prospectively of whom 73% (66%) had ulcerative colitis (UC), 488 (38%) had Crohn’s disease (CD), and 46 (4%) had IBD unclassified (IBDU). Crude annual rates for CD and UC patients regarding surgery, biological treatment and hospitalization are shown in Table 1. Significantly more CD patients in Western Europe received biological therapy (p < 0.05), while surgery and hospitalization rates did not differ between the regions (p > 0.05). In UC, surgery rates did not differ between the regions, while hospitalization rates were higher in Western Europe (p < 0.05). Cox regression analysis showed that in CD strictureing (B2) or penetrating disease (B3) and progressing from luminal disease to B2/B3 increased while early (<6 months from diagnosis) treatment with immunosuppressives reduced the risk of surgery and hospitalization. In UC, progressing to extensive colitis increased the risk of colectomy while females, extensive disease, need for prednisolone at diagnosis, and progressing to expansive disease carried the highest risk for hospitalization. The cumulative probability of CD patients receiving treatment with 5-ASA was 90% in Eastern Europe and 56% in Western Europe, 69% and 75% for prednisolone, 54% and 66% for immunomodulators, respectively. For UC patients the cumulative probability of receiving treatment with 5-ASA within the first year of disease was 100% in Eastern Europe and 91% in Western Europe, 44% and 52% for prednisolone, 27% and 30% for immunomodulators, respectively.
Conclusion: In an era of early and aggressive immunological therapy, surgery and hospitalization rates for CD and surgery rates for UC patients were similar in Eastern and Western Europe. Overall, surgery and hospitalization rates were comparable to population-based cohorts from the past decade and pre-biological era. The similar disease course may be in spite of more early and aggressive treatment with biologics and immunomodulators, with significantly more CD and UC patients in Western Europe receiving biologics.
Disclosure of Interest: All authors have declared no conflicts of interest.
There was a similar, significant increase for codeine (chi2 for trend, p < 0.005) when analyzed separately. Table 1 shows the association between opiate use and all-cause mortality in English primary care cohort of patients with IBD.

**Aims & Methods:** We used the English primary care database ResearchOne for this study which holds records from approximately 6 million individuals (>10% of the total population). We extracted relevant clinical codes and prescription data on all patients with IBD, and separated out those with ulcerative colitis (UC) and Crohn’s disease (CD). We created 4 categories of opiate medication use, namely; any opiate medication, codeine only, tramadol, and strong opiates.

We defined 3 groups of prescription density as none/infrequent users, moderate and heavy users as <1, 1–3 and >3 prescriptions per calendar year respectively. We examined the trend in opiate prescriptions for all IBD patients in 4 year blocks from 1990–2014 using chi2 for trend as a significance. Separate trends were produced for each of our opiate classes. We calculated a propensity score estimating the conditional probability of being prescribed an opiate medication based on pre-defined characteristics which may influence the prescription of opiates. All analyses were performed for each opiate medication class in CD and UC patients.

**Results:** We included 3517 patients with CD and 5349 with UC. Opiate prescriptions increased from 10% in 1990 to 30% in 2014 (chi2 for trend p < 0.005). There was a similar, significant increase for codeine (chi2 for trend, p = 0.008), tramadol (p < 0.005) and strong opiates (p < 0.005) when analyzed separately. Table 1 shows the association between opiate use and all-cause mortality in patients with IBD. Any opiate use in patients with UC was associated was with increased all-cause mortality (HR 1.67, 95% CI 1.25–2.23). The strongest associations were for heavy users of strong opiates in patients with CD (HR 2.18, 95% CI 1.20–3.95) and UC (HR 3.30, 95% CI 1.77–6.18). There was no association for prescriptions of tramadol at any prescription density in CD or UC.

**Conclusion:** Our study is the largest population based study of opiate use in patients with IBD. We have shown a significant increase in the prescription of opiates since 1990, with 30% being prescribed an opiate medication between 2010 and 2014. Prescriptions of codeine in UC and strong opiates in both CD and UC were associated with increased all-cause mortality. There appears to be a dose association as heavy users of strong opiates had the largest association with mortality. Observational studies are not proof of causality and there may be residual confounding. A dose response is a strong indicator that opiates could be responsible for the associations seen, which is consistent with other studies investigating opiates used for non-cancer pain in chronic disease. Randomised controlled trials would be unethical and not feasible to investigate this potential effect so population-based observational studies may provide the best estimate. Opiate prescriptions are increasing worldwide for chronic non-cancer pain, and individuals with IBD can now be included. Clinicians managing pain in individuals with IBD should consider the potential implications of prescribing, or continuing with opiate prescriptions as they are a marker for increased mortality.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** We aimed to: (1) evaluate the prevalence of periodontitis in patients with inflammatory bowel disease (IBD), (2) assess the impact of IBD activity and IBD therapy on parodontal outcomes.
Aims & Methods: In a prospective 6-months study, dental examination was performed on IBD and in 19 healthy controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth (the severity of periodontal destruction). Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis.

Results: Among the 54 included patients, 44 had Crohn disease (81%) and 31 were women (55%). At the time of dental examination, median age was 33 years (Q1 = 26; Q3 = 41), 20 (36%) were smokers and the median IBD duration was 8.4 years (3.4-16.3). Eleven (20%) were treated by corticosteroids, 27 (49%) by anti-TNF, 6 (10%) by other biologics and 8 had no IBD treatment. IBD was significantly associated with periodontitis (81% vs 27%; Odds Ratio 2.9, 95%CI:1.3-6.2). Mild, moderate and severe periodontitis were respectively observed in 34 (63%), 8 (15%) and 3 (5%) IBD patients. As compared to healthy controls, IBD patients had significant increase of BOP index (p = 0.008), probing death (p = 0.03), and REC index (p = 0.01). Patients with active IBD (Harvey Bradshaw index > 3 or Mayo Score > 2) had a significant increase of BOP index (p = 0.007) as compared to patients with inactive disease. A significant correlation between BOP and Harvey-Bradshaw index was observed (r = 0.44, p = 0.0018). Anti-TNF therapy was significantly associated with lower BOP index (p = 0.02). All patients with a diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with povidone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Conclusion: Inflammatory bowel diseases were associated with an increase risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of parodontal disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn’s disease is a chronic, immune mediated inflammatory condition which affects the gastrointestinal tract. NOD2/CARD15 mutations have been linked to an increased risk of Crohn’s disease and to some of its phenotypes. This study aimed to determine the presence of the above mutations in Arab patients suffering from Crohn’s disease in Kuwait.

Aims & Methods: Blood samples were obtained from 103 Arab patients with Crohn’s disease and 100 Arab control subjects. The genomic DNA was isolated from the samples using Qiagen DNA Blood mini kit. The isolated DNA were sequenced using ABI 3130xl Genetic analyzer, and specific mutations were identified in the NOD2 CARD15 sequence of 17 (16.5%) Arab patients and 9 (9%) Arab controls. The mutations were 34 (63%), 8 (15%) and 3 (5%) IBD patients.

Results: Table 1 shows the results of all homozygous and heterozygous mutations found in the control subjects. The mutation rs2066845 (SNP12, Exon8 2722G > T) was found only in one patient and no controls and rs2066847 (SNP13, Exon11 3020insC) was not detected in any of the patients or controls.

Conclusion: This study suggests that mutation in rs2066845 (SNP12, Exon8 2722G > T) occurs more frequently in Arab patients with Crohn’s disease compared to controls, but the disease is associated only with the homozygous mutation. Mutation in rs2066842 (SNP5, Exon4 802C > T) occurs more frequently in controls compared to patients and the heterozygous mutation appears to have a protective effect against Crohn’s disease in the Arab population. Mutations in rs2066844 (SNP8, Exon4 2104C > T) and rs2066847 (SNP13, Exon11 3020insC) were not seen in this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0329 GENETIC ASSOCIATIONS OF INFLAMMATORY BOWEL DISEASE IN SRI LANKA: A CASE-CONTROL STUDY OF PHENOTYPES AND POLYMORPHISMS

Introduction: There is limited data on genetic of inflammatory bowel disease (IBD) in populations where the condition is emerging, especially from South Asia.

Aims & Methods: A case [histologically confirmed ulcerative colitis (UC) and Crohn disease (CD) of ≥1 year duration] control [unrelated, healthy, gender matched] study was conducted at four major gastroenterology centres in Sri Lanka. Phenotypic data (type, location, severity, treatment types, response to treatment and complications) of cases were obtained. Cases and controls were genotyped for 16 selected variants with known IBD disease associations in Western and East Asian populations (IL12Rb1 rs1045431, IL23R rs11805303, ARPC2 rs2162347, IRGM rs132136189, IL26 rs2448290, IL12B rs3243507, IL17R rs2875, IL10 rs3042590, IL17F rs4613763, IL1RFL RELPM3 rs5771069, BMNF rs4061734, STAT3 rs347446, SMC1F rs7897997, LAMBI rs868774, HLA DRB5, DQA1, DRB1, DRA rs2690853, HLA B35, APEH rs9822268). Genotypes of all variants were determined by hypothesis testing associations that had a p-value of <0.003 were considered significant.

Results: There were 411 (males 46.9%) cases [UC-258 (62.8%), males-47.7%, CD-153 (37.2%), males-50.3%] and 465 (males-50.5%) controls. The following variants were associated with corresponding phenotypes: IL12Rb1 rs11805303 with IBD (all cases) (p = 0.001); IL23R rs1045431 with upper gastrointestinal (UGI) CD (p = 0.001); IL1RFL RELPM3 rs5771069 with relapsing IBD (p = 0.003); IL1RFL RELPM3 rs5771069 with treatment-refractory IBD (p = 0.005).

Conclusion: This first study, confirms the association of genetic variants of IBD previously reported in other populations, with clinical, prognostic and treatment phenotypes of IBD in a Sri Lankan (South Asian) population.

Disclosure of Interest: All authors have declared no conflicts of interest.
**P0330 VDR GENE BSM I POLYMORPHISM AND ULCERATIVE COLITIS**

Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin D receptor gene (VDR) associated with disorders of innate and adaptive immunity as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the VDR gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism of the VDR gene with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of the Bsm I polymorphism of the VDR gene (rs1544410) in UC among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method ("SNP-express" reagents, Lytech Co., Ltd., Russia) with electronic data representation of the amplification products. Statistical analysis was performed using the X² and Mann-Whitney tests. In the presence of statistically significant differences (p < 0.05), odds ratios (OR) with 95% confidence interval (CI) were calculated.

Results: It was found that the frequency of the allele B polymorphism of the VDR Bsm I gene was higher among patients with UC than in the control group (44% vs. 26%, p = 0.02), which increases the risk of this pathology by 2.2% (95% CI: 1.2–4.1). In the case of carriers of the B/B genotype, the risk of developing UC increased up to 3.5 times in comparison with the control group (21% vs. 7%, p = 0.02, 95% CI: 1.4–8.6), whereas in b/b genotype the risk of UC decreased (33% and 54%, respectively, p = 0.02, OR = 0.4, 95% CI: 0.2–0.7). Significant differences between carriage of the B allele Bsm I polymorphism and the features of the clinical course of the UC have not been established. However, it has been shown that in carriers of allele B, the clinical implementation of UC develops significantly later than in patients with the b/b genotype (43 and 28.5 years, respectively, p = 0.04).

Conclusion: The presence of carriers of the B allele Bsm I polymorphism of the VDR gene is a predictor of a high risk of ulcerative colitis with an increase in the age of diagnosis. Genotype b/B Bsm I polymorphism of the VDR gene has a protective effect in the development of ulcerative colitis among the residents of the Kemerovo region of the Russian Federation.

Introduction: Having a family history for inflammatory bowel disease (IBD) is the only known risk factor for disease development. Indeed, up to 30% of IBD patients report at least 1 first-degree relative with IB and, siblings carry the highest risk. Recent data have shown that genetic and serological markers may predict disease development. However, there are only few studies evaluating a genetically well-characterized population and at high risk for disease, such as siblings and twins. Therefore, aim of this study was to evaluate genetic and serological findings as markers of disease susceptibility in healthy siblings and twins of children with IBD.

Aims & Methods: This is the first phase of a prospective, longitudinal, multi-center, case-control study. Serum was collected from 80 siblings and twins of children with IB and 77 healthy controls with no family history for IBD. Genotyping (TaunmanMGX10 microarray, CytoGenetics, CA) was performed for variants of Bsm I polymorphism of the VDR gene (rs1544410). Serological studies included 6 autoantibodies (anti-CBir1, anti-ASCA IgG, perinuclear anti-neutrophil cytoplasmic antibodies (pANCA), antineutrophil cytoplasmic antibodies (anti-OMp), and antibacterial flagellin antibody (anti-CbIr1)), were determined by specific enzyme-linked immunosorbent assay (ELISA).

Results: Fifty-nine out of 80 cases (74%) and 50 controls (65%) were positive at least for one of the serum autoantibodies (p = 0.29) and a combination of any 4 of them was found in 3 cases (4%) and no controls (p = 0.28). No significant difference was found for any of the studied autoantibodies between children with IBD and controls. Homozygosity for any susceptibility gene variant was found in 60 out of 80 cases (75%) and in 52.77 controls (67.5%) (p = 0.37), with no significant association between family history and genotype status. No combination of gene variants significantly differed between cases and controls.

Conclusion: Our preliminary results argue against a role of commonly recognized genetic polymorphisms and microbial antibodies as markers of disease susceptibility in siblings of children with IBD. However, data from larger and prospective studies, possibly including microbial characterization, are warranted before drawing definitive conclusions.

Introduction: DNA methyltransferases are important epigenetic modification mechanisms of gene expression. Several studies have shown an association between impaired methylation with inflammatory bowel diseases (IBD) pathogenesis. DNM3TA and DNM3TB are two of the three members of the family of de novo DNA methyltransferases. Variants in these proteins are responsible for the establishment of the unique DNA methylation patterns and contribute to the normal development as well as in many diseases. However, it is unknown if DNM3TA may play a role during the mechanism involved in this abnormal methylation pattern and consequently the development of diseases.

Aims & Methods: To assess the function of DNM3TA in intestinal epithelial cells (IECs), human Caco-2 colon carcinoma cells were transfected with siRNA targeting DNM3TA, DNM3TB and DNM3TL. Gene expression analysis and DNA methylation analysis using qRT-PCR, RNA sequencing and 850k methylation profiling array were performed. As assay were performed. For long-term experiments, we established an inducible CRISPR/Cas9 genome editing to delete DNM3TA gene in Caco-2 cells. DNM3TA knockout Caco-2 cells were grown in a 3D-Matrigel culture system and after 2 weeks, spheroids cells were stained for actin/nuclei and subjected to confocal microscopy analysis.

Results: From the RNA sequencing data, approximately 1000 genes were found to be differentially expressed between cells lacking DNM3TA and controls. The KEGG pathway analysis identifies differentially regulated genes associated with several functional categories comprising extracellular matrix receptor interaction, focal adhesion and MAPK signaling pathway. In contrast, we observed no difference in DNA methylation between the groups. Furthermore, loss of DNM3TA induces abnormal/spheroids by reducing spheroids diameter and defect in actin organization and lumen formation. Thus, the observed morphological phenotype may be linked to the differentially regulated genes involved in the previous analysed pathways.

Aims & Methods: To assess the function of DNM3TA in intestinal epithelial cells (IECs), human Caco-2 colon carcinoma cells were transfected with siRNA targeting DNM3TA, DNM3TB and DNM3TL. Gene expression analysis and DNA methylation analysis using qRT-PCR, RNA sequencing and 850k methylation profiling array were performed. As assay were performed. For long-term experiments, we established an inducible CRISPR/Cas9 genome editing to delete DNM3TA gene in Caco-2 cells. DNM3TA knockout Caco-2 cells were grown in a 3D-Matrigel culture system and after 2 weeks, spheroids cells were stained for actin/nuclei and subjected to confocal microscopy analysis.

**P0333 ORMEL PROTEINS: CRITICAL REGULATORS OF FINE-TUNING OF THE UNFOLDING PROTEIN RESPONSE IN INTESTINAL INFLAMMATION**

Institute Of Clinical Molecular Biology, Christian-Albrechts-University and University Hospital Schleswig-Holstein, Kiel/Germany

Contact E-mail Address: S.stengel@ikmb.uni-kiel.de

Introduction: The endoplasmic reticulum (ER) plays a crucial role in maintaining cellular homeostasis by coordinating the processing and folding of secretory and membrane proteins. The accumulation of unfolded or misfolded proteins induces ER stress. The unfolded protein response (UPR) aims at restoring ER function and is comprised of three signaling branches via inositol-requiring enzyme 1...
(IRE1), double-stranded RNA-dependent protein kinase (PKR)-like ER kinase (Plerk) (Fig. S1). Moreover, statistical evaluations in CD patients (Table S1). Defects in ER stress response have been shown to predispose to chronic inflammatory bowel disease (IBD). Genome-wide association studies identified disease susceptibility loci in or adjacent to several UPR related genes including XBP1 and ORMDL3.

Atf6, our results suggest that ORMDL3 function in IPR signaling to gain insights into the molecular mechanisms promoting chronic intestinal inflammation. Using molecular cell biology approaches, we studied the effect of ORMDL3 on ATF6/6, PERK and IRE signaling in ORMDL3 deficient mice. In vivo and in vitro analyses in an acute and chronic DSS-colitis model using Ormd3-deficient mice. This study demonstrates for the first time the modulatory functions of ORMDL3 proteins as regulators of all three UPR signaling pathways. Also, our data suggest that ORMDL3 proteins constitute a precise fine-tuning mechanism of the UPR determining cell fate decisions in response to ER stress.

Conclusion: This study demonstrates the role of ORMDL3 in UPR signaling to gain insights into the molecular mechanisms promoting chronic intestinal inflammation. Using molecular cell biology approaches, we studied the effect of ORMDL3 on ATF6, PERK and IRE signaling in ORMDL3 deficient mice. This study demonstrates for the first time the modulatory functions of ORMDL3 proteins as regulators of all three UPR signaling pathways. Also, our data suggest that ORMDL3 proteins constitute a precise fine-tuning mechanism of the UPR determining cell fate decisions in response to ER stress.

Introduction: The most relevant scope of serologic antibodies in Crohn’s disease (CD) is to stratify the risk of complicated disease course. Significance of distinct antibody classes and their characterisation was rarely considered. We aimed to address these concerns.

Aims & Methods: Sera of 266 well-characterized CD patients (m/f:112/154, median age: 25 yrs, B1:80.1%, P1:18.0%) and 155 controls were assayed for serologic antibodies. EndoCAb IgA and a panel of non-specific immunoglobulin A (IgA) antibodies (IgA1, IgA2, IgA and secretory IgA) were also assessed by ELISA. An observational follow-up study (median, 143 months) was conducted to assess possible associations between serologic antibodies and the development of various complications and subsequent surgical interventions. A novel flow cytometry test system was established for characterisation of IgA type ASCA to reveal possible origin of the antibody.

Results: A total of 65.7% and 46.2% of the CD patients were positive for ASCA IgA and anti-OMP antibodies. Both ASCA types occurred equally. EndoCAb IgA positivity was more frequent (15.4% vs. 5.4%, p = 0.001) and sIgA levels were increased (median, 51 vs. 29 ug/ml, p < 0.001) in CD compared to controls. They were also associated with presence of IgA type anti-microbial antibodies. Contrary, ratio of IgA2/A1 in CD corresponded with the value of the controls. In Kaplan-Meier analysis, development of臻defile of IgA type anti-microbial antibodies. Contrary, ratio of IgA2/A1 in CD corresponded with the value of the controls. In Kaplan-Meier analysis, development of enzymatic anti-microbial antibodies was significantly associated with IgA type ASCA (pLogRank < 0.001 and pLogRank = 0.025, respectively), while development of enzymatic anti-microbial antibodies was significantly associated with IgA type ASCA (pLogRank = 0.008). Performance OMP IgA was equal to ASCA IgA, however sIgA was not. Anti-microbial antibodies remained independent predictors in multivariate Cox-regression analysis comprising relevant clinical factors.

Summary of multivariate Cox regression analysis for the association of serologic antibodies with complicated disease course

Without uncoupling of IgA antibody classes yielded clearly inferior performance. Analysis for IgA type ASCA and Omp IgA revealed that nearly doubled the increase in the proportion of IgA2 subtype (29%) and presence of the secretory component (69% of total ASCA IgA) concurrently.

Conclusion: Consideration of antibody classes is an important novel parameter in serological prediction in CD. Involvement of gut mucosal immune system is in center of IgA type antibody formation reflecting sustained exposure and dysregulated immunresponse to bacterial constituents.

Introduction: In Crohn’s disease (CD), accurate evaluation of location and small bowel involvement are necessary at the time of diagnosis for prognostic concern and planning of treatment strategy. Since Double Balloon Endoscopy (DBE) has been newly developed, we aim to examine deep small bowel either oral or anal it could be of great utility in the management of Crohn’s disease patients.

Aims & Methods: We aimed to evaluate the diagnostic yield and therapeutic impact of DBE on small bowel CD. The medical records of 180 CD patients, from October 2009 to April 2012, were retrospectively reviewed. Inclusion criteria were: only patients who had known CD based on clinical, colonoscopic and histological findings and had been subjected to DBE. If one patient underwent more than one DBE examination only the first examination was considered. The primary end point of our study was to evaluate small bowel involvement that is beyond the scope of conventional colonoscopy. The secondary endpoints were to determine the impact of DBE findings on management strategy of CD. The diagnostic yield of DBE in small bowel CD was determined. In addition, the changes in medical treatment, endoscopic intervention and surgical procedures, within three months after DBE, were analysed.

Results: Among 180 patients with CD, 90 patients underwent 168 DBE examinations and were included. The mean age of included patients was 40 ± 13.6 years. They were 63 males and 27 females. Eighty-nine (91%) patients with established CD underwent DBE for evaluation of small bowel involvement and 8 (9%) patients underwent DBE because of suspicion of CD and had been newly diagnosed. The overall diagnostic yield of DBE was 69%. DBE revealed small bowel involvement proximal to the terminal ileum in 40 (64.5%) patients; of them 17 (42.5%) patients had isolated small bowel CD. Within 3 months after DBE examination the management strategy of CD changed in 47 (52.2%) patients, based on DBE findings. The medical treatment escalated in 20 (23%) patients and decreased in 7 (9.1%). Forty-four (24%) patients underwent DBE-assisted balloon dilatation, and 6 (9.6%) patients underwent CD-related surgery.

Conclusion: DBE can be used to detect small bowel involvement in a significant proportion of CD patients. The DBE findings modified the management strategy in at least one half of CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Therapeutic adherence is crucial in the management of patients with inflammatory bowel disease (IBD). Poor adherence may lead to suboptimal control of the disease, decreased quality of life and increased health care costs.

Aims & Methods: 1) To evaluate the prevalence of non-adherence to treatment in Spanish patients with IBD and 2) To identify factors associated with low, medium and high adherence.

Contact E-mail Address: catherine@kebber.org

Introduction: Magnetic resonance enterography is now recognized by the European Crohn’s and Colitis Organization (ECCO) as a reference procedure to assess the intestinal involvement of Crohn’s disease (CD), including extra mural complications, as well as to monitor patients under treatment. A new MRI index of severity was developed in 2015 by the GETAID consortium, specifically to evaluate lesions located in the small intestine. This score, labeled CDMRIS (Crohn’s disease magnetic resonance index of severity), considers, for each 20-cm small bowel segment, the intensity of relative contrast enhancement (mild–moderate or severe), deep ulceration without fistula, “comb sign”, any fistula, and abscess. Although well standardized, this index has not yet been validated, either for the initial assessment of CD at diagnosis, or for monitoring patients under treatment. Its feasibility in routine practice has never been tested.

Aims & Methods: The aims of this study were to evaluate the feasibility of applying the CDMRIS score in clinical practice, to evaluate its variability after the initiation or optimization of an anti-TNF treatment, and to measure its correlation with an evaluation of clinical activity. Patients with known small bowel Crohn disease who underwent two MR examinations at 6–12 months were included between 2010 and 2015. Each exam was interpreted twice and the CDMRIS score was calculated on both exams in addition to classical criteria. All patients had a clinical evaluation over time, separating them in two groups: “active” and “inactive” disease.

Results: Seventy-two patients were included, with a mean CDMRIS of 3.4 at baseline, decreasing to 2.6 (p = 0.052) independently of clinical disease activity. The mean interval between the two MRIs was 15.4 months, and there was a significant larger decrease in the CDMRIS score when the interval was above 12 months. Two other radiological parameters decreased significantly: the rate of patients with a mural T2-hyperintensity (36.1% to 20.8% p = 0.042), with a good chimecorrelational correlation, and mean wall thickness (5.5 to 4.4 mm, p = 0.042).

Conclusion: This study demonstrated the feasibility of applying the CDMRIS in clinical practice, but sensitivity was too low to detect early changes. Accuracy for a long-term monitoring needs to be evaluated. Wall thickness and mural T2-hyperintensity emerged as the most sensitive radiological factors, significantly associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

5University of California San Diego, La Jolla/United States of America/CA
Introduction: Crohn’s disease (CD) with complications such as penetrating, strictureting, and perianal disease are called complicated CD. However, no validated, inexpensive, or sensitive models for prediction of risk are available in complicated CD. We have found that a novel immunological balance, the CD8+CD28+ ratio, was associated with BMI, CD4, and CD8 balance and the risk factors, for the newly diagnosed complicated CD. Seventeen patients with complicated CD were enrolled as the observation group, while the other 48 CD patients with no complications were enrolled as the control group. Peripheral blood samples were drawn from all the 65 newly diagnosed CD patients for CD8+ T cells testing through flow cytometry (FCM) when enrolling. The potential risk factors, including demographic, pathophysiological, and therapeutic factors were compared between the two groups. A 30-week follow-up group was performed, and the CD8+ T cells testing were repeated. The sensitivity and specificity of the CD8+ T cells’ level and balance in predicting were analyzed through receiver operator characteristic (ROC) curves. The cumulative remission lasting rates (CRLRs) under the different risk factors were analyzed using the Kaplan-Meier method.

Results: I. Risk factors: compared with the control CD group, patients with complicated CD had a larger proportion in male (P < 0.001), younger in age (P = 0.019), lower body mass index (BMI) (P < 0.0001), higher prescription rates in immunosuppressants (P = 0.029) and steroids (P = 0.015), as well as a significant higher surgical rate (P = 0.001). Pearson and Spearman correlation analysis showed that CD8+CD28+/CD8+CD28- (the ratio) was associated with BMI, CD4, CD8, and surgery (P < 0.0001). II. Follow-up and dynamic change of the ratios of CD8+CD28+/CD8+CD28- reached the bottom at the 30th week and were significantly lower at the 6th, 22nd, and 30th week during follow-up, in the complicated CD patients when compared to the control ones (all P < 0.05). A shorter lasting time of remission (LTR) was found in complicated CD patients (P = 0.044). ROC curve showed that CD8+CD28+/CD8+CD28- ratio could accurately predict the active stage for the complicated CD patients [area under curve (AUC) of 0.890, and 95% CI of 0.822 to 0.958], and the best sensitivity of 89.2% and specificity of 85.3% were found when the ratio was 1.03. II. Kaplan–Meier analysis: Undergoing of steroid and surgery was closely related to worse outcome for the complicated CD patients, and patients who underwent steroid and surgery had the significantly lower CD8+CD28+/CD8+CD28- ratio and lower CRLRs (all P < 0.05). Conclusion: Depending on steroids and surgery stands for a more severe disease activity and thus disqualifies the immunological balance, which could be the potential risk factors for lower CRLR. This ratio can predict the active stage sensitively for patients with complicated CD. More strategies should be taken when the ratio is to be lower than 1.03.

P0343 BOWEL PREPARATION QUALITY OF NR1006 VERSUS STANDARD 2L PEG WITH ASCORBATE AS ASSESSED BY COLONOSCOPISTS AT SITE: A POST HOC ANALYSIS FROM A RANDOMISED CONTROLLED TRIAL

J. Manning1, L. Clayton2, V. Lorenzo-Zúñiga García3

Contact E-mail Address: Jmanning1@nhs.net

Introduction: Successful colonoscopy requires effective bowel cleansing. NR1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The MORA study was a multicentre randomised Phase 3 clinical trial using blinded central readers to assess the cleansing efficacy of the overall colon and high-quality cleansing of the ascending colon by NR1006 vs standard 2L PEG with ascorbate (2L PEG + Asc) [1]. This post hoc analysis shows the cleansing assessment by site colonoscopyists, who typically guide clinical decision-making; hence this analysis may be more relevant for clinical practice than previous analyses.

Aims & Methods: In the MORA study 849 patients (males and females, aged 18–85) were randomly assigned in a 1:1:1 ratio to receive i) NR1006 in an evening/morning split-dose (N2D), or ii) NER1006 in a morning-only dose (N1D) or iii) 2L PEG + Asc in an evening/morning split-dose. The 796 subjects who underwent a colonoscopy and were assessed by a treatment-blinded site colonoscopyist included in this analysis. Cleansing was assessed according to the Harefield Classification Scale [2]; following segmental scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Results: The bowel preparation quality of NR1006 showed a statistically significant improvement over 2L PEG + Asc for the overall colon when both treatments were administered as an evening/morning split-dose (P = 0.003; 95% CI: 2.0–10.1%)(Table 1). NR1006 administered either as an overnight split-dose or morning-only dose produced high-quality cleansing of the ascending colon in a statistically significantly higher proportion of patients compared to 2L PEG + Asc (P < 0.001; 95% CI: 7.2–23.1% and P < 0.001; 95% CI: 7.2–22.5% respectively). Conclusion: Colonoscopyists assessed both dosing regimens of NR1006 as having a significantly increased rate of high-quality cleansing of the ascending colon when compared with 2L PEG + Asc: this cleansing is important in ensuring the detection of lesions in the ascending colon. When comparing similar overnight split-dose treatment regimens, NR1006 showed a significantly increased rate of bowel cleansing compared to 2L PEG + Asc.

### Results:

- For both preparations, site colonoscopist findings demonstrated similar or higher rates of cleansing success for the overall colon (>95%) and high rates of high-quality cleansing of the ascending colon (>73%), although statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists were notably higher than those previously reported by central readers.

### Conclusion:

For both preparations, site colonoscopist findings demonstrated similar or higher rates of cleansing success for the overall colon (>95%) and high rates of high-quality cleansing of the ascending colon (>73%), although statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists were notably higher than those previously reported by central readers.
Table 1: A comparison of bowel cleansing efficacy as assessed by site colonoscopy: patients were graded according to the En bloc cleansing and the quality of life. Patients were classified according to their clinical parameters, such as the Crohn's Disease Activity Index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship using not only clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrosis.

**Conclusion:** This study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrosis formed during healing of inflammation. We consider it important to demonstrate the relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrosis.

**Introduction:** Several studies in recent decades have revealed new roles for vitamin D. For example, vitamin D plays a role in regulating skeletal muscle, as well as in cardiovascular and renal physiology, producing anticoncettive effects, suppressing fibrosis, and as a regulator of the immune system. In light of these new roles, vitamin D is considered to be related to disease activity and intestinal fibrosis, including that seen in Crohn’s disease (CD). Several reports have demonstrated a relationship between vitamin D deficiency and CD activity according to clinical parameters such as Crohn’s disease activity index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship using not only clinical parameters, such as mucosal activity, mucosal inflammation, and intestinal fibrosis.

**Aims & Methods:** The aim of this study was to clarify the relationship between vitamin D deficiency and CD activity using endoscopic parameters, as well as clinical parameters. Of the CD patients visiting Nagoya University Hospital from May 2011 to February 2016, 82 patients were enrolled in this study. Serum 25-hydroxyvitamin D (25(OH)D) levels, disease activity, and clinical factors of the subjects were investigated prospectively. Endoscopic findings of 52 of the 82 total patients enrolled were investigated retrospectively from endoscopic records. This study design was approved by the ethics committee of Nagoya University Hospital. Clinical remission was defined as CDAI ≤ 150. Mucosal healing was defined as a simple endoscopic score for Crohn's disease (SES-CD) ≤ 1. Moreover, to evaluate endoscopic activity from two aspects (mucosal inflammation and fibrotic stenosis), we divided SES-CD score into endoscopic mucosal inflammation score and fibrosis score. No mucosal inflammation was defined as mucosal inflammation score ≤ 1, fibrosis score was defined as narrowing score 0. The primary endpoint of this study was the relationship between 25(OH)D and clinical activity. Secondary endpoint was the relationship between 25(OH)D and endoscopic findings, including mucosal healing, mucosal inflammation, and intestinal fibrosis.

**Results:** Mean age of the subjects was 41.1l, and the male/female proportion was 64/18. The mean serum 25(OH)D level of subjects was 17.1 ng/mL, and 61 cases (74.4%) were classified as severe deficiency or deficiency. Mean serum 25(OH)D levels of the clinical remission and clinically active groups were 18.7 ± 8.1 ng/mL and 12.4 ± 3.6 ng/mL, respectively (P < 0.001). In a multivariate analysis, low levels of serum 25(OH)D and serum albumin and positive C-reactive protein (CRP) results were correlated with clinical activity. Mean serum 25(OH)D levels of the mucosal healing and no mucosal healing groups were 24.0 ± 9.8 ng/mL and 15.1 ± 6.6 ng/mL, respectively (P < 0.001). Mean serum 25(OH)D levels for the no mucosal inflammation and mucosal inflammation groups were 21.6 ± 9.6 ng/mL and 14.3 ± 5.5 ng/mL, respectively (P < 0.001); and those of the no fibrostenosis and fibrostenosis groups were 20.2 ± 8.5 ng/mL and 14.2 ± 6.7 ng/mL, respectively (P < 0.001; Mann-Whitney U test). In a multivariate analysis, low serum 25(OH)D levels were related with mucosal inflammation and intestinal fibrotic stenosis of CD (P < 0.05; logistic regression analysis).

**Conclusion:** This study demonstrated the relationship between vitamin D level and disease activity in patients with UC. The disease pathology of UC consists of repetitive intestinal inflammation and intestinal fibrosis formed during healing of inflammation. We consider it important to demonstrate the relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrosis.

**Disclosure of Interest:** Inflammatory Bowel Disease (IBD), mainly represented by Crohn’s Disease (CD) and Ulcerative Colitis (UC), is a chronic, relapsing and remitting disease impairing patients’ quality of life (QoL). To maintain a high QoL and to decrease the inflammation burden, it is important to tightly monitor the disease and promptly treat relapses when they occur. The quality of care perceived by IBD patients play an important role in the management of IBD. An eHealth web application consisting of a validated Fecal Calprotectin (FC) home testing kit (Calpro SmartTM), questionnaires regarding disease activity and QOL has been developed to improve disease monitoring, patient empowerment and patient-caregiver communication.

**Aims & Methods:** The aim of this study was to evaluate patient satisfaction with an eHealth home monitoring solution during the participation in a one year trial. The trial includes 120 adult IBD patients which have been randomized into two groups; one performing a disease activity screening procedure every 3 months (3M) and the other screening only at the patient’s discretion, on demand (OD). Both groups used the web-program where they were requested to fill out a disease activity questionnaire, Harald-Bradhav Index (HBI) for CD or Simple Clinical Colitis Activity Index (SCCAI) for UC, and perform a home testing of FC. The results were compared by disease activity questionnaire and FC score. For disease activity questionnaire and FC score, the patients were requested to fill out a QOL questionnaire (Short- Inflammatory Bowel Disease Questionnaire (s-IDQ) as well as a questionnaire regarding their overall satisfaction with the trial and the home monitoring solution.

**Results:** To date, 83 patients have been included, 15 patients have dropped out (7 in OD-group and 8 in 3M-group) and 68 (3M-group: n = 32, 47%; OD-group: n = 36, 53%) patients have fulfilled the first year of follow-up and were included in the analysis. The trial lived up to the expectations in n = 63, 93% (3M-group: n = 29, 91%; OD-group: n = 34, 94%) of the patients and the support given to the patients was estimated to be sufficient by n = 67, 99% (3M-group: n = 31, 97%; OD-group: n = 36, 100%). Only n = 14, 21% (3M-group: n = 6, 19%; OD-group: n = 8, 22%) of the patients experienced difficulties with the application or the home testing kit and n = 64, 94% (3M-group: n = 29, 91%; OD-group: n = 35, 97%) wanted to continue to be monitored in an EHealth setting in the future. The mean s-IDQ scores at baseline were 58 (95% CI: 55–61) in the 3M-group and 54 (95% CI: 59–58) in the OD-group as well as 58 (95% CI: 54–62) in the 3M group and 61 (95% CI: 58–64) in the OD group at one year follow up. No difference in s-IDQ measured QOL was found between the two groups. However, patients in the OD group had a significant increase in mean S-IDQ score at follow up (P = 0.04).

**Conclusion:** Patients in both groups were generally satisfied by the home monitoring set up. Patients in the on-demand group also presented a significant increase in quality of life over time.

- D.V. Andersen: Calpro Inc. Norway has provided all fecal Calprotectin home testing kits used in this study.
IBD patients. Multivariate analysis using Cox regression model demonstrated the association revealed that the SMI has a strong correlation to body weight and O-PNI in patients (P = 0.032) using Kaplan-Meier method and log-rank test.

Results: Currently, 78 patients (33 male, 45 female; age 16-72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up 3-28 weeks (mean 8.5 months), mean age 35 years, 35 female, 21 male, CRP 12.2 mg/l were included into the interim analysis. In 28 patients with a score from 0-2 step-up treatment occurred in 7%, whereas in 28 patients with a score >2, step-up rate was 43% (p=0.0043). Differences between patients with a score 0-2 and >2 were age (41 vs. 28 years, p=0.0011), CRP <2 mg/l (17/28 patients vs. 0/28, p <0.0001), endoscopic score 1.4 vs. 2.7, p <0.05), perianal lesions 1/28 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and lever.

Conclusion: In this early analysis of a prospective study planned with a 5-year follow up, a significant proportion of patients with mild CD and simple mesalamine therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

P0349 A PROSPECTIVE STUDY TO PREDICT A MILD COURSE OF CROHN’S DISEASE: AN INTERIM ANALYSIS OF THE PROGNOSIS

Contact Email Address: wolfgang.kruis@googglemail.com

Introduction: Crohn’s Disease (CD) spans a wide severity range, from mild to severe, and the avoidance under- as well as overtreatment is challenging. While factors determining bad prognosis are studied in detail, factors predicting a mild course with the chance of simple treatments are less known. Here we show first results of a prospective evaluation of a retrospectively created score (JCC 2013;7:263) for prediction of mild CD which consists of age at diagnosis, CRP, an endoscopy score, presence of perianal lesions and complications.

Aims & Methods: This is a prospective, ongoing study performed in 12 IBD-specialized private gastroenterology practices (outpatients only) in Germany. All considered CD patients (diagnosis ≥5 weeks) were included. An initial screening ileocolonoscopy with histology, investigation of the perianal area, laboratory tests including CRP are performed and CD complications (stenosis, fistula, extraintestinal manifestations or fever >38°C) evaluated to complete of the above quoted score. Patients are treated at the discretion of the physician. In case of a score indicating a good prognosis (≥2) or of mild clinical appearance mesalamine is started. In all other cases patients are treated according to guidelines. 5 year follow up is planned for all patients. If initial therapy fails, treatment is escalated. Source data verification is performed by external monitors. Primary aim of the study is to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalamine therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This interim analysis presents preliminary data.

Results: In total, 404 patients were included with a mean age of 51.5 (SD 16.6), 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%), 60/355 (16.9%) were smokers. The prevalence of LTI and the correlation between TST/booster and QFT is shown in table 1.

Contact Email Address: amfoncontrol@gmail.com

Introduction: The Spanish Working Group on Crohn’s Disease and Ulcerative Colitis (GETECCU) and other international guidelines recommend testing of latent tuberculosis infection (LTI) before anti TNF therapy by screening with tuberculin skin test (TST) and, in a potential state of energy, double screening by TST and interferon-gamma release assays (IGRAs) or two-time tuberculin test (TST/booster). Routine repetition is not recommended.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and IGRA as using QUANTIFERON-TB (QFT) and the usefulness of repeating periodic (annual or biannual) screening in a population of IBD patients of Zarona (Spain). In a single cohort of IBD patients attended in the department of gastro-entology of Zarona Hospital, we implemented a questionnaire and collected TST/booster performed previously to February 2015. Afterwards, prospectively, between February 2015 to February 2017, TST and QFT were performed at the same day, and the TST/booster 7 days after. Finally we compared the results of the LT screening performed prospectively with the screening of the retrospective cohort.

Results: A total of 404 patients were included with a mean age of 51.5 (SD 16.6), 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%), 60/355 (16.9%) were smokers. The prevalence of LTI and the correlation between TST/booster and QFT is shown in table 1.
Prevalence of LTI in retrospective testing was of 54.246 (22.0%). Prospective testing of 201 patients (CDAI > 150) by CDAI revealed the follow up, 30,191 (15.7%) patients who were negative for screening before 2015 were converted in positive for LTI (95% CI [10.2–21.1]).

Conclusion: The prevalence of LTI in our area is high (32.6%). The simultaneous presence of capsule and QFT results in QFT+ population. The TST booster increases the detection of LTI even when is performed in patients without immunosuppressive treatments, in whom is not routinely recommended. The QFT is more useful in patients without immunosuppressive therapy. The results of QPT or even two years is useful in this population with high prevalence of LTI, since it may detect LTI in patients with previous negative tests (15.7%). The TST booster is essential due to the possible false negatives of QFT when screening patients on anti-TNF therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Magnetic resonance enterography (MRE) and capsule endoscopy (CE) are prime modalities for evaluation of small bowel in patients with Crohn’s disease (CD). However, detection of proximal jejunal and ileal inflammation may be underestimated. Magnetic resonance enterography global score (MEGS) was designed for quantification of small bowel inflammation on MRE. It is unclear whether these indexes are interchangeable for evaluation of mucosal inflammation in established CD.

Aims & Methods: We aimed to prospectively compare the quantitative evaluation of the small bowel inflammation by MEGS score and the Lewis capsule endoscopy score. Patients with known quiescent small bowel CD (for duodenum vs LS 1st tertile and proximal ileum vs 2nd tertile LS - both p < 0.001). Moderate correlation between both scores and FCP p < 0.001 for both. There was a weak correlation between LS and CRP p < 0.04 for both.

Conclusion: In our prospective study, CE and MEGS scores are strongly correlated and performed similarly for quantitative assessment of mucosal inflammation in established CD.

Disclosure of Interest: U. kopylov: The study was supported by a generous grant from the Helmsley Charitable trust. All other authors have declared no conflicts of interest.

P0352 WHICH ONE IS BETTER FOR ASSESSMENT OF ESTABLISHED CROHN’S DISEASE BY CAPSULE ENDOSCOPY: THE LEWIS SCORE OR THE CAPSULE ENDOSCOPY CROHN’S DISEASE ACTIVITY INDEX?

Introduction: Small-bowel capsule endoscopy (CE) is a prime modality for evaluation of the small bowel. The Lewis score (LS) and the Capsule Endoscopy Crohn’s Disease Activity Index (CECDAI) are validated endoscopic indices for quantification of small bowel inflammation on CE. It is unclear whether these indexes are interchangeable for evaluation of mucosal inflammation in established Crohn’s disease (CD).

Aims & Methods: We aimed to prospectively compare the quantitative evaluation of the small bowel inflammation by MEGS (for duodenum vs LS 1st tertile and proximal ileum vs 2nd tertile LS - both p < 0.001). Moderate correlation between both scores and FCP levels that was somewhat stronger for CE (p = 0.39, p = 0.002 vs p = 0.53, p = 0.001 for both). There was a weak correlation between LS and CRP levels that (p = 0.27, p = 0.04) and none for CECDAI and CRP (p = 0.21, p = 0.1).

Conclusion: Diagnostic Imaging, Sheba Medical center, Ramat Gan/Israel

Disclosure of Interest: All authors have declared no conflicts of interest.

P0353 CONCORDANCE BETWEEN TUBERCULIN SKIN TEST AND INTERFERON GAMMA RELEASE ASSAY FOR LATENT TUBERCULOSIS SCREENING IN INFLAMMATORY BOWEL DISEASE (META-ANALYSIS)

Introduction: Screening for latent tuberculosis infection (LTI) is mandatory prior to initiating anti-tumor necrosis factor (anti-TNF) medications. New guidelines recommend interferon-gamma release assays as first line screening method for the general population. Studies have provided conflicting evidence on the performance of interferon-gamma release assays (IGRAs), compared to tuberculin skin test (TST) in inflammatory bowel disease (IBD) patients. We assessed the concordance of these two tests in IBD patients and the effect of immunosuppression on their performance.

Aims & Methods: We performed a systematic search of MEDLINE, EMBASE and Cochrane Library databases, from 2011 to 2016, for relevant studies testing both TST and IGRA in IBD patients. The primary outcome was concordance between TST and IGRA. Secondary outcomes were effects of immunosuppressive therapy on both TST and IGRA. Immunosuppression was defined as either steroids more than 5 mg for at least two weeks, thiopurine, methotrexate or cyclosporine. We used the Mantel-Haenszel method for a pooled random effects model, given heterogeneity of studies included. We also compared the fixed effects model to exclude any effect of smaller studies. Heterogeneity between studies was analysed using the statistical I2, Q and Tau 2 tests. The quality of included studies was evaluated using a modified QUADAS-2 method.

Results: Sixteen studies, including 2488 patients with IBD, were included for the analysis. The pooled concordance between the TST and IGRA was 85% (95% confidence interval [CI] 81%-88%, p = 0.01). Effects of immunosuppression on both tests were reported in eight studies including 814 patients with IBD. The odds ratio of testing positive by TST if immunosuppressed was 1.14 (95% confidence interval [CI] 0.31–1.03, p = 0.06). The odds ratio of testing positive by TST if immunosuppressed was 1.09 (95% confidence interval [CI] 0.31–1.03, p = 0.06). The odds ratio of testing positive by TST if immunosuppressed was 1.09 (95% confidence interval [CI] 0.31–1.03, p = 0.06).

Conclusion: While concordance was 85% between TST and IGRA, the performance of IGRA seems to be negatively affected by immunosuppression. Given the importance of detecting latent TB prior to anti-TNF initiation, using only IGRA should be avoided in immunosuppressed IBD patients.

A. Ochieng. IS THE BEST METHOD TO MEASURE MEDICATION ADHERENCE? A284

Introduction: There is currently no accepted gold standard and the feasibility and utility of different adherence assessment tools in the routine outpatient clinic setting have not been fully examined. The aim of this service improvement project was to test the acceptability of self-report tools assessing thiopurine adherence in the IB clinic and to correlate the results with thiouguaine-nucleotide (TGN) levels.

Aims & Methods: Consecutive outpatients on thiopurine maintenance therapy for IBD for > 3 months were recruited from clinic. Patients self-reported adherence using three tools (drug usage scale (VAS), the validated Morsky adherence tool (MOR) and the validated Medication Adherence Report Scale (MARS)). TGN levels were classified as complete non-adherence (<100 and MMP low), partial adherence (TGN 100-235 and MMP low) or full adherence (>235 or MMP high). Correlation analysis was performed using Pearson tests.

Results: Of 100 approached patients none refused participation and TGN levels were available for 96. These included 38 women. Diagnoses were Crohn’s disease in 27, ulcerative colitis in 41 and 9 patients (25% with 5-ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant tool report tool 71% (TGN), 87% (VAS), 87% (Morsky) and 77% (MARS). VAS (Pearson 0.215; p = 0.005) and Morsky (Pearson 0.036; p = 0.001) correlated moderately with TGN, but MARS (Pearson 0.09; p = 0.39) did not. The patients who were non-adherent by TGN were detected by VAS in 3, Morsky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had lower TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morsky and 4 of 15 for MARS.

Conclusion: Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for routine use in all patients. TGN require a more invasive and expensive approach. Furthermore, TGN cannot detect “white coat adherence” (patients take medication only around appointments), which is the most likely explanation for normal TGN levels in patients reporting to be poorly adherent. Neither TGN nor self-report tools can be seen as the gold standard at present.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0357 IDENTIFICATION OF NON-INVASIVE BIOMARKERS TO DETECT ILEAL CEACAM6 OVEREXPRESSION AND ADHERENT ENTEROBACTERIA IN INFILTRATED ILEUM OF PATIENTS WITH ILEAL CD: RESULTS FROM THE CEALIVE MULTICENTER STUDY

Aims & Methods: Aims & Methods: We aimed to assess the correlation between the level of CEACAM6 in the ileal mucosa of CD patients with the presence of AIEC in the ileal mucosa. We used a prospective multicentre study (8 centers) to evaluate the expression of CEACAM6 in the ileum of CD patients and to correlate it with the presence of AIEC in the ileal mucosa.

Results: Overall, 102 patients were enrolled in the study (Table 1). 

Table 1: Baseline characteristics of the 102 CD patients included in the study.

Conclusion: Our study is the first to report the presence and impact of AIEC in CD patients and to demonstrate the potential of CEACAM6 as a minimally invasive biomarker of AIEC infection. We propose that CEACAM6 levels can be used as a screening tool to identify CD patients with a high risk of AIEC infection who could benefit from targeted treatments.
Ileal CEACAM6 level did not depend on disease severity or the site of biopsies, as the median level of ileal CEACAM6 was 854 pg/mg [570.9; 1646] and there was no difference in healthy or ulcerated zones (756 pg/mg [487; 1617] vs 947 pg/mg [604; 1820], p = 0.86). The median level of CEACAM6 from saliva was 3837 pg/ml [1889; 7338]. There was a positive correlation between the levels of CEACAM6 in saliva and CEACAM6 in the ileum (r = 0.47; p < 0.0001) in both macroscopically healthy areas (r = 0.53, p < 0.0001) and ulcerated areas (r = 0.39, p = 0.0082). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal CEACAM6 activity. Using a ROC curve (area under the curve (AUC) = 0.73), the cut-off value of 3800 pg/mg demonstrated the best performances to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9-90.6]) and positive predictive value (67.5% [74.9-95.3]). The number of enterobacteria was increased in CD patients with prior intestinal resection (562 [20164] vs. 116 [0;752] pg/mg, p = 0.03). Interestingly, the number of enterobacteria was also increased in AIEC positive-patients (640 [601029] vs. 60 [0;1029] pg/mg, p = 0.004). Using a ROC curve, we determined the best threshold of enterobacteria in the ileum to detect the presence of ileal AIEC bacteria. We found an area under the curve (AUC) of 0.70 (0.61; 0.77). The cut-off value of 60 cfu/biopsy demonstrated the best performances to detect the presence of ileal AIEC bacteria. The number of enterobacteria associated to ileal mucosa (cut-off value >60 cfu/biopsy) strongly predicted the presence of AIEC and then is a reliable test for AIEC screening with very high negative predictive value (94.1% [80.3-99.3]) and high sensitivity (91.7% [73.0-99.0]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-consuming and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identify that the number of enterobacteria associated to the ileum is a convenient and reliable test to screen CD patients for AIEC bacteria.

Introduction: Increasingly, immunosuppressive medications such as azathioprine and mercaptopurine are used in order to prevent relapse in inflammatory bowel disease (IBD) patients. It has been reported that such treatments increase the risk of developing all types of skin cancer. Education of these patients is key in order to promote their awareness of their increased risk and in particular gastroenterologists should counsel patients on sun protection strategies on initiating therapy. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician’s lack of knowledge was partly to blame.

Aims & Methods: Our aim was to determine Irish IBD clinicians’ knowledge of the skin cancer risk and advised photoprotective behaviours in this cohort. Cross-sectional descriptive study. We invited IBD clinicians via email to fill in an anonymous online survey designed to assess knowledge of skin cancer risk and prevention methods as recommended by the “Sunsmart” guidelines, as currently gastroenterology based guidelines are lacking. In addition their grade of training and clinical experience was noted.

Results: To date, 45 Irish Gastroenterology clinicians completed the online questionnaire. Of these, fifteen (33%) were consultants, fourteen (31%) gastroenterology trainees, four (9%) general medical trainees and twelve (27%) IBD nurse specialists. Overall, clinician’s knowledge of general factors associated with increased risk of skin cancer was reassuring; with all 45 (100%) knowing sun beds increased skin cancer risk and almost 100% (44, 98%) knew working outdoors incurred increased risk. 42 (93%) knew a personal history of skin cancer and previous blistering sunburn were risks; however, only 34 (79.1%) recognised family history as a risk. Regarding gender associated risk; only 67.4% (n = 29) knew men were greater risk than women of non-melanoma skin cancer (NMSC). Their knowledge of specific immunosuppressant risk was suboptimal; while many (37, 82%) recognized azathioprine was a risk factor for developing NMSC, only 22 (49%) knew anti-TNF treatments were strongly associated with an increased risk of malignant melanoma. Regards prevention strategies; the majority knew what changes to look for in a suspicious mole; 100% (n = 45) knew to be suspicious of changing color and 84% (n = 38) of an irregular border, but shockingly only five (11%) perform yearly skin checks on their patients on immunosuppressants. Their knowledge of preventative measures was also lacking; 37 (86%) knew patients should spf 50 but almost half (47% n = 20) thought it should be applied twice daily rather than two hourly (51% n = 23) and only 47% (n = 20) knew patients should stay in the shade from 11am-3pm. Regards their own practice; 39 (87%) report they emphasise the importance of sun protection in their patients; however, worryingly only 24 (55.8%) had heard of our national skin cancer prevention guidelines “Sunsmart”. Of interest; while physicians had a greater understanding of patient risk factors (p = 0.03), nurse specialists were more likely to emphasise the need for sunprotection in clinic (p < 0.0003), and of physicians, trainees had a more complete knowledge of all advised preventative measures (p < 0.03).

Conclusion: Our study highlights IBD clinicians’ suboptimal knowledge of immunosuppressant risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Association of serum S100A4 protein with UC and CD was confirmed. In CD, disease behaviour did not have impact on serum concentration of S100A4 protein. In CD, higher levels of serum S100A4 were observed in patients with ileo-colonic and colonic involvement compared to those with isolated small bowel involvement.

Introduction: Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may relate to severity of the disease.

Aims & Methods: The aim of the study was to determine the VitiD status in an Italian IBD cohort in relation to disease activity. Serum 25-hydroxyvitamin D was measured in 260 IBD outpatients, not supplemented with VitD (110 Crohn’s Disease (CD) and 150 Ulcerative Colitis (UC)); 145 males and 115 females; mean age 50.7±15 years), and compared to those of 205 healthy blood donors, matched by sex, age (+/-2 years) and month in which the blood sample was collected. VitD levels were correlated to C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Harvey Bradshaw Index (HBI) and Crohn’s Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.

Results: IBD patients were at higher risk of VitD deficiency (defined as ≤20 ng/ml) than controls (OR 4.5, 95%CI 2.9-6.9, p < 0.0001). Of 260 IBD patients, 156 (60%) had VitD deficiency, more often in CD than in UC (72.7% vs 48% respectively, p < 0.0001). Age ≤40 and ≥60 years, winter/spring season, CRP ≥0.5 mg/dL, ESR ≥20 mm/h, previous intestinal surgery and HBI ≥5 were significant risk factors for VitD deficiency. No differences were observed in relation to sex, smoking status, BMI, age at diagnosis, localization and behavior of disease, and need of steroids. There was a weak negative correlation between CRP values, HBI scores and VitD levels (R = –0.13, p = 0.037 and R = –0.26, p = 0.006 respectively).

Conclusion: VitD deficiency is significantly more common in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VitD deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0366 GASTRODUDENAL INFECTION IN PATIENTS WITH CROHN’S DISEASE – UPPER ENDOSCOPY ONLY IN SYMPTOMATIC PATIENTS?

Contact E-mail Address: mafalda_mp_sousa@hotmail.com

Introduction: The need for upper endoscopy in patients with Crohn’s disease (CD) without symptoms is controversial. The aim of this study was to establish the prevalence of gastroduodenal infection, regardless of symptoms, and its prognostic implications.

Aims & Methods: Patients from a single centre with established CD (n = 347) were retrospectively evaluated – inclusion criteria: upper endoscopy without treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, cryptic irregularity, erosion ulceration and granuloma in the absence of Helicobacter pylori (HP) infection).

Results: We included 140 patients - phenotype: 50% inflammatory, 31% strictureing and 19% penetrating; Location: 42% ileal, 45% duodenal and 13% colic. Upper endoscopy was performed in 19% for symptoms and in 81% for staging. Gastric macroscopic findings were detected in 49% (69/140); the most common were erosions (21%) and erthymematous mucosa (18%). Biopsies were performed in 56% of patients: chronic gastritis 66%, normal 23%, granuloma 5%, focal gastritis 2% and cryptic microabcess in 2%. HP was positive in 25% of patients. In the ileum, macroscopic lesions were detected in 24% of the patients; erosions (17%), granuloma 3% and erosion 3%. Applying macro/microscopic criteria, gastroduodenal involvement by CD was considered in 18% of the patients and was not correlated with the presence of symptoms, phenotype or localization of the disease. The prevalence of gastroduodenal involvement was a significant predictor of hospitalization.

Conclusion: The prevalence of gastroduodenal involvement by CD in this sample was 18%, and a larger percentage have macro/microscopic findings that are not disease specific. The presence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.

Contact E-mail Address: stack.roisin@gmail.com

Introduction: Small bowel (SB) Crohn’s disease (CD) strictures can be comprised of both inflammatory and fibrotic elements. An accurate tool to discriminate fibrosis and inflammation would be clinically useful to guide therapy and predict response. While the magnetic resonance index of activity (MaRIA) is a validated means to assess activity, to date, no specific tool has been developed to identify fibrotic from inflammatory disease. Lesions with a dense fibrotic margin exhibit delayed gadolinium enhancement on MRI. The role of delayed enhancement in assessment of SB CD strictures is unclear. Recent evidence suggests relative contrast enhancement (RCE) of >24% on delayed MRI sequences may accurately detect fibrosis.

Aims & Methods: To determine the feasibility of MRI SB stricture assessment with early (70s) and late (7mins) phase post gadolinium imaging comparing MaRIA, RCE and biochemical activity in patients with ideal CD. We performed a retrospective review of 208 consecutive MREs with known and suspected SBCD. MRE was performed as standard with additional coronal T1 sequences 7 minutes post gadolinium administration. Demographics, MRI findings and biochemical markers were recorded. Patients with stricture disease were further assessed. Two independent blinded Radiologists calculated RCE and MaRIA’s at 70 sec and 7 min.

Results: Median age 40.5 years; male n =83(39.9%), 117, 72 and 19 patients had known CD, suspected CD and indeterminate IBD, respectively. In total, 119(57.2%) MREs were normal. Ileitis, strictures and fistulas were found in 40(19.2%), 49(23.6%) and 10(5.1%) patients, respectively. While there was no difference in Hb between patient groups (Normal, Inflammatory and Stricture Disease); Albnum and CRP were statistically different between normal subjects and those with disease; albumin 42±2 g/L v 38.9±1 g/L in normal v stricture disease (p < 0.0181 95% CI -0.23 --0.02), CRP 8.8±3 g/L v 18.3±1 mg/L (p < 0.003 95% CI -0.46 --0.10) and v 29±mg/L (p < 0.002 95% CI -0.43 --0.11) amongst normal v inflammation and stricture respectively. Neither parameter could differ entiate between inflammatory and stricture disease. 26 MREs performed with ileal CD have been further assessed; median age =41 yrs, male =10(38%). RCE >24% and high T2 signal intensity (SI); 6/26 (23%) and 11/26 (42%). RCE increased in only 1/10 with a visible stenosis. Average MaRIA: 2/7 (7.7%) < 7 mm; 3/26 (11.5%) ≥11 moderate; 21/26 (80.7%) >11 severe. MaRIAs did not change significantly between 70 sec and 7 min. As expected T2 SI increased with MaRIAs; >11, ≥16 v 13 (p < 0.001, 95% CI 7.7–17.27). RCE did not correlate with MaRIs suggesting there is no a predictive factor for fibrosis. Consistent with MRE findings, CRP was higher in patients with MaRAl >11(13.3 ± 5.2) and lower in patients with RCE >24% (3.9 ± 14).

Conclusion: Unlike biochemical markers, MRI may be a useful means to differentiate between inflammatory and stricture disease. Further study is required to assess the long-term predictive value. RCE may be a useful adjunct to current MRI and help detect fibrosis in small bowel lesions and warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: A total of 520 patients who underwent CT enterography were identified, with median age of 42 years (range 17–79) and 52% were women. The main indication for CT enterography was CD staging (81%). A total of 351 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 59), hepatic cysts (n = 55) and saccular cysts (n = 46). The findings implicated orientations to another medical specialty in 80 patients (29%), the main ones being Urology (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); 1 suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

Conclusion: Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

P0368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE Carriage in Patients on IMMUNOMODULATOR for INFLAMMATORY BOWEL DISEASE

S.T. Law, W.M. Yip, K.K. Li

Department Of Medicine And Geriatrics, Tuen Man Hospital, Hong Kong/Hong Kong Pre

Contact E-mail Address: stl168@hotmail.com

Introduction: Clinical significance of asymptomatic Clostridium difficile (C. difficile) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

Aims & Methods: The aim of this study was to investigate the clinical implication of asymptomatic carriage of C. difficile in IBD patients.

Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013. Those cases were excluded if they had past history of total colectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate.

Stool specimen for C. difficile cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrollment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for C. difficile cytotoxin RT-PCR assay was obtained.

The primary outcomes were the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) and Ulcerative colitis Disease Activity Index (UCDAI) in ulcerative colitis (UC). The secondary outcomes were the proportion with asymptomatic carriage of C. difficile in IBD patients. The proportion with asymptomatic carriage of C. difficile was compared between the non-carriage and carriage groups in which all these flares were under-controlled by course of high-dose prednisolone.

The asymptomatic carriage group had a significant higher rate (33.33 vs. 7.45%, p = 0.007) and earlier onset (18.78 vs. 34.42 months, log rank p = 0.009). Mann-Whitney U, p 0.037) in evolving into clinical C. difficile infection as compared with the non-carriage group.

No other serious complications, such as toxic megacolon, colonic perforation, sepsis, and death, were reported in the both groups during the study period.

Clinical characteristics of the IBD patients with and without asymptomatic carriage of C. difficile

Introduction: Due to the relapsing and highly variable nature of ulcerative colitis (UC), it would be desirable to have reliable tools for measuring parameters of disease activity in order to monitor response to therapy and to detect relapse. In recent years it has already been shown that ultrasound is a useful tool to monitor the disease activity.1 The hypothesis of the TRUST&UC (TRANsabdominal UltraSonography of the bowel To monitor disease activity in subjects with Ulcerative Colitis) study is that transabdominal US is an easy to use, easily repeatable, and accurate diagnostic tool in the assessment of UC activity, in monitoring the disease course, and response to therapy.

Aims & Methods: TRUST&UC is a German ongoing prospective, observational multi-center study in patients with active UC. The primary objective of this study is the prospective evaluation of bowel wall US in response to therapy in order to assess its value in monitoring UC patients in routine medical practice. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity.

Results: 176 patients with active UC have been enrolled in 37 German IBD study group (GISG) centres until February 2017. 47.2% of the patients were female, median age was 38.9 years (range 19–77) with median disease duration of 152.2 days (range 0–1017). Of all the patients with a clinical flare defined by SCCAI >450: severe/fulminant) and Ulcerative colitis Disease Activity Index (UCDAI) >150: remission; 150–450: mild; 450: moderate-severe; and UCDAI >750: severe flare.

stratification was the case in 20.6% of the patients, as well as the easy accessibility of the monitoring program are crucial 

stratification was the case in 20.6% of the patients, as well as the easy accessibility of the monitoring program are crucial

P0371 SELF-MONITORING OF THE COLONIC INFLAMMATORY BOWEL DISEASE BY A RAPID HOME BASED FEACCAL CALPROTECTIN TEST AND A SYMPTOM QUESTIONNAIRE

A. Puolanne1, M.A. A. Färkkila1, K. Kolho2

1 Clinic Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland

2 Pediatric Gastroenterology, University of Helsinki Childrens Hospital, Helsinki/Finland

Contact E-mail Address: anna-maija.puolanne@hus.fi

Introduction: Feaccal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease (IBD) and commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-monitoring and eHealth technologies have been evaluated in managing patients with this life-long disease.

Aims & Methods: The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. The patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

Results: By the end of February 2017, 134 of the 180 included patients had completed the 12 months’ follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 14/91(15%) patients for 12 months. In the control group, 14/89 (16%) patients had filled in the symptom score at baseline and at 12 months. There was a significant difference of the adherence between patients stratified for IBD-diagnosis, age, or sex. The satisfaction of the patients with the program as well as the reasons for the discontinuation of the study and influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic was evaluated in both groups.

Conclusion: The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

P0373 CAN WE PREDICT THE LACK OF RESPONSE TO CYCLOSPORINE AS SECOND LINE THERAPY IN PATIENTS WITH ACUTE SEVERE COLITIS REFRACTORY TO CORTICOSTEROIDS?

Gastroenterology, University Hospital Sahloul, Sousse/Tunisia

Contact E-mail Address: aya_med@hotmail.fr

Introduction: Acute severe colitis (ASC) is a dangerous clinical condition that requires intensive intravenous (iv) corticosteroids treatment. Nevertheless, about 30-40% of patients fail to respond. Intravenous cyclosporine is an effective rescue therapy in steroid-refractory patients.

Aims & Methods: The aim of our study was to identify the clinical and biological predictive factors of lack of response to cyclosporine as second-line therapy in patients with ASC refractory to iv corticosteroids.

Results: Our study included 52 females and 38 males, with a mean age of 35 years (14-70 years). There were 34 patients with Crohn’s disease and 56 diagnosed with ulcerative colitis. Among the 90 patients enrolled, 68 patients (75.5%) had a good response to cyclosporine. Eleven patients were non responders and underwent second option treatment. A multiple linear regression analysis, more than 6 bloody stools per day before initiation of cyclosporine therapy, a C-Reactive Protein (CRP) greater than 45 mg/l prior to treatment, and at day 3 and 7 of treatment by ciclosporine (p = 0.007; 0.02 and 0.01 respectively), ESR greater than 30 mm at day 7 of treatment (p = 0.05), thrombocytosis at day 3 of treatment (p = 0.05), a Lichtiger colitis activity index scoring greater than 10 at day 3 of treatment (p = 0.001) and the need for blood transfusion (p = 0.0001) were significantly correlated with the lack of response to cyclosporine therapy. In a multiple linear regression analysis, only a CRP greater than 45 mg/l on day 7 of treatment, and the necessity of transfusion were predictive factors of no-response to cyclosporine (p = 0.008).

Conclusion: Cyclosporine therapy is rapidly effective in preventing surgery in patients with ASC with a response rate of 75.5%. A high CRP on day 7 of treatment with cyclosporine and the need for transfusion, predispose to poor response to intravenous cyclosporine.

P0374 CHANGES IN THERAPEUTIC STRATEGY AND OUTCOMES IN NEWLY DIAGNOSED PATIENT WITH CROHN’S DISEASE IN THE BIOLOGICAL ERA IN HUNGARY: A NATIONWIDE STUDY BASED ON THE NATIONAL HEALTH INSURANCE FUND DATABASE

11st Department Of Medicine, Semmelweis University Faculty of Medicine 1st Department of Medicine - 1st Department of Semmel, Budapest/Hungary
2Strategic Analysis Department, National Health Insurance Fund (OEIp), Budapest/Hungary
31st Department Of Medicine, Semmelweis University, Budapest/Hungary

Contact E-mail Address: zsuzsa.kurti@gmail.com

Introduction: Accelerated treatment strategy, including tight disease control and immunosuppressive therapy with non-steroidal immunomodulators (IM) and biological agents have become increasingly common in IBD.

Aims & Methods: The aim of the present study was to estimate the early treatment strategy and outcomes in newly diagnosed patients with Crohn’s disease (CD) diagnosed between 2004-2015 in Hungary based on the administrative database of the National Health Insurance Fund (OEIP). We used the administrative database of the National Health Insurance Fund (OEIP), the only nationwide state-owned health insurance provider in Hungary. Newly diagnosed CD patients were identified through a previously reported algorithm using ICD-10 LOINC codes for Crohn’s disease in the out-, inpatient, medical, surgical non-primary care records and drug prescription databases between 2004-2015. Patients were stratified according to the year of diagnosis and maximum treatment step during the first 3 years after the diagnosis.

Results: A total of 6173 (male/female: 46.12%/53.87%) newly diagnosed CD patients were identified during the observational period. Maximum treatment steps did not differ in patients diagnosed before and after 2009 (5-ASA: 11.7% vs. 11.5% p = 0.81, 5-ASA + anti-TNF: 64.0% vs. 63.5% p = 0.81, 5-ASA + anti-TNF: 30.5% vs. 30.5% p = 0.81). The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAG group than ST group.

In patients with intraepithelial neoplasia (IEN) or submucosal lesions, flat lesion was found in 15 lesions of CAG group and whereas no flat lesion was observed in ST group. The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAG group than ST group. The percentage of advanced cancer in 15 lesions of CAG group was found in 15 lesions of CAG group whereas no flat lesion was observed in ST group. The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAG group than ST group.

Conclusion: Most sporadic lesions were endoscopically distinct and local resection was safe if inflammation was controlled. After the sporadic lesions were resected in remitting UC patients, regular surveillance colonoscopy is necessary for the follow-up. In CAG group, 50, 5, 4 patients received total colectomy, local colectomy, EMR and polypectomy, respectively.

Contact E-mail Address: chuevana@mail.ru

Introduction: Numerous studies have shown that mesenchymal stromal cells (MSCs) have a high potential for differentiation and immunosuppressive properties. Currently under phase I and II clinical trials evaluating the efficacy and safety of MSCs in the treatment of patients with inflammatory bowel disease - ulcerative colitis and Crohn’s disease.

Aims & Methods: We aimed to compare the frequency of relapses and duration of remission for 5 years of follow up in patients with luminal Crohn’s disease (CD) and the total defeat of ulcerative colitis (UC) receiving therapy with mesenchymal stromal cells (MSCs), bone marrow. We compared the frequency of relapses in patients with luminal form of disease and patients with UC (total lesion) receiving MSCs. A group of patients (CD) aged 22 to 56 years (Me-28) (n = 47 cases) and 55.7% (n = 47 cases) p = 0.000; 5-ASA: 32.6% vs. 26.7% p = 0.157), respectively. In contrast, surgery rates were not different according to the maximum treatment step (at 36-30 day period: overall 16.0% vs. 15.5% (p = 0.672) anti-TNF 26.7% vs. 27.2% (p = 0.993), IS: 24.1% vs. 22.2% (p = 0.565), steroid 8.1% vs. 7.9% (p = 0.896), 5-ASA 10% vs. 11% (p = 0.816).

Conclusion: Distribution of maximal treatment steps and surgery rates were not significantly different, suggesting that maximal treatment steps can be used as proxy marker of severity in CD. Hospitalization rates during the first 3 years after the diagnosis decreased in all treatment groups, suggesting a change in the patient management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0378 EFFICACY AND SAFETY OF RECTAL 5-AMINOSALICYLIC ACID VERSUS CORTICOSTEROIDS IN ACTIVE DISTAL ULCEERATIVE COLITIS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS
X. Zhao, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China
Contact E-mail Address: zhaox917@163.com
Introduction: Ulcerative colitis (UC) is characterized by diffuse and continuous inflammation of the colon. Currently, the etiology and pathogenesis remain unclear. According to a previous epidemiological study, approximately 75% of newly diagnosed UC patients have active distal UC. Topical 5-aminosalicylic acid (5-ASA) and corticosteroids are used frequently in the treatment of active distal UC.
Aims & Methods: Our study aimed to determine the efficacy and safety of different topical drugs used to treat active distal UC. A random-effects model within a Bayesian framework was utilized to compare treatment effects and safety as odds ratios (ORs) with corresponding 95% credible intervals (CrI). The surface under the cumulative ranking area (SU CRA) and median rank (MR) with corresponding 95% CrI were calculated to rank the treatment outcomes.
Results: In the induction of clinical and endoscopic remission, most regimens showed significant advantages over placebo except topical budesonide 0.5 mg/d and hydrocortisone 100 mg/d. According to SU CRA and MR values, rectal 5-ASA 1.5 to 2.0 g/d + Beclomethasone dipropionate (BDP) 3 mg/d rendered the probability of being the best regimen to achieve clinical and endoscopic remission, followed by the separate use of 5-ASA 4 g/d and BDP 3 mg/d. The occurrence of adverse events was not significantly different between each treatment and placebo.
Conclusion: In conclusion, the combined use of topical 5-ASA and BDP proved to be the first choice for active distal UC and further well-designed researchers are warranted to assess its efficacy and safety.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Mesenchymal stromal cells (MSCs) are used for the treatment of chronic inflammatory and autoimmune diseases in recent years, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). In most cases, topical treatment with the use of bone marrow containing immunosuppressive mesenchymal stem cells is not sufficient to achieve complete control of disease activity. It is found that immunomodulatory drugs (azathioprine (AZA), methotrexate, 6-mercaptopurine, infliximab (IFP)), regardless of the concentration, do not affect the viability, differentiation, phenotype, and ability to inhibit proliferation of MSCs's progeny. However, studies conducted by Huang HR et al. demonstrate that IFP rendered minimal impact on the MSC proliferation, apoptosis and cell cycle, while azathioprine inhibited cell proliferation and induced apoptosis of MSCs in vitro [2].
Aims & Methods: The aim of the study was to evaluate the effectiveness of therapy mesenchymal stromal cells (MSCs) from the bone marrow of patients with Crohn's disease (CD) receiving azathioprine. 34 patients with inflammatory (luminal) form CD were divided into two groups. The first group of patients aged 19 to 58 years (n=29) were receiving anti-cytokine therapy with MSCs culture in combination with AZA. The second group of patients (n=1) aged 26 to 50 years (Me-31) received MSCs according to the recommended scheme without AZA. To assess the effectiveness of anti-inflammatory therapy was carried out after 2 months of therapy, field localization of the level of IL-6, TNF -α, IFN-γ, IL-1β and IL-18 in 24-hour serum samples 24 hours after the last injection of therapy.
Results: In the 1st group of patients receiving MSCs treatment, IL-6, TNF-α, IL-1β, IL-18 and IFN-γ were significantly lower compared to the placebo group (p<0.05). After 2 months of therapy MSCs level of IL-6, TNF-α, IL-18 and IFN-γ was significantly decreased (from 10.1 ± 0.8 pg/ml to 5.7 ± 0.6 pg/ml, from 7.0 ± 0.7 to 4.9 ± 0.6 pg/ml, from 6.3 ± 0.5 to 4.9 ± 0.4 pg/ml, and from 5.6 ± 0.7 to 4.2 ± 0.5 pg/ml, p<0.05). In the 2nd group, there was no significant difference in the level of these cytokines compared to the baseline (p>0.05).
Disclosure of Interest: All authors have declared no conflicts of interest.

In addition to the V565 concentrations in ileal fluid, partially dissolved MTs were recovered from the ileostomy bags of all subjects. Each 1665 mg dose contained a total of 135 MTs. 50 MTs were recovered 2h post dose from Subject 31001; these were not analysed for V565 as this was a post hoc analysis and the MTs were not stored in a way to enable reliable analysis. 64MTs (containing 135 mg V565) were recovered 3h post dose from subject 31002; 78MTs (458 mg) 3h post dose from subject 31004. The recovery of V565 to lesions distal to the ileum. This profile may patients with no ileostomy the partially dissolved MTs seen in this study are expected to provide active V565 to lesions distal to the ileum. This profile may be effective for IBD and merits further investigation as a potential oral treatment.

References: For subjects with an ileostomy (3 with 1; with a prior history of colonic obstruction) were given a single 1665 mg dose of V565. The dose was selected based on the prior demonstration of safety and tolerability of this dose and the likely maximum daily dose for initial clinical efficacy assessment. High concentrations of active V565 were demonstrated in the ileal fluid of all four subjects as shown in Table 1 below.

In the V565 concentrations in ileal fluid, partially dissolved MTs were recovered from the ileostomy bags of all subjects. Each 1665 mg dose contained a total of 135 MTs. 50 MTs were recovered 2h post dose from Subject 31001; these were not analysed for V565 as this was a post hoc analysis and the MTs were not stored in a way to enable reliable analysis. 64MTs (containing 135 mg V565) were recovered 3h post dose from subject 31002; 78MTs (458 mg) 3h post dose from subject 31004. The recovery of V565 to lesions distal to the ileum. This profile may be effective for IBD and merits further investigation as a potential oral treatment.

objectively evaluated by the IBD validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACT-F).

Aims & Methods: The main objective was to assess the efficacy of electroacupuncture (EAc) vs. sham EAc and no treatment for treating fatigue in patients with quiescent IBD in a single-blind randomized study. Secondary objectives were to assess changes in quality of life, depression, anxiety and sleepiness after treatment with EAc.

Methods: Fifty-two patients with quiescent IBD and severe fatigue (FACT-F < 40) (63.5% female, mean age 42 years) were randomized to EAc vs sham acupuncture group. Patients in the EAc EAc group performed a total of 9 acupuncture sessions during eight weeks (2 sessions/first week and one session per week during and after the treatment period).

Results: Both EAc and Sham group improved the FACT-F score post-treatment (EAP -9.53 points, 95% CI [-12.3 to -6.75, Basal Vs 9th session p < 0.001]; Sham -9.76 to -2.18, Basal Vs 9th session p = 0.003). Depression (8.95 points, 95% CI [4.13 to 13.8, Basal Vs 9th session p = 0.002], anxiety (10.6 points, 95% CI [3.6 to 17.6, Basal Vs 9th session p = 0.006) and sleepiness (3.46 points, 95% CI [0.096 to 2.83, Basal Vs 9th session p = 0.038). However, the differences in between EAc and sham and control groups were not significant (p > 0.05).

Conclusion: Both targeted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD.

References

Aims & Methods: We aimed to determine the efficacy of systemic or low bioavail-ability oral steroids in treating moderate to severe Remission (P<0.001) and for patients with and without prior ADA experience were allowed to enroll. The final long-term follow-up population of 89 steroid treatment patients (with at least 6 months of immunosuppressive treatment, and describe long-term follow-up of Inflammatory bowel disease (IBD) immunosuppressed patients (thiopurines or methotrexate) from our population-data registry were analyzed. For statistical analysis, Chi-square test, U Mann-Whitney test and Kaplan Meier survival analysis were used.

Results: 392 IBD patients with a median of 82 (6-271) months of immunosup-pressive (IMM) treatment were identified (table 1). 89 patients (23%) (33% UC and 66% CD) needed at least one steroid treatment during follow-up (63% systemic steroid and 37% low bioavailability oral steroid) with a median time of steroid treatment of 4 (1–168) months. Average time from IMM to steroid treatment was 26 (6–207) months. In IBD patients there were no differences regarding sex, age, disease, location, perianal disease, extra intestinal manifesta-tions, appendectomy, smoke habit, need for steroids at diagnosis and previous abdominal surgery between patients with no need of steroids and patients with steroid treatment during follow-up. In CD patients, biological treatment for perianal disease before IMM (p=0.0039) and fistulizing (B2) or fissuring (B3) behavior (p=0.005; OR 2.284) were risk factors for using steroids after IMM treatment. In UC patients, no statistically significant variables were iden-tified. 49 of these 89 steroid treatment patients (55%) needed biological treatment or surgery after a median of 13 months (0–178); 19 (21%) needed more than one steroid treatment (2–5) and just 31 patients (35%) did not need any other treat-ment. CD patients had higher risk (p=0.007; OR: 3.529) to receive biological treatment or surgery versus UC patients. Otherwise, the more months using steroids in UC patients, the greater risk for biological or surgery treatment (p=0.009). During follow-up, though it’s not statistically significant (p=0.078), we observe that 75% probability of rescue treatment for UC patients is 62 months compared to 36 months for CD patients. Conclusion: 23% of IBD immunosuppressive patients needed at least one steroid treatment after 6 months of IMM. Previous biological treatment and B2-B3 behavior predicted steroid treatment in CD patients, who had 3.5 times more risk to receive biological treatment or surgery after steroid treatment using it earlier than UC patients. Just 1/3 of patients who needed steroid treatment after IMM did not need any other rescue treatment.

Introduction: PYRAMID was an international multi-center non-interventional postmarketing registry assessing long-term safety and effectiveness of adalimumab (Humira® [ADA]) as used in routine clinical practice. Patients with and without prior ADA experience were allowed to enroll. The final long-term effectiveness of ADA is reported in adult ADA-naive patients (those who had not received ADA before registry enrollment) with moderate to severe Crohn’s disease (CD) who were treated according to the local product label.

Aims & Methods: All patients entering the registry were followed for up to 6 years. Effectiveness of ADA was measured using Physician’s Global Assessment (PGA; [a composite of Harvey Bradshaw Index and rectal bleeding score]), Short Inflammatory Bowel Disease Questionnaire (SIBDQ), and 4 components of the Work Productivity and Activity Impairment (WPAI) questionnaire, including absenteeism, presenteeism, overall work impairment, and activity impairment. Effectiveness measures, captured in all patients who received at least 1 dose of ADA in the registry and had at least 1 post-enrollment measurement, were summarized descriptively by the number of observations that were not missing at each registry visit; data were reported as observed. Values at enrollment are considered as baseline values.

Results: Among 5025 patients evaluated in the registry, 2057 (40.9%) were ADA-naive. Of these, 1199 patients (58.3%) were female; mean age 37.1 years at enrollment. Mean ± SD ADA exposure for the ADA-naive subgroup during the registry was 1118.5 ± 842.3 days. A total of 1082 patients (52.6%) had prior exposure to at least 1 anti-TNF/biologic; 853 (41.5%) and 831 patients (40.4%) used immunomodulators and corticosteroids, respectively, at enrollment. Mean change from baseline in effectiveness measures for patients with CD is shown in the table. Mean PGA score and SIBDQ as well as WPAI domains improved in ADA-naive patients from enrollment to 1 year and were sustained for up to 6 years (table). No new safety signals were identified in the registry.

Conclusion: At 1 year after entering the international postmarketing registry of ADA use in routine clinical practice, clinically meaningful improvements in disease activity, work productivity, and activity impairment were achieved in ADA-naive patients with moderately to severely active CD. These improvements were maintained for up to 6 years of the registry among the patients who remained in the study.

**Introduction:** Adalimumab (ADA) has been shown to improve clinical outcomes among patients (pts) with moderate to severe ulcerative colitis (UC) in a clinical practice setting. Evidence is limited about benefits of ADA among UC pts with different characteristics.

**Aims & Methods:** The aim was to examine clinical and pharmacoeconomic effects of ADA in pts with UC based on disease severity and prior use of tumour necrosis factor inhibitor (TNFI). InspiraADA details have been presented. Pts received ADA 160/80 mg at week (wk) 0/2 followed by ADA 40 mg eow at wks 4 through 26. Pts who did not respond to ADA by wk 8 were to discontinue. Pts who lost response at or after wk 8 could escalate to ADA 40 mg weekly. UC pts were categorized into subgroups based on physician global assessment (PGA) of disease severity (moderate [baseline PGA = 2] vs severe [baseline PGA = 3]) and previous TNFI use (naïve vs experienced). Proportions of pts with Simple Clinical Colitis Activity Index (SCCAI) response (defined as a decrease of ≥2 points vs baseline) and remission (defined as an SCCAI ≤2) were calculated for each cohort at wks 2, 8, 16 and 26. Change from baseline in HRQoL outcomes was calculated for each cohort at wks 2, 8 and 26. Change in Remission rate was associated with greater disease control in the induction period for pts with moderate than severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs.

**Conclusion:** ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs. Additional funding: AbbVie participated in the interpretation of data, review, and approval of the abstract. All authors contributed to the development of the publication and maintained control over the final content.

Cmax ranged from 5016.4 to 14253.6 h*ug/mL and 10.0 to 23.1 ug/mL, respectively. The pharmacokinetic (PK) profile of SC and IV formulation was evaluated by measuring the AUC0-last, which was followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC0-tmax, Cmax, Tmax, and T1/2.

**Results:** A total of 38 male subjects with median age of 23 years (range 19, 30 years) were treated emergent serious adverse events or systemic hypersensitivity reaction. In SC cohort, two subjects experienced mild injection site reactions, and both have resolved without any treatment. Mean AUC0-tmax and Cmax ranged from 5016.4 to 14253.6 h*ug/mL and 10.0 to 23.1 ug/mL, respectively, after a single SC injection of CT-P13. SC Cmax formation was absorbed slower into the systemic circulation (median Tmax ranging from 7.0 to 7.1 days) in comparison with IV formulation (median Tmax ranging from 2.2 to 3.2 hours) but the drug elimination measured by half-life (T1/2) was similar (mean range 11.3 to 12.2 hours) between SC and IV formulations, respectively. Bioavailability of CT-P13 SC was approximately 60.6%, when comparing across all CT-P13 SC cohorts to CT-P13 IV cohorts.

**Conclusion:** PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.
Disclosure of interest: All authors have declared no conflicts of interest.

PO390 CLINICAL RESPONSE TO VEDOLIZUMAB IN IBD PATIENTS IS ASSOCIATED WITH THE CONCOMITANT USE OF IMMUNOMODULATORS

I. Parisi, R. Vega, L. Whitley, S. Bloom, S. Mccourtney
Gt Medicine, University College London Hospitals, London/United Kingdom

Contact E-mail Address: ioannparis@hotmail.com

Introduction: The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn’s disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naive patients. Multivariate analysis searched for factors associated with response to treatment.

Aims & Methods: All patients with IBD who received at least three doses of Vedolizumab in UCLH since the drug was officially licensed in the UK were included in the study. Demographics, clinical and endoscopic response rates were recorded and analysis was conducted in the whole cohort and in the subgroups of Crohn’s and UC patients separately. Univariate analysis and logistic regression were conducted in order to identify important associations with clinical and resp

Results: 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn’s disease and the majority (n = 43, 73%) had mainly colonic inflammation (12 colonic Crohn’s, 29 UC, 2 IBDU). Median time from diagnosis to Vedolizumab initiation was 8 years. 17 (29%) were anti-TNF naïve (all UC) and 28 (67%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either a thiopurine or methotrexate. 95% (56/59) of patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline ≥3 points for Crohn’s patients or a reduction of partial Mayo score ≥2 points for UC patients. The rates of response were similar in Crohn’s and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95%CI 0.07–0.91, p = 0.0056). The two minor allergie reactions and two mild inflections.

Conclusion: Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn’s disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lymphocytic colitis (LC) is a common cause of chronic, non-bloody diarrhea. Budesonide has been shown to be effective in a few small case reports. Mesalazine has been proposed as a treatment option but no placebo-controlled trials have been reported. Thus, we performed a placebo-controlled, multicenter study to evaluate budesonide and mesalazine as induction treatments for lymphocytic colitis.

Aims & Methods: Patients with active lymphocytic colitis were randomly assigned to either budesonide 9 mg once daily or mesalazine 3 g once daily, or placebo for 8 weeks in a double-blind, double-dummy design. The primary endpoint was clinical remission defined by the Hauptschwelle-Criteria (1). Secondary endpoints included histopathology and safety.

Results: Based on an interim analysis the trial was stopped in accordance with the pre-specified adaptive design. The final analysis included 57 patients (19 per treatment group). Most patients were female (72%) and mean age was 59 years. The proportion of patients in clinical remission at week 8 was significantly higher in the budesonide group than in the placebo group (intention-to-treat (ITT) 79% vs 42%; p = 0.001). The difference in clinical remission at week 8 between mesalazine (63%) vs placebo failed statistical significance (p = 0.09).

The proportion of patients with histological remission at week 8 was higher with budesonide (68%) than with mesalazine (26%; p = 0.02) and placebo (21%; p = 0.008). The rate of adverse events did not differ among groups.

Conclusion: Oral budesonide 9 mg once daily is highly effective and safe for induction of clinical and histological remission in lymphocytic colitis, whilst oral mesalazine 3 g once daily was only numerically, but not statistically significantly better than placebo.

Introduction: Granulocyte and monocyte adsorptive apheresis (GMA) has been shown to be effective and safe in patients with inflammatory bowel disease (IBD). We report an interim analysis of a post-marketing surveillance study of granulocyte and monocyte adsorptive apheresis using Adacolumn® for patients with inflammatory bowel disease who have special situations (PARTICULAR).

Aims & Methods: The aim of the PARTICULAR study was to assess the safety and efficacy of GMA treatment in patients with IBD who have special situations. This study was an interim analysis of the multi-centre observational study conducted at 80 institutions in Japan. Data were collected from patients with ulcerative colitis (UC) or Crohn’s disease (CD) who received GMA between November 2013 and September 2016. Patients who had at least one special situation were included in the study. GMA was performed using Adacolumn® (JIMRO, Takasaki, Japan). Each patient received up to a maximum of 11 GMA sessions. Safety assessments were performed on all patients in this study. All adverse events (AEs) during the study period were recorded. AEs for which the causality of GMA could not be ruled out were defined as side effects (SEs). Feasibility problems (FPs) included blood withdrawal difficulty, venous pressure elevation, coagulation in the apheresis system and venous access difficulty. The safety of GMA was investigated in the following six special situation subgroups: the elderly (≥65 years), concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia (haemoglobin <10 g/dl), paediatric (<18 years) and other groups. We also compared AEs, SEs and FPs between the subgroups with/without each special situation by univariate analysis. The efficacy of GMA was also assessed in patients with UC. Patients with a partial UC disease activity index score (pUC-DAI) of <3, those with missing pUC-DAI scores and those receiving concomitant treatment with infliximab, adalimumab, tacrolimus or cyclosporine were excluded from efficacy assessment. pUC-DAI scores were calculated at the baseline and then after the final GMA session or when GMA therapy had to be discontinued because of AEs or FPs. Remission was defined as a pUC-DAI score of ≤2 with no individual sub-score exceeding 1 point. Patients who received additional treatment by the final GMA session, including infliximab, adalimumab, tacrolimus and cyclosporine, were considered non-responders to GMA.

Results: This study included 363 patients (304 UC, 59 CD). Among these patients, SEs and FPs were observed in 3.0%, 10.7% and 16.3% of the patients, respectively. There were 105, 112, 83, 43 and 39 patients in the elderly, concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia, paediatric and other groups, respectively. The incidence of AEs was significantly higher in patients on multiple concomitant immunosuppressants compared with those not receiving them. Likewise, the incidence of AEs was significantly higher in patients of the anaemia group compared with patients with haemoglobin ≥10 g/dl. The incidence of FPs was significantly lower in patients of the retreatment group with GMA group than in those who did not receive GMA for initial treatment (Table 1). The efficacy of GMA was assessed in 209 UC patients. The numbers of patients administered prednisolone, infliximab, adalimumab, tacrolimus and cyclosporine were 24, 6, 3, 6 and 1, respectively. The mean pUC-DAI score significantly decreased from 6.2 at baseline to 3.4 after the final GMA session (P<0.001) and the remission rate at the final GMA session was 43.5%.

Conclusion: This multi-centre observational study showed that GMA has an acceptable safety profile in IBD patients and sufficient effectiveness in UC patients who have special situations. However, care should be taken when GMA is used in patients with anaemia or those who have received concomitant treatment with multiple immunosuppressants.

References
state-wide hospital records. Psychological support was offered where scores on HADS and/or K6 indicated likely need.

**Results:** 500 patients were approached during the 12-month screening phase; 50.6% were male. 70.8% of all screening patients were women in patients with IBD, mean disease duration of 11 years, 43.3% in clinical remission, and 9.8% current smokers (Australia’s average 13.3%). Of these, 500, 67% participated in psychological screening, 38% scored within the clinical range, and 17% accepted psychological support. Gender was a significant predictor of participation in psychological screening; women were 62% more likely to participate than men. Analgesics and/or mental health medication increased the likelihood of scoring within the clinical range nearly fivefold (analgesic use OR = 5.32, p = .030; psycho OR = 6.94, p = .001). Significant predictors of accepting psychological treatment included older age (OR = 1.03, p = .041), anxiety (OR = 1.09, p = .045), general distress (OR = 1.11, p = .003) and lower quality of life (OR = 0.93, p = .042). At baseline, anxiety and depression were both negatively correlated with medication adherence (anxiety r = -0.32, p = .000; depression r = -0.20, p = .000) and overall quality of life (anxiety r = -0.78, p = .000; depression r = -0.78, p = .000). Depression and general distress were related to overall healthcare utilisation (depression r = -0.131, p = .005; general distress r = -0.124, p = .026). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of emergency department presentations (r = -0.124, p = .024), outpatient appointments (r = -0.119, p = .030), and appointment cancellations (r = -0.155, p = .005). Currently, approximately half of the twelve month follow-up data has been collected. Preliminary analysis shows improvements for patients’ mental health, quality of life and medication adherence (see table below).

*p < .05, **p < .01, ***p < .001

**Conclusion:** Psychological issues are prevalent in patients with IBD and associated anxiety, depression, and mental illness medication adherence are more likely to participate in psychological screening, and in general the screening procedure was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

**Introduction:** Demonstration of biosimilarity is based on the evaluation of pharmacological, biological, preclinical, and clinical data. Based on this totality of evidence, a biosimilar may be approved for use in the same indications for which the reference medicine is approved without conducting a clinical trial in each indication. A prerequisite for this extrapolation is clinical confirmation of biosimilarity in a patient population sensitive enough to detect potential differences in efficacy, safety, or immunogenicity between the proposed biosimilar and the reference medicine. GP2017, a proposed biosimilar to adalimumab, was evaluated in a phase III confirmatory study to confirm its non-inferiority against adalimumab as a treatment for plaque psoriasis.

**Aims & Methods:** To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients with moderate-to-severe chronic plaque psoriasis were randomized to receive an initial dose of 80 mg subcutaneous GP 2017 or reference adalimumab, followed by 40 mg every other week, starting one week after the initial dose, up to 17 Week. At Week 17, patients with ≥50% improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial study treatment or undergo a sequence of three treatment switches between GP 2017 and reference adalimumab until Week 51. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

**Results:** From randomization to Week 51, 168 and 171 patients received continuous treatment with GP 2017 or reference adalimumab, respectively. In the per-protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 51 were 75.2% vs 67.8%, respectively (p = 0.015). Investigator’s global assessment (IGA) response rates (IGA score of 0 [clear] or 1 [almost clear] and ≥2 point improvement from baseline) were also similar between the continual GP2017/reference adalimumab groups, increasing over time and remaining stable from Week 17 (60.0% [53.9%] to Week 51). Results: From the randomization to Week 51, 168 and 171 patients received continuous treatment with GP 2017 or reference adalimumab, respectively. In the per-protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 51 were 75.2% vs 67.8%, respectively (p = 0.015). Investigator’s global assessment (IGA) response rates (IGA score of 0 [clear] or 1 [almost clear] and ≥2 point improvement from baseline) were also similar between the continual GP2017/reference adalimumab groups, increasing over time and remaining stable from Week 17 (60.0% [53.9%] to Week 51).

**Contact E-mail Address:** iago.r.lago@gmail.com

**Introduction:** Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processing 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.
Aims & Methods: We performed a retrospective study of all patients treated with GMA (Adacolumn) in 3 IBD Units in Spain. The clinical and analytical data were assessed before and 1 month after the end of the GMA. The Ethics Committee of Euskadi approved the study protocol. The aim of our study was to evaluate the presence of clinical, analytical of technique-related factors associated to a better response to GMA.

Results: A total of 105 patients were included [51 female (49%), age 35.7 (SD 16.5)]. Ninety-three had UC (50% extensive, 45% left-sided), 10 Crohn’s disease (90% ileocolonic) and 2 IBD-U. Mayo score at baseline was 3.5 (SD 4.6) and Harvey – Bradshaw was 10.1 (SD 3.8). The Mayo endoscopic subscore was 1 (16%), 2 (56%) or 3 (23%). Almost all patients (97%) have been previously treated with steroids and 42% were exposed to biologics. At baseline, 85% were on steroids, 38% thiopurines and 18% biologics. None of the previous or concomitant treatments were associated with a better response to GMA. Fifty-six subjects received weekly sessions for 5 weeks processing 1800 ml/session in 60 minutes. Forty patients received an intensive GMA regimen: biweekly sessions with a mean of 8 sessions (SD 2.6), processing 888 ml/session (SD 1729) and lasting 1 hour (SD 24). The intensive group showed a slightly higher response rate to GMA as compared with those in the standard regimen (response rate 67% vs 55%, p = 0.28). Those subjects treated with > 5 sessions showed higher remission (24% vs 13%) and response rates (47% vs 24%) as compared to < 5 sessions (p = 0.004). A mean duration of > 60 min/session also showed better results in terms of remission (22% vs 16%) and response (45% vs 27%) when compared to <60 min/session (p = 0.04). There was also a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond. Considering its clinical efficacy in this clinical practice study. Increasing the number of sessions or its length were associated with a better response to GMA. The mean platelet volume and the platelet to lymphocyte ratio could help to predict the response.

P0399 ANDECALIXIMAB (ANTI-MMP9) INDUCTION THERAPY FOR ULCERATIVE COLITIS: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED, PHASE 2 STUDY

Contact E-mail Address: wsandborn@ucsd.edu

Introduction: Elevated levels of matrix-metalloproteinase-9 (MMP-9) and its degradation products are detected in patients with active Crohn’s disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds and inhibits MMP-9. It was found to be safe in a phase 1 dose-ranging study in UC subjects, where it showed clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab in subjects with active Crohn’s disease (CD). Aims & Methods: This was a double-blind, randomized, placebo-controlled 8 week induction study in adult CD subjects with moderate to severe disease activity (defined as: CDAI total score 220-450, weighted PR2 score ≥11 [standard CDAI: weightings: abdominal pain 0-3 +7 plus mean number of daily stools ≥2] and SES-CD total score ≥6 or ≥4 score if disease limited to ileum and/or right colon or ulcer presence and size score ≥2). Subjects were required to have an inadequate response, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-α antagonist or vedolizumab. Subjects were randomized 1:2:2:2 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W), 150 mg andecaliximab weekly (QW). Centrally-read sigmoidoscopies/colonoscopies were performed at baseline and week 8. The primary outcome was EBS clinical remission, defined as an Endoscopic subscore of ≤1, rectal Bleeding subscore of 0, and ≥1 point decrease in stool frequency from baseline to achieve a subscore of 0 or 1. Results: A total of 165 subjects from 23 countries were enrolled. The percentage (confidence intervals) of subjects achieving EBS clinical remission was similar between subjects treated with andecaliximab Q2W, and placebo: 7.4% (2.1-17.9%), 1.8% (0.9-6.6%) and 7.3% (2.0-17.6%), respectively. Confidence intervals overlap for all groups and no single EBS component subscore appears to have driven the results. No concerning imbalances occurred between the treatment groups (Table 1).
The frequency of adverse events (AEs) was similar between the treatment groups: placebo (67.9%), 150 mg Q2W (60.4%), 150 mg QW (62.3%), 300 mg QW (69.8%). Consistent AEs included abdominal pain, nausea, fatigue, anemia, and pyrexia. One AE led to study discontinuation in the placebo group (1.6%) compared to 2 in the 150 mg QW group (3.8%) and in the 300 mg QW group (7.5%). Three serious AEs occurred in the placebo group (10.7%) compared to 1 in the 150 mg QW group (1.9%), 6 in the 150 mg QW group (11.3%) and 8 in the 300 mg QW group (15.1%). Frequency of arthralgia and musculoskeletal pain was similar or lower in adalimumab groups compared to placebo.

percentage of subjects achieving clinical response/remission and endoscopic response was similar between treatment groups (Table 1).

Conclusion: SC adalimumab was well tolerated, however, none of the treatment regimens demonstrated a treatment effect in subjects with CD.

P0401 TUBERCULIN SKIN TEST CONVERSION RATE IN INFAMMATORY BOWEL DISEASE PATIENTS RECEIVING ANTI-TNF ALPHA AGENTS

M. Fragkaki, A. Mpitouli, I. Dimas, G. Paspatis, K. Karmissis

Gastroenterology, Venizelion General Hospital, Heraklion/Greece

Contact E-mail Address: gpaspatis@gmail.com

Aims & Methods: Few data exist regarding the kinetics of this test during therapy. Thus, we investigate the conversion rate of PPD-TST in IBD patients under anti-TNFAlphal treatment. Anti-TNFalphal-treated IBD patients followed up in our centre with a baseline PPD-TST underwent a second one during therapy. Those with a positive PPD-TST either at baseline or during therapy (d ≥ 10 mm in naïve and d ≥ 5 mm in those exposed to immunomodulators [IMS]) received 300 mg isoniazid orally for 9 months.

Introduction: Anti-TNFalpha therapy increases the risk of tuberculosis (TB) (re-)activation in inflammatory bowel disease (IBD) patients. Purified protein derivative tuberculin skin test (PPD-TST) is considered a pre-requisite at baseline. Results: Sixty-eight IBD patients have currently been enrolled (males: 51.47%, Crohn’s disease: 82.35%). Median age at IBD diagnosis was 33.1 years [IQR: 26.4, range: 17–54]. Patients with PPD-TST: 44.26 months [IQR: 42.8, range: 6.3–190.1]. Twenty patients were negative baseline PPD-TST, eight (19%) exhibited a positive 2nd PPD TST; three decreased & in one increased 7 mm). Out of the remaining 42 patients with a positive baseline PPD-TST remained positive (in 5 patients the diameter was 4.8, p = 0.009). In 92.6% of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation rate over time was significantly lower (p = 0.01, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, p < 0.0001).

Conclusion: AAA formation often occurs earlier than anticipated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenicity is lower for adalimumab compared to infliximab. However, one may occur. AAA may be more specific and predictive of ATI.

P0402 THE TEMPORAL EVOLUTION OF IMMUNOGENICITY IN INFILMAMTORY BOWEL DISEASE PATIENTS TREATED WITH ADALIMUMAB

1Gastroenterology Institute, - Gastroenterology institute, 2IL, Ramat Gan;Israel
2Gastroenterology, Rambam Health Care Campus, Haifa;Israel
3Gastroenterology, Meir Medical Center, Kfar Sabib;Israel
4The Kamila Goscarnska Institute Of Gastroenterology, Asaf Harofeh Medical Center, Zerifin;Israel

Introduction: Adalimumab and anti-adalimumab-antibodies (AAA) levels have been associated with clinical outcome of Crohn’s disease (CD). Nevertheless, because adalimumab is usually self-injected at home, prospective serial-sampling studies are scarce. Thus, data on the temporal evolution of adalimumab immunogenicity is still limited, and the validity of comparisons of adalimumab versus infliximab immunogenicity remains questionable.

Aims & Methods: Our aim was to assess trends in adalimumab and AAA levels over time and their clinical implications. CD patients starting adalimumab therapy were followed prospectively in three participating medical centers in Israel, by establishing a program for home-visits by physicians at induction and every 3 months, or in case of relapse. At each home visit, patients’ clinical activity score were determined and blood tests obtained for CRP, drug and AAA trough levels. AAA levels were determined by a drug-tolerant assay. A comparison with temporal evolution of infliximab immunogenicity in a previously reported cohort using the same assay and methodology was additionally performed.

Results: 102 CD patients starting adalimumab were prospectively followed. Fourteen (14%) experienced primary non-response and 20 (20%) lost response to adalimumab therapy during maintenance. Thirty-three (32%) developed AAA, which were more common among those previously exposed to adalimumab (p = 0.002) but were not affected by co-treatment with immunomodulators or not (p = 0.28). AAA developed as early as week 2 in 18/33 (55%) of AAA positive patients (7/18 with history of interrupted therapy), and in 26/33 (79%) within 4 weeks. In week 2 2 AAA had 34% of primary non-response compared to 9% in patients without early AAA (OR = 4.8, p = 0.009). In 92.6% of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation rate over time was significantly lower (p = 0.01, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, p < 0.0001).

Conclusion: AAA formation often occurs earlier than anticipated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenicity is lower for adalimumab compared to infliximab. However, once they occur, AAA may be more specific and predictive of ATI.

P0403 GOLIMUMAB IN ULCERATIVE COLITIS, REAL-LIFE PROSPECTIVE COHORT STUDY FROM A SINGLE REFERRAL CENTRE OF CENTRAL ITALY

L. Grossi1, V. Vecchione1, S. Coccicollo,2 R. Tavan1, M. Di Berardino1, A. Sepe1, C. Di Giacomo,3 N. Russo1, V. D’Addetta1, L. Marzio2

1Digestive Sciences, G. d’Annunzio University, Pescara/Italy
2Department of Physiotherapy, University of Pescara, Pescara/Italy
3Department of Physiotherapy, University of Pescara, Pescara/Italy

Introduction: Golimumab (GLB) has been the last anti-TNF agent authorized for the treatment of Ulcerative Colitis (UC). Results from registratory trial (PURSUIT) documented a clinical response in 51% of patients after 6 weeks
of GLB with 47.4–94% of patients maintaining the effect after one year. Due to its restricted use, data are still few with a focus on clinical efficacy of patients receiving golimumab in the routinely activities. In our region GLB became available starting July 2015.

Aims & Methods: Aim of this study has been to prospectively evaluate the efficacy and safety of GLB for the treatment of UC in the real-life setting of our referral centre. 13 patients (7 male, 4 female) with moderate to severe UC were enrolled in the study from June 2015 to December 2016. Patients received an induction dose of GLB 200 mg s.c. at baseline, 100 mg at week 2 and then a maintenance dose of 100 mg for a body weight < or ≥ 80 kg, respectively, with no optimization allowed. Partial Mayo score was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score >30% and >3 points vs baseline) and in the maintenance period, the secondary end point being the steroid-free clinical response (Partial Mayo score <2 with all sub scores <1) at the end of the induction phase and then at the maintenance phase. Complete follow-up is available for all patients at week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sided colitis (LE) in 70%, pancolitis (PC) in 23% and proctitis (PR) in 7% of patients. Ten patients (77%) were anti-TNF naive, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/13 (62%). Three patients resulted in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission (both patients are in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and non-naïve patients. No significant adverse events were reported in the study period.

Conclusions: Our results seem to suggest that Golimumab, as compared to registratory trials, is able to induce a better initial clinical response but shows a higher secondary loss of response in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimization is still a matter of discussion.

Contact E-mail Address: juanes@clinic.ub.es

Introduction: The Observational Postmarketing Ulcerative colitis Study (OPUS) registry was conducted to collect long-term (5 years) real-world clinical practice safety data in patients with moderate to severe ulcerative colitis (UC) treated with originator infliximab and to compare this safety profile to that of UC patients treated with standard therapies.

Aims & Methods: The OPUS registry was a prospective, non-randomized, observational study that followed patients with UC (in routine practice in 14 European countries) who were enrolled to receive treatment with either originator infliximab or standard therapy (defined as initiation or dose-increase of corticosteroids or azathioprine) as determined by their treating physician. Adverse events (AEs) were recorded during the 5-year follow-up period; at any point during these 5 years of observation, the patient’s therapy could be changed to any other UC therapy, based on the physician’s clinical judgment. Frequency of events was evaluated in nine pre-specified categories (serious infection, infusion-related reaction, fatality, worsening or new case of congestive heart failure (CHF), central and peripheral demyelinating neurological disorder, hematological condition, malignancy/lymphoproliferative disorder, autoimmune disorder, or hepatobiliary event). Multivariable Cox proportional hazards (PH) models were assessed time-to-first AE for the originator infliximab and standard therapy groups, using an intent-to-treat approach, in eight of the pre-specified categories (infusion-related reactions were not compared between originator infliximab and standard therapy). The likelihood ratio statistic of PH models assessed time-to-first AE for the originator infliximab and standard therapy groups, compared with the standard therapy group, had more severe disease at baseline, based on partial Mayo score (PMS): 46.0% of patients in the originator infliximab group had severe disease (PMS of 7–9 out of 9), compared (53.0%) in the standard therapy group. In time-to-first event analyses for risk factors/confounders, enrollment into the originator infliximab group was associated with a higher risk of serious infection (hazard ratio = 2.08, 95% confidence interval [CI] 1.42, 3.06; p < 0.001) compared with enrollment into the standard therapy group (Table). No notable risk differences between groups were identified for hematological condition, autoimmune disorder, malignancy/lymphoproliferative disorder, hepatobiliary event, and fatality (Table). Because of very low incidence of AEs in the categories of CHF and demyelinating disorder (103/530, 95% confidence interval 0.05 to 0.20 in each group), multivariable time-to-event analyses could not be performed for these categories.

Conclusion: Data from 5-year safety follow-up of patients with moderate to severe UC in this non-randomized registry population demonstrate that, compared with the standard therapy group, patients enrolled in the originator infliximab group had an increased risk of serious infection. This finding is consistent with the previously established safety profile for originator infliximab in the treatment of UC. In this large registry, the originator infliximab group, compared with the standard therapy group, had not a significantly increased risk of a hematologic condition, autoimmune disorder, malignancy/lymphoproliferative disorder, hepatobiliary event, CHF, demyelinating disorder, or fatality. No new safety concerns were observed with originator infliximab in the OPUS registry.

**Aims & Methods:** In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopic score ≥2) received induction treatment with GLM 200 mg SQ (at week 0) and 100 mg (at week 2) followed by 50 or 100 mg at week 6, in patients with a bodyweight of less or more than 80 kg, respectively. Serum GLM concentrations were measured at day 0, 4, 7, 14, 18, 28, 42 and 56, as well as anti-GLM antibody levels, C-reactive protein (CRP) and albumin serum concentrations. Serum GLM concentrations were measured with an enzyme-linked immunoassay and anti-GLM antibody levels were measured with a drug-sensitive antigen binding test, both developed by Sanquin laboratories. Endoscopic response was defined as disease duration at age, disease duration at baseline, history of previous dysplasia.

**Table 1:** Median golimumab trough concentrations and AUCs at week 2 and 6

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 was associated with improved endoscopic outcomes.

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor being investigated for moderately to severely active ulcerative colitis (UC). We performed a systematic literature review (SLR) and network meta-analysis (NMA) to compare the efficacy and safety of tofacitinib to available tumour necrosis factor inhibitors (TNFi) and integrin receptor antagonists for induction therapy of adults with moderately to severely active UC.

**Aims & Methods:** Using indexing and free-text terms, searches were conducted in the EMBASE, MEDLINE, CENTRAL, DARE, and CINAHL databases to identify RCTs published as of January 2015. Proceedings of relevant conferences from 2012–2014 were also reviewed. Comparators of interest were infliximab, golimumab, adalimumab and vedolizumab. Two reviewers independently assessed studies for inclusion, and extracted and validated the study/patient data. Fixed- and random-effects Bayesian NMAAs were conducted to compare efficacy outcomes and rates of adverse events (AEs) at 6–12 weeks in the overall population (TNFi-naïve or exposed) and by prior TNFi exposure.
Results: Twelve induction trials were identified from the SLR (ACT 1 & 2, EUCALYPTUS, GEMINI-I, PURSUIT SC, TOFACTINIB PHASE 2, Feagan 2005, 1 Probert 2003, 2 UC-SUCCESS, ULTRA 1, ULTRA 2, Suzuki 2014) and included in the NMA. Unpublished data from tofacitinib Phase 3 induction trials (OCTAVE 1 & 2) were also used in the analysis. Fixed-effects NMA showed that tofacitinib 10 mg twice daily (BID) is associated with a higher rate of mucosal healing (80% vs 36% in the overall population (odds ratio [OR] 1.82 [95% credible interval [CrI] 1.06, 3.14]); and vs vedolizumab 300 mg (OR 3.71 [95% CrI 1.37, 10.64]) and etrolizumab 300 mg (OR 12.09 [95% CrI 6.84, 22.73]) in TNFi-naive patients. A higher rate of clinical remission was seen with tofacitinib 10 mg BID vs adalimumab in TNFi-exposed patients (OR 11.93 [95% CrI 1.37, 10.64]) and etrolizumab 300 mg (OR 12.09 [95% CrI 1.68, 14.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall and TNFi-naive populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggeregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CrI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

Conclusion: This NMA suggests that tofacitinib may be more effective as induction therapy in moderately to severely active UC than adalimumab and vedolizumab in TNFi-exposed patients, and is associated with a higher rate of mucosal healing than adalimumab in the overall population. Rates of specific safety events were similar between tofacitinib and TNFi treatments.

Introduction: Patients with inflammatory bowel disease (IBD) experience higher rates of C. difficile infection (CDI) than the overall population, often lack typical risk factors, and frequently experience severe and recurrent episodes. MODIFY I/II were global trials of the efficacy and safety of bezlotoxumab (bezlo: a human monoclonal antibody against C. difficile toxin B), in which bezlo was superior to placebo at preventing CDI recurrence (rCDI) in participants with primary or recurrent CDI given antibacterial drug treatment for CDI. Participants with IBD could be enrolled if, in the opinion of the investigator, symptoms were more likely due to CDI than IBD.

Aims & Methods: The objective of this post-hoc subgroup analysis was to summarize CDI-related outcomes, including initial clinical cure and rCDI, through 12 weeks in participants with IBD enrolled in the MODIFY trials. CDI-related outcomes through 12 weeks in the subset of IBD participants enrolled in the MODIFY trials included: initial clinical cure (no diarrhea during the 2 consecutive days following completion of ≤14 days of an antibacterial drug treatment for CDI); and rCDI (new episode of diarrhea associated with a positive stool test for toxigenic C. difficile in participants who had achieved initial clinical cure). For this post-hoc analysis, participants randomized to bezlo or axotumab + bezlo were pooled and are referred to as the “bezlo” group and participants randomized to placebo or axotumab were pooled and are referred to as the “no bezlo” group.

Results: Overall, 2559 participants were included in the mITT population; 1554 participants were randomized to a bezlo group and 1005 were randomized to a no bezlo group. There were 44 participants with IBD; 23 (52.3%) had ulcerative colitis; 18 (40.9%) had Crohn’s disease; and 3 (6.8%) had non-characterized IBD. Compared with participants without IBD, participants with IBD tended to be younger, were more often treated as outpatients, were more often immunocompromised, and a smaller percentage had severe CDI. Among IBD participants, a higher proportion had initial clinical cure in the no bezlo group compared with the bezlo group and there was a higher proportion of participants with rCDI in the no bezlo group compared with the bezlo group. In IBD participants who did not receive bezlo, most of the recurrences (5 of 7) occurred within 4 weeks after study infusion, while most of the recurrences among participants who received bezlo occurred after week 4 (3 of 4).

Conclusion: Participants with IBD and CDI enrolled in the MODIFY trials were younger, more likely to be diagnosed with CDI as an outpatient, to be immunocompromised, and to develop rCDI compared with non-IBD participants. Bezlo yielded a 27.2% absolute reduction (50% relative reduction) in the incidence of rCDI in participants with IBD. The efficacy of bezlo in preventing rCDI may extend to patients with IBD, but additional data are needed due to the limited cohort size.

Disclosure of Interest: show that switching from IFX-biological to IFX-biosimilar is feasible and safe.

Results: So far, we included 47 patients from 6 secondary Dutch Teaching hospitals. 35 patients had CD and 12 had UC. 27 patients were female, 20 were male. Mean age at inclusion was 42 years. 21 patients have finished the 30-week follow-up. Randomization was performed in a 2:1 ratio (65% to IFX-biosimilar). The primary endpoint was number of patients in remission at week 30. We measured C-reactive protein (CRP), faecal calprotectin (FCP), infliximab trough level (TL) and anti-drug antibodies [ADAs]. Patients were asked to fill in SIBDQ and Mayo or HBI questionnaires three times during the study period. Adverse events (AE) and serious adverse events (SAE) that patients experienced were documented.

Results: So far, we included 47 patients from 6 secondary Dutch Teaching hospitals. 35 patients had CD and 12 had UC. 27 patients were female, 20 were male. Mean age at inclusion was 42 years. 21 patients have finished the 30-week follow-up. Randomization was performed in a 2:1 ratio (65% to IFX-biosimilar). One patient experienced a relapse of IBD, this patient received IFX-biosimilar. 2 patients experienced a serious adverse event (SAE) that patients experienced were documented.

HISTOLOGIC MEASURES OF MUCOSAL HEALING CORRELATE WITH ENDOSCOPIC MEASURES OF DISEASE ACTIVITY IN BASELINE CD FOLLOWING INDUCTION THERAPY WITH THE JAKI INHIBITOR FILGOTINIB IN ACTIVE CROHN’S DISEASE: RESULTS FROM FITZROY STUDY

Aims & Methods: We analyzed the success of fecal microbiota transfer (FMT) via encapsulated cryopreserved microbiota or via endoscopic jejunal application to 14 patients with chronic, antibiotic-refractory pouchitis. Antimicrobial therapy was performed either via encapsulated cryopreserved microbiota or via endoscopic jejunal application to 14 patients. Stool samples for FMT preparation derived from three unrelated healthy donors. Patients were treated by FMT every 4 weeks according to the individual therapeutic outcome. Stool samples before FMT and during follow-up were subjected to microbial community structure analysis through high throughput sequencing of the V1-V2 regions of the 16S rRNA (1), clinical response and mucosal inflammation was assessed by fecal calprotectin (FCP) levels.

Results: Clinical response occurred in 7 of 14 patients after two to four FMTs. 4 patients showed clinical worsening and 3 patients showed no improvement. FCP dropped in responders from 536 mg/kg stool (med.; min-max: 116–3000) to 150 mg/kg (191–1409), whereas in patients with flare FCP values increased from 160 mg/kg (115–175) to 450 mg/kg (1221–1778). Microbiota analysis of 10 patients and two donors revealed a significantly lower diversity in pouchitis patients compared to healthy donors as assessed by the total phylotype number, the Shannon diversity and Pielou evenness. In patients showing response, typical members of the microbiota in diversity was observed. This increase in diversity was due to the successful establishment of the donor microbiota as assessed by the analysis of sample-similarity matrices constructed using the Bray-Curtis algorithm and a detailed analysis of the taxonomic composition. The encapsulated fecal microbiota was as effective as the endoscopic jejunal application in its capacity to restructure the recipient microbiota. We found an increase in the diversity and an overall restructuring of the microbiota into a composition resembling the donor not necessarily correlated with clinical outcome and clinical worsening was observed during three FMTs where the established microbiome structure remained stable. Increasing in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

USTEKINUMAB– AN ALL PATIENTS ANALYSIS FROM THE UNITI STUDIES: RESPONSE AND REMISSION AFTER 16 WEEKS OF INDUCTION THERAPY

Aims & Methods: Patients achieving clinical response 8 weeks after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w dosing. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249 and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The response rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7% vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

Results: Of the 219 patients not in clinical response in UNITI 1&2, 37.6% and 60.5% respectively were in clinical response 8 weeks after the first maintenance dose (90 mg SC). Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection (16 weeks after the IV induction dose) for UNITI1&2 are 47.4% and 73.7% respectively (see table for response and remission rate). Similar assessments were calculated in the sub-population who were anti-TNF naïve upon enrollment into UNITI-2.

Response rates and Remission rates for all patients 16 weeks after induction of 6 mg/kg IV UST

<td>72.9</td>
<td>60.4</td>
</tr>
</tbody>
</table>

Conclusion: These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.
REAL-WORLD PATTERNS OF TREATMENT DISCONTINUATION, FLARES, AND HOSPITALISATIONS AMONG INFLAMMATORY BOWEL DISEASE PATIENTS WITHIN 12 MONTHS OF INITIATION OF VEDOLIZUMAB OR INFliximab

Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naïve. All patients with IBD (ulcerative colitis or Crohn’s disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥3 infusions within 98 days of index date); (2) were ≥18 years of age at index; (3) had ≥365 days of medical history prior to index (“baseline”); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic ≤90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids), respectively. Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ≥60% of patients in each cohort. In the baseline period, ~70% of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 1.9 years for IFX initiators. Median time to treatment discontinuation was 244 (IQR: 194–307) days for VDZ initiators vs. 98 (IQR: 45–168) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Conclusion: Among biologic-naïve IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

P0415 OXIDATIVE STRESS ENHANCES THE ANTIGEN PRESENTING FUNCTION OF COLONIC EPITHELIAL CELLS BY INDUCING CD80 IN THE EARLY STAGES OF COLONIC CARCINOCNEGENESIS

C. Marchiori1, A. Kotsafti1, I. Angriman3, C. Castorol2, A. Porzionato4, P. Brun4, M. Scarpa2, I. Castagliul01, M. Scarpa2

Introduction: Cancer development has been linked to oxidative stress by increasing DNA mutations or inducing DNA damage, genome instability and cell proliferation. Interestingly, reactive oxygen species (ROS) seem to modulate antigen presentation, a crucial event in the immune surveillance mechanisms. We recently showed that expression of the co-stimulatory molecule CD80 on epithelial cells has a critical role during the immune surveillance process occurring in colon carcinogenesis2. Remarkably, ROS have been involved in the transcriptional regulation of CD80 gene expression3; in addition, oxidative DNA damage was directly correlated to CD80 expression in colon mucosa dysplasia3.

Aims & Methods: Therefore, the aim of this work was to examine the role of ROS on CD80 expression in colon epithelial cells using an in vitro and an in vivo model of colon carcinogenesis. A mouse colorectal cancer cell line, CT26, was used to quantify the expression of CD80 in response to pro-oxidant (such as Antimycin A and H2O2) and antioxidant (N-acetyl cysteine) stimuli in presence of N-acetylcysteine significantly reduced AOM-induced CD80, MHC-I and MHC-II up-regulation in colonic epithelial cells (p < 0.01) but not by NF-kB pharmacological inhibition. In vivo administration after AOM treatment.

Results:

In CT26 cells ROS-generating agents (Antimycin A and H2O2) caused a significant increase of CD80 mRNA (p = 0.01) and protein level (p < 0.001). H2O2-induced CD80 up-regulation in colon epithelial cells was significantly inhibited by N-acetyl cysteine (p < 0.001) and by p38MAPK inhibitor (p = 0.001) but not by NF-kB pharmacological inhibition. In vivo administration of N-acetylcysteine significantly reduced AOM-induced CD80, MHC-I and MHC-II up-regulation in colon epithelial cells (p < 0.001 and p < 0.001, respectively). Moreover, CD8+CD28+ vs Healthy, IBS (n = 15) IBS patients based on their mucosal antimicrobial gene expression Cytokine-gene expression in sigmoid colon biopsies from patients with IBS, defined as either immuno-active or immuno-norm based on systemic and mucosal cytokine profiles (Benett et. al Am J Gastro, 2016), and healthy subjects was assessed by Human Antibacterial Response RT2 Profiler PCR Array. Targeted 16S rRNA gene pyrosequencing was performed on fecal microbiota. To identify discrimination profiles based on multiple variables between IBS patients and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >0.7 was performed.

Results:

Table 1: Differences in mucosal antimicrobial mRNA expression between IBS (Immuo-active and Immuno-norm) and healthy subjects.

Data presented as p-values (Mann-Whitney t-test) * = non significant. We included 31 IBS patients (16 females, median age 32 (25-44) years) and 16 healthy subjects (8 females, median age 27(24-30) years). An OPLS-DA model demonstrated that the antimicrobial profiles differed between IBS and healthy subjects (R² = 0.54, Q² = 0.16). The mucosal mRNA expression of 14 antimicrobial genes was downregulated, while one gene was upregulated in IBS patients compared to healthy subjects (Table 1). Antimicrobial profiles did not differ between IBS patients subgrouped according to their predominant bowel habit (R² = 0.02). An OPLS-DA model showed discrimination between immunoo-active (n = 16) and immuno-norm (n = 15) IBS patients based on their mucosal antimicrobial profiles (R² = 0.91, Q² = 0.61). This finding was corroborated by four antimicrobial genes being altered between the two IBS groups (Table 1). Adding healthy subjects to the model revealed three differing antimicrobial profiles for each respective group (R² = 0.44, Q² = 0.30). Compared to healthy subjects, 19 genes in the immuno-active and immuno-norm IBS groups were differently expressed (p < 0.05, Table 1). Only one of the antimicrobial genes differently expressed between IBS patients and healthy subjects was associated with faecal microbiota in immunoo-norm IBS patients (Conserved Helix-Loop-Helix Ubiquitous Kinase (CHUK) with Anaerovorax r = -0.76, p < 0.01). In the immuno-active IBS group 11 associations were identified, including TNF
Receptor Superfamily Member 1A (TNFRSF1A) with Bifidobacterium (n = 0.9). p = 0.08). Conclusion: The intestinal antimicrobial gene profiles differ between subsets of IBS patients and healthy subjects. An altered ability to recognize microbiota associated with immune activity and the relative abundance of gut bacteria may play a role in the complex pathophysiology of IBS.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the effect of internal and external drainage on obstructive jaundice rats on intestinal mucosal barrier function with special reference of intestinal immune-mediated index expression. Sixty male Sprague-Dawley rats were randomly assigned to four groups: OJ, sham operation (SH), internal biliary drainage (ID) and external biliary drainage (ED). All animals underwent surgical ligature of the bile duct, except SH was produced by separating common bile duct locally but not dividing on day 1. Then ED and ID were reoperated on day 8 for biliary drainage procedure. Blood from inferior vena cava were collected for the test of DAO and slgA activities by the method of ELASA. The terminal ileum specimens of each groups were collected for observation of the morphological changes with haematoxylin-eosin (HE) staining. The expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5 mRNA were measured by Reverse transcription polymerase chain reaction (RT-PCR). The expression was evaluated by Chi’s method was 2.158 0.579, while the impaired intestinal mucosa have different degrees of recovery and ID group was more similar to SH group in intestinal mucosal morphology. The levels of the DAO in OJ group were remarkably more dramatic than that in SH, ID and ED groups while slgA were decreased (p < 0.01), and the activities of the DAO, slgA in ID group were similar to the level of SH group (p > 0.05), different to the level of ED group (p < 0.01). The changes of the plasma DAO and slgA activities were significantly correlated with the conditions of intestinal mucosa (p < 0.01). The expression of RD-5 mRNA in OJ group were decreased significantly than that in SH, ID and ED groups while GP-BAR1 mRNA, IgA mRNA, plgR mRNA were increased (p < 0.01). Interestingly enough, after external bile drainage, there is no improve-ment in IgA mRNA and plgR mRNA (P > 0.05). But in ID, the relative expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01). while the mRNA expression of GP-BAR1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GP-BAR1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of SH group (P < 0.01). After internal and external biliary drainage to alleviate OJ respectively, the GP-BAR1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, P < 0.01; ID vs SH, P > 0.05) and lower than that of in ED group (P > 0.05). Conclusion: The differential expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5 mRNA and activities of DAO and slgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a regulatory mechanism between GP-BAR1 and intestinal immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosa barrier.

Introduction: The old age is one of the most important risk factors for recurrent C. difficile Infection (CDI). However, risk factors among the elderly patients are largely unknown.

Aims & Methods: The purpose of this study was to investigate risk factors associated with recurrent CDI in the elderly. Patients 65 years of older with positive CDI toxin test between January 2005 and December 2016, who received either oral metronidazole or oral vancomycin therapy were included. Recurrent CDI was defined as another positive laboratory result for C. difficile toxin between 15 days and 90 days after initial positive diagnostic test. Clinical charts of relevant factors in 633 patients with positive CDI toxin tests were reviewed. Continuous variables were tested via Student’s t-test, and categorical data was analyzed via Chi-Square test. All variables with P < 0.1 in the univariate analysis were included in the multivariable logistic regression analysis.

Results: The overall mean age was 77.0 ± 7.0 years. In 96 (15.2%) of 633 patients, C. difficile toxin was detected again after the initial test. The length of hospital stay was longer in recurrent CDI group than in non-recurrent group (80.54 ± 89.44 vs. 43.81 ± 65.42, P < 0.001). Patients with eGFR < 60 ml/min/1.73 m² were at higher risk for the development of recurrent CDI than those with normal renal function (OR 1.844; 95% CI, 1.139–2.985; P = 0.015). There were no significant differences on mean age (77.21 ± 6.65 in recurrent CDI group vs. 77.01 ± 7.04 in non-recurrent CDI group, P = 0.799) and proton pump inhibitor therapy (OR 1.277; 95% CI, 0.825 to 1.977, P = 0.272) between both groups. Renal function and length of hospital stay were significantly associated with recurrence of CDI.

Conclusion: In this study, impaired renal function and prolonged hospitalization were related to the increased risk of recurrent CDI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0421 CLINICAL CHARACTERISTICS OF CYTOMEGALOVIRUS COLITIS: 15 YEAR-EXPERIENCE IN A TERTIARY MEDICAL CENTER

P. Lé1, R. Wu2, C. Chiu1, C. Kuo1, M. Su1, C. Lin1, J. Hsu3

Contact E-mail Address: puohsien@gmail.com

Introduction: Cytomegalovirus (CMV) colitis in adults is mostly described in immunocompromised patients (solid organ or hematopoietic stem cell transplant recipients, patients with human immunodeficiency virus (HIV) infection, use of immunosuppressive drugs, including steroid or chemotherapeutic agents), and often has worse outcome than in children. Besides, it was also frequently presented in patients with known or subsequent new diagnosis inflammatory bowel disease [1, 2]. However, there are only case reports and few case series with limited patients (below 15 cases) among immunocompetent individuals without known or inflammatory bowel disease [3–5]. The largest meta-analysis study of cytomegalovirus colitis in immunocompetent hosts included 44 patients and noted advanced age, male gender, presence of immune-modulating comorbidities and need of surgical intervention negatively influencing survival in 2005 [6]. The case number of CMV colitis in immunocompetent patient seemed increasing in our hospital these years. There was no single study showing comprehensive clinical characteristics, identifying the independent factors of in-hospital mortality and comparing the differences between immunocompetent and compromised patients with CMV colitis. Therefore, we tried to clarify the issue in this study.

Aims & Methods: We enrolled 42 immunocompetent patients and 27 immunocompromised patients with CMV colitis diagnosed by immunohistochemistry stain between April 2002 and December 2016 in Linkou Chang Gung Memorial Hospital, a 3383-bed tertiary medical center and referral center in Taiwan. We analyzed the risk factors of in-hospital mortality and overall survival. Furthermore, we compared the clinical differences between immunocompetent and immunocompromised patients with CMV colitis.

Results: Early diagnosis (before 9 days) was independent predictor of in-hospital mortality in CMV colitis patients. IUCA admission (P = 0.010), requisite days of diagnosis ≥ 9 days after admission (P = 0.018), shock (P = 0.001), respiratory failure (P = 0.033), hemoglobin < 10 g/dL (P = 0.002), Creatinine ≥ 1.37 mg/dL (P = 0.004) and CRP ≥ 59 mg/dL (P = 0.011) negatively impacted on overall survival. There were older and more comorbidities in immunocompetent group. However, the in-hospital mortality rate and overall survival rate was similar to immunocompromised group. Besides, Clostridium difficile infection or steroid use didn’t affect in-hospital mortality rate and overall survival rate neither. Melenia was first and most common symptom in immunocompetent group, but diarrhea in the other.

Analysis of the clinical factors associated with in-hospital mortality in all patients

Characteristic | Odd ratio | 95%CI | P-value

Introduction: Clostridium difficile associated diarrhea (CDAD) is a common nosocomial infection. The most commonly prescribed treatments, metronidazole and vancomycin, have a primary cure rate of 90% but in 1 out of 4 cases suffer a relapse in the following months. A disrupted microbiota is thought to increase the risk of relapse. Rifaximin is a non-absorbable antibiotic that suppresses C. difficile proliferation.

In a trial of 68 patients Carey et al. found that a course of rifaximin after standard therapy reduced relapse rate though not significantly1.

Aims & Methods: We aimed to further investigate the efficacy of rifaximin to prevent CDAD relapse in a parallel group, randomised, placebo controlled trial in 23 hospitals in England. Population: age ≥ 18 with resolution of CDAD after treatment with metronidazole or vancomycin, defined as cessation of diarrhea for ≥ 2 days. CDAD diagnosis required evidence of toxin production or pseudomembranes at endoscopy. Exclusion criteria were pregnancy or breast feeding; life expectancy <4 weeks; unable to take intervention (hypersensitivity or swallowing disorder); > 5 days elapsed since treatment. Randomisation was stratified by hospital using a remote, internet-based system. Participants, clinicians and researchers were blind to allocation. Intervention: Rifaximin 1200 mg daily for two weeks then 600 mg daily for two weeks, in three divided doses. Comparator: identical placebo.

Primary Outcome: relapse ≤ 12 weeks after treatment initiation, defined as diarrhoea (≥ 3 type 6 or 7 stools per day) for 2 days with evidence of toxin production. Sample size: The planned sample size was 180 to detect a difference in relapse of 20% (30% placebo, 10% rifaximin) with 80% power, allowing for loss to follow-up of 20%. EudraCT 2012-003205-10; www.clinicaltrials.gov NCT01670179; ISRCTN 65163992

Results: Recruitment occurred December 2012–March 2016. Of 2157 patients screened, 151 were eligible, willing and randomised before funding limits were reached (74 placebo, 77 rifaximin). Primary outcome data were available on 130.

Mean age was 71.9 (SD 15.3).
36% were in-patients at start of intervention. 13% had a prior recorded episode of CDAD in the previous 12 months. 26% were using proton pump inhibitors prior to CDAD diagnosis, with a higher rate of use in the rifaximin group (32% vs. 15.9%) on placebo relapse reduced within 12 weeks compared to 11/69 (15.9%) on rifaximin, a difference between groups of –13.7% (95% CI –28.1% to 0.7%, p = 0.06). The relapse also was 0.54 (95% CI 0.28 to 1.05, p = 0.07).

During 6-month safety follow up 9 participants died in each group (12%). Adverse event rates were similar between groups.

Conclusion: CDAD relapse rate was 13.7% lower than on placebo. The confidence interval means that lack of effect remains possible but the estimated effect size is similar to Carey’s trial1 with meta-analysis of the trials showing a statistically significant effect. The effect size is similar to that reported for fidaxomycin at 40 days2, or for bezlotoxumab at 3 months3. Age and mortality rate were higher in our trial which may reflect greater similarity to the population at risk. Comparative trials of the effectiveness and cost effectiveness of alternative treatment strategies should follow.

All other authors have declared no conflicts of interest.

References
Aims & Methods: The traditional fear that every acute appendicitis will eventually perforate leads to prompt surgery, but this fear may be outdated. In-hospital delay of surgery for acute appendicitis has been subject of a large number of studies. However, consensus about the consequences of delaying appendectomy is lacking, which is reflected in variety or absence of recommendations in guidelines.

Aims & Methods: This study was to assess in-hospital delay of surgery and determine risk factors for perforation in patients with acute appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections and postoperative morbidity. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152,314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.98–1.17) and 1.09 (95% CI 0.95–1.24), respectively. For a delay of 24 hours or more, the adjusted odds ratio was 1.32 (95% CI 1.20–1.44) compared with 24 hours or less. Pooled unadjusted data showed a decreased risk for complicated appendicitis when appendectomy was delayed for 24 to 48 hours, however statistical uncertainty in this interval increased considerably compared to the first 24 hours.

Conclusion: Delaying appendectomy for up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

notably contributed by elderly patients, of which the incidence has increased by threefold over the period. Recurrence at 60 days increased from 5.7% in 2006 to 9.1% in 2014 (P = 0.001). The increased use of proton-pump inhibitors accounted for 58.8% of the surge.

**Conclusion:** The incidence of *C. difficile* infection has increased more than threefold, and was associated with an increased disease recurrence and use of proton-pump inhibitors. Our results suggest need for further surveillance in Asia which hovers half of the world’s population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Bleeding (BB) is the most common complication following polypectomy, especially in cases with large pedunculated polyps. Although the clip application before snare polypectomy may decrease PPB, there were few prospective randomized studies to confirm the efficacy of prophylactic clip application. This study aimed to investigate whether prophylactic clip application for large pedunculated colorectal polyps could decrease PPB and to evaluate associated risk factors of BB.

**Aims & Methods:** We enrolled 137 pedunculated polyps (≥1 cm in size) in 116 patients who underwent polypectomy. Polyps were randomized into the two groups with or without prophylactic clip application. Immediate PPB was defined as bleeding that continued for over 30 seconds from the polypectomy site and graded from grade 1 to 4, and delayed bleeding was defined as a history of haematochezia from the day of procedure to the day of first visit of outpatient clinic.

**Results:** Sixty-seven polyps were included in the clip group and 70 polyps in the control group. Immediate PPB occurred in 6 cases (9.0%) of the clip group vs. 9 cases (12.9%) of the control group (P = 0.008). Delayed bleeding occurred in five polyps in both groups (P = 0.943). The prophylactic clip application was a significant factor for lowering immediate PPB in the univariate (OR 0.215, 95% CI 0.081–0.571, P = 0.002) and multivariate analysis (OR 0.210, 95% CI 0.074–0.591, P = 0.003). The occurrence of immediate PPB of grade 3–4 which needed endoscopic treatment was lower in the clip group than in the control group (4.5% vs. 20.0%, P = 0.008). However, that of grade 1–2 was not different in both groups (4.5% vs. 11.4%, P = 0.208).

**Conclusion:** The prophylactic clip application in large pedunculated polyps ≥1 cm is effective in reducing immediate PPB. Polyp size and stalk diameter are associated with PPB.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Heparin replacement (HR) during periprocedural periods is described in various guidelines as the recommended method while discontinuing warfarin. However, the rate of post-colonic polypectomy bleeding in patients undergoing HR has been reported to be as high as 20%. As an alternative method to HR, colonic polypectomy without discontinuation of warfarin may be feasible, however there is still insufficient evidence. The aim of this study was to assess the safety of colonic polypectomy/endoscopic mucosal resection (EMR) without discontinuation of warfarin during periprocedural periods.

**Aims & Methods:** This is a prospective multicenter single-arm exploratory study in Japanese patients who received warfarin for the purpose of prevention of thrombosis were prospectively enrolled and underwent colon polypectomy or EMR without discontinuation of warfarin. Conventional clip closure of the resection site was performed in all cases and oral diet was resumed 2 days after the procedure. The primary outcome was post-polypectomy/EMR bleeding that was confirmed by emergency endoscopy or a decrease in the hemoglobin level of >2 g/dl with haematochezia even if the bleeding site was not identified.

**Results:** Between January 2015 and November 2016, a total of 30 consecutive patients (M:F = 26:4, 69.9±8.0 years) were enrolled in this study after written informed consent was obtained. A total of 81 lesions (tumor diameter: 5.4±2.9 mm, adenoma 70, others 10, lost lesion 1, number of prophylactic clips 4.9±2.2) were treated by polypectomy/EMR. Four patients experienced post-polypectomy/EMR bleeding (4/30: 13.3%) in 3–11 days after the procedure, although no cases required blood transfusion. In 3 of these bleeding cases, a single responsible site was identified by emergency endoscopy. Therefore, the confirmed rate of post-polypectomy/EMR bleeding based on the number of recorded lesions was 3.9% (3/76), but may range to 9.9% (8/81). There were no other adverse events.

**Conclusion:** The rate of post-colonic polypectomy/EMR bleeding in patients without discontinuation of warfarin single therapy was comparable to that in patients undergoing HR. Conventional polypectomy/EMR with discontinuation of warfarin is feasible and may reduce the hospitalization associated with HR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

(2.98% vs 1.49%, respectively). No patients experienced recurrent bleeding and a 18-month follow-up.

### Discussion of Interest

**P0432 EARLY VERSUS STANDARD COLONOSCOPY – A RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH ACUTE LOWER GASTRO-INTESTINAL BLEEDING: RESULTS OF THE BLEED STUDY**

I. Van Rongen 1, B. Thomassen 1, L. Perk 1

1 Gastroenterology, Haaglanden MC, The Hague/Netherlands
2 Landsteiner Institute, Haaglanden Medical Centre, The Hague/Netherlands

Contact E-mail Address: inge.vanrongen@gmail.com

**Introduction:** The incidence of acute lower gastrointestinal bleeding (LGIB) is estimated at 0.9 to 2.0% per 100,000 person years and male/female ratio of 1.18. In the developed world, 55% of LGIB cases are in the elderly. The incidence of LGIB is observed at 21 adults per 100,000 person years and male (82.1%) in the anticoagulant group were higher than those in the normal group (67.7%:11.2 years and 64.1%). There was no significant difference between the groups in size of poly and morphology. In the anticoagulant group, 34 patients received heparin bridging therapy with warfarin 30, warfarin + antiplatelet 1, rivaroxaban 1 and 33 patients discontinued anticoagulants (warfarin 8, warfarin + antiplatelet 1, rivaroxaban 10, apixaban 8, dabigatran 4, edoxaban 2). The incidence of PPC was no difference between two groups (1, 1 patient, respectively). There was no difference between the groups in age, sex, size of polyp and morphology. Recurrent bleeding didn’t occur. In the discontinued group, 1 patient developed acute myocardial infarction in next day after colonoscopy polypectomy.

**Conclusion:** Patients taking anticoagulants had an increased risk of PPC compared with the control even if the anticoagulants are discontinued. Heparin-bridge therapy might be responsible for increased PPC in patients taking anticoagulants.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0433 THE COMPARISON OF DIRECT ORAL ANTICOAGULANTS (DOAC) AND WARFARIN FOR ANTAGOCULATION IN THE PATIENTS WITH GASTROINTESTINAL BLEEDING**

Gastroenterology, Mitsui Memorial Hospital, Tokyo/Japan

Contact E-mail Address: kenken.kojiken.529@gmail.com

**Introduction:** Direct oral anticoagulants (DOAC) are now popularly used as anticoagulation for atrial fibrillation and deep vein thrombosis, as well as Warfarin. But, direct comparison of DOAC and warfarin in the patients with gastrointestinal bleeding was little reported.

**Aims & Methods:** We retrospectively analyzed 18 on DOAC and 60 cases on Warfarin in the patients with gastrointestinal bleeding from January 2011 to March 2017 on the basis of single-center experience in Japan. We analyzed controlled red cell (CRC) and fresh frozen plasma (FFP) transfusion rate, the duration from bleeding to endoscopy, from endoscopy to discharge and from bleeding to discharge in both group. In DOAC group, each 6 patients took dabigatran, rivaroxaban and Apixaban.
Thrombotic embolism during hospitalization, n (%) 0 (0.0%) 1 (1.7%) 0.47

The duration from bleeding to discharge, days 9.8/C6 6.2/C6 longer in Warfarin group (9.0/C6 5.6% vs 20.0%, p/C6 0.11). The duration from bleeding to endoscopy had no significant difference between both group (5.5 days vs 3.2/C6 0.2 days, p = 0.52), but the duration from endoscopy to discharge was significantly longer in Warfarin group (9.0/C6 5.5 days vs 23.0 ± 3.0 days, p = 0.03). Also, the duration from bleeding to discharge was significantly longer in Warfarin group (9.8/C6 5.4 days vs 24.2 ± 3.0 days, p = 0.02). Thrombotic embolism during hospitalization occurred only 1 (1.7%) of Warfarin group.

Conclusion: The duration of hospitalization was significantly shorter in the group of the patients with gastrointestinal bleeding, and the rate of FFP transfusion in Warfarin group of the patients with gastrointestinal bleeding was 31 (51.7%) of Warfarin group. Hemoglobin tended to be lower both groups. Upper gastrointestinal bleeding occurred 6 (33.3%) of DOAC group and 31 (51.7%) of Warfarin group. Hemoglobin trended to be lower in both groups. DOAC group had no difference regarding prothrombin time (PT-INR) was significantly prolonged in Warfarin group.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0435 INCREASED INCIDENCE OF OVARIAN CANCER FOLLOWING COLORECTAL CANCER: A KOREAN NATIONWIDE COHORT STUDY**

D.W. Shin1, D.H. Lee1, H.S. Kim1

1Internal Medicine, SNUBH, Seongnam/Korea, Republic of

Contact E-mail Address: delight0618@naver.com

Introduction: In Korea, colorectal cancer is the most common cancer among old aged women over 65 years old. The incidence of colorectal cancer, in particular, is dramatically increasing due to environmental factors such as the westernized eating habits. Furthermore, due to advancements in medicine, the survival rate of those with advanced colon cancer is increasing. An increased risk of malignant tumors associated with colorectal cancer has been suggested recently, but adequate studies have not been conducted. The purpose of the study is to determine whether ovarian cancer is more common in the women diagnosed with colorectal cancer than in the general population. If a woman diagnosed with colorectal cancer indeed has a higher incidence of ovarian cancer, a screening test can be performed on high-risk patients.

Aims & Methods: This was a retrospective cohort study using data registered in the National Health Insurance Corporation as a cancer diagnostic code since 2007. In Korea, once cancer is diagnosed, this information is recorded by the National Health Insurance Corporation with a relevant code, and this system provides every patient’s data for medical research purposes. The colorectal cancer group includes patients newly enrolled with the corresponding diagnostic code (ICD-10 code C18, C19, and C20). The 56,682 colorectal cancer patients and 288,119 sex-age- and region-matched population were recruited. Propensity score matching methods were used to facilitate the creation of comparison group that is similar. Each cancer patient was matched to five individuals in the unexposed cohort. All data was followed up by a new diagnostic code of ovarian cancer (ICD-10 code C56) was given. After adjusting for sex, age, smoking, drinking, exercise and comorbidities (diabetes mellitus, hypertension, and hyperlipidemia), further analysis was performed. The hazard ratios and 95% confidence intervals were calculated via Cox proportional hazards regression models. Statistical analysis will be performed with SPSS Version 24.0. When P ≤ 0.05, the result was defined as statistically significant.

Results: Patients with colorectal cancer were followed up for an average of 4.4 years until the occurrence of ovarian cancer. During the follow-up period, 338 out of 288,119 (0.12%) colorectal cancer patients and 258 out of 288,119 (0.09%) people in the general population were diagnosed with ovarian cancer. Ovarian cancer was more common in the colorectal cancer group than the general population [Hazard ratio (HR) 7.13, 95% Confidence interval (CI) = 5.05–10.04]. The colorectal cancer group was conducted only for those who had medical checkup data within one year (14, 190 patients in colorectal cancer group, 71,933 people in the control group). Even though the subjects in this group were adjusted for several factors (age, sex, smoking, drinking, exercise, diabetes, hypertension, and hyperlipidemia), ovarian cancer was no difference in cancer group and control group [HR 7.12, 95% CI = 5.05–10.04]. Colorectal cancer patients had a higher risk of ovarian cancer across all age groups including patients under the age of 55 years [HR 10.69, 95% CI = 6.26–18.26] and patients older than 55 years [HR 5.17, 95% CI = 3.26–8.19].

Conclusion: In conclusion, data from the National Health Insurance Corporation revealed that the incidence of ovarian cancer in colorectal cancer patients was higher than that of the general population. In woman diagnosed with colorectal cancer, the screening test should be done to monitoring the occurrence of ovarian cancer. Further research is necessary to determine the interactive association between the development of ovarian cancer and colorectal cancer, and large prospective studies are needed.

Introduction: Colonoscopy is an imperfect tool. Several publications confirm colorectal cancer may manifest after a negative colonoscopy.(1) The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term.(1) Post-colonoscopy colorectal cancer (PCCCR) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening(2). Although there is overlap between these two terms, they are not synonymous. PCCCR can be thought of as the overarching term. PCCCR can be subcategorized into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval is recommended, up to 10 years following the colonoscopy).

Aims & Methods: The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers- PCCCR/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool(4). An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient representative) were summoned by the World Endoscopy Organisation (WEO); the final panel consisted of 20 voting members. The following topics were addressed by 2 working groups (WGs):

1. Aetiology WG
   a. Terminology of aetiology categories
   b. Risk factors/potential explanations of PCCCR
   c. How to ascribe potential explanations
d. Minimal colonoscopy, history and radiology datasets to examine PCCCR
   e. Molecular tests to be performed to examine PCCCR
   f. Prevention of PCCCR in high-risk groups

2. Performance WG
   a. PCCCR calculation & reporting
   b. PCCCR monitoring
   c. PCCCR papers-peer review
d. Post-imaging CRC A literature search was performed in MEDLINE and Cochrane using terms “colorectal cancer AND interval cancer”, “healthcare quality assurance AND colorectal cancer” and “healthcare quality assurance AND colorectal cancer AND interval cancer”. The final output consisted of 391 articles. Proposed statements were subjected to anonymous voting via e-mail correspondence. Each statement was scored on an scale of 1 (strongly agree) to

Excess risk of second primary cancers in young-onset colorectal cancer survivors

Introduction: Colorectal cancer (CRC) is still the third most common malignancies in the US according to Colorectal Cancer Statistics, 2017[1]. During past decades, the incidence and mortality of CRC among individuals aged over 50 years are declining significantly, while the rate of CRC in the young is sharply on the rise (up to 60% for young CRC patients) [2–3]. Excluding rate of young-onset CRC, coupled with increased survival relapse, would definitely lead to accumulation of young survivors considerably. There is a growing study reporting the risk of second primary cancers (SPCs) in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC were at high risk of second malignancies (SPCs) in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC were at high risk of SPCs, with increased age. There is a growing study reporting the risk of second primary cancers (SPCs) in certain cancer survivors, including CRC.

Aims & Methods: To address this important gap, we aimed to quantify the relative risk of SPCs after a diagnosis of CRC in the young CRC survivors. We conducted this retrospective study by utilizing the Surveillance, Epidemiology, and End Results (SEER) database and identified primary CRC patients with subsequent cancers between 1973 and 2013. We excluded cases with less than 6-months latency restriction. Standardized incidence ratios (SIR) and absolute excess risk (AER) were calculated to assess the relative risk for SPCs. SIRs for subgroup analysis were further stratified by gender, race, calendar year, localized stage, SEER stage, cancer subsite, radiation therapy. All statistical tests were performed by SEER*Stat version 8.3 and a P value <0.05 was considered statistically significant. Our study was approved by the review board of Zhijiang Institute of Gastroenterology, Sir Run Run Shaw Hospital, China.

Results: In total, there were 54,472 survivors who developed 51,084 SPCs during the follow-up, including 3283 young (young aged 50). The SIR of all sites significantly decreased with increased age. Compared with the general population, SIRs of all solid tumors and hematological disease were significantly increased in the young. There was significant 43% risk of SPCs in young survivors (SIR = 1.43, 95%CI = 1.39–1.48, AER = 33.85) and slight increases in old survivors (SIR = 1.02, 95%CI = 1.01–1.03, AER = 4.20). For young survivors, small intestine (SIR = 3.86), colon (SIR = 3.77), rectum (SIR = 3.36), bile ducts (SIR = 3.70) were the most observed, a recommendation for or against a particular statement required both >50% of participants in favour in <20% preferring the comparator. Failure to meet this resulted in no recommendation. The GRADE system for rating evidence and strength of recommendations was applied to final statements.

Conclusion: This is the first consensus aiming to standardise terminology around PCCRC. Each previous study defined PCCRC differently, making its use for aetiology attribution and quantitative assessment of cases. A Root-Cause Analysis Approach to SPCs in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC were at high risk of SPCs, with increased age. SIRs of all solid tumors and hematological disease were significantly increased in the young.

United European Gastroenterology Journal 5(5S)
FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as screening tool. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screenees about the risk of developing a colorectal carcinoma after a negative FIT.

Contact E-mail Address: anna.forsberg@ki.se

Introduction: Age and family history of colorectal cancer (CRC) are the strongest risk factors for CRC. Obesity, commonly assessed based on body mass index (BMI), is associated with an increased risk for CRC in men but the association is weaker in women and differs between studies. We investigated which of the following body composition measures: BMI, waist-hip ratio (WHR), weight-height ratio (WHR), weight-hip-height ratio (WHHR), a Body Shape Index (ABSI) and percent body fat that best predict the development of CRC in men and women.

Aims & Methods: We used data from Malmö Diet and Cancer cohort in Sweden, including 16,840 women and 10,903 men (mean age, 58.1 years at baseline), followed for a median of 19.8 years. We identified cases with CRC until the end of 2014 using national Swedish registers. Hazard ratios (HR) for CRC, colon cancer (CC) and rectal cancer (RC) per one standard deviation increase in each body composition measure respectively were calculated using Cox regression models, stratified by sex and adjusted for age, alcohol consumption, smoking, education and physical activity. Likelihood ratio tests and C-statistics were calculated to identify the anthropometric measure that improves the null model the most.

Results: Incident CRC occurred in 880 individuals (477 women) during follow-up. All body composition measures apart from WHHR significantly predicted CRC in men but the association was weaker in women and differed between studies. We identified WC as the best predictor based on C-statistics and LR-test (HR per standard deviation [SD] increment, 1.19; 95% CI, 1.08-1.31, LR-test p < .001, C-statistics 0.6278). The association between WC and CRC was only found in men with a BMI above 25. All body composition measures apart from WHHR significantly predicted CC in men, again WC was the best predictor (HR 1.25; 95% CI, 1.11-1.42, LR-test p < .001, C-statistics 0.6444). ABSI was the only measure significantly associated with risk for RC in men (HR, 1.24; 95% CI, 1.05-1.47). In women neither of the measures was significantly associated with an increased risk for CRC, CC nor RC.

Conclusion: In this Swedish population-based cohort study on well-characterized participants, body composition measures predicted CRC in men but not in women. WC was the best predictor in men, in women WC was the best predictor of CRC and CC in men and the association was only significant in overweight/obese men in stratified analyses. Gender difference in the interplay between sex and measures of adiposity in the adipose tissue may explain the lack of associations in women.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: T helper 17 (Th17) cells participate in the progression of various cancers. Both tumor-promoting and tumor-suppressing effect have been reported. The role of Th17 cells in colorectal cancer (CRC) remains controversial and the specific mechanism of how Th17 cells affect the development of CRC remains to be explored.

Aims & Methods: The study aimed to clarify the role of Th17 cells in CRC and identify the underlying molecular mechanisms. The percentage of Th17 cells and IL-17 expression were evaluated via flow cytometry, enzyme-linked immunosorbent assay and immunohistochemistry in tissue samples and peripheral blood. Effects and underlying molecular mechanisms of IL-17 cells on epithelial-mesenchymal transition (EMT) process were explored in vitro using IL-17 transfection and in nude mice by implanting IL-17 overexpressed CRC cells. To detect the expression of Th17 cells in CRC, SW480 cells were co-cultured with Th17 cells via transwell system. Cancer signaling phospho antibody microarray was used to explore the potential signaling pathway. The clinical significance of Th17 cells was investigated in tissue microarrays containing CRC tissues from 90 patients following surgery using immunohistochemistry.

Results: A higher percentage of Th17 cells and serum IL-17 level were found in CRC patients than healthy controls, and Th17 cells presented a gradual upward trend in normal epithelium-adenoma-carcinoma sequence. The overexpression of IL-17 significantly promoted cell proliferation and cancer cell invasion, and induced apoptosis in vitro and in vivo. IL-17 overexpression reduced the expression of E-cadherin and induced the expression of Snail, β-catenin, and Vimentin in both SW480 cells and tumor xenografts, suggesting that IL-17 could induce the EMT process in CRC. When co-cultured with Th17 cells, SW480 cells could directly promote the EMT process of tumor cells. Furthermore, using cancer signaling phospho antibody microarray, we found that PI3K/AKT/Snail signaling pathway played a key role in the regulation of EMT. EMT process could be reversed by LY294002 and IL-17 mAb intervention, suggesting that IL-17/PI3K/AKT/Snail pathway played a vital role in Th17 cells-induced EMT in CRC. Supporting these findings, in human CRC tissues, immunostaining indicated that the percentage of Th17 cells was significantly associated with E-cadherin expression and AKT phosphorylation. The clinical significance of Th17 cells was authenticated by revealing that the combination of intratumoral Th17 cells and E-cadherin served as a better prognosticator for postoperative tumor recurrence than either marker alone.

Conclusion: Th17 cells promote EMT process and facilitate tumor progression via activating IL-17/PI3K/AKT/Snail signaling pathway in CRC.

INTRODUCTION

Dyslipidaemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidaemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent. [1–4] It is unknown whether lipids and lipoproteins cause cancer or are intermediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidaemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5–6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidaemia and CRC.

AIMS & METHODS: We aimed at determining whether dyslipidaemia is causally linked to CRC risk and to explore association of statins with CRC. A case-control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiological questionnaire that included lifetime regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested on regular statin use and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

RESULTS: The LDL genetic risk score was significantly associated with statin consumption (OR = 1.07, 95%CI 1.05–1.10, p = 4.4e-11). The dyslipidaemia genetic risk score was not significantly associated with CRC for either of the target lipids alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested on regular statin use and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

Introduction: Mitochondrial glutamate transporter (SLC25A22) is a key regulator in glutamine metabolism with reported roles in DNA methylation via histone and DNA hypermethylation. The role of SLC25A22 in DNA and histone methylation in CRC, its underlying mechanisms, and the association of SLC25A22 with epigenetic dysregulation in human CRC cohorts.

Aims & Methods: We aim to 1) evaluate the impact of mutant KRAS on DNA and histone methylation in CRC; 2) examine the role of SLC25A22 in DNA and histone methylation in KRAS-mutant CRC; 3) elucidate the underlying mechanisms that underlies SLC25A22-mediated epigenetic dysregulation; and 4) investigate the clinical implication of SLC25A22 in CRC.

Results: Using three pairs of isogenic cell lines harbouring wild-type and mutant KRAS (DKS80/WT vs DLD1(mutant); HKEC3/WT vs HT29(mutant); ICTC/WT vs ICT-KRAS(mutant)), we demonstrated that significant DNA and histone H3 hypermethylation in cell lines expressing mutant KRAS. DNA hypermethylation was associated with the up-regulation of 5-hmC, indicating sup- pressive DNA demethylation in KRAS mutant CRC cell lines. Metabolomic analysis revealed that KRAS mutation modified glutaminolysis via TCA cycle leading to high succinate and fumarate to -ketoglutarate, which was to pivotal in suppressing the enzymatic activity of dioxygenases such as TET and ALKBH, thereby leading to hypermethylation in CRC patients. DNA methylation was determined by the Illumina 880K methylation array and Methyl Light qMSP assays. Histone methylation was determined by Hi-C. Consistently, SLC25A22 expression was identified to be highly correlated with Glut1 expression and correlated with H3K9me3 and H3K4me3. Interestingly, simultaneously APC-loss and KRAS activating mutations synergistically up-regulated the expression of SLC25A22, a key regulator of glutamine metabolism via the TCA cycle. CRISPR-Cas9-mediated knockout of SLC25A22 knock- out cells significantly decreased DNA hypermethylation in KRAS-mutant CRC cell lines. Moreover, histone H3 hypermethylation was reduced at multiple histone marks after the knockout of SLC25A22. These data implied that SLC25A22 inhibited DNA and histone demethylases by promoting the produc- tion of active form of fumarate and succinate and suppressed the expression of SLC25A22 knockdown on DNA and histone methylation in KRAS-mutant CRC cell lines. In addition, succinate restored cell growth in SLC25A22 knockout cell lines, suggesting that epigenetic dysregulation was closely associated with tumorigenicity. In human CRC, SLC25A22 expression was positively associated with CIMP (P < 0.0001) and histone H3K36me2 methylation status (P < 0.0001).
Conclusion: SLC25A22 promotes the tumorigenicity of KRAS mutant CRC by up-regulating ATP synthesis and histone hyperacylation, an effect further enhanced by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

P0447 FOLLISTATIN-LIKE PROTEIN 1 SUSTAINS COLONS CANCELL GROWTH AND SURVIVAL
G. Bevivino1, V. De Simone1, R. Iizzo2, M. Di Giovangigliu1, S. Sedda1, E. Fraternali1, A. Rizzo2, F. Rosi2, C. Stolfi2, G. Monteleone1

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival and cell cycle were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control AS. Western blotting, neuraminidase treatment, expression of proteins involved in cell cycle progression, poly ADP-ribose polymere (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (CdK2), with no modification of early G1 phase proteins (i.e. cyclin D1). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Introduction: TP53 mutation in colon cancer, TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potentials, the effect of TP53 mutation on malignant potential of colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the function of TP53 mutation in colon cancer cells, by using recently established lentiviral CRISPR Cas9 system.

Aims & Methods: Two types of TP53 mutation were generated in LS174T cells, which are derived from human colon adenocarcinoma with wild-type TP53 (WT-TP53) and the down-regulation of TP53 target genes, suggesting that both mutants induced loss of function of TP53. We then assessed the effect of both TP53 mutants on various malignant potentials, resulting equally in accelerated cell growth, enhanced invasiveness and the resistance against DNA-damaging treatment compared to WT-TP53. Moreover, both mutants showed more frequent formation of 3D sphere and more expression of Lgr5 than WT-TP53, suggesting the promotion of cancer stemness by TP53 mutation even after being adenocarcinoma.

Conclusion: We for the first time showed the direct effect of TP53 mutation on malignant potential in colon cancer cells. Loss of function of TP53 induced by not only TP53Ex10 but also TP53Ex3 mutation, might promote malignant potentials including cancer stemness at the late phase of carcinogenesis. In general, TP53 protein in cancer region is represented as TP53Ex10 mutation. However, negative staining of TP53 might also be careful for TP53 mutation to estimate malignant potential in colon cancer, since N-terminal mutation of TP53 in colon cancer has already been reported.

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphiceptin analog with mu- and kappa-opioid receptor affinity, resulted in the development of acute phase of experimental colitis (induced by dextran sodium sulfate (DSS)) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane [AOM] (10 mg/kg) and subsequent addition of DSS (1.5% w/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1 mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the necropsy and clinical score was assessed and the samples were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly increased total number of colonic tumors as well as colon thickness and width after 14 weeks of disease induction. Myleoperoxidase activity, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoylin and eosin staining confirmed inflammation and anti-tumor activity of P-317, as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group.

Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

Introduction: Colorectal cancer (CRC) is the third most common type of cancer worldwide and is the second leading cause of death due to cancer. The expression of C-IAP2 and PERK are associated with increased risk of colorectal cancer. High expression of C-IAP2 and PERK is known to be correlated with disease progression and poor prognosis. Several recent studies have shown that HMGBI is over-expressed in various types of cancers, including CRC, and those cases with higher expression of HMGBI are associated with lymphatic metastasis, distant metastasis and poor prognosis. Studies have shown that HMGBI is over-expressed in various types of cancers, including CRC, and those cases with higher expression of HMGBI are associated with lymphatic metastasis, distant metastasis and poor prognosis. Additionally, several recent studies have shown that HMGBI is over-expressed in various types of cancers, including CRC, and those cases with higher expression of HMGBI are associated with lymphatic metastasis, distant metastasis and poor prognosis. Additionally, several recent studies have shown that HMGBI is over-expressed in various types of cancers, including CRC, and those cases with higher expression of HMGBI are associated with lymphatic metastasis, distant metastasis and poor prognosis.
secreted by cancer cells may be involved in occurrence of tumor metastasis. 

In a study by Lu et al., the authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupffer cells which promoted development of liver.

Furthermore, some researchers have shown that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1 are found in tumors of different stages. AUC 55 metabolites may be useful for diagnosis and treatment of CRC. However, whether HMGB1 has any role in the development of CRC metastasis is not clear. In this study, we investigated the effects of HMGB1 on CRC, and the possible underlying mechanisms were examined.

Aims & Methods: In order to investigate the relationship between high-mobility group B1 (HMGB1) and colorectal cancer (CRC) and the probable underlying pathogenic mechanism. In this prospective study, patients with CRC undergoing primary surgery and healthy subjects (control group) were included from July 2013 to December 2015. Serum HMGB1 concentration was determined using ELISA and HMGB1 mRNA expression was detected by RT-PCR method.

Immunohistochemical analysis was performed to determine HMGB1, pERK and c-IAP2 protein expressions in the cancer tissue.

Results: The CRC patients and CRC and 50 healthy subjects underwent HMGB1 testing. Resected specimen of CRC patients for HMGB1 mRNA and protein expression analysis. Serum HMGB1 levels in CRC patients were higher than that of the control group (8.42 ± 1.79 μg/L, P < 0.05).

The serum HMGB1 levels in CRC patients with distant metastasis were significantly higher (13.32 ± 6.12 vs. 7.57 ± 5.14 μg/L, P < 0.05). The expression of HMGB1 mRNA and protein expression in CRC tissues were significantly higher than in the adjacent normal mucosa. HMGB1 protein expression positively correlated with the lymph node metastasis. There was positive correlation between HMGB1 and c-IAP2 (r = 0.457, P < 0.05), HMGB1 and pERK (r = 0.461, P < 0.05) as well as pERK and c-IAP2 (r = 0.399, P < 0.05).

Conclusion: HMGB1 expression in CRC correlates with distant and lymph node metastasis. It may inhibit apoptosis by inducing activation of pERK and cIAP2.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. We previously reported that certain miRNAs (miR-143, -145, -7, and -34a) were differentially expressed in samples of tumors and paired non-tumorous samples taken from the same patients with colorectal tumors, and there was a close relationship to adenoma-carcinoma sequence for these miRNAs expression.

Aims & Methods: In this study, we examined the miRNA expression profiles of multiple colorectal adenomas comparing between sporadic colorectal adenoma and familial adenomatous polyposis (FAP). We examined the miRNA expression profiles (miRs-143, -145, -7, and -34a) and morphological appearance of 102 sporadic colorectal adenomas (SA), 27 tumors of multiple colorectal adenoma (over 10 adenomas/one patient, MA), 21 tumors of FAP and 114 sporadic cancer (SC).

Results: The expression levels of miRs-143 and -145 were reduced in all tumors compared with the paired non-tumorous samples in the same patient. Especially, these miRNAs were significantly reduced in MA (P = 0.042 and P = 0.004) and FAP (P = 0.027 and P = 0.022) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas (P < 0.001). The expression levels of miR-34a were significantly down-regulated in CA (P < 0.001). MA (P < 0.001), and FAP (P = 0.006) compared with SA.

Conclusion: These findings suggest that the malignant potential of MA and FAP was higher than SA, therefore MA needs strict follow-up like FAP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Group II. However, only MPV was significantly lower in Group II compared to group 1 (8.6±1.1 vs 8.2±1, p < 0.001). The cut-off value of MPV in predicting CRC from patients with normal colonoscopic findings was 9.15 fl with a specificity and sensitivity of 80% and 91% respectively (r = 0.892). MPV and PCT were also significantly higher in patients with neoplastic polyps compared to patients with non-neoplastic polyps (MPV: 8.7±1.1 vs 8±1, p < 0.001 and PCT: 0.23±0.07 vs 0.19±0.05, p = 0.003).

Conclusion: MPV and PCT may have a role as useful and simple markers in the diagnostic evaluation of patients with colorectal cancer from patients with normal colonoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopic examination.

4Radiology, Maastricht University Medical Centre, Maastricht/Netherlands

Contact E-mail Address: doenja.lambregts@gmail.com

Introduction: Rectal cancer patients with clinical evidence of a complete response after chemoradiotherapy may be selected for watchful waiting instead of surgical resection (although currently mainly within the scope of clinical trials). The clinical selection of potential candidates for watchful waiting to date is mainly done using a combination of imaging (MRI) and endoscopy. However, it is known that with this strategy up to 29% of complete responders may still be missed. Failure to identify complete responders will deny these patients the option of watchful waiting as a result of which they will receive potentially unnecessary surgery. Investigating the reasons why some complete responders are missed with current selection tools can help to further optimize our selection strategy and help improve the identification of potential candidates for watchful waiting in the future.

Aims & Methods: Aim of this study was to assess what can be learned from operated (‘missed’) pathologic complete responders by re-evaluating their post-surgery results, suggesting that the selected features are robust and do not necessarily correlate to neoadjuvant treatment response and may be used as imaging biomarkers in the clinical setting.

The standard MRI protocol included T2-weighted (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment T2W-MRI and ADC maps. For the four manual delineations across different readers/delineations. For the four manual delineations ±300/300 features per reader remained significantly performafter FDR correction. However, these features did not sustain after FDR correction for the fully automated segmentation. A final subset of 266 features remained stable and perform

</tbody>
</table>

Conclusion: Main reasons for missing a complete response after CRT are heterogeneous T2W-MRI signal, massive/spiculated fibrosis, residual diffusion-signal, yTN+ disease and residual mucosal abnormalities at endoscopy. Knowledge of these advanced features referring to help improve the selection of patients for watchful waiting in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In patients with locally advanced rectal cancer (LARC) that show a very good response to neoadjuvant treatment, organ-preserving treatments such as watchful waiting may be a good alternative to surgery and can improve functional outcome and quality of life. If we can predict upfront (i.e. before start of CRT) how patients will respond to treatment this may create opportunities to further personalize and optimize the neoadjuvant treatment to enhance the chance of a good response, thereby ultimately offering more patients the chance of organ preservation. A promising new tool in this regard is ‘Radiomics’.

Radiomics refers to a collection of analytical methods to convert images into high dimensional data via a set of quantitative descriptors called ‘features’. These features have the potential to uncover disease characteristics that cannot be detected by means of conventional (visual) imaging evaluation. The aim of this study was to develop a Radiomics signature1 of patients with LARC and evaluate its potential value for pre-treatment prediction of the response to neoadjuvant chemoradiotherapy.

We retrospectively assessed the primary staging MRI’s (1.5T of 124 LARC patients treated with CRT. The standard MRI protocol included T2-weighted (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment MRI. A final subset of 266 features remained stable and perform

P0456  CORRELATION OF ELECTRICAL AND VISCOELASTIC PARAMETERS OF ERYTHROCYTES WITH FATTY ACID COMPOSITION OF THEIR MEMBRANES AND SERUM IN PATIENTS WITH COLORECTAL CANCER

I. Prudnikova
Institution of Internal and Preventive Medicine, Federal State Budgetary and Scientific Institution, Novosibirsk, Novosibirsk/Russian Federation

Contact E-mail Address: dr.prudnikova@mail.ru

Introduction: An analysis of the efficient implementation of the guidelines for screening colorectal cancer (CRC) in patients with first diagnosed CRC (according to the archival case histories of the two medical institutions in Novosibirsk) was performed in 2013-2016, and leading reasons of late CRC diagnostics were identified.

Aims & Methods: We aimed to investigate the correlation of the electrical and viscoelastic parameters of erythrocytes with the fatty acid composition of their membranes and blood serum in patients with colorectal cancer (CRC) of different stages. 46 patients (median age of 53+9 years old) with CRC of various localizations and stages and 16 conditionally healthy patients were examined. Electrical and viscoelastic parameters of erythrocytes have been observed by dielectroviscosimetry. Fatty acid composition of erythrocyte membranes and serum has been studied using GC/MS system triple quad Agilent 7000B USA.

Results: Erythrocytes of patients with CRC were characterized by increasing the proportion of deform cells with reduced strain amplitude and surface charge (low levels of cell velocity to electrodes and dipole moment) (p<0.001:0.05). Metastasis was associated with an increase in the cell electrical conductivity, a sharp decrease of polarizability, and an increase in the tendency to hemolysis (p<0.0001:0.03). Saturated fatty acids prevailed in composition of erythrocyte membranes in patients with CRC; omega 6/omega 3 fatty acid index was decreased, while the level of linoleic acid was significantly increased as related to oleic acid in serum of the patients with CRC compared to the healthy people (p<0.01:0.04). The observed shifts correlated with a disease stage (r=0.04; p=0.04). The erythrocyte strain amplitude was associated with the level of unsaturated fatty acids in erythrocyte membranes (r=0.58; p<0.05), as well as with summarized viscosity (r=-0.47; p=0.03) and rigidity (r=-0.41; p<0.05). While the level of hemolysis of erythrocytes and their tendency to aggregate correlated with the level of lysofatty acids of fatty acids (r=0.54, p<0.04; r=0.42, p<0.05). The surface charge of erythrocytes more closely correlated to the level (C16:2 and C18:1) in the blood serum (r=-0.42; p=0.06). There was a sharp decrease in the crossover frequency to the high-frequency range (p=0.03), a decrease of the cell capacity (p<0.01), and a decrease of polarizability at high frequencies (106, 0.5 x 106 Hz) (p=0.02:0.05), as well as a decrease of C18:3, C20:2, C20:5 and C22:6 levels in erythrocyte membranes (but not in blood serum) at stages of CRC.

Conclusion: Revealing changes in the parameters of erythrocytes and fatty acid composition in blood serum associated with a stage of the disease can be promising for diagnostics and the case follow-up of patients with CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0457  CLINICOPATHOLOGICAL STUDY OF LATERALLY SPREADING TUMORS OF THE COLORECTUM

M. Iwabuchi, M. Sugimura, S. Toda, K. Uki
Gastroenterology, Sendai Medical Center, Sendai/Japan

Contact E-mail Address: s7856@sanj.go.jp

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified into four subtypes according to their morphologic and histologic characteristics: (a) non-adenomatous type (LST-NG), (b) granular nodular mixed type (LST-GM), (c) non-granular flat-elevated type (LST-NFG), and (d) non-granular pseudo-depressed type (LST-NGP). Clinical features of each subtype of LSTs have not been fully evaluated.

Aims & Methods: The aim of this study was to clarify the clinicopathological characteristics and features of colorectal LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 5352 endoscopically resected specimens during January 2007 and December 2016 at our institution. A total of 422 LSTs were detected. We assessed the clinical features (mean age, size, location, Incidence of concomitant carcinoma) according to their subtypes.

Results: Of these 422 lesions, a total of 11 (2.6%) were LST-NG, 34 (8.1%) LST-GM, 106 (24.9%) LST-NGM and 28 (6.6%) LST-NGP. Mean age of patients with each subtype was 68.3 years old for LST-NGH, 67.1 for LST-GM, 67.9 for LST-NFG, and 67.2 for LST-NGP. Male to female ratio (M/F) was 1.21 for LST-NGH, 2.05 for LST-GM, 1.95 for LST-NFG, and 1.65 for LST-NGP. Mean size of LST-NGH (21.2 mm) and LST-NGP (21.2 mm) was significantly larger than that of LST-NFG (17.0 mm) and LST-NGPD (15.1 mm). All subtypes were located predominantly in the proximal colon. Incidences of concomitant carcinomas in LST-NGH, LST-GM, LST-NFG, and LST-NGP were 2% (1 out of 151), 16.3% (34 out of 209), and 57.1% (16 out of 28), respectively. Incidences of concomitant submucosal carcinomas in LST-NGH, LST-GM, LST-NFG, and LST-NGPD were 0% (0 out of 151), 14.7% (5 out of 34), 1.9% (2 out of 209), and 25.0% (7 out of 28), respectively.

Conclusion: Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0458  POST-INVESTIGATION COLORECTAL CANCER RATES INCLUDING POST COLONOSCOPY COLORECTAL CANCER RATES IN A DISTRICT GENERAL HOSPITAL: THE POOLE EXPERIENCE MARCH 2015 TO FEBRUARY 2017

S.D. Parry, T. Deacy, E. J. Williams
Dept. Of Gastroenterology, Poole Hospital NHS, Poole Dorset/United Kingdom

Contact E-mail Address: sally.parry@poole.nhs.uk

Introduction: Post-colonoscopy colorectal cancer (PC-CRC) rates are proposed as a quality indicator of a colorectal screening programme. Literature is growing but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT CRC rates in Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study1.

Aims & Methods: Retrospective audit of all patients diagnosed with CRC during a two year period 1st March 2015-28th February 2017 identified via the Somerset Cancer registry database for Poole Hospital using Crystal software. Previous colonoscopy and CT Colonoscopy (CTC) or CT abdomen results in the 3 years preceding the diagnostic investigations were reviewed across two neighbouring hospitals sharing the same electronic patient records. If patients had multiple surveillance colonoscopies the latest was counted as false negative as in previous studies.

Results: 416 patients were identified, 67 were excluded (39 non adenocarcinoma, 3 out of area, 12 patients where earlier decision was best supportive care, 6 patients diagnosed at laparotomy, 2 patients with abnormal PET scans and 6 with incomplete datasets). 348 patients were included for analysis. Colorectal cancer was diagnosed by colonoscopy in 200 patients and by CTC or CT in 148 patients. The PC-CRC rates in Poole hospital were 2.6% (95% CI 1.8-3.4) in the surveillance group and 0.3% (95% CI 0.2-0.5) in the diagnostic group. The overall PC-CRC rate was 6.5 (+3.6, –2.2) % (90% confidence interval). In the surveillance group, 1 patient with a high grade polyp was detected, but did not transfer to assessing quality indicators at a local level. All patients with each subtype was 68.3 years old for LST-GH, 67.1 for LST-GM, 67.9 for LST-NFG, and 67.2 for LST-NGP. Male to female ratio (M/F) was 1.21 for LST-NGH, 2.05 for LST-GM, 1.95 for LST-NFG, and 1.65 for LST-NGP. Mean size of LST-NGH (21.2 mm) and LST-NGP (21.2 mm) was significantly larger than that of LST-NFG (17.0 mm) and LST-NGPD (15.1 mm). All subtypes were located predominantly in the proximal colon. Incidences of concomitant carcinomas in LST-NGH, LST-GM, LST-NFG, and LST-NGP were 0% (0 out of 151), 14.7% (5 out of 34), 1.9% (2 out of 209), and 25.0% (7 out of 28), respectively.

Conclusion: Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

Introduction: The fecal immunochromometric test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.

Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (GITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the ≥20mg hemoglobin/g of feces threshold. We performed a descriptive analysis of the differences detected during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.

Result: We included 1061 patients without CRC and a complete baseline colonoscopy; 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0±8.9 months with no difference between both groups (p=0.2). There were significant differences regarding age (67.5±12.7 years vs. 64.8±13.5 years, p=0.04) and sex (45.9% vs. 52.0% females, p=0.04) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CRC, 6 gastric, 2 small intestine adenocarcinoma, one eosinophilic gastritis, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9–4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.7%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8–2.1). However, the risk of death due to GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2, 95% CI 1.2–8.9).

Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of CSL.

Introduction: A new indication for translational colonic obstruction (TCT) placement is an alternative endoscopic treatment for ACO; however, the oncological outcomes of TCT placement for the curative treatment of CRC remain unknown.

Aims & Methods: Data were retrospectively reviewed from patients with distal stage II/III CRC who underwent surgery between January 2007 and December 2011 at two Japanese affiliate hospitals with an interchange of endoscopists and surgeons. Stent endoscopic treatment and emergency surgery were the other performed TCT placement as the standard treatment for CRC with ACO. To analyze the efficacy of TCT placement, we compared long-term outcomes for stage II/III CRC with ACO among patients in the two institutions.

Result: In total, 764 patients with distal stage II/III CRC were identified for this study. Among the 764 patients, 690 did not have ACO (non-ACO group), and 74 had ACO (ACO group). In the non-ACO group, we confirmed that the surgical quality was equivalent between the two institutions, with no significant differences in overall survival (OS) (P=0.271) or disease-free survival (DFS) (P=0.184). Among the 74 patients with ACO, 27 underwent emergency surgery (surgery group) and 47 underwent TCT placement (TCT group). The rate of primary resection/anastomosis was higher in the TCT group than in the surgery group (91.5% vs. 22.2%; P<0.001). No significant differences were noted between the two groups in OS and DFS (surgery vs. TCT: 5-year OS, 65.9% vs. 58.1%; P=0.452) or DFS (surgery vs. TCT: 5-year DFS, 47.6% vs. 43.1%; P=0.755). Subset analysis also showed no significant differences in OS and DFS between patients with stage II and stage III CRC.

Conclusion: TCT placement can achieve similar long-term outcomes to those of emergency surgery, with a high rate of primary resection and anastomosis for distal stage II/III CRC with ACO.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Self-expandable metallic stent placement for malignant colorectal obstruction has been widely used; however, factors affecting the technical difficulty of stenting remain unclear.

Aims & Methods: The aim of this study was to clarify the factors associated with the technical difficulty of stenting for malignant colorectal obstruction. We established the Colonic Stent Procedure Research Group to provide instructions on how to safely perform stent placement, and then, we conducted this prospective, single-arm, observational, multicenter clinical trial between October 2013 and May 2014 in Japan. Thirty-two facilities participated in this study. A double-wire woven uncovered stent was placed by using a standard through-the-scope colonoscopic placement technique in each patient. Stent deployment time was defined as the time from reaching a lesion with a colonoscope to finish stenting. Technically difficult cases of stenting were defined as independent factors of the technical difficulty in stenting. We defined the technical difficulty of stenting for malignant colorectal obstruction. The median total procedural time in the cohort with technical success was 30 minutes (IQR, 18–42 minutes). The median deployment time was 21 minutes (IQR, 11–31 minutes). Forty-nine patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting. The following were identified as independent factors of the technical difficulty in stenting: presence of ascites (odds ratio, 2.483; 95% confidence interval [95% CI], 1.17–5.29; p=0.02), placement of stent over lesion (odds ratio, 4.80; 95% CI, 1.10–21.1; p=0.04).

Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining all 196 patients were succeeded in stenting. Of these, 100 were men (51.3%). The median age was 72 years old (interquartile range (IQR), 62–82 years old). One hundred eleven patients (57%) underwent stenting as a bridge to surgery, and 85 (43%) underwent stenting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients required colostomy. For colonic perforation, the median total and clinical success rate of double-wire woven uncovered stent placement for malignant colorectal obstruction. Clinicians should perform this procedure carefully in patients with presence of ascites.

Introduction: Colorectal cancer is the third most common cancer in the world and the fourth leading cause of cancer death. Treatment strategy for colorectal cancer is selected considering clinical stages. TI colorectal cancer (T1CRC) can be treated with endoscopic resection. If patients have pathological risk factors such as deep submucosal invasion, budding, por/muc pathological features and lymphovascular invasion, they considered to be at high risk of lymph node metastasis based on the indication of Japanese Society for Cancer of the Colon and Rectum guideline. In such cases, the selection of subsequent option is important and has been frequently decided by clinicians’ customs and preferences. However, it is not clear whether these risk factors adequately predict patients’ clinical practice.

Aims & Methods: This research aims at revealing the prognosis and clinicopathological features of pathologically high-risk T1CRC patients (the high-risk group) with and without additional surgery; followed up by computed tomography, ultrasound, endoscopy, and tumor marker (CEA: carcinoembryonic antigen). To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as T1 colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosed as “high-risk” and clinicopathological features, presence or absence of recurrence and the final state as of February 2017. We used the Kaplan-Meier product limit method and the Log-rank test to compare OS, CSS, and RFS between AS and FU groups. In clinical setting, based on the guideline indication, the clinician offered subsequent options and described their risks and benefits, and the patient expresses his or her preferences and values. Factors considered through selecting treatment strategy were extracted from informed consent and provider’s note of electronic medical records.

Results: Among 162 T1CRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU), 20 patients were performed additional surgery with lymph node dissection (AS) and tumor marker (CEA: carcinoembryonic antigen). To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as T1 colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosed as “high-risk” and clinicopathological features, presence or absence of recurrence and the final state as of February 2017. We used the Kaplan-Meier product limit method and the Log-rank test to compare OS, CSS, and RFS between AS and FU groups. In clinical setting, based on the guideline indication, the clinician offered subsequent options and described their risks and benefits, and the patient expresses his or her preferences and values. Factors considered through selecting treatment strategy were extracted from informed consent and provider’s note of electronic medical records.

Results: Among 162 T1CRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU), 20 patients were performed additional surgery with lymph node dissection (AS). Four patients treated with additional radiation therapy were excluded. Median survival time was 39 (FU) and 62 (AS), respectively. (p value=0.81) between FU and AS groups. From provider’s notes in electric medical records, factors considered in selection of FU were extracted as follows: Patient’s values and preferences 8, sole presence of “depth” risk factor 7, possible intensive surgery due to T1CRC located in the lower rectum 3, other advanced malignancy 1, and perioperative risks: advanced age 5, past history of abdominal surgery or radiation 2 and severe comorbidities 12 (chronic heart failure 4, chronic kidney disease 2, connective tissue disease 2, lung disease 1 and abdominal surgery or radiation 2). In the other two groups, 12 patients were non-e-curable patients and 3 patients were non-e-curable patients.

Conclusion: Among high-risk group after endoscopic resection of T1CRC, no significant difference in OS, CSS nor RFS are detected between FU and AS groups. Factors considered in selecting FU were patient values and preferences, sole presence of “depth” risk factor and severe comorbidity including perioperative risk. Shared decision making should be achieved subsequent option in the high-risk group.

Results: In this study we developed and tested a controlled-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. A fully apposed, laser-cut nitinol stent was coated with a polymer matrix allowing slow release of paclitaxel. Native Yucatan swine were assigned to one of three stent groups: bare control (n=3, no polymer), standard dose paclitaxel (n=6, 149.4 µg paclitaxel) and challenge dose (n=3, 538.0 µg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group, one in the intrahepatic/hilar region and a second in the common bile duct placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlass® DS cholangioscopy and cholangiography with a targeted 6 month study endpoint. At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary matrix allowing slow release of paclitaxel. Naïve Yucatan swine were assigned to one of three standard dose animal. Stents in one standard dose animal migrated out of the bile duct between 15 and 30 days post-implant. Given the observed 60% reduction in tissue ingrowth and improve biliary stent patency rates.

Aims & Methods: In this study we developed and tested a controlled-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. At 60 days post-implant, moderate mucus and biofilm formation was observed within the stent, however in only 3 animals biliary ductal dilation was observed. At 60 days post-implant, no apparent differences in outcome were observed among the 3 stent control group by 60 days post-implant. Given the observed 60% reduction in tissue ingrowth and improve biliary stent patency rates.

Results: At 30 days post-implant, no significant tissue reaction to any stent was observed. However, all animals displayed mild bioloin formation and increased intraductal mucus production. Substantial dilation of the common bile duct was noted in 51% animals with no apparent relationship between drug coating and duct dilation. At 60 days post-implant, moderate mucus and biofilm formation was observed within the stent, however in only 3 animals biliary duct dilation persisted and majority of stents were fully apposed to the duct wall. Although some animals displayed minimal tissue hyperplasia at the proximal end of the stents, no tissue overgrowth or stent embedding was observed in any animal. Up to 60 days post-implant, no persistent clinical symptoms were observed in any animal. Some rapid dose animal out of the bile duct between days 15 and 30, this animal is not included in patency results. At both 30 and 60 day timepoints, no apparent differences in outcome were observed among the three study groups.

Conclusion: At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary system, even at challenge condition doses. Although the cause of bile duct dilation observed in all stent groups has not been conclusively identified, we hypothesize the cause may be distal stent impaction and intermittent (clinically insignificant) obstruction of the papilla and/or stent, resulting in retained mucus and bile. Bile duct dilation, in turn, has reduced the opportunity for tissue overgrowth and all stent groups, which was expected to occur in the bare stent control group by 60 days post-implant. Given the observed 60% reduction in diameter of dilated ducts between days 30 and 60, we expect increased rate of apposition. Ongoing efforts include controlled follow-up for an additional 120 days, and in a second cohort, determination of in vivo drug release rates in the bile duct over a 30 day period. Future cholangioscopic and histopathological assessment of these swine will further clarify the safety and effectiveness of paclitaxel stent coatings to mediate bile duct tissue ingrowth. A total of 33 (64.7%) patients underwent subsequent surgery after EMR, and 18 (35.3%) chose endoscopic follow up. The histological characteristics of these swine will further clarify the safety and effectiveness of paclitaxel stent coatings to mediate bile duct tissue ingrowth.

Introduction: Cholangiocarcinoma and pancreatic adenocarcinoma account for over 190,000 new cases of pancreaticobiliary malignancy worldwide annually. For palliation of obstructive jaundice in these patients, plastic or self-expanding metal stent (SEMS) is placed. However, re-occlusion rates for covered SEMS range from as high as 36% for uncovered metal stents, 25% for covered metal stents and 52% for plastic stents. Tissue ingrowth accounts for up to 76% of obstructions of bare metal stents. Stent occlusion can result in recurrent obstruction and typically requires endoscopic re-intervention. Therefore there is a real clinical need to reduce tissue ingrowth and improve biliary stent patency rates.

Aims & Methods: In this study we developed and tested a controlled-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. An expanded nitinol stent was coated with a polymer matrix allowing slow release of paclitaxel. Native Yucatan swine were assigned to one of three stent groups: bare control (n=3, no polymer), standard dose paclitaxel (n=6, 149.4 µg paclitaxel) and challenge dose (n=3, 538.0 µg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group, one in the intrahepatic/hilar region and a second in the common bile duct placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlass® DS cholangioscopy and cholangiography with a targeted 6 month study endpoint. At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary matrix allowing slow release of paclitaxel. Naïve Yucatan swine were assigned to one of three standard dose animal. Stents in one standard dose animal migrated out of the bile duct between days 15 and 30, this animal is not included in patency results. At both 30 and 60 day timepoints, no apparent differences in outcome were observed among the three study groups.

Conclusion: At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary system, even at challenge condition doses. Although the cause of bile duct dilation observed in all stent groups has not been conclusively identified, we hypothesize the cause may be distal stent impaction and intermittent (clinically insignificant) obstruction of the papilla and/or stent, resulting in retained mucus and bile. Bile duct dilation, in turn, has reduced the opportunity for tissue overgrowth and all stent groups, which was expected to occur in the bare stent control group by 60 days post-implant. Given the observed 60% reduction in diameter of dilated ducts between days 30 and 60, we expect increased rate of apposition. Ongoing efforts include controlled follow-up for an additional 120 days, and in a second cohort, determination of in vivo drug release rates in the bile duct over a 30 day period. Future cholangioscopic and histopathological assessment of these swine will further clarify the safety and effectiveness of paclitaxel stent coatings to mediate bile duct tissue ingrowth.
Aims & Methods: In this prospective study, we evaluated the overall survival (OS) of CRC patients treated with first-line chemotherapy and undergoing surveillance at our institution. The study population consisted of 131 patients with colorectal cancer (CRC). The patients were divided into two groups: Group A (n=71) consisted of patients who underwent surgical resection of colorectal cancer, and Group B (n=60) consisted of patients who underwent first-line chemotherapy. The patients in both groups were followed for a median of 58.6 months and 69.1 months, respectively. The median survival times for Group A and Group B were 112.6 and 106.4 months, respectively.

Conclusion: The results of this study suggest that surgical resection is associated with overall survival benefit compared to first-line chemotherapy for patients with colorectal cancer. However, further studies are needed to confirm these findings.

Disclosure of Interest: All authors have declared no conflicts of interest.
incidences of metachronous colorectal neoplasms were compared with each other group. Log rank test.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.6 times in group A, 61.6 months and 3.4 times in group B, and 72.3 months and 2.7 times in group C, respectively. The cumulative incidences of metachronous neoplasm were 24.1% (100 patients with 375 low-grade adenomas) in group A, 14.7% (73 with 168) in group B, and 6.6% (34 with 56) in group C, respectively. The prevalence of metachronous non-index lesion was highest in group A followed by those in group B and C, with significant differences between group A and B (p < 0.005), B and C (p < 0.001), and A and C (p < 0.001). The cumulative incidences of metachronous index lesion were 7.2% (42 patients with 45 high-grade adenomas or cancers) in group A, 5.1% (25 with 27) in group B, and 2.3% (12 with 15) in group C, respectively. The prevalence of metachronous index lesion was highest in group A followed by those in group B and C, and significant difference was observed between group A and C (p < 0.001), and B and C (p < 0.05). The cumulative incidences of metachronous invasive cancer were 1.0% (6 patients with 6 invasive cancers) in group A, 1.4% (7 with 7) in group B, and 0.2% (1 with 1) in group C with no significant difference. Logrank test revealed that the cumulative incidence of non-index lesion was highest in group A, and statistical differences were observed between group A and B (p < 0.0001), and between group B and C (p < 0.0001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.05), and between group B and C (p < 0.005).

Conclusion: The results of a long-term colonoscopic follow-up disclosed a significantly higher prevalence of metachronous advanced neoplasms in patients with adenoma >5mm in size resected at baseline compared to those with diminutive polyps left untreated at baseline. Persons with no polyps at baseline colonoscopy were at very low risk of advanced neoplasia within five years during follow-up.

predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages reduced physical activity (7).

Aims & Methods: In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidant styles such as denial and disengagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pooled: N = 250), the variables investigated in Study 1 were measured alongside hypochondrisis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test a priori hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate with both neuroticism and GI symptom severity were included (see Results table). Coping styles were assumed to covary, and the model in Study 2 assumed a covariance relationship between somatisation and hypochondrisis.

Results: Significant standardised path model coefficients involving neuroticism across the two studies. In Study 1, neuroticism exerted indirect effects on sympotm burden through substance-use-based coping and somatisation, as well as through disengagement-based coping and somatisation. In Study 2, neuroticism affected GI symptom burden through denial-based coping and somatisation, as well as through denial-based coping and hypochondrisis. An indirect effect of neuroticism through self-blame and somatisation, with the two intermediary variables relating negatively to each other, was observed in Study 1. (Note: *p < .05, **p < .01, *p < .05. n.s. denotes non-significant coefficients).

Conclusion: Somatisation and hypochondrisis were found to be intercorrelated in the relationship between neuroticism, avoidant coping (through substance-use, disengagement and denial) and GI symptom burden. Two interpretations of the findings are: (1) avoidant coping can stimulate somatisation, leading to reduced physical activity, which can interfere with digestion; and (2) GI symptoms are among the wide range of functional somatic symptoms that can arise from avoidant coping. These findings open new avenues for multidisciplinary treatment of disengagement and denial and GI symptom burden through substance-use-based coping and somatisation, as well as neuroticism through self-blame and somatisation, with the two intermediary effects on symptom burden via row variables.

**Disclosure of Interest:** The expression of CRF1 and CRF2 on HT29 cell surfaces was blocked by irrelevant polyclonal RT-PCR, and CRF1 and CRF2 receptor antagonist treatment with 100 nM CRF for 72h, the transmission of FITC-labeled Dextran was measured by using a transwell chamber; the structural changes of tight junctions were observed under transmission electron microscopy; the Messenger RNA expression of CK8, F-actin, occludin, claudin-1, and ZO-1 and their protein expression of CK8, F-actin and ZO-1 were detected by immunoblotting and immunofluorescence. The activity of RhoA was detected by immunoprecipitation. Furthermore, effects of CRF on intestinal epithelial permeability were examined in CK8-silenced HT29 cells, which were constructed by shRNA interference.

**Results:** CRF treatment increased FITC-labeled Dextran permeability, caused opening of tight junctions, induced increased fluorescence intensity of CK8 and decreased intensity of ZO-1, claudin-1, and occludin, together with structural disruption. The expression of F-actin, occludin and claudin-1 was downregulated. RhoA activity peaked at 30 min after CRF treatment. The increased permeability and the downregulation of claudin-1 and occludin induced by CRF treatment were not blocked by CRF8 silencing. Nevertheless, CK8 silencing blocked the effects of CRF with regard to decrease in the expression of F-actin and ZO-1 and increase in RhoA activity.

**Conclusion:** CRF may increase intestinal epithelial permeability by upregulating CK8 expression, activating the RhoA signaling pathway, promoting intestinal epithelial cytoskeleton remodeling, and decreasing the expression of the tight junction protein ZO-1. Other CRK8-independent pathways may lead to decreased expression of claudin-1 and occludin, which also contributes to increased intestinal epithelial permeability.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The complex pathogenesis of irritable bowel syndrome (IBS) is not well understood. Drossman et al., in the Rome III Diagnostic Criteria, suggested that IBS is a functional bowel disorder and a category of functional GI disorders. The diagnosis of IBS is based on symptom assessment and the Rome III Diagnostic Criteria. According to an epidemiological study, IBS mainly affects young adults of 20–40 years old, and the quality of their lives is seriously affected. The pathogenesis of IBS has not been clarified. Consequently, the usual treatment of the disease in Western medicine involves symptomatic therapy, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients’ symptoms and quality of life, increasing numbers of patients have begun to seek treatment with TCM. A series of randomized, block-controlled trials have shown that TongXie-YaoFang(TXYF) formula can significantly improve the clinical symptoms, such as diarrhea and abdominal pain or discomfort, of patients with IBS and improve the quality of their lives. However, the specific mechanism of it has not been completely elaborated. The purpose of this paper is to observe the regulating effects of TXYF-formula on colonic epithelial secretion via relevant ion transporters.

**Aims & Methods:** We aimed to investigate the pharmacological effect of TongXie-YaoFang(TXYF) formula, a Chinese herbal formula, on D-IBS rats. A neonatal maternal separation plus restraint stress(NMS+RS) model of D-IBS has been established to study the interference between stress and the development of IBS. The effect of TXYF-formula on colonic epithelial secretion can be used as an indicator of the disease. The treatment of TXYF-formula on D-IBS has been clarified. Consequently, the usual treatment of the disease in Western medicine involves symptomatic therapy, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients’ symptoms and quality of life, increasing numbers of patients in China have begun to seek treatment with TCM. A series of randomized, double-blind, placebo-controlled trials have shown that TongXie-YaoFang(TXYF) formula can significantly improve the clinical symptoms, such as diarrhea and abdominal pain or discomfort, of patients with IBS and improve the quality of their lives. However, the specific mechanism of it has not been completely elaborated. The purpose of this paper is to observe the regulating effects of TXYF-formula on colonic epithelial secretion via relevant ion transporters.
P0475 DIOSMECTITE CHRONIC TREATMENT SUPPRESSES GUT VISCERAL HYPERSENSITIVITY AND INTESTINAL TRANSIT ACCELERATION INDUCED BY CHRONIC STRESS IN RAT

Introduction: Stressful life events may trigger the symptoms of irritable bowel syndrome (IBS). Preclinical chronic stress models have been developed in animals to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silicate clay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhoea but also the functional abdominal pain experienced in chronic IBS. However, the effect of diosmectite treatment on IBS visceral hypersensitivity has never been investigated.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. Visceral hypersensitivity was induced by repeated colorectal distension (CRD) (10 cm, n = 10) and stress was randomized to one of four groups: diosmectite (500 mg/kg), diosmectite (500 mg/kg, WAS procedure), water (0.5 ml/rat) or water (0.5 ml/rat, WAS procedure). Treatment was for 5 days, with the WAS procedure conducted once daily. The test apparatus consisted of a Plexiglas tank with a block affixed to the center of the floor. The tank was filled with fresh room temperature water to within 1 cm of the top of the block. Rats were placed on the block for a period of 1 h every day. For both conditions (basal and after WAS), intestinal transit was evaluated by fecal output measurement. Visceral sensitivity was evaluated with colorectal distensions (CRD) 0.8, 1.2 and 2.0 mL placed at 1 cm from the anus. Rectal withdrawal reflexes were tested before and after treatment with diosmectite.

Results: Under basal conditions, chronic oral treatment with diosmectite did not modify visceral sensitivity in response to CRD (20 ± 2 vs. 23 ± 1 cpm/5 mm for vehicle and 20.6 ± 4 vs. 24 ± 2 cpm for 1.2 mL; p = 0.97 and p = 0.75 respectively) or intestinal transit in comparison with control group (p = 0.33). WAS treatment significantly increased the number of abdominal contractions at both 0.8 and 1.2 ml of CRD vs vehicle values (30.1 ± 2.5 vs. 19.7 ± 2.8 at 0.8 ml; p < 0.05) and 34 ± 2 vs. 24 ± 2 cpm at 1.2 ml (p < 0.05). One hour after the beginning of the last WAS session a significant increase of the fecal output in comparison with vehicle was observed (6.3 ± 1.1 vs. 0.3 ± 0.3; p < 0.05) and 5.5 ± 2 vs. 2.0 ± 2 at 1.2 ml (p < 0.05). Under basal conditions and 30 min after the last WAS session.

Conclusion: For the first time, these data illustrate in wistar rat, that diosmectite treatment is able to suppress WAS-induced visceral hypersensitivity to colorectal distension. This study adds relevant evidence to the use of diosmectite treatment in the management of IBS.

Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 15053126120@163.com

Introduction: Bifidobacterium with appropriate doses has been suggested to improve the gut transit in patients with IBS. Bifidobacterium bifidus has been reported. The negative effect of Bifidobacterium has been rarely studied and reported.

Aims & Methods: We aimed to study the effects of gavage administration with Bifidobacterium bifidus for two weeks on the visceral hypersensitivity of rats. Colonic visceral hypersensitivity (CVH) was induced by colonic injection of 0.5% acetic acid (AA) in 10-day old rats while control (NS) induced with 0.9% normal saline. The abdominal withdrawal reflexes (AWR), induced by colorectal distension (CRD), was used to quantify the level of colonic sensitivity in adult rats. The CVH rats in 42-day old were treated by gavage administration with Bifidobacterium bifidus (1010 CFU/day) for two weeks (CVH-Bifi). Other CVH rats were treated with 0.9% NaCl (CVH-NS). A group of control with normal sensitivity was treated with sham gavage (Con-sham). In day 56th, another AWR was assessed, and the hippocampus and prefrontal cortex (PFC) were separated and used to analyze the c-fos, NMDAR 2A, NMDAR 2B with western-blot.

Results: After two-week gavage, the CVH-Bifi presented lower volume than that of CVH-NS in CRD, though without significant difference (2.35 ± 0.28 vs.2.40 ± 0.64, p = 0.11). No significant difference was found between CVH-Bifi and Con-sham as well. In hippocampus, c-fos of CVH-Bifi was higher than CVH-NS (0.37 ± 0.08, p = 0.032) and CVH-NS (0.77 ± 0.23 vs.0.84 ± 0.10, p = 0.171). The NMDAR2A of CVH-Bifi was higher than that of Con-sham (1.04 ± 0.22 vs. 0.51 ± 0.16, p = 0.055). In PFC, the NMDAR2A of CVH-Bifi was significantly higher than that of CVH-NS (0.63 ± 0.14 vs. 0.21 ± 0.05, p = 0.004) and Con-sham (0.63 ± 0.14 vs.0.20 ± 0.07, p = 0.001).

Conclusion: We reported the negative effects of Bifidobacterium bifidus gavage, which induced higher activation of c-fos and higher expression of NMDAR 2A in hippocampus and PFC. The effects of Bifidobacterium bifidus and its metabolites on visceral sensitivity needs further study to clarify.

Introduction: DA-9701, a newly developed prokinetic agent formulated with Biochanin A and Corydalis rhizoma, has been shown to effectively treat functional dyspepsia. Recently, it has also been suspected to improve gastrointestinal motor function.

Aims & Methods: The aims of this study were to assess the effect of DA-9701 on colonic transit time (CCT) and symptoms of functional constipation. We prospectively enrolled 33 patients with functional constipation based on the Rome III criteria. The patients received 30 mg DA-9701 three times a day for 24 days. CCT was estimated initially and at the end of the treatment. We also analyzed symptoms such as spontaneous bowel movements (SBMs), straining, stool form, feeling of incomplete emptying and anorectal blockage, abdominal discomfort and pain, overall defecation satisfaction, and incidence of adverse events.
Results: Twenty-seven patients completed the study. DA-9701 was associated with reduced CTT from 13.0 ± 9.8 to 23.7 ± 9.1 hours (P = 0.001). Segmental CTT also significantly decreased after treatment (right CTT: from 14.0 ± 8.2 to 7.5 ± 4.7 hours, P = 0.001; rectosigmoid transit time: from 14.2 ± 11.9 to 9.5 ± 10.9 hours, P = 0.021). In conclusion, all constipation-related subjective symptoms, including SBM frequency, significantly improved compared to those before treatment. Serious adverse events did not occur.

Conclusion: DA-9701 accelerates colonic transit and safely improves symptoms in patients with functional constipation. Therefore, we suggest that this novel agent could help to treat patients with this condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: No studies have investigated how commonly individuals meeting the new Rome IV IBS criteria seek medical care for their bowel symptoms, or what factors determine medical consultation.

Aims & Methods: We aimed to characterize health care-seeking behaviour in Rome IV IBS subjects in a large multi-national population sample. Data was retrieved from a large Internet survey. The survey was completed by 6300 individuals distributed equally between United States, United Kingdom and Canada. Equal sex, age and education distribution across the countries was ensured by use of quota-based sampling. The survey included questions on demographics, the Rome IV diagnostic questionnaire, the Patient Health Questionnaire (PHQ-12), the 8-item Short Form (SF-8) quality of life (QOL) questionnaire, health care utilization and past gastrointestinal (GI) disease diagnoses by doctors. Respondents with an organic GI disease were excluded from the IBS population. IBS consultants were defined as individuals meeting Rome IV IBS criteria who had visited a doctor for GI symptoms.

Results: 6300 individuals completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4 ± 17.1 years) to be included for analysis (1949 US, 1994 UK, 1988 Canada). After excluding 36 individuals due to lower GI organic disease, 305 subjects (5.1%; 66% female; mean-age 44.7 ± 14.5 years) fulfilled diagnostic criteria for IBS. From these, 195 (64%) had consulted a doctor for GI problems. IBS consultants had equal sex distribution (63.6% vs. 69% female (p = 0.4) and somatization scores (p = 0.34) as non-consulters, but were older (mean age 47.1 ± 14.8 vs. 40.5 ± 13.1 years), more concerned about their bowel function (p < 0.001), more frequently bloated (p = 0.001), and experienced greater impact on social activities (p = 0.008). The distribution of the most bothersome symptom was similar (p = 0.38), and abdominal pain was the predominant symptom in both groups. See table for details. The frequency of doctor visits for non-GI health issues did not differ (p = 0.15), but IBS consultants had undergone more abdominal surgery (p = 0.04). IBS consultants also reported higher consumption of GI related (p < 0.001), prescribed pain (p < 0.001), and anti-depressive medications (p = 0.03), but had similar consumption of anxiety (p = 0.11) and over the counter pain medications (p = 0.34) as non-consulters. See table for details.

## Conclusion

Among individuals who meet Rome IV criteria for IBS in the general population, those who are older, have more frequent bloating, have greater concern about their bowel function, and who are more socially affected by their bowel symptoms, are more likely to consult doctors about their bowel symptoms. In contrast, IBS consultors and non-consultors do not differ in their abdominal pain severity or extra intestinal symptom burden. [Support: The Rome Foundation].

Aims & Methods: The aim of this study was to compare the expression of membrane transporters in mucosal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Mucosal biopsies were obtained from the unprepared sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative 2−ΔΔCt method.

Results: Colonic expression of SLC7A5 and SLC3A2 (together comprising the amino acid transporter LAT1+4F2hc) was significantly lower in IBS patients, but not in PI-IBS patients, compared to healthy controls (P < 0.001). The expression of SLC7A8 (LAT2) tended to be lower in IBS patients compared to controls (P = 0.08). Mucosal gene expression of the short chain fatty acid transporter SMCT1 (SLC5A8) was lower in both IBS-patients and PI-IBS patients compared to healthy subjects (P < 0.01).

Conclusion: The amino acid transporters LAT1 and LAT2 appeared to be affected in IBS patients, but not in PI-IBS patients, compared to healthy subjects, suggesting a possible alteration in amino acids transport in this patient group. Furthermore, our results suggest a lower uptake of short chain fatty acids in both IBS- and PI-IBS patients. Altered expression of these transporters may be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration and therefore deserves further study in IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonic diverticulitis is one of the most common gastroenterological diseases. Though diverticulitis is typically benign, many individuals develop diverticular disease (DD). DD is thought to stem from a complex interplay of environmental, dietary and genetic factors; however, the exact pathogenesis remains unknown.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagens of the connective tissue in the development of diverticulitis. Genetic polymorphisms COL3A1 (rs1334464, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulitis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs1334464, rs1800255 and rs1800012 were associated with diverticulitis. After multivariate logistic regression analysis, they were not linked with the risk of developing colonic diverticulosis in general; when selectively analyzing genders, the minor allele (AA) in rs1334464 remained significantly associated with diverticulitis in men (P = 0.007).

Conclusion: Our study shows that a variant of COL3A1 rs1334464 is associated with risk of developing colonic diverticulosis in Caucasian men, while COL1A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Most colonic diverticulitis can be conservatively treated, but some need surgical intervention due to intestinal complications. Risk factors associated with complications of diverticulitis have been reported mainly from Western countries, but few from Asian countries including Japan.

Aims & Methods: In this study, we aimed to determine risk factors for complications of colonic diverticulitis in Japan. Two hundred and eighty-two patients with acute diverticulitis who were hospitalized from November 2011 to November 2016 in our hospital were studied. Diagnosis of diverticulitis was based on symptoms, physical examination, blood tests, and results of computed tomography. We retrospectively collected data of medical history, examinations, and therapy. Risk factors associated with complications were analyzed by using logistic regression.

Results: Of the 282 patients, 183 (64.9%) patients had right-sided diverticulitis, and 70 (24%) had complications; perforation (n = 55), fistula (n = 8), abscess (n = 5) and stenosis (n = 4). The rate of complication was highest in sigmoid colon (88.6%) when compared with other locations; ascending colon (10%), transverse colon (1.4%) and descending colon (0%). Multivariate analysis identified the location of sigmoid colon (odds ratio 62.2, 95% confidence interval (0.38–1.67) when compared with other locations; ascending colon (10%), transverse colon (1.4%), and descending colon (0%).

Conclusion: The sigmoid colon was a significant risk factor for complication of colonic diverticulitis in Japanese patients. Acute colonic diverticulitis in the sigmoid colon should carefully be treated with surgical interventions in mind.

Introduction: Although symptoms occur in only 20% of patients harbouring diverticula, Diverticular Disease (DD) of the colon DD represents the 8th disease as burden in USA. Several treatment are currently advised in managing those patients, but their impact on the burden of the disease is unknown. The recent DICA endoscopic classification has been developed and validated for the classification of DD, founding that treatment of DICA 1 and DICA 3 patients did not impact significantly in terms of acute diverticulitis occurrence/recurrence and surgery occurrence. Our aim was to assess the impact of using DICA classification on the burden of DD in Italy.

Aims & Methods: We assessed retrospectively the overall and the cost/year of treatment (or rifaximin, or any other treatment, including probiotics, fibers, systemic antibiotics and spasmylinics) in DICA 1, DICA 2 and DICA 3 population. Analysis of diverticulosis prevalence was estimated according to data population provided by Italian Institute of Statistics (ISTAT). Cost of treatments is evaluated according to data on drugs’ consumption collected during the DICA study.

Results: According to 2015 ISTAT population data, we estimated that >8 million of Italian people >60 years may have diverticulosis. According to our endoscopic assessment that about 75% of diverticular population are on DICA 1, about 30% on DICA 2, and about 13% on DICA 3. According to the drugs’ consumption recorded during our study, we estimated that overall about 679 million of euros could be spent in Italy in treating those patients. In particular, >387 million of euros are spent in DICA 1 population, >205 million of euros in DICA 2 population, and >88 million of euros in DICA 3 population. Considering that medical treatments did not show any significant advantage when treating DICA 1 and DICA 3 people in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence, we can estimated that >475 million of euros could be spent in Italy without any significant benefit for DD population.

Conclusion: DD has a significant burden for National Health System in Italy. DICA endoscopic classification may have a significant impact of this burden, helping to select DD people who effectively need treatments in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence.

Introduction: Symptomatic Uncomplicated Diverticular Disease (SUDD) is a clinical entity that, although benign, significantly affects quality of life of patients. Acute diverticulitis may occur in those patients, sometimes needs of surgical treatment, and may cause mortal complications, although not frequent.

Results: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0492 IMPACT OF TREATMENTS ON FECAL MICROBIOTA AND FECAL METABOLIC PROFILE IN SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE OF THE COLON

Introduction: Fecal microbiota and metabolome may be altered in patients with Symptomatic Uncomplicated Diverticular Disease (SUDD). In particular, we found that Akkermansia muciniphila species was significantly increased in SUDD patients when compared with asymptomatic diverticulosis and healthy people, as well as PLS-DA analysis of NMR-based fecal metabolomics showed significant discrimination between HC and AD patient. Our aim was to assess the effect of current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

Aims & Methods: Thirteen consecutive female patients, living in the same district and suffering from SUDD, were studied. Patients were treated with a 2-week course of 30/g/day fiber supplementation (3 patients), 1.6 grams/day of mesalazine (3 patients), 900 billion of day of probiotic mixture VSL#3 (currently available in Europe as VivoMix)5, 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microorganisms. High-resolution proton nuclear magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.

Results: The overall bacterial quantity did not differ before and after treatment (p=0.449). The overall amount of Akkermansia muciniphila species was significantly reduced at T1 (p=0.017) and T2 (p=0.026), while at T3 it became similar to that of T0 (p=0.9). The amount of Lactobacilli group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. All treatments showed the same behaviour and influencing fecal metabolome except for rifaximin group, in which we did not find any metabolic change neither at the end of treatment nor during the washout period.

Conclusion: This preliminary study confirms that Akkermansia muciniphila may play a pathogenetic role in the occurrence of SUDD. We found also that current treatments for SUDD patients are able to influence metabolic activity in those patients except for rifaximin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Natural history of colonic diverticulosis and diverticular disease (DD) is poorly known, and available data derived mostly from retrospective cohort studies.
Aims & Methods: Aim of this study was to assess, in a cohort of patients with colonic diverticula, the incidence of new cases of symptomatic uncomplicated diverticular disease (SUDD) and diverticulitis, and recurrence of diverticulitis after 1-year of follow-up. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of two months. Inclusion criteria were: informed consent; age ≥18 years and endoscopic/radiological-confirmed colonic diverticula. Outpatient/telephone visits were scheduled every 6 months. The clinical data (patients’ characteristics and habits, characteristics of DD, comorbidities and therapies) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients’ features associated with new occurrence of SUDD and diverticulitis.

Results: 1217 patients were enrolled. Characteristics of each subgroup of patients are reported in the table.

**Results:** 1217 patients were enrolled. Characteristics of each subgroup of patients are reported in the table.

**Disclosure of Interest:** R. Cuomo: Speaker and consultant for Alfa Wassermann, G. Barbara: Speaker and consultant for Alfa Wassermann, F. pace: Speaker and consultant for Alfa Wassermann, B. Annibale: Speaker and consultant for Alfa Wassermann, A. Andreozzi: Speaker and consultant for Alfa Wassermann, M. Carabotti: Speaker and consultant for Alfa Wassermann. All other authors have declared no conflicts of interest.

**Introduction:** Patients with symptomatic uncomplicated diverticulosis (SUD) and those with diverticulitis share similar clinical patterns characterized by abdominal pain or change of bowel habits. In clinical practice, differential diagnosis between the two conditions may be useful in the diagnostic approach and therapeutic management.

Aims & Methods: Our aim was to assess the features of abdominal pain in patients with SUD and PD. Patients were categorized according to the following criteria: 1) diverticulosis (presence of diverticula in the absence of abdominal symptoms); 2) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); 3) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. T test was used to compare QoL scores. Logistic regression was performed to identify patients’ features associated with the presence of subtypes of DD. A p value <0.05 was considered statistically significant.

**Conclusion:** These data showed that, with respect to diverticulosis, female gender and presence of GI comorbidities are associated with SUD, whereas younger age, family history for DD and female gender are associated with PD. Furthermore, patients with diverticulitis have higher physical and mental scores compared both to patients with SUD and PD, suggesting that SUD and PD reduced QoL of the affected patients.

**Disclosure of Interest:** R. Cuomo: Speaker and consultant for Alfa Wassermann, D. Santambrogio: Speaker and consultant for Alfa Wassermann, F. pace: Speaker and consultant for Alfa Wassermann, B. filled in long-lasting pain questionnaire. Abdominal pain lasting <24 h was reported by patients with SUDD (86.3%) and 119/134 with PD (77.3%) (p = 0.026). Symptom severity score was higher in PD group than in SUDD group, but this difference was not statistically significant (5.5 ± 2.4 vs 5.1 ± 2.2 cm; p = 0.130). Patients with PD had short-lived pain located more frequently in left lower abdomen (50.6% vs 23.7%; p = 0.002), whereas long-lasting pain was more prevalent in patients with SUDD (29.6% vs 20.8%; p = 0.058). Pain lasting > 24 h was more prevalent in PD group compared to SUDD group (62.1% vs 52.6%; p = 0.029). Pain severity was higher in patients with PD and the presence of fever was significantly more often associated with pain in SUDD patients (53.6% vs 23.7%; p < 0.01), whereas more frequently was diffuse in SUDD patients (17.3% vs 71.5%; p < 0.001). Moreover, in patients with PD, pain lasting > 24 h and fever was associated to 2.6 ± 5.9 vs 2.4 ± 0.9 (p = 0.64) inhibition of contraction. VIP-induced relaxation was significantly decreased in PD patients and should be carefully assessed in clinical work-up of diverticular disease.

Intrinsic myogenic alterations are present in colonic asymptomatic diverticulosis and complicated diverticulitis, both in the circular and longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticulitis, ended in a muscular synthetic pro-fibrotic switch.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0497 THE ONCOCENIC MIR-491-5P/MIR-875-5P NOTCH3-PHLDB2 AXIS IN GASTRIC TUMORIGENESIS

Introduction: aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysregulated Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH1 in GC was achieved from online available dataset. The mRNA and protein expression of NOTCH3 was examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, monolayer colony formation, cell migration and invasion assays through siRNA-mediated knockdown. The prediction of miRNAs which potentially target NOTCH3 was performed by www.microRNA.org and TargetScan. The regulation of NOTCH3 by putative miRNAs was confirmed by qRT-PCR, Western blot and dual luciferase activity assay through ectopic overexpression of miR-491-5p and miR-875-5p. The functional downstream targets of NOTCH3 were identified by gene expression microarray.

Results: NOTCH3, but not NOTCH1, 2, 4, is uniformly up-regulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MKN28 cells exhibited significant anti-oncogenic effect in vitro. NOTCH3 downregulation suppressed cell proliferation, reduced monolayer colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown or miR-875-5p overexpression in AGS cells exerted tumor-suppressive function by inhibiting cell proliferation and inducing apoptosis. More importantly, the expression of miR-491-5p showed negative correlation with NOTCH3 mRNA expression in primary GC samples and over-expression of NOTCH3 rescued the inhibitory effect of miR-491-5p and miR-875-5p. Pleckstrin Homology Like Domain Family B Member 2 (PHLDB2) is identified as the functional downstream target of miR-491-5p and miR-875-5p. PHLDB2 knockdown significantly inhibited cell proliferation and promoted apoptosis, which phenocopies NOTCH3 knockdown or miR-875-5p overexpression. In primary GC samples, the expression of PHLDB2 and NOTCH3 showed positive correlation in The Cancer Genome Atlas (TCGA) cohort. Thus, the miR-491-5p-miR-875-5p-NOTCH3-PHLDB2 oncogenic cascade was constructed.

Conclusion: NOTCH3 is over-expressed and plays an oncogenic role in gastric carcinogenesis through its direct downstream PHLDB2. The activation of NOTCH3 in GC is partly due to the silence of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. These findings comprehensively revealed the activation of Notch signaling pathway and provided clinical translational potential for GC.

Introduction: We found that tumor suppressor gene FOXF2 was silenced in gastric cancer (GC) through promoter hypermethylation. Restoration of FOXF2 suppressed GC tumorigenesis through inhibition of canonical Wnt
signaling pathway. However, the molecular mechanism of FOXX2 in GC is still unknown.

**Aims & Methods:** We hypothesize that FOXX2 transcriptional upregulates a novel E3 ligase that targets β-catenin for degradation. We aim to investigate the molecular mechanism of FOXX2 in GC and identify such E3 ligase by PPI Chromatin Immunoprecipitation (ChIP) assay and luciferase assay.

**Results:** FOXX2 significantly decreased both nuclear and cytosolic levels of β-catenin in a dose-dependent manner. The overexpression of FOXX2 suppressed the TOP-flash luciferase reporter and reduced Wnt target gene expression in GC cells.

**Conclusion:** Overexpression of FOXX2 significantly increased luciferase reporter and reduced Wnt target gene expression in GC cells.

**Introduction:** Obestatin, a 23-amino acid peptide derived from the ghrelin peptide precursor, was originally isolated from human stomach and characterized to bind selectively to the G protein-coupled receptor GPR39. Obestatin is expressed in healthy stomach, oxyntic glands but also in a few cells of the neck section (pre-chief cells). This expression co-localized with PGI expression in both cell types. The mucous neck cells were positive for PGI and negative for GPR39. Obestatin also exerted a dose-dependent stimulatory effect on PGI secretion in the in vitro explant culture of human stomach, being significant for 100 and 200 nM compared to the control sample at 20 min (39% and 66% over control, respectively), for 200 nM at 40 min (51% over control) and 100 nM at 60 min (64% over control).

**Conclusion:** The obestatin/GPR39 system is physiologically involved in the stimulation of pepsinogen secretion in the healthy human stomach.

**P0503** SERUM EXOSOMAL miRNAs EXPRESSION AS NOVEL BIOMARKERS FOR DETECTION OF ESOPHAGEAL ADENOCARCINOMA

H. Chen

Jiangyong County Hospital, Nanjing/China

Contact E-mail Address: chenhuan088@hotmail.com

**Introduction:** Novel biomarkers for diagnosis of esophageal adenocarcinoma (EAC) are urgently required. Currently, there is increasing evidence suggesting that serum exosomal miRNAs may be potential noninvasive biomarkers for certain diseases. The objective of the present study was to find and investigate whether exosomal miRNAs could be effective biomarkers for EAC.

**Aims & Methods:** In the present study, exosomes were isolated from the serum of both EAC patients and normal controls. Total RNA was extracted from exosomes and miRNA levels were compared between EAC and control patients in serum exosomes. We also sought to investigate the relevance of exosomal miRNA expression to clinicopathological factors in EAC.

**Results:** We measured levels of several exosomal miRNAs, including miR-21, miR-16, miR-25, miR-155, miR-192, miR-92a, in 9 EAC patients and 9 controls. Total RNA was extracted from exosomes and miRNA levels were compared between EAC and control patients in serum exosomes. We also sought to investigate the relevance of exosomal miRNA expression to clinicopathological factors in EAC.

**Conclusion:** Serum exosomal miRNAs can be isolated, measured, and may serve as potential biomarkers in EAC patients. miRNA microarray or next-gen sequencing analyses and larger sample sizes are needed to validate these early results.

**Introduction:** Endoscopic variceal band ligation (EVBL) is an effective procedure to control and prevent variceal bleeding in patients with liver cirrhosis. Although EVL has some complications, yet these complications are related to post-EVL ulcers. Few data exist regarding therapy of post-ligation ulcer and treatment been most empirical with drugs used for peptic ulcer disease. An effective protocol for the prevention of variceal bleeding complications after EVL is desirable.

**Aims & Methods:** We aimed to compare the efficacy of rebamipide, sucralfate and pantoprazole in treatment of post banding variceal ulcers. Seventy-five patients with esophageal varices eligible for elective band ligation represented the population of the study. The patients were allocated into three groups; rebamipide group, they received rebamipide 100 mg 3 times daily; pan- toprazole group, they received pantoprazole 40 mg/day orally at morning; sucralfate group, they received sucralfate 1 gm every 6 hours, for 14 days beginning at the next day of band ligation. Subjects underwent EGD 14 days after banding.
Primary outcomes included the size and number of ulcers and the subjects’ reports of pain, dysphagia, chest pain and vomiting.

Results: At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient is statistically significant less in rebamipide group when compared to pantoprazole and sucrafate (P < 0.01). Chest pain, dysphagia and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebamipide is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with no significant effect on post banding ulcer formation. Rebamipide can be used routinely in settings of post-EVL as a good alternative to pantoprazole and sucrafate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: A total of 113 patients were included in the study. The median GBS was 10 (IQR: 7–12). The cut off for GBS at 4, and a CT number at 50HU. The endoscopic treatment percentage of the group of GBS ≤ 4 and CT number ≤ 50HU was 63.5%, GBS ≤ 4 and CT number < 50HU was 30.6%, GBS > 4 and CT number ≥ 50HU was 33.3%, GBS < 4 and CT number < 50HU was 11.1%. We counted that GBS ≤ 4 was 1 point, CT number ≤ 50HU was 1 point. The points were added up to a total score that predicts the necessity for endoscopic treatment. Those scoring 2 points was about 60 percent for the necessity for endoscopic treatment, 1 points was about 30 percent, 0 point was about 10 percent. AUROC of this model was 0.69.

Conclusion: Using both the GBS and CT in combination performed better for predicting the necessity of endoscopic treatment for patients presenting with upper gastrointestinal bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

operative bleeding is still one of the most important adverse side effects. 1, 2

Proton pump inhibitors (PPIs) have been widely used for the treatment of endoscopic submucosal dissection-induced gastric ulcers. However, post-EOBD bleeding compared with EPZ.

Aims & Methods: We compared the incidence of bleeding after gastric ESD between subjects treated with VPZ and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the VPZ group, 9 in the EPZ group) were excluded for simultaneous resection of two or more sites. A case in which active bleeding or exposed vessels were observed on the bottom of ulcers with hematemesis, melena or a drop of not less than 2 g/dl of Hemoglobin within 4 weeks after ESD was defined as “post-ESD bleeding”. In addition, we perform second-look endoscopy on the day after ESD. A case in which hemostasis was needed with hemorrhage of Forrest Ib or more when we underwent second-look endoscopy was defined as “next-day hemostasis case”. We investigated retrospectively post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Results: Gender, age, resected specimen diameter, oral antiemetic administration, and drainage were not significantly different in both groups. Two of the 19 patients in the VPZ group (10.5%) and 6 of the 70 patients in the EPZ group (8.6%) had post-ESD bleeding (Table). In addition, 6 patients in the VPZ group (31.6%) and 37 patients in the EPZ group (52.9%) had next-day hemostasis. There was no significant difference in both groups regarding post-ESD bleeding (p = 0.678) and next-day hemostasis (p = 0.197). However, next-day hemostasis was somewhat higher in the EPZ group than that in the VPZ group. That is possibly because EPZ or VPZ was first administered mostly from the day before ESD in both groups in our hospital, moreover, VPZ rapidly inhibited gastric acid secretion after administration compared with PPIs.

Table: Incidence of post-ESD bleeding and next-day hemostasis

<table>
<thead>

Results: A total of 201 patients received clopidogrel with aspirin and 199 patients received ticagrelor with aspirin were recruited. Mean ± standard deviation age was 66.2 ± 11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs. 100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 days vs. 251 days, respectively (p = 0.216). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44% in clopidogrel group vs. 66.7% in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 (95% confidence interval CI: 0.99–3.7, p = 0.093). By multivariate logistic regression analysis, duration of DAPT < 180 days (RR 3.26; 95% CI 1.89–5.69, p < 0.001) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04–17.71, p < 0.001).

Conclusion: Risk of GIB is almost two times higher among patients received clopidogrel with aspirin compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT < 180 days and previous GIB might be minimized the risk of GIB event after receiving DAPT.

P0512 REAL-LIFE ANALYSIS OF FREQUENCY, LOCATIONS AND BLEEDING SOURCES IN UNSELECTED EMERGENCY PATIENTS DURING NON-VITAMIN K ANTICOAGULANT (NOAC) THERAPY AND COMPARISON TO CONTROLLED APPROVAL STUDIES

M. Raithel1, H. Albrecht2, L. S. Maass3, S. Peter4, A.K. Kluger1, M.F. Neurath2, A. F. Hagel1

Introduction: Non-vitamin K direct oral anticoagulants (NOAC) are increasingly used in thromboembolic disorders due to an efficacy at least equally as vitamin K antagonists (VKA) and/or significantly higher safety for intracerebral bleeding or major bleedings of any source. In the approval studies, there was no generally increased bleeding rate for all types of bleeding, but different gastrointestinal bleeding (GIB) rates for apixaban, dabigatran, edoxaban and rivaroxaban.

Aim: The current study aimed at including consecutively unselected patients manifesting with a GI bleeding under anticoagulation in 2014. All patients who were diagnosed with a GI bleeding under NOAC or VKA therapy in the emergency department of the University Hospital Erlangen were analyzed. Their data were entered in a registry and evaluated in terms of bleeding type, localization, use of proton pump inhibitor and frequencies. These real-life results were then compared with the published data from important approval studies, reporting each on the above mentioned NOACs.

Results: 31 patients with GI bleeding, 31 patients received VKA (14.5%) and 23 patients (10.8%, n.s.) had NOAC with major bleeding rates of 68% and 61%, resp. In patients with VKA 87% had an upper GIB, 12% lower GIB, and none had a rectal bleeding (0%). During NOAC therapy, a similar distribution was found with 71% and 17%, but the proportion of rectal bleeding was higher with 10%.

This frequency of GIB rates in unselected emergency patients is significantly higher than reported in the controlled NOAC approval studies that included selected patients (8%-3.6% GIB). In these NOAC studies a lower rate of upper GIB (55%, 0-71%), a higher rate for lower GIB (32%, 17-84%) and rectal bleeding (15%, 10-47%) was found. Although NOACs are associated with a lower rate for GIB than VKA in the setting of emergency patients, NOACs show a shift of the type of bleeding to lower GIB or rectal bleeding sources in our analysis from emergency patients and in the NOAC approval studies. Only 50% of patients with NOAC were on proton pump inhibitor therapy.

Conclusion: The frequency of GIB in everyday life is approximately 10% higher than reported from the controlled NOAC studies, irrespective of the type of anticoagulation used. NOACs were associated with a non-significantly lower bleeding rate compared with VKA, but major GIB rates were similar. VKA with a bioavailability of 100% after oral ingestion showed a tendency of higher rates of upper GIB, while NOACs with a reduced GI absorption rate of 7-68% were found to occur more frequently at lower GIB sites. Thus, prior to any anticoagulation, a pre-therapeutic risk analysis for the occurrence of GIB is still required. Certain patient groups (anemia, aortic valve stenosis, renal insufficiency, NSAIDs, etc.) can benefit from proton pump inhibitor therapy, early endoscopy with intervention, or NOAC differential therapy.

P0514 CLINICAL CHARACTERISTICS OF FUNCTIONAL DIARRHEA DEPENDING ON WHETHER THEY ARE CHEMOSENSITIVE OR NOT

V. Hammer, K. Hammer, M. Führer, J. Hammer
Department Of Gastroenterology And Hepatology, Medical University of Vienna, Wien/Austria

Contact E-mail Address: jcapsaicin@yahoo.com.au

Introduction: Augmented chemosensitivity to capsaicin has been demonstrated in a proportion of dyspeptic patients, as can be determined by an oral capsaicin capsule test (Hammer et al, JGMS 2008). Sensations induced by gastric capsaicin are distinct from sensations induced by stimulation of mechanoreceptors (Hammer & Vogelsang, JGMS 2007).

Aims & Methods: The aim of the study was to determine clinical characteristics of FD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. N = 49 outpatients with confirmed FD received an oral sensitivity test with 0.75 mg capsaicin at two occasions, before and after ingestion for 4 weeks. Symptomatic responses to capsaicin at the initial test allowed stratification to a capsaicin positive (chemosensitive) and a capsaicin negative (not chemosensitive) patient group. Symptom diaries for upper and lower gastrointestinal symptoms (visual analogue scales) were completed in the week before and during capsaicin ingestion and weekly aggregate symptom scores were calculated. Results are given as median; 25%/75%, p < 0.05 was considered significant.

Results: 33% FD had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily aggregate upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4 (4.1;7.5)) than in capsaicin negative patients (6.6; 4.1 (8.1) (p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by ~3.3 (~4.9/~2.0; p < 0.001) in capsaicin positive and ~2.6 (~4.6/~2.0; p < 0.01) than capsaicin negative patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by ~1.0 (~1.8/~0.1; p < 0.05) in capsaicin positive but not significantly altered (~0.6; ~1.7/~0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of chemosensitive patients (p < 0.01).

Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative FD, but compared to controls a dysregulation in TGM-1 activity levels throughout our GORD biopsies. This result also correlates with an observed reduction in the expression of ADAM17, a regulator of TGM-1 activity.

P0516 INFLUENCE OF PRUCALOPRIDE ON SECONDARY PERISTALIS IN REFLUX PATIENTS WITH INEFFECTIVE ESPHAGEAL MOTILITY

C. Chen, W. Lei, C. Yi, T. Liu, J. Hung
Department Of Medicine, Huallen Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation and Tzu Chi University, Huallen/Taiwan

Contact E-mail Address: harry.chchen@msa.hinet.net

Background: Prucalopride, a 5-hydroxytryptamine (5-HT₃) receptor agonist, is useful in the treatment of chronic constipation by improving colon motility. Prucalopride also promotes secondary peristalsis in healthy adults (Clin Transt Gastroenterol. 2016).

Aims & Methods: We aimed to determine whether prucalopride would augment secondary peristalsis in reflux patients with IEM. After a baseline recording of primary peristalsis, secondary peristalsis was stimulated by slow and rapid mid-esophageal injections of air in 15 patients. Two separate sessions with 4 mg oral prucalopride or placebo were randomly performed.

Results: Prucalopride significantly increased primary peristaltic wave amplitude (68.1 ± 10.0 vs. 55.5 ± 8.8 mmHg, p = 0.02). The threshold volume for triggering secondary peristalsis was significantly decreased by prucalopride during slow (9.3 ± 0.8 vs. 12.0 ± 0.8 mL, p = 0.04) and rapid air injection (4.9 ± 0.3 vs. 7.1 ± 0.1 mL, p = 0.01). Secondary peristalsis was triggered more frequently after application of prucalopride (55% [43–70%]) than placebo (45% [33–50%]) (p = 0.008). Prucalopride didn’t change pressure wave amplitudes during slow air injection (84.6 ± 1 vs. 57.4 ± 13.8 mmHg, p=0.19) or pressure wave amplitudes during rapid air injection (84.2 ± 8.6 vs. 69.5 ± 12.9 mmHg; p = 0.09).

Conclusion: Prucalopride enhances mechanosensitivity of secondary peristalsis and promotes motor properties of primary peristalsis in IEM patients. Our study suggests that prucalopride could be a therapeutic option in the management of GERD patients with significant esophageal hypomotility.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Symptoms compatible with diabetic gastroparesis (DG) affect up to 1 in 5 patients with type I diabetes mellitus. Those affected suffer postprandial

and control biopsies using a targeted assay combined with subsequent IF analy-
sis (66). Compared to controls, prucalopride dysregulated in TGM-1 activity levels throughout our GORD biopsies. This result also correlates with an observed reduction in the expression of ADAM17, a regulator of TGM-1 activity.

Conclusion: The observed increase in nuclear LOR combined with the sporadic cytoplasmic INV localisation, dysregulation of TGM-1 activity and reduced A17 enzyme functions to reinforce barrier function through its ability to crosslink involucrin (INV), revealed sporadic regions of cytoplasmic localisation in multiple GORD biopsies, different from the specific membranous localisation observed in all control samples analysed. The transglutaminase-1 (TGM-1) enzyme functions to reinforce barrier function through its ability to crosslink LOR and INV during terminal differentiation in epithelial tissues at the cellular membrane. Analysis of TGM-1 enzymatic activity was performed in all GORD...
nasea, vomiting, abdominal pain and impaired gastric control. Repeated hospital admissions are common. Endoscopic normality is in most patients. Impaired gastric function is thought to cause the condition. DG does not respond reliably to intensive insulin regimes or prokinetic medications. Jejunal nutrition (JN) is an option in patients that cannot maintain their weight. The benefits are thought to follow improved nutrition and glucose control and glycaemia; however, we have observed that some DG patients eat normally during and after JN (i.e. a quasi-pharma-cological effect). One explanation could be that DG represents a failure of oral nutrition to "switch" the stomach from the fastest to the fed state. According to this hypothesis, nutrients delivered direct to the small bowel triggers the release of peptide hormones that induce normal gastric function.

Aims & Methods: The study tests the hypothesis that JN prior to a test meal improves postprandial symptoms (primary outcome) and gastric function. Diabetic patients with severe symptoms (gastroparesis cardia symptoms index (GCSI) > 27), diabetic controls (GCSI < 14) and healthy controls entered a randomized, double blind, controlled trial. An insulin glucose infusion controlled glycaemia. A JN feeding tube was placed at endoscopy with biopsies taken from the stomach and duodenum. Either liquid nutrient (2 kcal/min) or water was infused for 60 min. Afterwards the Nottingham Test Meal was ingested (NTM liquid: 400 mL, 300 kcal; solid: 12 non-nutrient agar beads 1). Symptoms were documented by VAS, gastric function by MRI and the GL-peptide response was monitored over 120 min using published methodology. Bayesian methods provided 95% posterior ("credible") intervals and mixed model analysis compared response to intervention and between groups.

Results: 9 DG patients, 9 diabetic and 12 healthy controls were recruited. There was no difference in sex distribution, age, weight, medical history (e.g. duration of disease) or endoscopic findings (including histology) between groups. DG patients had more psychiatric co-morbidity and reported higher satiety, bloating and pain after ingestion of the NTM than diabetic and healthy controls (p < 0.05). Sensuations were not affected by NG in the controls; however, fullness, bloating and pain were reduced by JN in DG patients (p < 0.05). Compared to water, JN induced a greater GL-peptide response (e.g. PP, GLP-1) and initial liquid GE was slower (gastric content volume after meal: GCSI > 31 ± 13 mL higher, p = 0.019). Subsequent liquid GE was similar in both study conditions (T30 = 3 ± 8 min, p = 0.727). Anticholinergic wave (ACW) frequency was 2.7 (2.6–2.9) min in health and was highest in diabetic controls (3.1 (2.7 to 3.3) min). Solid GE was more rapid after JN than water (2 (1 to 3) beads emptied ≤60 min) and, again, was highest in diabetic controls (3 (1 to 7) beads emptied ≤60 min).

Numerically the GL-peptide response was less pronounced in both diabetic groups than healthy controls; however, the difference was not significant and a correlation with postprandial symptoms or gastric function was not identified.

Conclusions: This clinical study demonstrates beneficial effects of JN on fullness, bloating and pain after a 400 mL test meal in diabetic patients with moderate-severe symptoms compatible with gastroparesis (GCSI > 27). Additionally, solid GE was accelerated after JN; however, this effect was not limited to DG patients and, thus, the treatment effect that improved symptoms could not be identified. Few patients in DG group had objective evidence of abnormal gastric motor function and the benefit of "prior JN" on symptoms was not limited to patients with slow GE. However, it was observed that diabetic controls had relatively rapid ACW and solid GE. Future studies will identify patients who may benefit from this novel approach to treatment. P0518 PER-ORAL ENDOSCOPIC MYOTOMY IN TREATMENT NAIVE VERSUS PRIOR TREATMENT FAILURE CASES – OUTCOME IN OVER 500 PATIENTS

Z. Nabi, M. Ramchandani, R. Chavan, S. Darisetty, R. Kalapala, D.N. Reddy Gastroenterology. Asian Institute of Gastroenterology, Hyderabad/India

Contact E-mail Address: zaherennabi1978@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) has emerged as an efficacious treatment modality for achalasia cardia (AC). Prior treatment (PT) may affect the outcomes of subsequent. The impact of prior treatment on clinical and technical success of POEM is not well known. Small studies with short follow-up indicate that POEM is safe and feasible in PT failure cases. However, there is paucity of large studies with long-term follow-up.

Aims & Methods: In this study we aim to compare the safety and efficacy of POEM in treatment naive (TN) cases versus prior treatment (PT) failure cases.

The data of consecutive patients with AC who underwent POEM at a single tertiary care center from (January 2013 to November 2016) was analysed retrospectively. A comparative analysis was performed between TN and PT failure cases. Technical and clinical success, adverse events (AE), operative time (OT) for POEM were compared between TN versus PT failure cases.

Results: Overall, 502 patients with AC underwent POEM during the study period. 260 patients (51.8%) were TN and 242 (48.2%) patients had PT. Type II AC was the most common subtype in both the groups (TN -63.5% vs PT – 57.8%) followed by type I and type III. There was no significant difference with regards to AC subtypes between the two groups. The distribution of patients according to prior treatment history is as follows – PHD (205), LHM (23), LHM and PBD both (7), botulinum toxin injection (4) and POEM (3). Significantly more patients in the PT group had sigmoid oesophagus (47 vs 18). Mean OT was significantly more in the PT group when compared to the TN group (PT vs TN -74.9 ± 30.6 vs 67.0 ± 27.1 min; P = 0.002). On multivariate analysis- type of AC, dilated esophagus (> 6 cm) and type of knife used were significant predictors of OT. Technical (98.1% vs 97.1%, P > 0.05) and clinical success (94.9% vs 91.9% of POEM were similar in TN and PT cases. Gas related events and mucosotomies were equal in both groups (TN-35.7% vs PT-33.1%; p=0.57). Objective evidence of gastroesophageal reflux was found in 17/53 patients (32.1%) in PT group as compared to 11/44 (25%) in TN group (p=0.50).

Conclusion: POEM is equally efficacious and safe in treatment naive and prior treated cases. POEM should be considered in treatment failure cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0519 ESOPHAGEAL REFLUX BURDEN IN RELATIONSHIP TO ESOPHAGOGLASTRIC JUNCTION (EGJ) AND ESOPHAGEAL BODY FUNCTION ON HIGH RESOLUTION MANOMETRY (HRM)

1Washington University in St. Louis, St. Louis/United States of America/M
2Digestive Physiology, Hospital Edouard Herriot, Lyon/France
3Department Of Surgery, Oncology & Gastroenterology, University of Padua, Padua/Italy
4Northwestern University, Chicago/United States of America/IL

Introduction: Both EGJ and esophageal body motor abnormalities are found on esophageal HRM in reflux disease, and contribute to reflux burden assessed using acid exposure time (AET) on ambulatory reflux monitoring. Mean nocturnal baseline impedance (MBNI) represents a new paradigm that may assess longitudinal esophageal reflux burden, but its precise role in clinical esophagology, particularly in relation to AET, remains unclear.

Contact E-mail Address: rengara@wustl.edu

Purpose: To compare the MBNI and AET at EGJ and esophageal body level in patients with normal and high reflux burden.

Methods: A total of 135 consecutive patients were prospectively enrolled. The MBNI and AET at EGJ and esophageal body were calculated and compared with the symptom score and AET at the entire esophageal body level. The AET at EGJ and esophageal body were calculated by the number of symptom-related reflux events at each level.

Results: The MBNI at EGJ were statistically higher than esophageal body in patients with high reflux burden (55.8% vs 32.1%, p=0.001). There was no difference at the esophageal body level in patients with normal and high reflux burden. The MBNI at EGJ was also higher than esophageal body in patients with normal reflux burden (51.8% vs 44.6%, p=0.002).

Conclusion: The MBNI at EGJ is a useful parameter to assess the reflux burden at EGJ level. Further studies are needed to confirm these findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: Our aim was to evaluate the complex interrelationships between disrupted esophageal motor abnormalities, and esophageal reflux burden in this ongoing multicenter collaboration. Esophageal function studies from patients with persisting reflux symptoms were reviewed from four centers (2 in each in Europe and US) for this preliminary report. EGJ morphology was categorized using HRM into hypotensive (EGJ-CI <4 mmHg/cm), hiatus hernia (HH, manometric separation between lower esophageal sphincter and crural diaphragm) and intact EGJ (normotensive EGJ-CI, no HH). Esophageal body metrics were characterized using Chicago Classification v 3.0 into intact, ineffective esophageal motility (IEM) and absent contractility. Total and supine AET were extracted from ambulatory pH-impedance studies. Baseline impedance was calculated at the 5 cm impedance channel (to correspond to AET) at three stable 10-min time periods (1, 2, and 3 AM) during the ambulatory pH-impedance study and averaged to yield MNBI (normal >2292 ohms). Univariate and multivariate analyses were performed to assess EGJ and esophageal body predictors of esophageal reflux burden, and to discern the value of MNBI in comparison to AET.

Results: 1244 patients (53.4±0.4 yr, 59.6%F) undergoing esophageal motor testing using HRM (Medtronic, Duluth, GA) and ambulatory pH or pH-impedance monitoring studies performed off antacid therapy were included. A hypotensive EGJ was noted in 70.9%, HH in 34.0%, IEM in 26.3% and absent contractility in 3.5%. A disrupted EGJ and absent contractility had the highest proportions with AET > 6%; combinations thereof raised the proportions even higher (Table, p <0.001 for each comparison to intact EGJ and/or esophageal body). Compared to an intact EGJ, the odds ratio (OR) of total AET > 6% with HH was 2.0 (95% CI 1.1-3.9, p = 0.04). Supine AET >2 was even more impacted (HH: OR 2.4, 95% CI 1.3-4.5, p = 0.007; HH+hypotensive EGJ: OR 3.3, 95% CI 2.1-5.2, p <0.001). A hypotensive EGJ was not discriminative of AET or MNBI values. Concordance between AET and MNBI thresholds was noted in 401 of 596 studies (67.2%; both abnormal in 24.8%, both normal in 42.4%). When concordant and abnormal, proportions with EGJ and esophageal body abnormalities were highest (p <0.05) compared to concordant and normal AET/MNBI, and discordant studies. On multivariable regression with categorical (p =0.0001), increasing HH size (p =0.002), lower EGJ-CI (p =0.04), and increasing numbers of ineffective supine swallows (p =0.043) were independent linear predictors. Only the presence of HH was an independent categorical predictor of abnormal MNBI (p =0.0001), increasing HH size (p <0.0001) and proportions of ineffective supine swallows (p <0.0001) were independent linear predictors.

Proportions with abnormal reflux burden in relationship to EGJ and esophageal body motor findings on high resolution manometry

*p <0.05 compared to intact EGJ and/or esophageal body function **p < 0.05 compared to AET > 6% EGJ: esogastrogastic junction; AET: acid exposure time; MNBI: mean nocturnal baseline impedance; IEM: ineffective esophageal motility, HH: hiatus hernia

Conclusion: A disrupted EGJ and IEM on esophageal HRM are independent predictors of elevated esophageal reflux burden. Hierarchical HRM evaluation of EGJ and esophageal body metrics adds accuracy to categorization of esophageal reflux burden.

Disclosure of Interest: All authors have declared no conflicts of interest.
achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (±13) mmHg to 13 (±5) mmHg (p < 0.0001). The presence of peristaltic recovery was neither associated with normalization of IRP (IRP normalized in 17/28 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, p = 0.25), nor with overall treatment success of POEM (Eckardt score <3).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophageal contractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Medical treatments, endoscopic balloon dilatation, Botox and Heller myotomy are treatment modalities for managing achalasia. Recently per oral endoscopic myotomy (POEM) has become a new option for achalasia patients and since 2010 it has become widespread. Earlier, anterior myotomy was used in this technique but in the last few years there are studies reporting that posterior myotomy is more effective. However, there are limited numbers of publications comparing anterior and posterior myotomy. This study aimed to investigate the effect of myotomy site on POEM, to our knowledge it is the first time in Europe and our country.

Aims & Methods: Between May 2014 and January 2017, POEM was performed to 225 achalasia patients at the gastroenterology clinics under general anesthesia by an endoscopist experienced at endoscopic submucosal dissection and trained to 225 achalasia patients at the gastroenterology clinics under general anesthesia.

Results: There were 114 patients in group A, 111 patients in group P. There was no statistical difference between the groups in regards of tunnel length, myotomy length, tunnel entrance time and frequency of homeostatic forces use (p > 0.05). However duration of opening the tunnel, myotomy, closure of the tunnel and total procedure time were significantly shorter in group P (p < 0.05). Eckardt and dysphagia scores before the procedure were similar in both groups. After the procedure Eckardt scores were significantly low in all patients (p < 0.0001). Demographic features and data of the procedures are shown in the table below. Mucosal damage during the procedure occurred in 3 patients and capnoperistoneum developed in 71 patients. All complications were treated endoscopically. Controls at 3rd month was performed to 151 patients among which revealed esophasitis grade A in 24, grade B in 6 and grade C in 3 patients.

Conclusion: According to our results posterior approach can shorten the procedure time in POEM compared to anterior myotomy. This may be due to a better angle of approach with endoscopic equipments for posterior myotomy.

We believe that long-term results will also show the effects of myotomy site on clinical outcome of patients.

Introduction: Beer has been related to gastroesophageal reflux (GER) and dyspepsia (1, 2), based on its alcohol and gas content. Main objective was to evaluate if moderate regular and non-alcohol beer consumption is related to postprandial
dyspeptic symptoms after a controlled meal. Secondary objectives were to evaluate its relation with postprandial GER and gastric accommodation and to evaluate its relation with daily digestive symptoms under real conditions.

Aims & Methods: Healthy people over 18 years old, free of frequent digestive symptoms (< once a week) and GER disease (GERD), were included. Basal symptoms were assessed through PAGI-SYM (3) and QOLRAD (4) questionnaires, both validated to Spanish. Study was divided in two substudies based on the study intervention: 33 cl of regular beer (substudy 1) and the same amount of non-alcoholic beer (substudy 2). Mineral water (33 cl) was the control intervention in both substudies. Each participant was its own control. The study lasted two weeks (control study week and intervention study week). Each week started with a visit to the laboratory at 7:30 h am, when a pHimpedance catheter was placed and taken off 24 hours later. Gastric accommodation was assessed through the maximum tolerated volume during a nutrient drink test (ENSURE®; HN, 500 ml) in a rhythm of 15 ml/min, after the ingestion of beer (intervention) or water (control). It was defined as the volume after which the test finished or the participant reported the maximum punitation for any dyspeptic symptoms (early satiety, bloating, epigastric pain and nausea), which were asked every 5 minutes (1 meant no symptom and 5 meant the highest perception). GER was evaluated in the postprandial period and during 24 hours through pHimpedance register. Weekly symptoms evaluation was made though a diary adapted from PAGI-SYM questionnaire and sum of symptoms was used for analysis. Data were collected daily through email. Variables were compared between both visits and weeks in both substudies using a non parametric test for matching data. Participants should drink 33 cl of beer before lunch and dinner during the intervention week. Other alcohol drinks were prohibited during the study.

Results: Ten participants were enrolled in substudy 1, mean aged 24 years old (SD 4, 1 (18–32); 80% were men. Twenty participants were enrolled in substudy 2, mean aged 23.4 years (SD 5.5 (20–38)); 65% were men. No significant differences were detected in the increase of symptoms during the nutrient drink test between control and intervention visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies. Reflux episodes after nutrient drink test and reflux episodes registered in 24 hours did not show significant differences between control and study visits. The sum of weekly symptoms did not show any difference between control and intervention weeks in both substudies.

Conclusion: Moderate beer consumption (regular and non-alcohol beer) does not cause an increase of dyspeptic symptoms and reflux in healthy people. It has been shown in a controlled situation (nutrient drink test and pH impedance register) as well as real life (diary weekly symptoms). Gastric accommodation and reflux episodes have either shown to be affected by moderate beer consumption.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea 1, 2. Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD 3–5. Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might exist among patients with rumination syndrome.

Aims & Methods: We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophageal high resolution impedance manometry (HRIM) and/or fulfilled ROME II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4–6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom 4–6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent (within 30 days) intake of NSAIDS and pregnant and/or lactating females were excluded. Duodenal biopsies obtained were routinely processed to formalin fixed paraffin-embedded tissue blocks which were cut at 3μm, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm2 in sections. Individual sections were also assessed for the presence of Brunner’s glands (BG) and intraepithelial lymphocyte counts (IEL)/100 enterocytes. This was done in order to distinguish the first part of the duodenum from the second part (D1 vs D2) and the second part generally without BG, (D2) and intraepithelial lymphocyte counts (IEL) 100 enterocytes.

Results: Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. Controls (10) had a mean age of 34.3 (range 19–69) and 80% were female. The mean eosinophil counts/biopsy fragment (+/− Brunner’s glands (BG), showed no difference in counts in the sections +/− BG (D1 vs D2), p=0.8. No overt pathology was noted, but IEL counts were significantly higher in rumination patients (mean 15, range 8–29, and 2 cases had lymphocytic duodenosis) vs controls (mean 11, range 11–18), p=0.02. Compared to controls, there was a significant increase in the mean eosinophil count among the patients with rumination syndrome rumination, 26 pm2 (range 16–42), vs 18 mm2 (range 10–28), p=0.006.

Conclusion: These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome compared to controls have not previously been described. Therefore, a potential role of duodenal immune mechanisms in the pathophysiology of rumination syndrome warrants further enquiry.

Results:
A total of 101 gastroparesis patients (71% female, 20-86yrs, mean 55yrs) were prospectively enrolled. Abnormal gastric emptying was defined as a gastric emptying time of greater than 50% of previous meal at 180 minutes. Delay in gastric emptying was significantly associated with a decrease in quality of life (p < 0.01) and an increase in healthcare utilization (p < 0.001). The presence of gastroparesis was significantly associated with lower levels of sleep (p < 0.001), lower levels of physical activity (p < 0.001) and lower levels of exercise (p < 0.001). The presence of gastroparesis was also significantly associated with lower levels of social activity (p < 0.001) and lower levels of work and school activity (p < 0.001).

Conclusion: This is the first study to examine the relationship between gastroparesis and sleep, physical activity, exercise, social activity, work and school activity. These findings suggest that gastroparesis is associated with a decrease in quality of life and an increase in healthcare utilization.

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

**Aims & Methods:**

Data from an online survey of 6300 individuals aged ≥18 years in the United States, United Kingdom and Canada (2100 in each country) including the Rome IV diagnostic questionnaire for adults and demographic questions was used. Quota-based sampling ensured equal proportions of sex, age groups, and educational distributions across countries. Prevalence and frequency of esophageal symptoms in the past 3 months and putative functional esophageal disorders were retrieved from the Rome IV questionnaire. Symptoms were considered present if they occurred at least weekly for dysphagia, chest pain, and globus, and at least twice weekly for heartburn. Variables with a p ≤ 0.1 in univariate analyses were entered into a multivariate analysis (logistic regression) to identify factors independently related to esophageal symptoms. As endoscopy and pH measurement are parts of the clinical diagnosis of esophageal disorders in the Rome IV criteria, we only describe esophageal symptoms compatible with functional esophageal disorders. Somatization was assessed with the Patient Health Questionnaire (PHQ)-12.

**Results:**

Data from 5177 participants (47.8% female; mean age 46.7 years; 1645 US, 1734 UK, 1798 Canada) were retained for analysis after 369 inconsistent responders and 754 previously diagnosed with gastroesophageal reflux disease (GERD). Exclusion criteria for functional disorders were age <18, GERD, and presence of other FGIDs, using medications for gastrointestinal symptoms, somatization, cannabis use, and certain foods (see table 1). When individuals with GERD were included in re-analyses, GERD was a significant predictor for chest pain and heartburn (OR 1.939 and 1.525), but not globus and dysphagia. The prevalence of symptom constellations consistent with Rome IV esophageal diagnoses was 1% for globus, 3.2% for functional dysphagia, 0.7% for reflux hypersensitivity, 0.8% for functional chest pain, and 5.2% for functional heartburn. There was a significant difference in symptoms consistent with any functional esophageal disorder between USA 7.0%, UK 1.1% and Canada 1% for functional heartburn. There was a significant difference in symptoms consistent with Rome IV esophageal diagnoses was 1% for globus, 3.2% for functional dysphagia, 0.7% for reflux hypersensitivity, 0.8% for functional chest pain, and 5.2% for functional heartburn. There was a significant difference in symptoms consistent with any functional esophageal disorder between USA 7.0%, UK 1.1% and Canada 1% for functional heartburn. There was a significant difference in symptoms consistent with any functional esophageal disorder between USA 7.0%, UK 1.1% and Canada 1% for functional heartburn.
Several studies have provided information on the prevalence of different atopic conditions in adult EoE patients compared to control groups of subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have varied and the selection bias for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. We therefore performed a systematic review and meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control population.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently by two (AA and AJL) of the authors. A third author (AM) independently extracted information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary estimates, including 95% confidence intervals (CI), were calculated for each season and month, whenever possible.

Results: Of the 2945 references identified, data was collected from 21 studies including a total of 53,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls was not structurally considered in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with eosinophilic esophagitis (EoE) patients, and healthy controls, all of whom were endoscopically assessed with a diagnosis of EoE specifically ruled out. In all cases, EoE was considered as independent from GORD and other upper GI tract diseases. Some studies included database-registered subjects as being part of a diagnosis group. The criteria for defining a diagnosis of atopy among EoE patients and control subjects varied widely across the different studies, from self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses. Overall, allergic rhinitis was significantly more common in EoE patients compared to control subjects (OR 5.5 [95% CI: 3.27, 9.53; I2 = 67.9%]) as were bronchial asthma (OR 3.06 [95% CI: 2.01, 4.66; I2 = 83.4%]) and eczema (OR 2.86; 95% CI, 1.88, 4.36; I2 = 57.2%), Food allergies and other atopic conditions were also assessed. No significant publication bias was found in studies dealing with allergic rhinitis and eczema in EoE. Finally, our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95% CI, 0.78, 1.24).

Conclusion: The present study shows that an accurate diagnosis of asthma is lacking in most of the research evaluating the prevalence of asthma, rhinitis, and eczema among EoE patients. Still, the prevalence of these three conditions seems to be significantly higher in children and adults with EoE as compared to control subjects. Furthermore, we identified a need for more standardized information on indices related to asthma and eczema in the general population and use standard definitions of allergic rhinitis, asthma (including its severity and level of control), skin allergy, and food allergy (rather than mere sensitization) when assessing and documenting concurrent allergic diseases in EoE patients. This would help in defining a diagnosis of atopy in EoE patients and control subjects and assessing the prevalence of allergic conditions in both populations without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. We therefore performed a systematic review and meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control population.

to steroids (64% vs 36%; p = 0.002). Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. (p = 0.007).

Conclusion: A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histological one.

Conclusion: Esomeprazole, rabeprazole and pantoprazole administered at double daily dose were equally effective in determining endoscopic and histologic remission in patients with PPI-REE. These data, although obtained in a small sample of patients, suggest that the pharmacokinetic and pharmacodynamic differences among these drugs do not affect their effect on PPI-REE patients.

P0538 SYMPTOM PATTERNS AND TYPES OF GASTROESOPHAGEAL REFLUXES SIGNIFICANTLY DIFFER IN GROUPS OF EROSI V ESOPHAGITIS AND NON-EROSSIVE FORM OF GASTROESOPHAGEAL REFLUX DISEASE (GERD) PATIENTS

M. Konovalova, S. Morozov, V. Isakov
Gastroenterology And Hepatology, Federal Research Center of Nutrition and Biotechnology, Moscow/Russian Federation

Contact E-mail Address: sunnysister@mail.ru

Introduction: Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients’ symptoms with characteristics of refluxes obtained by 24-h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M ± s) 42 ± 4.8 yrs) and 49 controls (22 men, 27 women, age (M ± s) 46 ± 6.7 yrs) were examined using 24-hours esophageal pH-impedance recordings (Ohmega, MMS, The Netherlands; 2×6-h impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline esophagitis 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients’ symptoms were classified according to Montreal classification.

Results: Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (Table 1). However higher number of acid refluxes, higher GERD-Q score and DeMeester score were present in ERD. The total number of gastroesophageal refluxes didn’t differ between ERD and NERD groups of patients.

Conclusion: ERD and NERD groups of patients are characterized by different symptom patterns and types of gastroesophageal refluxes registered with 24-hours esophageal pH-impedance monitoring. These findings could reflect differences in pathogenesis and clinical manifestations of mentioned forms of GERD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological anatomical mechanisms and the presence of extraesophageal symptoms. Exhaled breath condensate (EBC) and saliva are two easily obtainable samples that could be used in monitoring of patients suffering from gastroesophageal reflux disease. The aim of this study was to compare the pH and total ionic profile of EBC with 24-hour multichannel intraluminal impedance and pH monitoring (MII-PH) and salivary PEPtest in a group of patients with acid reflux (pH < 4), weakly acid reflux (pH 4–7) and healthy controls.

Aims & Methods: A portable EBC sampler was used for collection of EBC. 10 mL sample aliquots of EBC were analyzed. For pH measurement, the CO2 from EBC was washed out with Na2CO3 gas for 10 min. A pH value with CO2 washed out was used with a pH microelectrode and total ionic profile (ammonium, cations, organic acids - NH4+, K+, Ca2+, Na+, Mg2+, Cl-, CO3–, NO3–, SO42–, acetate, lactate, propionate, butyrate) was analyzed by capillary electrophoresis in each sample. Saliva was collected using the commercial PEPtest sampling containers, applied to the PEPtest lateral flow devices and analyzed using the device reader. The data from EBC were compared with MII-PH and PEPtest. In total the study comprised of 39 participants. The patients were divided by dominant findings from MII-PH in groups with acid reflux (n = 17), weakly acid reflux (n = 8) and without reflux (n = 14).

Results: The values of pH (after CO2 removal with Na2CO3) were significantly higher in the group with acid reflux (p < 0.01), mean pH 7.13, interquartile ranges 6.83–7.47 and in the group with weakly acid reflux (p < 0.01) (7.37, 7.18–7.57) vs. healthy controls (6.8, 6.65–6.99). Butyric acid (BA) was the second most significant parameter that was significantly elevated (p < 0.01) in both patient groups (acid reflux- mean BA 2.29 µM, weakly acid reflux- mean BA 3.31 µM) compared to healthy subjects (mean BA 0.69 µM).

Further statistically significant differences were found in chloride (Cl–), nitrite (NO2–) and sodium (Na+) ions concentration. BA was elevated (p < 0.01) in group with acid reflux vs. healthy controls and NO2– and Na+ were elevated (p < 0.01) in weakly acid reflux group vs. healthy controls. The data of examined parameters showed no statistically significant differences within the groups. In the groups of patients with acid reflux, the incidence of high pepsin concentration (above 75ng/ml) was found only in 50% of the patients.

Conclusion: We found statistically significant difference in pH and selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can

P0539 LARYNGEAL DISORDERS AND CHRONIC COUGH IN ADULTS WITH AND WITHOUT EROUSIVE ESOPHAGITIS: A CASE-CONTROL STUDY IN ALBANIA

Introduction: Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

Aims & Methods: Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 108 patients with erosive esophagitis (aged 46.6 ± 16.3 years) and 273 controls (aged 46.4 ± 16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors were also collected. Binary logistic regression was conducted to assess the association of erosive esophagitis and extra-esophageal symptoms.

Results: Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentariness and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9%, respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all socio-demographic characteristics and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR = 3.1, 95%CI = 1.7–5.7), and even more so with laryngeal disorders (OR = 4.4, 95%CI = 2.6–7.4). In all models, the association of erosive esophagitis with extra-esophageal symptoms was strong and independently related to the symptoms separately (fully-adjusted model: OR = 4.6, 95%CI = 2.9–7.3).

Conclusion: Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper endoscopy should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders.

Introduction: Impedance-pH testing is actually considered the gold standard diagnostic tool for reflux assessment. In fact, it allows to characterize any type of gastro-esophageal reflux (GER), namely acid and non-acid, and therefore permits – in presence of typical reflux symptoms – to diagnose functional heartburn (FH) based on the lack of abnormal acidic or non-acidic refluxate (i.e. normal number of reflux episodes and negative reflux-symptom association). Gastrin-17 (G17) has been proposed as a non-invasive marker of GERD, due to the negative feedback between acidic output and this hormone. Indeed, preliminary data showed that intermediate values of G17, between very low to normal levels, may identify patients with abnormal non-acid reflux.

Aims & Methods: We aimed to correlate various patterns of refluxate (i.e. predominant acidic refluxate, predominant non-acidic refluxate and no reflux at all), as assessed by impedance-pH, with different levels of G17 in endoscopy-negative subjects with heartburn. Thirty-five consecutive patients (19F/16M, mean age 47 years, range 31–56 years), all reporting heartburn since 6 months with at least 3 episodes/week, entered the study. All patients underwent upper endoscopy and medication – in presence of typical reflux symptoms – to diagnose functional heartburn (FH), suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

Introduction: As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve a non-surgical control. Linx procedure, Stretta have been proposed as less invasive options.

Aims & Methods: We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap grading of 1 to 3. We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients. Patients with significant reflux of relux had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probes (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

Results: Technique: Crescentic ARMS of the esophagogastric junctional (EJG) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal valve at gastric cardia. All the patients who underwent ARMS had a significant reduction in the DeMeester score, with predominant decrease in the reflux acid exposure. 7/12 patients were able to discontinue all the medical therapy. PPI dose reduction was possible in the other patients with a mean reduction of 50%, alginates were stopped in all patients and HRA were also discontinued.

Conclusion: Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardio opening, while preserving and/or creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost “mechanically-stitched” appearance. The mucosal flap is rebuilt and looks well-defined. Furthermore, the lesser curve side

</table>
of the EGI is shortened with scar formation, and greater curve of EGI (his site) is not restored and therefore retains postprandial acidity as a mucosal flap valve. The quantity of mucosa to be resected to induce appropriate (“not too tight and not too loose”) scar formation is a key issue in this procedure. Total circumferential resection causes strictureing as demonstrated in previous studies, while subtotal dissection, which we have termed crescentic, produces better results in this regard, while still resulting in symptom control. Mucosal flap valve grading is not only a good predictor of reflux in these patients but also is a prognostic marker of effectiveness of ARMs, i.e. higher the grade worse the outcome. Thus, the extent and pattern of mucosal resection (17 vs. ESD) according to the mucosal flap valve grading may be a better predictor of outcome than a box standard procedure. This technique has a potential role in people with oesophageal dysmotility wherein Nissen’s fundoplication is relatively contraindicated.

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, bone mineral density (BMD), true fractional calcium absorption (TFCA), and serum and urine mineral levels in healthy postmenopausal women taking PPIs or placebo for 26 weeks.

Aims & Methods: Postmenopausal women aged 45–75 were randomised to daily oral 60-mg dexlansoprazole (DEX), 40-mg esomeprazole (ESO), or PBO for 26 wks with follow-up at wk 52. Primary endpoints were 26-wk % change vs placebo in procollegen type 1 terminal propeptide (PINP) and C-terminal telopeptide of type 1 collagen (CTX). Additional endpoints included changes in BMD (26 and 52 wks) and serum and urine mineral levels (26 wks). Fractures between baseline and wk 26 were recorded as adverse events. TFCO (0 and 26 wks) was measured in a subset (n = 34) of patients.

Results: Excluding 1 disqualified site, 115 women were randomised and 93 completed the study. There were no substantial differences in age, BMI, baseline serum calcium, or vitamin D levels between groups. The bone turnover markers PINP and CTX were within normal range during 26 wks of PPI therapy. Within each group, there was no statistically significant 26-wk change in bone turnover, except a small increase in CTX levels with DEX (0.12 ng/mL, 95% CI 0.03–0.23). The 26-wk median % increases in PINP from baseline vs PBO (difference in median % change [95% CI] = 19% (7%–30%) for DEX and 18% (7%–30%) for ESO. CTX levels increased vs PBO by 27% (13%–43%) for DEX and 22% (8%–36%) for ESO. PPI effects on BMD, serum and urine mineral levels, and parathyroid hormone were not statistically different vs PBO. Median % change from baseline in TFCO vs PBO was not statistically significant for DEX, but was significant for ESO (6%, 95% CI 2%–11%).

No spontaneous fractures occurred during treatment; 1 traumatic foot fracture (DEX) and 1 humerus fracture (circumstance unknown; ESO) occurred during follow-up.

Conclusion: 26 wks of DEX or ESO therapy increased bone turnover markers, but did not reduce BMD, TFCO, or serum or urine mineral levels. ESO increased TFCO by <1%. Although bone turnover markers increased with PPI therapy, levels remained within the normal ranges. No clear explanation for an association between PPI therapy and fracture risk was found in this study.

Introduction: pH-impedance reflux monitoring inhibit gastroesophageal reflux; however, remains unexplored effect of alginates on postprandial processes in the stomach.

Aims & Methods: 25 patients (14 F, age 23–69) with typical GERD symptoms, participated in this study. All patients underwent a 3-hour combined gastroesophageal pH-impedance monitoring with standardized breakfast (muffin and coffee). To determine the effect of alginates on postprandial reflux and pH in the esophagus and stomach, all patients underwent a repeat of similar monitoring the next day. On this day, they took alginate after breakfast. The difference in pH in the esophagus, in two parts of the stomach and the different types of gastroesophageal reflux (acid, low acid, alkaline, liquid, gas & mixed) was estimated. To evaluate the effects of raft-forming alginate on the severity of postprandial reflux in patients with GERD and for the postprandial stomach content.

Results: Monitoring with alginate showed significantly (P < 0.05) less number of acid [average values 5.42 ± 0.69 (M ± s) vs. 3.33 ± 0.43 during 1st postprandial hour and 3.96 ± 0.8 vs. 1.82 ± 0.57 during 2nd postprandial hour] and gas [0.26 ± 0.06 vs. 0.08 ± 0.05 during 1st postprandial hour and 0.47 ± 0.35 vs. 0 during 2nd postprandial hour] gastroesophageal reflux, but increased of number low acid reflux [2.52 ± 0.46 vs. 3.91 ± 0.82 during 1st postprandial hour (P < 0.05), 4.08 ± 0.42 vs. 2.16 ± 0.45 during 2nd postprandial hour; P > 0.05]. Also noted is a significant (P < 0.05) increase in the pH in the esophagus for 120 minutes after ingestion [average pH values 6.04 ± 0.27 vs. 4.86 ± 0.23 during 0–60 min., and 5.93 ± 0.25 vs. 4.15 ± 0.26 during 60–120 min.]. In the gastric cardia (a typical place of formation of postprandial acid pocket) showed significant (P < 0.05) higher values for the first 60 minutes after intake of alginate [pH 4.3 ± 0.37 vs. 3.04 ± 0.25], during 60-90 min, pH values wasn’t significantly (P > 0.05) different [2.75 ± 0.45 vs. 2.43 ± 0.28]. In the stomach body no significant effect of the drug on pH was recorded [average values for stomach 2.56 ± 0.46 vs. 2.1 ± 0.18 during 1st postprandial hour and 2.29 ± 0.49 vs. 2.09 ± 0.18 during 2nd postprandial hour; P > 0.05].

Conclusion: Our findings demonstrate that raft-forming alginate is an effective means for the prevention of postprandial acid and gas reflux and to reduce the injurious effect of acid in the esophagus. At the same time alginate showed no effect on stomach content in the postprandial period, it means that the main mechanism of action is through the movement of postprandial acid contents of the lower esophageal sphincter, but not the neutralization of stomach acid, unlike nonraft-forming antacids and PPIs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: S-isomer (S) pantoprazole is more bioavailable and less dependent ever, remains unexplored effect of alginates on postprandial processes in the stomach.

Aims & Methods: We aimed to evaluate the efficacy and safety of 10 mg S-pantoprazole for treatment of non-erosive reflux esophagitis (NERD). This study was designed as a multicenter, randomized, double-blind, placebo controlled trial.NERD was defined as reflux symptoms and normal endoscopy findings. Patients were allocated to either 10mg S-pantoprazole or placebo once daily for 4 weeks, after which reflux symptoms were reassessed. Recurrence of symptoms was assessed at 4 weeks after cessation of medication. The efficacy endpoints were complete relief of symptoms, improvement of reflux symptoms, and safety.

Methods: Eighty-eight: patients randomly assigned into the pantoprazole group (25 males, 43.7 years old) and 86 to the placebo group (32 males, 43 years old), and 163 patients were subjected to a per protocol analysis. A higher proportion of patients in the S-pantoprazole group had complete symptom relief (33% vs. 14%, P < 0.001). In both groups, symptoms of heartburn, acid regurgitation and epigastric discomfort were 0.66, 1.82, and 0.57. The factors associated with poor symptom responsiveness to PPI were older age, female sex, greater body mass index and symptom severity in both groups.

Conclusion: S-pantoprazole (10 mg) was more efficacious than placebo in providing reflux symptom relief in patients with NERD, especially acid regurgitation.

Disclosure of Interest: All authors have declared no conflicts of interest.
Despite PPI therapy.

Conclusion: A tailored approach to refractory NERD, guided by MII-pH monitoring. Subjects were subgrouped into 3 categories according to Zerbib's classification: i) Acid reflux (presence of pH < 4 for at least 1.1% of record time), ii) Non acid reflux (symptom association probability to pH > 4 reflux episodes > 95%) and iii) Functional heartburn (no pathologic reflux, with symptom association probability < 50%). MII-pH guided therapy was performed as follows: patients with acid reflux received PPI at double dose, patients with non acid reflux PPI at full dose plus alginates and patients with functional heartburn levosulpiride 75 mg/day for 4 weeks. A visual analogue scale (VAS) ranging 0–100 was administered before and after such tailored therapy to evaluate overall symptoms. Responders were defined by VAS improvement of at least 10%. Comparisons between continuous variables were performed by ANOVA or paired/unpaired t-test where required, and Fisher’s exact test was applied to categorical variables. Variables with statistical significance p < 0.10 at univariate analysis were selected by binomial multivariate regression analysis, aimed to investigate factors predictive of response to tailored therapy.

Results: Thirty-four patients with refractory NERD were selected (female:male ratio 20:14, mean age 47.4 ± 12.8). Twelve had acid reflux, 7 non acid reflux and 15 functional heartburn. Overall effectiveness of tailored therapy was 82.3% (28 out of 34), and it did not differ between subgroups (91.7% acid reflux, 71.4% non acid reflux, 80.0% functional heartburn, p = 0.31). At univariate analysis, therapy failure directly correlated with dysphagia (OR = 0.15, p = 0.10) and intensity with sensation of slow digestion (OR = 7.70, p = 0.05). However, at multivariate analysis, these parameters were not statistically significant. We found a mean VAS reduction of 30.2 ± 24.9, which was similar between acid reflux (36.7 ± 22.7), non acid reflux (30.0 ± 27.7) and functional heartburn (25.7 ± 23.5) p = 0.15.

Conclusion: A tailored approach to refractory NERD, guided by MII-pH monitoring, demonstrated to be effective, independently from disease subtype. Therefore it should be advised to patients who complain of symptom persistence despite PPI therapy.

Aims & Methods: Organoid cultures are widely used because they mimic in vitro differentiation of self-organizing stem cells and represent the perfect model to study stem cell interaction in basic and translational research. We developed an in vitro organoid model of human BE to investigate the potential to modulate the metaplastic process using an innovative anti-BMP2/4 llama-derived Dwarfbody (DB). Endoscopic BE biopsies were implanted into immunocompromised mice intramuscularly and grown for a period of three months with DB or control serum. These structures were assessed histologically and immunohistochemically (IHC) using panels of squamous, intestinal and stem cell markers.

Results: Biopsies from patients with Barrett’s esophagus formed a columnar epithelial layer containing goblet cells and recapitulated the crypt and villous regions seen within BE glands. IHC validation confirmed that the xenograft structures were of human origin and expressed markers of intestinal differentiation (CKS, CDX2 and villin). In contrast to patients with the BMP inhibitor lead to the formation of multi-layered squamous epithelium expressing both the stem cell maker p63 and the squamous marker CK5.

Conclusion: Preliminary results demonstrate that inhibition of BMP2/4 in vivo leads to inhibition of squamous epithelium. These preliminary results may be translated to the clinical setting in order to improve treatment of BE and as such prevent the development of esophageal adenocarcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0550 GASTRIC CARDIA GLANDS MANIFEST APPARENT BROAD DIFFERENTIATION POTENTIAL, AS EVIDENCED BY HOXA13 EXPRESSION, IMPLICATIONS FOR THE ORIGIN OF BARRETT’S ESOPHAGUS

V. T. Jannaat, M.j.m. Smits, M.J. Bruno, M.C.w. Spanader, M. P. Peppenborsch

Introduction: Metaplastic phenomena in the upper gastrointestinal tract are still poorly understood. A prominent theory is that Barrett’s esophagus originates from metaplastic glandular epithelium. However, in absence of evidence that the gastric stem cell has broad differentiation potential, this theory remains controversial. The gastroesophageal junction is a high prevalence area for metaplasia and subsequent cancer. Characteristic of this area are the gastric cardia glands which feature only the most proximal part of the anatomic gastric cardia. Recent evidence from human and mouse studies has shown Barrett’s esophagus can originate from these gastric cardia glands. 1-3 If it can be shown that gastric cardia glands contain elements associated with positional misspecification, this theory could be substantially bolstered. Hox genes are a family of transcription factors that convey positional information. The 3’ to 5’ sequence of Hox genes corresponds to the sequence in which they act along the anterior to posterior axes of the gut. This property is termed colinearity and links clustering to function. In gastrointestinal physiology, HOXA13 is a 5’ member of the HOX4 cluster, has an expression pattern restricted to the colonic epithelium. However, pathological metaplastic lesions of the esophagus and stomach are also characterized by Hoxa13 expression. This in parallel with the similarities of these lesions with physiological gastric morphology. Hence, investigating Hoxa13 expression in gastric cardia glands appears a rational strategy in assessing the potential of this gastric cardia epithelium to serve as the origin of Barrett’s esophagus.

Aims & Methods: We aimed to determine Hoxa13 expression in physiological gastric cardia glands. Firstly, strips of tissue from surgical specimens containing squamous esophageal epithelium, gastric cardia glands, and oxyntic stomach glands, were collected. These were continuous strips, from proximal to distal, to preserve morphological information. Material from three patients was selected, they suffered from either a neuroendocrine tumor, or decompensated achalasia, or an adenocarcinoma. Antibodies against Hoxa13 were found not to be specific. Therefore, RNA in situ hybridization by RNA-scope was performed to visualize Hoxa13 RNA. Secondly, a Hoxa13 GFP x C57BL/6J heterozygous mutant mouse model was used. In these animals, the cardiac glands were analyzed directly for GFP expression using a fluorescence confocal microscope.

Results: All three patients showed Hoxa13 expression of a portion of gastric cardia epithelial cells. The squamous epithelium, the oxyntic epithelium, and the cardiac glands did not show any signal. The signal is located relatively close to the base of the crypts of the cardiac glands. The Hoxa13 GFP x C57BL/6J heterozygous mice showed GFP expression localized to the nucleus of some of the epithelial cells of the cardiac gland. No nuclear signal was detected in the squamous or oxyntic epithelium. The colonic epithelium of the mouse showed nuclear GFP signal. Rectal squamous epithelium was negative as well as ileal epithelium, in accordance with Hoxa13 colinearity in mouse and human. A littermate negative for Hoxa13 showed no signal in either the gastric cardia glands or in metaplastic ileum. 

Conclusion: Gastric cardia gland epithelial cells in both human and mouse exhibit Hoxa13 expression. All other physiological upper gastrointestinal tract tissues are Hoxa13 negative in line with Hox gene colinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett’s metaplasia in the gastric cardia and might be indicative of Barrett’s not being a true transdifferentiation.

Introduction: Barrett’s oesophagus is defined as the replacement of the normal stratified oesophageal squamous epithelium with a multilayered columnar intestinal-like epithelium. Dipeptidyl peptidase-4 (DPP4) is an integral membrane glycoprotein that is highly expressed on the small intestinal brush border. DPP4 is part of a larger enzyme family that also includes DPP8, DPP9 and fibroblast activation protein (FAP).

Aims & Methods: We aimed to characterise DPP4 enzyme activity in a panel of oesophageal metaplasia, dysplasia and cancer cell lines, and in Barrett’s oesophagus patient biopsies. FLO-1, OE33 and JH-EsoAd1 (oesophageal adenocarcinoma), OE21 and TE7 (oesophageal squamous cell carcinoma), GihTERT, GoHTERT, ChTERT (dysplastic Barrett’s) and QhTERT (non-dysplastic Barrett’s) were grown to confluence in T75 flasks using standard cell culture techniques. Oesophageal squamous tissue biopsies were collected from non-Barrett’s patients participating in the Flinders Medical Centre screening endoscopy program (n = 6). Duodenal and gastric tissue biopsies were also collected as positive and negative control tissue respectively. Membrane and soluble enzyme activity was determined in cell and tissue extracts using colorimetric enzyme assay using the DPP selective substrate H-Gly-Pro-pNA. Sitagliptin (a DPP4 inhibitor) and IL-17A

Results: Relatively high DPP activity was detected on the membrane of OE33 (13.92 mm pNA/min/mg protein), GihTERT (6.93 mm pNA/min/mg protein), GoHTERT (2.65 mm pNA/min/mg protein) and QhTERT (1.80 mm pNA/min/mg protein) compared to all other cell lines, where activity was <1 mm pNA/min/mg protein of 1 mM sitagliptin inhibited enzyme activity in OE33 cells, indicating that membrane enzyme activity was specific to DPP4. Cytoplastic DPP activity was highest in FLO-1 (3.77 mm pNA/min/mg protein) and ChTERT (2.39 mm pNA/min/mg protein). Addition of 1 mM sitagliptin did not reduce cytoplastic DPP activity in FLO-1 cells, suggesting the presence of other peptides. High DPP4 activity was detected in the membrane fraction of duodenal biopsies (45.90 ± 8.55 mm pNA/min/mg protein) compared to gastric (3.35 ± 1.59 mm pNA/min/mg protein) and oesophageal biopsies (0.65 ± 0.71 mm pNA/min/mg protein). In contrast, differential DPP activity was detected in the soluble fraction of all duodenal, gastric and oesophageal tissue biopsies. Using 1μM sitagliptin, this was found to be specific to DPP4 in oesophageal samples, but likely derived from other peptides in gastric and duodenum associated with the gut.

Conclusion: Our preliminary in vitro findings suggest a differential pattern of DPP activity in Barrett’s metaplasia and dysplasia, which could have potential significance as a biomarker target for the continuum of Barrett’s oesophagus. Human tissue sample collection is ongoing to define specific DPP enzyme activity and expression in tissue specimens from Barrett’s metaplasia and dysplasia subgroups compared to normal, non-Barrett’s tissue.

Aims & Methods: Biopsies from patients with a new diagnosis or surveillance for BE were obtained at endoscopy and frozen. Immunohistochemistry was performed on frozen sections for proteins including MUC5AC, MUC2, MUC6 and P63. A panel of antibodies specific to different gland phenotypes was used to classify biopsies completely in Barrett’s oesophagus (BE), but how these phenotypes are related and evolve is unknown. Genetic diversity is an established risk factor for cancer development in BE, yet as phenotype not genotype is selected for and as the gland is the unit of selection, we suggest that phenotypic diversity may confer a role in cancer progression. Exploiting mutations in the mitochondrial genome (MtDNA) as a marker of clonality we have demonstrated that the glandular phenotypes seen in Barrett’s represent an evolutionary pathway and that phenotypic diversity also leads to an increased cancer risk.

Results: A total of 112 BE biopsies from patients progressing to dysplasia were classified into 4 distinct gland phenotypes. Genetic diversity was assessed by Next-Generation sequencing of the mitochondrial genome (MtDNA), which showed a significant increase in mtDNA diversity in those biopsies progressing to dysplasia.

Conclusion: During routine endoscopy samples from healthy volunteers were obtained and analysed by flow cytometry as controls (n = 5).

Results: During progression from BE to EAC an increase of CD4+ cells was observed. The number of IL-22+ cells in malignant tissue compared to healthy controls was significantly increased. Addition of 1 mM sitagliptin did not reduce cytoplasmic DPP activity in FLO-1 cells, suggesting the presence of other peptides. High DPP4 activity was detected in the membrane fraction of duodenal biopsies (45.90 ± 8.55 mm pNA/min/mg protein) compared to gastric (3.35 ± 1.59 mm pNA/min/mg protein) and oesophageal biopsies (0.65 ± 0.71 mm pNA/min/mg protein). In contrast, differential DPP activity was detected in the soluble fraction of all duodenal, gastric and oesophageal tissue biopsies. Using 1μM sitagliptin, this was found to be specific to DPP4 in oesophageal samples, but likely derived from other peptides in gastric and duodenum associated with the gut.

Conclusion: Our preliminary in vitro findings suggest a differential pattern of DPP activity in Barrett’s metaplasia and dysplasia, which could have potential significance as a biomarker target for the continuum of Barrett’s oesophagus. Human tissue sample collection is ongoing to define specific DPP enzyme activity and expression in tissue specimens from Barrett’s metaplasia and dysplasia subgroups compared to normal, non-Barrett’s tissue.

Introduction: Barrett’s Oesophagus (BE) is an acquired condition resulting from oesophageal reflux that causes Barrett’s metaplasia, dysplasia and cancer. Risk factors for BE progression to dysplasia and cancer include obesity, nicotine, and alcohol consumption. BE progression may lead to cancer and can progress to dysplastic lesions, which ultimately lead to oesophageal adenocarcinoma (EAC). The incidence of EACs is rising in the Western world and 5-year survival rates are below 20%. Hence, new and prognostic markers are needed. Since levels of interleukin (IL)-22 in IL-17A-producing cells are associated with a poor prognosis in colorectal cancer we wanted to investigate their influence in EACs.

Aims & Methods: None of the patients enrolled in this study received chemoradiotherapy prior to surgery and all patients had pathologically confirmed BE, EAC. mRNA expression levels of interleukin in tumour tissue and non-malignant peritumoral samples of 39 patients were measured. Immunohistochemical analysis was conducted to investigate interleukins during the progression from BE to EAC. Interleukins were investigated in non-malignant tissue samples from healthy volunteers and analysed by flow cytometry as controls (n = 5).

Results: During progression from BE to EAC an increase of CD4+ cells was observed. The number of IL-22+ and IL-17A+ cells as well as the number of FOXP3+ cells/mg tissue increased in oesophageal cancer and in its peritumoral tissue as compared to healthy controls. The relative amounts of IL-22- and IL-17A- cells decreased while an increase of FOXP3+ cells was observed. Also more IL-10+ cells/mg tissue were observed in the tumours. In accordance to the latter finding high IL-10 mRNA expression levels were associated with poor survival in EAC patients. Interestingly, high levels of IL-10 mRNA expression levels of IL-10 in the non-malignant peritumoral tissue also correlated with poor survival.

Conclusion: During progression from BE to EAC the infiltration of CD4+ immune cells increases. While the relative amount of pro-inflammatory cells decreases, the amount of FOXP3+ immune cells increases. This suggests a differential pattern of immune cells increases. While the relative amount of pro-inflammatory cells decreases, the amount of FOXP3+ immune cells increases. This suggests a differential pattern of immune cell infiltration.

SURVEILLANCE GUIDELINES IN THE MANAGEMENT OF ADHERENCE TO QUALITY INDICATORS AND

P. V. Draganov2,
This was a Single-center retrospective study of endoscopies (EGDs) performed for biopsy protocol, (2) identify predictors of practice patterns, and (3) to assess standardized classification (Prague Criteria) and a systematic four-quadrant
The aims of this study were to evaluate (1) adherence to

Contact E-mail Address: hannahalhas@gmail.com
Introduction: The importance of skilled endoscopic assessment of Barrett’s oesophagus (BO) has been clearly established and forms part of the British Society of Gastroenterology guidelines1. Use of Prague classification when reporting on areas of BO improves standardisation, and adherence to the Seattle biopsy protocol (quadrant biopsies every 2 cm) when sampling Barrett’s mucosa is thought to improve dysplasia detection2. In East Kent Hospitals NHS Foundation Trust we have created a dedicated nurse-led BO surveillance endoscopy list with the aim of improving compliance with guidelines and the quality of biopsies taken. Here we present a retrospective observational study of patients who underwent upper GI endoscopy on a general endoscopy (GE) list compared with those who had an endoscopy on a GE list from 2012–2013. The same search was performed for patients who were scoped on the DBO list from 2014–2016. Endoscopy reports were reviewed to assess the use of Prague classification and determine numbers of biopsies taken. Biopsy results were reviewed on our electronic pathology database.

Results: One hundred procedures for BO surveillance on GE lists were audited, comprising 65% male patients with median age 68 years; 60% were performed by a consultant gastroenterologist and the remainder were performed by other operations including surgical consultants and gastroenterology registrars. Of the 105 procedures on the DBO lists, 63% of patients were male, median age 70 years. Prague classification was used in 94% of endoscopy reports on the DBO lists compared with 5% on the GE lists. The Seattle biopsy protocol was observed in 70% on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was similar in both groups: 8/105 (7.6%) on the DBO list and 6/100 (6%) in the GE group. All (100%) of the dysplasia detected on the GE lists occurred in procedure performed by consultant gastroenterologists.

Conclusion: Our comparison shows that observance of Prague classification is significantly higher on the DBO lists when compared with GE lists (94% vs 5%), and compliance with the Seattle biopsy protocol is similarly higher (74% vs 30%). These are indicators of higher quality endoscopic surveillance on DBO lists. However, this did not translate to a different dysplasia detection rate which appeared to be more influenced by the endoscope operator since all of the dysplasia detected on GE lists was identified by consultant gastroenterologists. We believe our comparison highlights the additional familiarity of endoscopists and possible greater experience of endoscopists regularly taking BO biopsies. We therefore recommend that all Barrett’s oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adenocarcinoma near the esophagogastric junction is one of the most lethal GI malignancies known. Surgical treatment of these cancers carry determinative factors of patient survival. Older persons often differ from the younger adult population in terms of biological and functional perspectives; as such, they may have particular needs which require an interdisciplinary approach and intervention, especially when faced with a cancer diagnosis.

Aims & Methods: The aim of this study was to detect expression of TGF-ß and CD-44 in age specific subgroup of patients with adenocarcinoma of gastric cardia.

Results: Elderly patients have statistically significant better survival (median 20.2 month) compared with young patients (median 15.4 month) (p = 0.045). The median survival rate of patients without TGF-ß and/or CD-44 expression was significantly lower (7 m) than that of patients with positive expression (15 m) (p = 0.003). Regardless of patients age, CD-44 was significantly higher in the cancer tissue of elderly patients than in younger (p < 0.035). But no significant difference was observed in the TGF-ß expression between group A and group B cancers tissue (p = 0.005).

Conclusion: The biology of tumors may be different in elderly patients, leading to a lower rate of tumor-related mortality. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Barrett’s oesophagus (BO) is considered a premalignant condition for esophageal adenocarcinoma (OAC). Once diagnosed, interval endoscopic surveillance is recommended to promote early detection of dysplasia and cancer. Occurrence and incidence of dysplasia and cancer among BO vary across populations. Recent studies show BO patients mortality is mainly related to non-oesophageal cancer and cardiovascular morbidity.
**Aims & Methods:** In this cross-sectional study, our aims were to describe the local BO clinical, endoscopic and histologic profile in our tertiary referral centre, and discover whether the Prague classification and biopsy requirements are filled. We identified and included all consecutive patients with oesophageal intestinal metaplasia (identified by the presence of goblet cells) from March 2009 to May 2015. All endoscopies and biopsy reports were reviewed: BO segment length, use of the Prague classification, endoscopic abnormalities, treatment modalities, and histologic findings of dysplasia. Participants were sent a clinical questionnaire, via which pertinent clinical data including personal and familial cancer history, were collected.

**Results:** Clinical profile- Our cohort consists of 406 patients, with a mean age of 60.9±13.3 years, 69% were male. Endoscopic profile- Mean maximal BO length (Prague classification M) was 2.8±1.9 cm (reported in 49.6% of endoscopies) Mean circumferential BO (Prague classification C) was 4.9±3.1 cm (reported in 18.1% of endoscopies). Histologic profile- Low-grade dysplasia/LGD was seen in 4.4% of patients, high-grade dysplasia (HGD) in 3%, intramucosal carcinoma (IMC) in 0.7%, and OAC in 2%. A subgroup of 250 patients underwent more than one endoscopy, allowing for prospective interactive analysis. They had 914 years of follow-up, with a mean number of endoscopies of 4.7±3. The incidence rates of LGD, HGD, IMC, OAC per 1000 patient years were 20.8, 15.3, 2.2, and 7.6 respectively.

One hundred and fifty-five patients returned the questionnaire. In this subgroup analysis, we learned BO was diagnosed at 57.8±12.5 years of age, with a mean duration of 4.9±5.7 years. A personal history of non-oesophageal malignancy was reported in 15.4%. A family history of BO, OAC and non-oesophageal cancer were reported in 5.2%, 4.5%, and 35.4%, respectively.

**Conclusion:** Compared to the information gathered by Katz et al (1), we demonstrated a lower rate of LGD, but comparable rates of HGD and OAC. The personal and familial history of non-oesophageal malignancy was higher than the oesophageal malignancy rates. Our findings may support the importance of age appropriate non-oesophageal malignancy screening in BO patients. Physician compliance in reporting BO according to the Prague classification is lacking. Factors associated with our local BO profile as well as the implication of family history requires further prospective studies.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Barrett esophagus (BE) is a premalignant condition for esophageal adenocarcinoma (EAC) where recommendations for BE surveillance guidelines aim to reduce treatment and improve quality of care. Data on the extent to which level BE surveillance guidelines are followed are scarce.

Aims & Methods: The objectives of this systematic review and meta-analysis were to quantify adherence to BE surveillance guidelines in (1) BE patients with dysplasia and (2) identify factors that are associated with adherence. A systematic literature search was performed using EMBASE, MEDLINE, PubMed, and Web of Science up to September 2016. Studies reporting adherence in at least one of the following four domains were selected: surveillance interval, biopsy protocol, landmark identification, and histopathological information. Relevant publications were assessed using the STROBE statement for observational studies (http://strobe-statement.org/). Adherence was considered a prevalence ratio and reported as a prevalence ratio for the associated factors were reported as odds ratios with analysis of heterogeneity (I² statistic).

Results: From a total of 373 studies, 49 were eligible for this meta-analysis. For BE surveillance in non-dysplastic BE patients, adherence varied from 28.3% (95% CI 20.9%; 35.1%) in patients with low-grade dysplasia, but with large heterogeneity (I² = 98.2%) and T = 100%, adherence to the Seattle protocol was 47% (95% CI 33.6%; 61.3%), T = 100%, length of BE was reported according to the Prague classification in 34% (95% CI 23.3%; 44.4%), T = 98.0% and in 51% (95% CI 27.7%; 65.5%, T = 99%) of patients with dysplastic BE the histology samples were reviewed by a second pathologist. Shorter BE length, an academic practice setting, younger age and the involvement of the clinical set-up incorporating a multifaceted intervention program were associated with better adherence. Endoscopists following the Seattle protocol detected more dysplasia.

Conclusion: Adherence to guidelines for the surveillance of BE is far from optimal and highly heterogeneous. A clinical set-up of a dedicated BE surveillance program is needed, for example follow-up within a research program, involvement of a dedicated nurse managing the program or guideline promotion by using posters stating recommendations. Besides initiating more and better studies to facilitate the creation of evidence-based guidelines, more effort should be directed to stimulate and monitor the implementation of guidelines in clinical practice.

treated by endoscopic resection were prospectively recruited from 16 hospitals throughout Japan. This cohort study was approved by the institutional review board at each hospital, and we obtained written informed consent from all patients. Using Lugol chromoendoscopy, we evaluated the dysplastic squamous epithelium in the esophagus. Lugol voiding lesion (LVL) was graded into 3 categories (A = no lesion; B = 1 to 9 lesions; C = ≥ 10 lesions per endoscopic view). Endoscopic images obtained from eligible patients at study entry were centrally reviewed in a blinded fashion by three endoscopists to determine the grade of LVL. ALDH2 status was determined by questionnaire facial flushing after alcohol drinking (present and past flushing—inactive ALDH2, never flushing = active ALDH2). Lifestyle surveys were conducted using a self-assessment questionnaire. Data collected between July 2000 and Dec 2001 from a different cross-sectional cohort (n = 1042; M/F = 610/432) were used as an historical control.

**Results:** Between Sep 2005 and May 2010, 330 patients (M/F = 278/52) were registered. The proportions of the different grades of LVL were A = 50 (15.2%), B = 174 (52.7%), and C = 106 (32.1%). After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), liking high-temperature food (4.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in inactive ALDH2 than in non-inactive ALDH2 (OR = 2.73, p < 0.0001) or LVL grade C associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 385) than active ALDH2 (OR = 138) (p < 0.05).

**Conclusion:** The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Metachronous multiple squamous cell carcinoma (SCC) of the oesophagus and the head and neck often occurs in patients who previously underwent endoscopic resection (ER) for SCC of the oesophagus. This has become a problem regarding the curability of ER. Katada et al reported that alcohol abstinence significantly decreased the risk of developing a secondary SCC of the oesophagus, based on a prospective study of 330 patients from 16 hospitals. However, there are few studies that have investigated the risk of developing a secondary SCC of the oesophagus and the head and neck based on the genetic polymorphisms of alcohol dehydrogenase-1B (ADH1B) and aldehyde dehydrogenase-2 (ALDH2) which are closely associated with developing oesophageal SCC. No studies have evaluated the risk of developing a third (or more) SCC after ER for SCC of the oesophagus.

**Aims & Methods:** The study group included patients who underwent ER for SCC of the oesophagus. All patients were followed up by using endoscopic examination for ≥ 2 years. Overall, 128 patients were included in the study. The drinking and smoking histories before and after ER were carefully documented. To examine two single nucleotide polymorphisms (SNPs) on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of blood (serum) from 61 (n = 61) patients. The subjects were classified as rare drinkers who consumed < 1 units/week, current drinkers who consumed 1 to 8.9 units/week (light drinkers), 9 to 17.9 units/week (moderate drinkers), or ≥ 18 units/week (heavy drinkers); alcohol consumption (1 unit = 22 g, the ethanol content of one serving of sake). The physicians recommended all subjects to temperate in drinking and smoking. We retrospectively evaluated the risk of metachronous SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

**Results:** Between Sep 2005 and May 2010, 330 patients (M/F = 278/52) were registered. The proportions of the different grades of LVL were A = 50 (15.2%), B = 174 (52.7%), and C = 106 (32.1%). After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), liking high-temperature food (4.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in inactive ALDH2 than in non-inactive ALDH2 (OR = 2.73, p < 0.0001) or LVL grade C associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 385) than active ALDH2 (OR = 138) (p < 0.05).

**Conclusion:** The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

they were not recommended additional therapy. The remaining eight patients had lymphovascular invasion or SM2 were recommended additional therapy. In total 33 cases were treated only by ER without additional therapy. Besides 97% (32/33) of those cases had no recurrence except for one case with a lymph node recurrence, which was successfully treated by additional CRT. The other 12 cases treated with postoperative CRT or ESD were recommended additional therapy. They underwent CRT (n = 4), radiotherapy (n = 3), or esophagectomy (n = 3). No recurrence was observed after the abovementioned treatments. At the end of the follow-up, the 3-year overall and disease-specific survival rates were 81.7% and 100%, respectively. Considering ER alone, MM/SM1, 76% of all cases were completed their treatment only with ER, and 24% of high risk case for metastasis were treated appropriately with additional therapy.

Conclusion: Conclusions: Our study suggests that ER is a valid treatment for esophageal SCC with a preoperative predicted invasion depth of MM/SM1.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are the first line treatment for superficial esophageal squamous cell carcinoma (SCC). Comparatively to surgery, endoscopic resection is minimally invasive and associated with a lower morbidity and mortality.

Aims & Methods: Evaluation of the endoscopic resection efficiency for superficial esophageal SCC and long-term outcome. Primary outcomes were recurrence rate after endoscopic resection defined as local recurrence or metastatic evolution. We conducted a retrospective multicenter study in 5 french tertiary care hospitals. All patients treated by EMR or ESD for histologically proven SCC were consecutively included. Esophageal SCC was defined as superficial after macroscopic evaluation including Lugol staining and endoscopic ultrasonography (EUS). Curative resection was defined as pT1a with free resection margins, without lympho-vascular emboli.

Results: Between 1998 to 2016, 132 patients were enrolled and 148 tumors were resected (EMR = 80, ESD = 68). The mean age was 63.9 [35.7–86.0] years-old and 108 (73%) patients were male. Mean tumor size was 15.0 mm in the EMR group and 35.0 mm in the ESD group (p < 0.001). The complete resection rate in the ESD group was 95.2% versus 30% (24/80) and 10/68 (68.8%) (p < 0.0001). The mean follow-up period was 22 months. The recurrence rate was 14.2% (19/80 in the ESD group) and 2/68 in the ESD group (p = 0.001). At 12 months, recurrence-free survival rate was 84.4% and 74.6% at 24 months. Factors associated with recurrence in univariate analysis were: tumors size (p = 0.013), resection by EMR (p = 0.001), piecemeal resection (p = 0.016), and microscopic positive margins (p = 0.044). In multivariate analysis, risks factors for recurrence were: resection by EMR (OR = 7.315; IC [1.685–31.762]; p = 0.008) and tumor size > 2.635; IC [1.065–6.519]; p = 0.036). At 24 months, recurrence-free survival rate was 95.2% in ESD group, versus 59.8% in EMR group (p = 0.001). For infiltrating tumors ≥3 m, metastasis free survival rate at 24 months were 100.0% after complementary treatment by radio-chemotherapy, and 62.2% without complementary treatment (p = 0.042).

Conclusion: Endoscopic resection of superficial esophageal SCC is safe and efficient. According to our results, ESD should be preferred to EMR because it is associated with a higher curative rate and an increased recurrence free survival rate. Disclosure of Interest: All authors have declared no conflicts of interest.

P0568 CURATIVE CONDITIONS AFTER ENDOSCOPIC RESECTION FOR MM/SM1 OESOPHAGEAL SQUAMOUS CELL CARCINOMA BASED ON LONG-TERM OUTCOMES

Introduction: Oesophageal squamous cell carcinoma (ESCC) with invasion into the muscularis mucosa up to the submucosa (MM/SM1) has approximately 10% lymph node metastasis and is a relative indication for endoscopic resection (ER) as per the Japanese Esophageal Society (JES) guidelines. The consideration criteria for additional treatment of MM/SM1 ESCC are as follows: (1) lymphovascular invasion, (2) SM1, (3) positive vertical margin, and (4) diffuse pattern of infiltration (IN). However, the clinical validity of the JES guidelines has not been established. We evaluated the curative conditions after ER for MM/SM1 ESCC based on long-term outcomes.

Results: We enrolled 98 consecutive MM/SM1 ESCC who underwent ER between August 1992 and October 2013 and were followed up for more than 3 years at Hiroshima University Hospital. As per the JES guidelines, the e-curable group was characterised by en bloc resection lesions with pathological MM, tumor infiltration pattern (INF) a/b, VM0, ly0 and v0. We evaluated the clinicopathological characteristics of the patients and lesions between the 2
groups. The proportion of patients with additional treatment after ER was significantly lower in the e-curable group (23%, 9/39) than in the non-e-curable group (39.9% (p < 0.05). Operation, radiotherapy, and chemoradiotherapy were administered to 3 (8%), 4 (10%), and 12 (5%) patients, respectively in the e-curable group and to 7 (12%), 22 (37%), and 10 (17%) patients, respectively in the non-e-curable group. The 5-year overall survival rates in the e-curable and non-e-curable groups were 97% and 75% (p < 0.05), respectively. The overall survival rate was significantly higher in the e-curable group. Three deaths (10%) occurred due to primary cancer. The other reasons were as follows: other organ cancer (10 cases), heart failure, 4 cases; pneumonia, 3 cases; and others, 11 cases. The 5-year disease-specific survival rates in the e-curable and non-e-curable groups were 100% and 98%, respectively. The lymph node recurrence rates in the e-curable and non-e-curable groups were 3% (1/39) and 7% (4/49), respectively. The local recurrence rates in the e-curable and non-e-curable groups were 0% (0/39) and 7% (4/49), respectively. The 5-year recurrence-free survival rates in the e-curable and non-e-curable groups were 97% and 98%, respectively. The 5-year recurrence-free survival rates in the group with IFNa and no lymphovascular invasion was higher than the group with INFb, INFc, or lymphovascular invasion was 100% and 87%, respectively. The recurrence-free survival rate was significantly higher in the group with INFα and no lymphovascular invasion than in the group with INFb, INFc, or lymphovascular invasion.

Conclusion: Our outcome data support the clinical validity of the e-curable conditions after ER for MM/SM1 ESCC of the JES guidelines. However, MM/SM1 ESCC with INFα and no lymphovascular invasion may have more possible curative conditions after ER without additional treatment.

Introduction: The endoscopic submucosal dissection (ESD) allows en-bloc resection of early gastric cancer (EGC) with wide resection margins [1, 2]. En-bloc resection resulted in adequate resection margins and reduced local recurrence. When compared to gastrectomy, endoscopic resection should theoretically result in better perioperative outcomes and quality of life [3]. There is currently no study in the literature which directly compares laparoscopic assisted gastrectomy against ESD for treatment of intramucosal EGC. The objective of the study is to compare clinical, oncological and immunological outcomes of endoscopic submucosal dissection (ESD) against laparoscopic assisted gastrectomy (LAG) for treatment of early gastric cancer.

Aims & Methods: All patients with endoscopic diagnosis of early gastric cancer (EGC) and biopsy confirmed to be high grade dysplasia or adenocarcinoma were reviewed. They were then staged using investigations including image enhanced endoscopy, EUS and CT and those predicted to be T1a (intramucosal) neoplasms were randomly assigned to receive ESD or LAG. ESD were performed according to the standard procedure, while LAG were performed with D1+ lymph node phadentectomy. The baseline demographics, clinical perioperative outcomes, immunological and oncological outcomes were compared between the two groups. Primary outcome was rate of complication after operation.

Results: From 2011 to 2016, 36 patients with early gastric cancers were randomly assigned to receive ESD (n = 18) or LAG (n = 18). There was no difference between the two groups in terms of age, gender, ASA grade and baseline demographics (Table 1). ESD was associated with significantly shorter operative time (108.4 ± 58.8 vs 266.2 ± 47.8 mins, p = 0.001), hospital stay (4 (3–6) vs 8 (4–14) days; p = 0.001) and lower complication rate (1 (5.6%) vs 7 (4–13); p = 0.041). There was no mortality at 30 days for the two groups while those in ESD group tolerated full diet earlier (2 (1–5) vs 5 (3–12) days; p < 0.001). Patients who received ESD had significantly lower level of CRP as well as VAS pain scores on postoperative days 1, 2, 3 and 7 when compared to LAG. The median follow-up was 41.5 months for ESD group and 36 months for LAG group, and there was no difference in the cancer recurrence and overall survival. 27.8% of patients required re-intervention after ESD.

Conclusion: Our prospective randomized study showed that patients treated by ESD had significantly lower complication rate and better perioperative outcomes when compared laparoscopic assisted gastrectomy. ESD should be the first line treatment for intramucosal early gastric cancers.

Introduction: Pre-malignant conditions and lesions of the stomach (PCLS): atrophy, intestinal metaplasia and dysplasia are risk factors for the development of stomach cancer; therefore, its diagnosis is very important to identify patients with greater probability of this malignant neoplasm. The Clinical Guidelines recommend that during endoscopy procedure, to avoid an under diagnosis, biopsies of different areas of the stomach should be taken even when no lesion is evident in order to identify PCLS that are generally multi-focal. The initial identification of patients with this type of lesions and their subsequent stratification with the OLGA and OLGUIM systems allows defining the subgroup of patients that merit follow-up because they have a higher risk of developing gastric cancer. However, there is a discrepancy between endoscopists, because it is now preferred to take biopsies directed at the lesions and not to do them systematically at fixed sites, so that no lesion is observed.

Aims & Methods: We aimed to evaluate and compare the prevalence of PCLS in biopsies taken from gastric mucosa with or without lesion during the endoscopic examination. A retrospective, cross-sectional study was performed on 356 dyspeptic patients. We reviewed the reports of esophagogastroduodenoscopies at the Trujillo Regional Teaching Hospital-Perú from October 2016 to March 2017. This study included reports which were consigned diagnosis with biopsies of different areas of the stomach. These biopsies were sent in different vials. Permission was obtained from the Hospital’s research committee. Those reports that had a diagnosis of stomach cancer, gastrectomy, and those with not biopsy parameters

(continued)
or those in which the biopsies were still taken from the different anatomical areas were excluded. A total of 331 patients were included, and 10 of them were excluded.

**Results:** Of 148 patients were admitted to the study. The mean age was 49.7±9.3 years, 60% were female (CE: 52.67, 95%), 264 were sent with biopsies with the different areas of the stomach distributed as follows: 148 of antrum, 54 of antrum, 48 (32.4%) duodenal biopsies of antrum, angle and body. From 148 patients, 116 (78.4%) had an endoscopic diagnosis of normal gastritis or mucosa and 32 (21.6%) had endoscopic diagnosis of PCLS. From 116 patients with endoscopic diagnosis of gastritis or normal mucosa, LCPM was identified in 46 patients (39.6%) (p < 0.001) and 1 of them were low-grade dysplasia. From 32 of patients with suspected endoscopic PCLS, the diagnosis was confirmed with histology in 26 patients (81.2%). A total of 72 patients had PCLS vs. 32 who were initially suspected (p < 0.01), with a total patients of 104 (74.6, 95%).

**Conclusion:** Pre-malignant conditions and lesions of the stomach (PCLS) can show as normal mucosa or gastritis during endoscopic procedure. 39.9% of patients who underwent endoscopic procedure with presumptive gastritis had PCLS. PCLS may be under-diagnosed if random biopsies are not taken. Therefore, taking biopsies from areas without suspected PCLS causes a change in the clinical management of patients, both for the initial diagnosis and for the staging according to OLGA and OLGUM systems.

**Introduction:** Endoscopic treatment of sporadic duodenal adenoma is mainly performed in tertiary centers because it is technically challenging and associated with major complications (perforation 1–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non-ampullary sporadic duodenal adenomas (SDA) in two tertiary centers in a large series and to determine the predictive factors of outcomes with a long follow-up.

**Aims & Methods:** This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endoscopic treatment by EMR for SDA histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the endoscopic treatment and adverse events (Perforation, intra-procedural bleeding, delayed bleeding, others). There were analysed with multivariate analysis.

**Results:** 134 procedures were performed. The mean patient age was 65 years (33–85), 50.7% were women. The mean SDA size was of 20.7 mm (5–50 mm), mostly located in the second duodenum (61.2%). 64.9% of the adenomas had a villous component, 33.4% with high grade dysplasia and 7.5% with in situ or intramucosal adenocarcinoma. 61.5% were upgraded significantly the lesion size and its endoscopic resection rate of 96.2% which was associated in multivariate analysis with the lesion size and depressed en bloc. The en-bloc resection rate of was 44%. Vertical margins were negative in 91.8% of the cases. Negative lateral and vertical margins was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis. Delayed bleeding occurred in 13.4% of the cases and was associated with a larger lesion size and the presence of high-grade dysplasia or adenocarcinoma. Usual use of antplatelet or anticoagulant did not increase the risk of bleeding after pre operative management. A prophylactic hemostasis was realized for 61% of the procedure, by clips alone or associated in 72.3% of the cases. Prophylactic clipping reduced significantly the risk of delayed bleeding. Perforation occurred in 3.7% of case. Median follow-up was of 31.2 months with at least one follow-up endoscopy (78.3%). Final success of endoscopic treatment occurred in 83.8% of the case. 30 patients had a recurrence (28.6%). 13 among them were successfully retreated with endoscopy, 12 still receiving endoscopic treatment with multiple sessions, and 5 were referred to surgery. In multivariate analysis, the main risk factor for recurrence was the lesion size.

**Conclusion:** Endoscopic treatment of SDA appears to be effective and relatively safe in tertiary centers. The bleeding complications were endoscopically controlled and their occurrence could be reduced with clipping prophylactic hemostasis. Perforation is rare. Recurrence rate is frequent and associated with piece meal resection but can be endoscopically managed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Additional surgery should be recommended in patients with non-curative endoscopic resection for early gastric cancer (EGC). However, this decision has often been hesitated according to patient condition such as advanced age or comorbidities. After the recognition of recurrence, the salvage surgery has been considered difficult. However, little has been reported on it. Aim of this study was to clarify the results of salvage surgery for recurrence after non-curative ESG for EGC using data from multicenter retrospective study (EAST study). Of 15,785 patients who underwent ESD for EGC at 19 participating institutions from January 2000 to August 2016, we collected data for patients who met the current curative criteria for EGC were retrospectively reviewed. Among 1969 patients enrolled into EAST study, 1064 patients underwent additional surgery, and 905 patients were observed without any additional treatment. We evaluated first site of recurrence, clinical course after salvage surgery, and long-term survival on non-treatment group. Recurrence was classified regional LNM, and distant metastasis.

Results: Over a median follow-up period of 64 months, recurrence was detected in 27 patients. Among them, 2 patients were excluded from this study due to missing data. A total of 15 patients with recurrence were only local site (7 recurrence site alone regional LNM 7), and distant metastasis 15 (60%). The first treatments for recurrence were endoscopic treatment 1, salvage surgery 7 (28%), chemotherapy 6, and best supportive care 11. One only patient was alive without any recurrence for 31 months after salvage surgery. And one patient died of acute myocardial infarction just one month after salvage surgery. In the remaining 5 patients, recurrence was detected at 0, 2, 3, 5, 30 months after salvage surgery, and all of them died of gastric cancer. Median survival time of all 25 patients with recurrence was 5 months from recurrence. Median survival time of 7 patients who underwent salvage surgery was only 7 months from salvage surgery.

Conclusion: More than half of recurrence after non-curative ESD without additional surgery was distant metastasis, and the survival rate after salvage surgery was quite low.

Introduction: Due to the increase of elderly patients who are often receiving antithrombotic therapy for cardio- and cerebrovascular diseases, postprocedure bleeding after endoscopic treatments for early gastric lesions has become one of the major concerns of therapeutic endoscopists. The Japan Gastroenterological Endoscopy Society (JGES) and other related associations published the Guidelines for Gastroenterological Endoscopy in Patients Undergoing Antithrombotic Treatment in 2012. According to the guideline it is not necessary to suspend an antplatelet agent before endoscopic treatments including endo- scope mucosal resection (EMR) or endoscopic submucosal dissection (ESD) if the agent is not combined with other antithrombotic drugs (monotherapy). On the other hand it is recommended that anticoagulants should be substituted with heparin before EMR/ESD. The aim of this study is to clarify the efficacy of the recommendations of the guideline.

Aims & Methods: In this study 888 early gastric lesions in 783 patients who underwent EMR/ESD at our hospital between January 2012 and March 2017 were retrospectively analysed. Postprocedure bleeding was defined as: (1) hematochezia, melena for which an emergency endoscopy was required and (2) bleeding which were confirmed with a repeat endoscopy after a drop ≥2 g/L of haemoglobin level.

Results: The total number of patients undergoing antithrombotic therapy was 78, out of whom 38 patients were taking antiplatelet agents only, 29 were taking anticoagulants only, and 11 were taking the both. The antithrombotics were suspended in 22 cases (Group A), substituted with heparin in 18 (Group B), and kept continued in 38 (Group C). Postprocedure bleeding was encountered in 31 out of 783 cases (4.0%), 21 of which occurred in patients on antithrombotic therapy (21/78: 27%) whereas 10 of which occurred in those without (10/752: 1.3%). A univariate analysis between the patients with postprocedure bleeding and those without concerning such variables age, gender, the diameter and number of the resected lesions, use of antithrombotics, and the expertise of the operating endoscopist revealed that only the use of antithrombotics was significant risk factor for the postprocedure bleeding (odds ratio = 15.926, 95% confidence interval: 7.415-34.280, p = 0.001). However, the rate of postprocedure bleeding was not significantly different among Group A, B and C. Among the 21 bleeding patients with antithrombotics, the agent had been suspended or substituted with heparin before EMR/ESD in 10 and had been continued without suspension in 11. There was no significant difference of bleeding rate between the two groups.

Conclusion: The use of antithrombotics was a significant risk factor for the postprocedure bleeding after EMR/ESD for early gastric lesions. The rate of bleeding was not significantly different regardless if the antithrombotics were suspended, substituted with heparin, or continued without suspension.

**Introduction:** Atrophic gastritis and intestinal metaplasia are the cancerization field in which gastric cancer (GC) develops in case of intestinal type. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC.

**Aims & Methods:** The aim of this study is to evaluate the usefulness of OLGA and OLGIM staging according to Lauren's histological classification of GC in considering with other risk factors of gastric cancer. From January 2006 to December 2015, 607 GC patients and 677 control subjects were enrolled who underwent esophagogastroduodenoscopy. Biopsies were taken from the greater and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM stage (0–IV) was recorded by combining antral with body atrophy and was defined by a positive result on any of these tests. Multivariate logistic analysis was performed for the age, sex, smoking, alcohol and family history of GC.

**Results:** GC patients had more high-risk OLGA stages (25.9%) than controls (6.8%, P < 0.001) and high-risk OLGIM stages (18.3%) than controls (4.9%, P < 0.001). In the multivariate logistic analysis, Old age (odds ratios (ORs), 1.932; P < 0.001), Male (1.193; 0.847–1.679; P = 0.312) were independent risk factors for GC as well as intestinal type (Table). High-risk OLGA stages were significantly associated with increased risk of GC in comparison to low-risk (OR, 3.778; P < 0.001): intestinal-type (OR, 4.318; P < 0.001) and diffuse-type (OR, 2.920; P < 0.001) (Table). High-risk OLGIM stages were also significantly associated with increased risk of GC in comparison to low-risk (OR, 3.051; P < 0.001): intestinal-type (OR, 3.981; P < 0.001).

**Conclusion:** High-risk OLGA and OLGIM stages were useful for intestinal type as well as diffuse type. This usefulness will be increased when combined with H. pylori infection and family history of GC in regions with high prevalence of GC. Analysis regarding specific interaction among these three factors is undergoing.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0578 RISK FACTORS FOR LYMPH NODE METASTASIS OF ULCERATIVE TYPE INTRAMUCOSAL EGC
T. Kim, T.J. Kim, H. Lee, J.H. Lee, J.J. Kim
Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: Attach836@naver.com

Introduction: Endoscopic submucosal dissection (ESD) is not currently accepted as an alternative treatment to surgery in ulcerative type EGC due to relatively higher probability of lymph node metastasis (LNM). This present retrospective analysis examined the correlation of various histologic factors with the presence of lymph node metastasis in ulcerative type EGC.

Aims & Methods: A retrospective analysis on 200 patients with ulcerative type EGC who underwent radical gastrectomy with D2 lymph node dissection. Several clinicopathologic factors were investigated to identify predictive factors for LNM: tumor size, histopathologic type of tumor, lymphovascular invasion and depth of invasion. Multivariable logistic regression analysis was performed to evaluate the risk factors for LNM.

Results: The total rate of LNM was 15.5% (31/200). The rate of LNM was 2.1% (2/95) in the lesions confined to the mucosa and 27.6% (27/105) in those that had infiltrated the submucosa. On univariate analysis, depth of invasion (p = 0.001) was significantly associated with LNM. There was no significant association between tumor size, histopathologic type of tumor, and lymphovascular invasion (p > 0.05). On multivariate analysis, only lymphovascular invasion (p = 0.001) was significantly associated with LNM. There was no significant association between tumor size and lymph node metastasis in ulcerative type EGC.

Conclusion: Ulcerative EGC confined to the mucosa could be considered for candidate for curative ESD due to the low risk of LNM. This finding should be confirmed by more data from other centers, which focus on the LNM after ESD for ulcerative type intramucosal EGC.

Introduction: Gastrointestinal cancers are one of the most common malignancy worldwide. Especially endoscopic submucosal dissection (ESD) for early gastrointestinal cancers have been considered as the current standard cancer treatment. However, lack of counter traction during dissection procedure is one of major difficulty. To overcome this problem, we developed new endoscopic technique using robotic manipulator and conducted study about efficacy and safety in vitro animal study.

Aims & Methods: A novel robotic suture manipulator is composed of control panel and a working arm, which grasp and move objects at the end of scope. A total of 10 pig stomachs were used for the test. Porcine stomachs were assigned randomly to two groups and ESD was performed on mucosa of stomach using conventional technique and endoscopic technique with robotic manipulator. Endoscopic experts and novice endoscopists performed ESD in 2 parts (antrum & body) of stomach. During procedure, robotic manipulator lifts up dissected tissue of stomach to make better visibility. Procedure time, complete resection rate, and complication such as perforation were recorded.

Results: The average procedure time for the robotic manipulator and conventional ESD was 42 minutes and 45.9 minutes. In novice endoscopists, the average procedure time using robotic manipulator is faster than conventional ESD group (p = 0.05). Both endoscopic expert and novice endoscopist completed the ESD procedure for en bloc resection of target lesions using KUMC robotic manipulator. There was no difference in complete resection rates between two groups. No complication such as perforation was occurred in both groups during the procedures. There was no difference depending on resected location in stomach.

Conclusion: The robotic manipulator, which can perform ESD more easily showed feasible result comparing with conventional ESD. ESD using robotic manipulator could be helpful, especially in novice endoscopists. This research proposes a novel approach for safe and feasible method during ESD.

Introduction: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. An advantage of IRE is its ability to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Several clinical trials for applying IRE to human organs such as liver, pancreas and kidney are conducted and several clinical trials for applying IRE ablation for gastrointestinal tumors also have been conducted recently. Here, we developed new endoscopic IRE device, and studied about its effectiveness and feasibility in animal model.

Aims & Methods: Newly developed endoscopic IRE ablative catheter works with single channel of endoscope. A pair of dipolar electrodes consist of pre-shaped f 0.63 mm nitinol wire and the distance between each electrode is 10 mm. The electrodes are loaded within banded tube for stent delivery system then deployed when the IRE catheter put in stomach through the endoscope. We performed endoscopy and IRE ablation was done on pig’s stomach mucosa by using endoscopy with newly developed IRE catheter. We divided pig’s stomach into 2 parts (antrum & body), and IRE ablation was applied on each part of the stomach. Pigs were sacrificed after 24 hours, and we collected their stomachs with surgical technique. Following fixation, tissues were stained with H&E.

Results: Ten male Yorkshire pigs and 2 pigs in vitro stomachs were used in this study. The tissue with H&E stain showed diffuse cell death 24 hr after IRE ablation.

BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. *Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency; five or more times/week, one to four times/week, less than one times/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004; < 500, 500, 500-999, 1,000, 1,000-1, 490, 000, ≥ 1, 500, 000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.
Consistent with the mechanism of action of IRE on the cell membrane only, there was complete cell death within the IRE lesions without intervening live cells. But there was no difference in histology depending on gastric part in which ablation was applied. During the study, no complication was observed in pigs in 24 hours after ablation.

Conclusion: The new endoscopic IRE device, which can perform IRE ablation on gastrointestinal tract using endoscopy showed safe and feasible result.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0582 ENDOSCOPIC SMALL CAPACITY FORCEPS INCREASE THE PATHOLOGICAL DIAGNOSIS OF GASTRIC INDEFINITE NEOPLASIA

Kochi Red Cross Hospital, kochi/Japan

Contact E-mail Address: space-rendez-vous@sings.jp

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up. The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastric Cancer, diagnoses of GIN are attributed, at least partly, to the full size of biopsy specimens. Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (SIF) were used (April 2010–March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011–March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy(EGD). We counted the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., size, macroscopic appearance, and color tone), endoscopist experience level, biopsy samples, and diagnostic procedures were investigated in both groups diagnosed as GIN. The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 8420 patients who underwent EGD in the first period, 2, 584 (30.7%) underwent gastric biopsy with SIF. Among the 15,986 patients who underwent EGD in the second period, 4, 204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93% (205/2584) and 7.54% (317/4124) of the SIF and SmF groups, respectively (P = 0.556). GIN was diagnosed in 34.2% (883/2584) and 43.2% (1755/4124) of the SIF and SmF groups, respectively. The difference was significant (P = 0.048). The two groups diagnosed as GIN did not differ significantly in terms of the patient characteristics, lesion characteristics, endoscopist experience level and biopsy-related hemorrhage. The mean minor-axis lengths of the biopsy samples were 1.50 ± 0.50 mm and 1.38 ± 0.40 mm in the SIF and SmF groups, respectively. The SmF group samples tended to be shorter (P = 0.008). In both groups, 40% of the final diagnoses were epithelial neoplasia; no significant differences were observed.

Conclusion: SmF use may increase the rate of GIN. Thus, SmF use should be avoided with a standard caliber endoscopy.

Introduction: Stomach cancer is a leading cause of cancer-related death in the world. It is well known that stress and nitrosamines can play an important role in the cancer. However, the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. But, there is no clinical and epidemiological evidence that the nitrosamines itself can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (over-population during 9 months); 2) the daily using of toluidine (2 g/kg) in food and water with nitrates (2 g/l); 3) the combined effects of stress + nitrates. The
upper endoscopy was performed using our in-room custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

Results: Using upper gastroscopy, we studied the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucousa during the first 3 months. In the third month 35% (7 of 20) of animals demonstrated small percent peptic ulcer (n = 11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (small, n = 21 and large, n = 9). Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa observed 4 months after the beginning of daily using of toluidine and nitrites in 75% of rats (30 of 40). These rats showed symptoms of atrophic gastritis. Other 25% (5 of 20) of animals did not demonstrate any changes in gastric mucosa. Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. As similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160). Tumor lesions was accompanied by the development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160). Tumor lesions was accompanied by the development of peptic ulcers and atrophic gastritis. Introduction: Gastric cancer (GC) is a major burden worldwide accounting for 7% of all cancer cases and 5% of all cancer-related deaths. The etiology of GC is multifactorial and involves carcinogenic agents (e.g., Helicobacter pylori (H. pylori) infection), dietary habits, and genetic factors. Understanding the molecular mechanisms underlying the complex interactions between environmental factors and host genetic predisposition is essential for the development of effective preventive and therapeutic strategies.

Aims & Methods: In the current study, we aimed to investigate the association between single nucleotide polymorphisms (SNPs) in the PTGS1 and PTGS2 genes and the risk and phenotype of GC. We included 603 unrelated Spanish individuals with GC and 603 age- and sex-matched healthy controls. Genotyping was performed for 20 SNPs, including 12 from the PTGS1 gene and 8 from the PTGS2 gene. The association analysis was performed using logistic regression, and the significance level was set at p < 0.05.

Results: Our results showed a significant association between the PTGS1 -2578C allele and an increased risk of GC (OR: 1.70; 95% CI: 1.16–2.48). However, no significant association was found between the PTGS2 -1195G allele and GC risk.

Conclusion: Our findings suggest that the PTGS1 -2578C allele may be a potential biomarker for the risk of GC. Further studies are needed to replicate these findings and to better understand the underlying mechanisms.

P0986 GASTRIC JUICE FREE AMINO ACID PROFILING AS A METHOD FOR DISCOVERING POTENTIAL BIOMARKERS OF GASTRIC CANCER
J. Lin1, Y. L. Zhou1, R. S. Lin1, Y. Xue1, E. X. Yan1, M. L. Meng1, J. B. Sao1, J. J. Lu2
1Department Of Gastroenterology, Peking University Third Hospital, Beijing/China
2United European Gastroenterology Journal 5(5S)

Introduction: Gastric cancer (GC) contributes a heavy burden to the global health, especially in Asian countries. Early diagnosis is crucial to improve patients’ outcome, but reliable biomarkers are desperately needed. In our previous studies, we established several endogenous fluorescence spectra of gastric juice for GC diagnosis and screening [1, 2], isolated and identified three fluorescénes candidates (aromatic amino acids, AAAs), which can be used to distinguish GC patients from controls. However, the characteristic fluorescence of the whole metabolic spectra of gastric juice free amino acids (GFJAs) in GC patients remains unclear. Most previous investigators have reported on the changes of amino acids’ concentrations in the peripheral blood, urine and tissues of GC patients [3, 4].

Aims & Methods: In order to determine the metabolic patterns of GFJAs in GC and NGD patients, gastric juice samples were collected from GC patients (n = 47) and age-matched NGD patients (n = 83) from December 2015 to May 2016, and then measured by an automatic amino acid analyzer. Orthogonal partial least squares discriminant analysis (OPLS-DA) and Mann-Whitney U test are used for data analysis. The diagnostic value of GFJAs was evaluated by ROC curve. Furthermore, significantly altered metabolic pathways were identified by pathway analysis using public databases such as KEGG and MetaboAnalyst 3.0.

Results: GFJAs profiles significantly differed between the GC and NGD patients. A total of 14 kinds of GFJAs, whose first principal component of variable importance in the projection (VIP) value exceeding 1 and P-value less than 0.05, were screened as differential GFJAs. Compared with the NGD patients, GC patients had higher levels of threonine, serine, alanine, valine, methionine, isoleucine, leucine, tyrosine, phenylalanine, lysine and arginine,
together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 1). The 14 GJFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC, particularly, leucine, threonine and serine are the most altered three GJFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than the combined AUC of 3 AAAs (0.841, 95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-tRNA biosynthesis metabolism was excessively activated, which significantly responsible for the above alterations in gastric juice.

Conclusion: GJFAA profiles may be helpful for improving GC diagnosis even in the early stage and for providing more information about its metabolism. Leucine, threonine and serine, three non-AAAs, warrant further validation as alternative metabolic biomarkers for GC.

Contact E-mail Address: liujian-825@163.com

Introduction: It is reported that aromatic amino acids (AAAs) in gastric juice could be used as potential diagnostic biomarkers to screen gastric cancer (GC) [1–3]. However, the underlying mechanism remain elusive [4]. Our group had conducted several studies on the correlations on the reasons to cause such phenomenon before. The candidate molecules: 1) L-type amino-acid transporter 1 (LAT1), which is involved in the enhancement transport of amino acids and the accumulation of AAAs near cancer foci; 2) intracellular amino acid-metabolizing enzymes, such as indoleamine 2, 3-dioxygenase (IDO) and monoamine oxidase (MAO); 3) proteins involved in intracellular protein degradation or autopsy, (e.g., SQSTM1/p62) had been examined [5]. However, because of the difference in the expression of the above proteins in different pathological classifications of GC, it is impossible to explain the phenomenon that the elevation of AAAs’ levels in gastric juice in almost all types of GC patients.

Aims & Methods: To investigate the role of proteolytic enzymes matrix metalloproteinase-2/9 (MMP-2/9) in the abnormal elevation of AAAs’ concentrations in gastric juice of GC patients, gastric mucosal specimens and gastric juice samples were sequentially collected from 29 GC patients who had a relatively matched non-neoplastic gastric disease (NGD) patients. The expression levels of MMP-2/9 and type IV collagen (Col IV) in gastric mucosal tissues were examined by immunohistochemical staining while the levels of AAAs in gastric juice were measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Furthermore, the association between them was evaluated by Spearman correlation analysis.

Results: On the one hand, the expression intensity of MMP-2/9 in GC group were significantly higher than those in NGD group, while Col IV was merely slightly higher than that in NGD group (P < 0.001 for all). Moreover, there was a positive correlation between the expression level of MMP-2 and MMP-9 (rho = 0.439, P < 0.01), but they were both negatively correlated with Col IV (rho = −0.454, P < 0.01; rho = −0.392, P < 0.01). On the other hand, significantly higher levels of AAAs in gastric juice were observed in GC patients than those in NGD individuals (P < 0.001 for all). Ultimately, the expression levels of MMP-2/9 in gastric mucosal tissues were both positively correlated with the concentrations of AAAs in gastric juice (MMP-2; rho = 0.282, 0.295, and 0.293, respectively, P < 0.001 for all; MMP-9; rho = 0.457, 0.455, and 0.417, respectively, P < 0.001 for all), but Col IV was negatively correlated with them (rho = −0.283, −0.280, and −0.273, respectively, P < 0.01 for all) (Table 1).

Table 1: Relationship between the expression levels of MMP-2/9 and Col IV in gastric tissues and the levels of AAAs in gastric juice

**represents significant correlation using Spearman correlation analysis when the confidence level was 0.01; ***represents significant correlation using Spearman correlation analysis when the confidence level was 0.001.

Conclusion: The overexpression of MMP-2/9 resulting in the degradation of Col IV in basement membrane and extracellular matrix may lead to the variation of AAAs’ levels in gastric juice of GC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several studies have demonstrated serum PGII level as a marker of the functional gastric mucosa, and a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, which provides a binding site for the transcription factor for the PG2 gene, in association with the PG2 circulating level and clinical parameter in population at risk for GC and AGG patients.

Aims & Methods: Genetic function of 180 patients (67 GC, 71 first-degree relatives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was assessed by gastropanel test. We investigated the PG2 TATA BOX polymorphism frequencies in relation to serum PG2 (sPG2) expression level, HP positivity and risk for GC. TATA BOX DNA fragments were amplified by PCR and analyzed by the capillary-electrophoresis (GeneMapper software). Association among clinical data and PG2 polymorphisms were estimated by Receiver operating characteristic (ROC) curve and linear regression analyses.

Results: After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL PG2 cut-off was 70.15% and 79, 65% sensitivity and specificity, respectively (AUC: 0.75, p < 0.0001). We obtained 26 different PG2 TATA box fragments (630 bp to 479 bp). These fragments were grouped into 4 sized categories (1 = 308–400 bp; 2 = 401–436 bp; 3 = 437–438 bp; 4 = 439–479 bp). A positive correlation among the increase of PG2 sized fragments and the sPG2 level was found in the GC group (linear regression y = 16, 438 + 2, 864 x, p = 0.02)

Conclusion: In the literature, we confirm sPG2 level as a marker discriminating between GC and individuals at risk for GC (ie ACAG and FDR) in our series. We also reported a correlation between the shortest PG2 TATA BOX fragments and the lower PG2 level. Since highest PG2 level was related to the GC condition, our data suggest that carriers having longer TATA BOX region may produce higher sPG2 level than patients with shorter condition. The clinical significance of the differences in PG2 level associated with the TATA BOX fragments, by interfering with the transcriptional factor and then with the expression of other encoding gene, appear to be an intriguing new aspect. This study should be important to deeper understand the physiopathological PG2 role in GC.

P0590 HELICOBACTER PYLORI INFECTION ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE: A LARGE-SCALE COHORT STUDY

T. Kim, T.J. Kim, H. Lee, J.J. Kim

Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack86@naver.com

Introduction: Previous studies suggested a link between Helicobacter pylori (H. pylori) infection and nonalcoholic fatty liver disease (NAFLD), yet large-scale longitudinal studies are lacking to elucidate this association.

Aims & Methods: A cohort study of 17,028 adults without NAFLD at baseline, who participated in a repeated health screening examination including an H. pylori-specific immunoglobulin G antibody test, was conducted to evaluate the association between H. pylori and NAFLD development. Fatty liver was diagnosed by ultrasonography.

Results: During the 83,130 person-years follow-up, participants with H. pylori infection had a higher rate of incident NAFLD than those who were uninfected. In a multivariable model adjusted for age, sex, body mass index, smoking status, alcohol intake, regular exercise, year of screening exam, eating status, alcohol intake, regular exercise, and education level. H. pylori, helicobacter pylori; HR, hazards ratio; CI, confidence intervals.

*Estimated from Cox proportional hazard models adjusted for age, sex, body mass index, year of screening exam, smoking status, alcohol intake, regular exercise, and education level.

Conclusion: H. pylori infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. H. pylori infection may play a pathophysiologic role in NAFLD development, indicating that H. pylori eradication might play a role in reducing risk of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0591 HELICOBACTER PYLORI INFECTION STATUS IN HUMAN IMMUNODEFICIENCY VIRUS-POSITIVE PATIENTS

Gastroenterology & Hepatology, Osaka National Hospital, Osaka/Japan

Contact E-mail Address: seiya_weckle_0728@yahoo.co.jp

Introduction: Helicobacter pylori infects the gastric mucosa and causes chronic gastritis via the immunoreaction of the host. By contrast, the human immunodeficiency virus (HIV) infects CD4-positive T lymphocytes and destroys the immune system of the host. Some studies pointed out that the H. pylori infection rate is lower in HIV-positive patients. This is because in these patients, H. pylori is incidentally eradicated by the course of antibiotic therapy for HIV infection and because the supply of nutrients to H. pylori is prevented by the decrease in the number of CD4 lymphocytes.

Aims & Methods: We enrolled 290 HIV-positive patients who underwent esophagogastroduodenoscopy in our Hospital between January 2013 and September 2016. As end points of H. pylori infection examination, we retrospectively examined the presence of gastric mucosa atrophy, H. pylori infection, H. pylori eradication, and comorbidity. As end points of HIV infection examination, we quantified the number of CD4 lymphocytes and the titer of HIV and investigated the presence of acquired immunodeficiency syndrome (AIDS). Based on these data, we examined the relationship between H. pylori and HIV infections.

Results: Of the 290 patients, 281 were men and 9 were women, whose median age was 46 years (range, 22–82 years). Ninety patients had atrophic gastritis or stomach or duodenal ulcer, of whom 40 underwent examination for H. pylori infection. The median number of CD4 lymphocytes in the 21 H. pylori-positive cases was 48,169.3 (range, 108–952/µL), the titer of HIV ranged from non-detection to 1,590,000 copies/mL, and one patient had AIDS. Meanwhile, the median number of CD4 lymphocytes in the 19 H. pylori-negative cases was 331 µL (range, 15–989) and the titer of HIV ranged from non-detection to 1,590,000 copies/mL, and three patients had AIDS. H. pylori eradication therapy was applied in 18 of 21 H. pylori-positive cases. The success rate of primary H. pylori eradication was 37.5% (6/16 patients) and that of secondary eradication was 70% (7/10 patients). In addition, 2 (7.7%) of the 26 patients with stomach or duodenal ulcer needed urgent hemostasis. Five (6.7%) of the 74 cases of atrophic gastritis had gastric cancer, of which two were undifferentiated stomach cancers.

Conclusion: In our study, the number of CD4 lymphocytes was higher in the HIV-positive patients with H. pylori infection, implying that the high CD4 count was suggested to be associated with persistent H. pylori infection. In addition, the success rate of H. pylori eradication was shown to be insufficient in HIV-positive patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients' zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 55,360 patients with hepatic encephalopathy were included in the study, of which 20 had H. pylori infection. The mean patient age was 60 years and 42% were female. After adjusting for confounders using multivariate analysis, patients with and without H. pylori had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.71, 95% CI: 0.62–4.74, p = 0.30). As far as resource utilization, patients with and without H. pylori had similar adjusted odds of hospitalization (aOR: 1.02, 95% CI: 0.88–1.16, p = 0.60), LOS (adjusted mean difference: 1.7 days, 95% CI: −0.02–3.42, p = 0.52), and total hospitalization charges (adjusted mean difference: $16588, 95% CI: $4499–$37675, p = 0.12). However, patients with H. pylori had higher adjusted total hospitalization costs compared with patients without H. pylori (adjusted mean difference: $6128, 95% CI: $1141–$11115, p = 0.01).

Conclusion: Presence of Helicobacter pylori has no impact on inpatient mortality among patients with liver cirrhosis and hepatic encephalopathy. In addition, the presence of Helicobacter pylori is not associated with any increase in resource utilization among this patient population, with the exception of total hospitalization costs. It is surprising to note that, although total hospitalization costs differed between the two groups, they received the same total hospitalization charges from admitting hospitals.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0595 RANDOMIZED CONTROLLED STUDY OF A NOVEL TRIPLE NITAZOXANIDE (NTZ) CONTAINING THERAPEUTIC REGIMEN VERSUS THE TRADITIONAL REGIMEN FOR ERADICATION OF HELICOBACTER PYLORI INFECTION

S. Abd-Esalam1, M. A.H. Shehat1, H. Elmesseri1, R. Talata2
1Tropical Medicine Department, Tanta university, Tanta/Egypt
2Microbiology Department, Tanta university, Tanta/Egypt

Contact E-mail Address: sherif_tropical@yahoo.com

Introduction: Helicobacter pylori infection has become more and more resistant to conventional first-line treatment regimens. So, there is a considerable interest in evaluating new antibiotic combinations and regimens. Nitazoxanide is an anti-infective drug with demonstrated activity against protozoa and anaerobic bacteria including Helicobacter pylori.

Aims & Methods: This work is designed to evaluate the efficacy and safety of a unique triple Nitazoxanide containing regimen as a treatment regimen in Egyptian patients with Helicobacter pylori infection.

Methods: Two hundred and twenty four patients with upper Gastro-intestinal tract (GIT) dyspeptic symptoms in whom Helicobacter pylori induced GIT disease were confirmed were included in the study. They have been randomized to receive either Nitazoxanide 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days or Metronidazole 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days.

Results: Laboratory evaluation for Helicobacter pylori antigen within the stool was done 6 weeks after cessation of Helicobacter pylori treatment regimens to assess the response.

Results: The response to treatment was significantly higher in group 1 of Nitazoxanide treatment regimen than group 2 of traditional treatment regimen. Overall success (94.6%) of 118 patients who completed the study in group 1 showed complete cure while only 63 cases (60.6%) of 104 patients who completed the study in group 2 showed the same response according to per-protocol (PP) analysis (p = 0.001). The regimen was well tolerated by all the patients enrolled in the study.

Conclusion: Nitazoxanide-containing triple therapy is a promising therapy for the first-line eradication of Helicobacter pylori. (ClinicalTrials.gov Identifier: NCT02422706)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is some evidence that previous use of macrolides is a useful predictor of the likelihood of standard triple therapy failure in H. pylori eradication (Lim SG, et al. Dig Liver Dis 2016). The goal of this study is to evaluate whether previous intake of various macrolide antibiotics can predict failure to eradicate H. pylori using first-line clarithromycin-containing regimens.

Aims & Methods: Between February 2014 and June 2016 a total of 250 patients with H. pylori infection were prospectively included in a study whose goal was to assess the eradication rates obtained with first-line clarithromycin-containing regimens on our health area. Patients were randomly assigned to one of two regimens: A:Triple therapy (PPI, amoxicillin, clarithromycin, optimized with a double dose of PPI) for 10 days; and B:Concomitant therapy (PPI, amoxicillin, clarithromycin, and metronidazole administered concurrently) for 10 days. The eradication was evaluated by the Stool antigen test or with the Urease test in patients those patients with a gastroscopy performed after the treatment. A total of 113 patients in the group A (58 women; Median age: 54 years; Range: 21–79) and 106 patients in the group B (56 women; Median age: 49 years; Range: 18–81) completed the study protocol. The electronic medical records of the patients, which contain information regarding all the medication prescribed to the patient during the previous 12 years, were reviewed and the intake of macrolides (clarithromycin, azithromycin and erythromycin) was registered.

Results: 89/219 patients (40.6%) had received at least one treatment with macrolides during the previous 12 years. H. pylori eradication rates with the two treatment regimens are shown in Table 1.

Table 1: H. pylori eradication rates in patients with and without previous intake of macrolides.

<table>
<thead>
<tr>
<th></th>
<th>Previous use of Macrolides</th>
<th>No previous use of Macrolides</th>
<th>p</th>
</tr>

Introduction: Due to increasing prevalences of clarithromycin resistance in H. pylori infection, current guidelines recommend quadruple therapies as first-line therapy1–3. Bismuth quadruple therapy (BQT) has been proven superior to standard triple therapy in clinical trials4, however little is known about the efficacy of BQT in clinical routine practice.

Aims & Methods: In a prospective single center cohort study we analyzed consecutive patients in whom three-in-one capsule BQT (Pylarer® + omeprazole) has been prescribed between 1/2013 and 12/2016. All patients were instructed in a standardized fashion and a prospective follow-up was planned. In a subgroup of patients, genotypic susceptibility testing for clarithromycin and levofloxacin by PCR was carried out on gastric biopsies before treatment. Treatment outcome was assessed by 13C urea breath test or by histology not earlier than 4 weeks after completion of treatment.

Results: Three-in-one capsule BQT has been prescribed in 322 patients (mean age 41 years (18–80), 65% female, 26% active smoker). 71% of patients had a migrational background including Southern-/Eastern Europe, Eurasia/ Central Asia, Southwest-Asia, Africa, and Central/South America. PCR results were available in 163 patients (50.6%) and identified resistance to clarithromycin and levofloxacin in 29 (17, 8%) and 20 (12, 3%) of cases, respectively. BQT was administered as firstline, secondline and rescue treatment in 74%, 17% and 9% of cases, respectively. 5 patients discontinued treatment prematurely due to side effects (1, 8%) and 43 patients were lost to follow-up (13, 4%). By modified intention-to-treat and per-protocol analysis the H. pylori eradication rates were 94, 9% (95% CI: 92, 1–97, 5%) and 96, 7% (95% CI: 94, 4–98, 8%), respectively. The low number of treatment failures (n = 9) did not allow to identify risk factors for failure.

Conclusion: Three-in-one capsule bismuth quadruple therapy is highly effective and safe for treatment of H. pylori infection in clinical routine practice, irrespective of the patient’s migrational background or the number of previous treatment failures.

Introduction: Background: Eradication of Helicobacter pylori (H. pylori) infection represents a clinical challenge. The current requirements demand eradication rates above 90%, which has made that the use of triple treatment including clarithromycin or metronidazole had been give up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth subcitrate potassium, metronidazole, and tetracycline (BMT) have shown high eradication rates in clinical trials.

Aims & Methods: We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of H pylori infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed H pylori infection eradication indication. Patients were treated for ten days with a galenic preparation containing bismuth subcitrate potassium 140mg, metronidazole 125 mg, and tetracycline 125 mg, three capsules four times daily, and esomeprazole 40mg twice daily and probiotic during 30 days. The primary endpoint was H. pylori eradication rate. The H. pylori infection was based on the urea breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures. Patients were followed up for 13 years (311, esomeprazole 388 days), which excluded patients who did not complete the study or who had previous protocol violations, were also conducted to confirm the ITT results.

Conclusion: A total of 100 patients, 60 (60.0%) women and 40 (40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [44.0 to 50.2] years. Twenty-five (25.0%) patients had a prior history of using medications to treat H. pylori eradication, 75 (75.0%) patients had an allergy or intolerance to clarithromycin, amoxicillin, and PPI. In the ITT population, the eradication rates were the 90.7% (68/75) and the 80.0% (20/25) depending on whether the PPI-BMT treatment was administered as first-line or as rescue therapy, respectively. In the PP population, the eradication rates were the 98.6% (66/67) and 95.2% (21/22) in those patients treated with PPI-BMT as first-line or as rescue therapy, respectively. Eighteen (18.0%) patients reported at least one adverse event.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPI) for a first-line Helicobacter Pylori (H. pylori) eradication.

Aims & Methods: We retrospectively analyzed data from first-line H. pylori eradication treatment (vonoprazan or PPIs with 400 mg clarithromycin and 1500 mg amoxicillin and 400 mg omeprazole) in a Spanish hospital (Hospital Zarzuela, Madrid/Spain) between June 2015 and October 2016. The patients were randomly assigned to receive 7-day P-CAB therapy (vonoprazan 20 mg twice daily, n = 498) were compared with those who received 7-day PPI therapy (lansoprazole 30 mg/day, n = 216, rabeprazole 20 mg/day, n = 138). The primary endpoint was the cure rate, defined as one negative urea breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) and per-protocol (PP) compliance and adverse events were also assessed for each study group.

Results: ITT and PP analysis of the first-line H. pylori eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5% (132/175), 63.9% (70/111), 68.0% (79/115), and 63.2% (78/123), respectively. The vonoprazan eradication rates were significantly higher than those of these PPIs (P < 0.05), respectively. There was no significant difference in the adverse events between the two therapies.

Conclusion: 7-day first-line triple therapy is more effective than 7-day PPI based triple therapy as a first-line H. pylori eradication without differences in tolerability.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Most Helicobacter pylori (Hp) infections are asymptomatic but 15% of those infected with Hp will eventually experience dyspepsia symptoms or ulcer.

Aims & Methods: We aimed to evaluate the cost effectiveness of population screening and eradication for Helicobacter pylori (Hp). This was a cost effectiveness analysis and cost utility analysis alongside randomized controlled trial with 13-years follow-up, with a random sample of the general population from the county of Funen, Denmark. 20,011 individuals aged 40 years and over were invited to participate in the study, with a response rate of 88.7% (17,607). The primary endpoint was the rate of Hp infection when combined with 400 or 800 mg/day clarithromycin (CAM).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Vonoprazan (VPZ) is a novel, orally bioavailable, potassium-competitive acid blocker and PPI for the treatment and prevention of acid-related gastrointestinal diseases. A Phase III study revealed that VPZ is superior to lansoprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).
the patients with low eGFR, 65.3% [34/53] in the patients with high eGFR [P = 0.034], or it was significantly higher in the VPZ group than that in the EPZ group (79.3% [23/29] versus 50% [11/13], respectively, [P = 0.025]). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [P = 0.016]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [P = 0.21]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [P = 0.33]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric/duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400mg/day CAM and 1500 mg/day ABPC was similar to that of EPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR. It is necessary to determine the most appropriate conditions that will maximize the therapeutic effect of VPZ-based triple therapy.

P0604 ASSOCIATION BETWEEN GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE AND H. PYLORI INFECTION

M. Matsueda, H. Kinugasa, K. Miyahara, M. Nakagawa Internal Medicine, Hiroshima City Hiroshima Citizens Hospital, Hiroshima/Japan

Contact E-mail Address: maaaayay0917@gmail.com

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is gastric adenocarcinoma with low-grade atypia occurring in the mucosa of the fundic gland without atrophy, and is recognized that it is not related to H. pylori (Hp) infection. However, GAFG is also found in Hp-infected and past Hp-infected patients as well as in Hp-uninfected patients. It is not often clear the relationship between the progress of GAFG and Hp infection.

Aims & Methods: Ten lesions of GAFG resected endoscopically or surgically in our hospital from December 2010 to October 2016 were classified as Hp-uninfected (n = 3) and past Hp-infected (n = 7). Each endoscopic and clinicopathological features were examined.

Results: Median age of Hp-infected/past Hp-infected/Hp-uninfected were 65/71/54.5 years old, respectively, male ratio was 100/80/0%, occupied site U area infection was not clear. In Hp-uninfected group/past Hp-infected group/Hp-uninfected group (submucosal invasion was found at 80/100/0%, p = 0.035).

According to endoscopic features, background mucosa of gastric fundus gland mucosa without atrophic change was found in 100/100/0%, whitish color in 67/60/50%, submucosal tumor shape in 67/60/60%, dilated vessels with branching architecture in 100/100/50%. The association with Hp infection was not clear. In immunohistochemical staining, MUC6 positive/mucin-1 positive, MUC6 positive, Pepsinogen I positive, MUC2 negative, CD 10 negative in all cases, whereas the rate of MUC5AC positive was significantly higher in the Hp-uninfected group as 0.2/100% (P = 0.045). We reported that black pigmentation is recognized in GAFG (stomach and intestine 50:1521–1531, 2015), but no association between Hp infection and black pigmentation was observed. On the other hand, the rate of PPI administration divided pigmentation (n = 6)/no pigmentation (n = 4) are 50/0%, and it is suggested that the pigmentation in GAFG may relate with PPI (p = 0.091).
Celiac disease (CD) is a life-long autoimmune disease affecting the small bowel of CD patients, and to look for a possible association between mucin profile and gluten-free diet (GFD). It’s now considered as multisystem disorder. A recent study by Zhu et al. [1] has highlighted the importance of mucin expression in the small bowel of CD patients, and its role in the pathogenesis of the disease.

**Materials and Methods:**

This study aimed to assess the current knowledge about mucin expression in the small bowel of CD patients, and to look for a possible association between mucin profile and gluten-free diet (GFD). The evolution of liver disorders after GFD was assessed. The chronic liver disease was often decompensated and the hepatic signs for cirrhosis were in the foreground masking the response to GFD.

**Conclusion:**

It is recommended to look for hepatic abnormalities during CD and even to think of the diagnosis of CD in front of liver cytolysis syndrome without obvious cause in the clinical setting.

**Disclosure of Interest:**

All authors have declared no conflicts of interest.

Aims & Methods: In this study we investigated the TLRs 2, 4, 7, 9 genes expression in the intestine with celiac disease compared with healthy control. Blood samples from 120 CD patients diagnosed according to the Iranian Society for Gastroenterology were collected and 120 healthy individuals were served as a control group during 2016. Also, among them, 20 duodenal biopsy specimens were collected randomly. Total RNA for both blood samples and biopsy specimens was isolated using a standard commercial kit. The mRNA expression of TLRs were quantified by relative qPCR with B2M as a reference gene.

Results: Significantly higher expression of TLR4 and TLR9 mRNA was observed in blood samples of CD patients compared to the healthy controls (P < 0.05); but there were no significant differences between expression of TLR2 and TLR7 mRNA compared to the controls. Furthermore, TLR4 and TLR2 expression level was increased in CD biopsy specimens compared to controls, whereas expression of TLR9 mRNA was decreased in CD patients. No significant differences in expression of TLR7 was observed in biopsy specimens.

Conclusion: The result of this study show that the alteration of TLR4 and TLR9 genes expression in intestinal mucosa of CD can be detected in PBMs in peripheral blood. This data supports the implication of innate immune system in the pathomechanism of celiac disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Coeliac disease (CD) is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4).

Aims & Methods: The aim of this study was to define GI symptoms reported in an Australian cohort with a doctor diagnosis of CD and compare with those not reporting CD. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate ¼ 51%). This study evaluated CD patients (n=376) and non-affected cohort (n=3449) and the self report of GI symptoms.

Results: The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84–1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhoea, bloating, distension, epigastric burning and early satiety (see Table). There was no significant difference observed in symptoms of post-prandial fullness, nausea, constipation, abnormal stool consistency, or straining with defecation. The prevalence of FD as defined by Rome III criteria in the CD cohort was 37.5% (95% CI 22.7–54.2) compared to 13.9% (95% CI 12.8–15.1) in the non-affected population (OR 2.7, 95% CI 1.9–3.7, p < 0.001). There was no significant difference in the prevalence of IBS in the affected compared with the non-affected cohort (30.8% versus 22.2%, p = 0.2).

Table: Gastrointestinal symptoms reported by patients with and without self reported coeliac disease (CD). Items reported as greater than one day per week (*) or greater than or equal to “often” (**) self report of CD self report of CD - No p value

</table>

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia are significantly higher in patients with a doctor diagnosis of CD than unaffected population. Studies using self biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful (3), this study supports these views.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0613 MALE GENDER AND UNDERWEIGHT ARE ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH NEW DIAGNOSES OF COELIAC DISEASE

Department Of Medical-surgical Sciences And Translation Medicine, Sant’Andrea Hospital, University Sapienza, Rome,Italy

Contact E-mail Address: gloria.galli5@gmail.com

Introduction: Osteoporosis is a systemic skeletal disorder characterized by low bone mass and micro-architectural deterioration with increase of bone fragility and consequent fracture risk. About 50–75% of patients (pts) with untreated coeliac disease (CD) suffer from bone mass loss (osteopenia or osteoporosis). Despite this strong correlation, guidelines do not express with certainty on the need to undergo a dual-energy X-ray absorptiometry (DEXA) scan in every patient with new diagnosis of CD. Recently, the DEXA screening was suggested for CD peri-post menopausal females, males over 55 yrs, pts with overt malabsorption or with a history of fragility fractures. Studies on bone mineral density (BMD) in CD pts led to discrepant results, probably due to heterogeneous designs.

Aims & Methods: The aim of this study was to evaluate, in a cohort of consecutively newly diagnosed CD adults, the prevalence of BMD alterations at diagnosis time and to evaluate associated clinical features. From January 2004 to December 2016, 258 consecutive pts (F = 72.4%) were diagnosed with CD. All pts were adults (median age 38, range 18–72 years), had atrrophic disease and were invited to undergo a DEXA within 3 months from diagnosis to screen for osteoporosis (T-score < −2.5) or osteopenia (T-score < −1 and ≥−2.5). A total of 214 (82.9%) pts underwent the DEXA scan and were included in the study (F = 71.5%, median age 38, range 18–72 years). On the basis of DEXA results (codified according to WHO classification) pts were divided into 3 groups: pts with normal BMD, with osteopenia, and with osteoporosis. For each patient, reported risk factors for low BMD (underweight, alcohol intake, drugs, menopause, smoke) and serological PTH values were assessed. The signs/symptoms associated to CD and their duration before diagnosis, autoimmune/non-autoimmune comorbidities, familiarity for CD, previous fractures and serological assays (specific antibodies for CD, ferritin, cholesterol, triglycerides, and albumin) were also assessed. All the variables described were analyzed and compared between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis.

Results: At the DEXA scan, 85 (39.7%) and 129 (60.3%) pts had normal or low BMD, respectively. Among pts with low BMD, 91 (42.5%) had osteopenia and 38 (17.8%) osteoporosis. At logistic regression, clinical features significantly associated with osteoporosis were male gender (OR 4.7; 95%CI 1.3 to 17.4), underweight (OR 8.1; 95%CI 1.8 to 35.3) and increased PTH values (OR 5.1; 95%CI 1.4 to 18.8), while age ≥60 years and gastrointestinal symptoms at diagnosis time, menopause, alcohol intake and previous fractures were not associated. Clinical features significantly associated with osteopenia were underweight (OR 4.0, 95% CI 1.4 to 11.2) and increased PTH values (OR 2.6, 95%CI 1.1 to 6.4).

Conclusion: In newly diagnosed coeliac pts, the overall prevalence of BMD alterations was more than 60%, with osteoporosis in nearly 1/5. Osteoporosis was significantly associated with male gender, underweight and increased PTH. This study suggests that at CD diagnosis, DEXA scan might be of benefit, in particular in male underweight pts.

3Psychology, Macquarie University Psychology, North Ryde/Australia

Contact E-mail Address: Michael.Potter@hnehealth.nsw.gov.au

Introduction: Coeliac disease (CD) affects 0.6–1% of the population worldwide (1). Wheat avoidance in the absence of CD is common, and studies report a population prevalence of self-reported wheat or gluten sensitivity (SRWS) of...
up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extra intestinal symptoms on ingestion of wheat or gluten-containing food (2, 3).

Aims & Methods: The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on wheat avoidance. GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve.

Results: The prevalence of SRWS in this cohort was 13.5% (455/3331, 95% CI 12.5–14.9%). Only 11% (95/950) of these subjects had received a doctor diagnostic of symptom-related wheat intolerance (SRWS) from 18 to 50 years (36 men and 38 women) were examined. According to Rome IV criteria (2016), 21 had irritable bowel syndrome (IBS) with predominant diarrhea (54.8%), bloating (37.6%) and abdominal distention (30.8%). In a multivariate analysis, a diagnosis or SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia syndrome (30.8%).

Conclusion: The prevalence of irritable bowel syndrome (IBS) and functional dyspepsia syndrome (FD) is high in this cohort. SRWS may be one of the causes of functional bowel disease in people who report wheat avoidance symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
as celecoxib. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

Aims & Methods: Between 2003 and 2016, 559 patients referred to our hospital for diagnosis had an abnormal small intestine. The presence of co-morbid systemic disorders was excluded in all of them. After an overnight fast and at the same time in the morning, all the subjects underwent evaluation of post-prandial modifications of serum levels of pro-inflammatory cytokines (IL-1β, IL-6, TNFα), endogenous antioxidant system (uric acid), glucose, insulin and lipopolysaccharide (LPS), measured as putative factors responsible for inflammatory response. Serum samples were collected at fasting and every 30 minutes for a 4-hour period after an oral gluten load of 2 gr (in 10 HV) or 20 gr (in the other 10 HV). The presence and severity of symptoms such as epigastric pain, epigastric burning, fullness, early satiety, abdominal pain, abdominal distension, bloating, flatulence, nausea, vomiting, belching, heartburn, regurgitation, diarrhea, and headache, were evaluated by visuo-analog scale at fasting and every 30 minutes in the post-prandial period.

Results: In comparison with mean fasting values, none of the measured parameters showed a significant increase in the post-prandial period after the ingestion of 2 gr of gluten. On the contrary, after the ingestion of 20 gr of gluten mean post-prandial values of TNFα and IL-2 showed a significant increase (2.45 ± 1.75 pg/mL and 0.65 ± 0.31 pg/ml) as compared to mean fasting values (1.17 ± 1.49 pg/mL and 0.29 ± 0.15 pg/ml, p < 0.05). Mean post-prandial values of uric acid were also significantly higher (74.89 ± 5.02 mmol/l) than fasting values (45.34 ± 10.08 mmol/l, p < 0.05). No significant differences were detected in IL-6, glucose, insulin and LPS after the ingestion of the 20 gr gluten oral load. Symptoms were absent after both oral loads.

Conclusion: The ingestion of 2.g. but not a low, oral load of gluten induces a significant post-prandial inflammatory response causing the activation of the main endogenous anti-oxidant system. In HV, these activations are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-oxidant post-prandial response in patients with gluten-related disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0620 Therapeutic Action of KETOCENIC ENTERAL NUTRITION in OBESE and OVERWEIGHT PATIENTS: A RETROSPECTIVE INTERVENTIONAL STUDY

C. Papadina1, P. Bassi2, G. Cappello3, R. Shidrawi4
1Gastroenterology, Homerton University Hospital, London/London/United Kingdom
2Statsconsultancy, London/London/United Kingdom
3Clinical Nutrition, Rome/Italy

Contact E-mail Address: cinzia.papadina@nhs.net

Introduction: Ketogenic Enteral Nutrition (KENTM) is a modification of Blackburn’s protein-sparing modified fast, using a hypocaloric, ketogenic liquid diet. The study is about Ketogenic enteral nutrition (KENT) in overweight and obesity at treatment of the metabolic syndrome and the influence of nocturnal hour infusion. It is a retrospective analysis that examines safety, weight loss and body composition changes after three sequential 10-d cycles of KENT therapy.

Aims & Methods: Anthropometric and bio-impedance data from 629 patients were obtained before and after the complete KENT cycle. The study focuses on the change in outcomes from the first cycle to the second cycle and from the first cycle to the third cycle. The following outcomes were evaluated: weight, waist circumference, BMI, fat mass, lean mass, phase angle, wellness marker, water mass as a percentage of total body weight. The cycle 1, 2 and 3 outcomes were analyzed using descriptive statistics (mean, standard deviation, n) summarizing the outcome at each cycle. Statistical tests were used to test for significance between paired cycle 1 and cycle 2 outcomes and also between paired cycle 1 and cycle 3 outcomes. For normally distributed outcomes, the paired t-test was used. Whereas for skewed outcomes, the Wilcoxon signed-ranks test was used. Scatter plots were used to plot percentage of weight loss against phase angle. The Pearson’s correlation coefficient was calculated. Regression analysis for the outcome percent change in weight from cycle 1 to cycle 2 for phase angle and basal metabolic rate (BMR)/Weight ratio as predictors was carried out.

Results: The results suggested significant changes for all analyzed parameters. There were significant decreases in weight, waist circumference, BMI, fat mass, lean mass, dry lean mass and phase angle. Quantitative changes in lean mass and lean mass were negligible with respect to changes in fat mass. There was also a statistically significant increase in water mass as a % of total body weight and wellness marker from cycle 1 to cycle 3. The Pearson’s correlation coefficients r = 0.18, p = 0.004 and r = 22, p = 0.04 indicated changes in cycle 1 and cycle 3 in percentage of weight excess to be significantly, positively correlated to phase angle and BMR/Weight. The Pearson’s correlation coefficient was calculated. Regression analysis for the outcome percent change in weight from cycle 1 to cycle 2 for phase angle and basal metabolic rate (BMR)/Weight ratio as predictors was carried out.

Conclusion: KEN treatment is safe, well tolerated and results in rapid fat loss without detriment to dry lean mass.

Disclosure of Interest: All authors have declared no conflicts of interest.
Mean weight regain was 4 kg during this period. Most patients (62%) regained weight control after IGB removal: lack of psychological support and nutrition counseling were two of these. 81.3% (182) were women. During the use of IGB, patients lost an average of 15% of their body weight; representing a mean loss of 66% of excessive weight. Between 2 and 5 years after removal of IGB, 67% (150) of the subjects had regained weight; the mean weight regained was 4 kg during this period. Most patients (62%) regained 10% to 19% of weight lost during treatment. The mean weight regained increased during follow-up, but without significant difference among groups: 2 years [n = 10]: 4.06 ± 4.91 kg; 3 years [n = 83]: 8.66 ± 8.96 kg; 4 years [n = 54]; 9.99 ± 8.44 kg and 5 years [n = 3]: 19.96 ± 12.24; (p = 0.51). The lower the HMI at the beginning of the treatment, the greater the weight regain after the IGB withdrawal. This correlation was inverse (r = -0.20) and significant (p < 0.01). The correlation was stronger and more significant with patients who had withdrawn the balloon at two years (r = -0.31, p < 0.001) followed by those in whom balloon withdrawal was undertaken four years before (r = -0.23, p = 0.03). Weight regain group contained more individuals who did not perform psychological and nutritional follow-up and who were also sedentary, during and after treatment. Each year, after removal of IGB, the chance of regaining weight increased 1.5 times. No follow-up with a nutritionist after the procedure increased chance of weight regain in 1.8 times. Lack of follow-up with a psychologist during treatment had a weight regain 1.9 times increased. Multivariate logistic analysis determined risk factors for weight regain according to time span after IGB removal. After 2 years of balloon removal, the significant risk factor was lack of follow-up with a psychologist during treatment; increasing the chance of weight regain 1.13 times compared with those subjects that received psychological counseling. An independent significant risk factor for weight regain after 3 years of IGB removal was the lack of follow-up with a nutritionist after the use of IGB. Chance of weight regain was 3.36 times higher in this group than in patients who did the nutritional follow-up. After 4 years of IGB removal, sedentary behavior was an independent and significant risk factor, increasing the chance of weight regain 3.86 times compared with physically active behavior.

Details of dystrophy, inflammation and necrosis and reduction of the NASH incidence. visceral obesity. In male rats, there were more pronounced changes. It was established that under condition of obesity caused by the introduction of MSG, the level of adiponectin in serum decreased but leptin in VAT was increased. S significantly improvement lipid profiles and histological state of liver: decrease of dystrophy, inflammation and necrosis and reduction of the NASH incidence.
Also consumption of S led to reduction of pro-inflammatory cytokines and leptin and increased anti-inflammatory cytokines and adiponectin.

Conclusion: Thus, the introduction of S reduced the obesity, that shows the effectiveness of therapy for the prevention of obesity.

P0624 IMPROVED EMPLOYMENT OF INTRAGASTRIC BALLOON FOR WEIGHT LOSS: A PRELIMINARY ANALYSIS
Department Of Internal Medicine, Division Of Gastroenterology And Hepatology, Korea University Anam Hospital, Seoul/Korea, Republic of

Contact E-mail Address: drchunjh@chol.com

Introduction: Endoscopic bariatric approaches are gaining traction as possible treatment modalities for obesity. Especially, intragastric balloon was demonstrated to be associated with a significant weight loss in obese patients. Despite many advances in the design and material of intragastric balloon devices, there still remains a need for improved devices which is safer, faster, and less expensive than before. In the present study, we evaluated feasibility of newly developed intragastric balloon.

Aims & Methods: We used a newly developed intragastric balloon with improved employment for this study. The intragastric balloon was supplied as delicately rolled up inside a thin silicon sheath and mounted by surrounding the endoscope. Endoscopic intragastric balloon placement and positioning was simply performed; a total of 10 pigs were submitted to the novel intragastric balloon placement. We evaluated feasibility of the intragastric balloon and compared procedure time between the novel intragastric balloon and End-ball (Endalis, Brignais, France) intragastric balloon.

Results: In all cases, the novel intragastric balloons were successfully placed under usual sedation of diagnostic endoscopy. The procedures were simple and fast; the mean insertion time was 41.3.12.4 and 153.8 sec in novel intragastric balloon group and end ball group, respectively. The mean inflation time was 412.4±2.12.3 sec in novel intragastric balloon group and end ball group, respectively.

Conclusion: This preliminary data suggest that the procedure with the new intragastric balloon attain technical improvements in the placement without severe adverse events. The new intragastric balloon could offer constantly effective procedure regardless of the ability of the endoscope practitioner.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0625 IS RE-IMPLANTATION OF THE DUODENAL-JEJUNAL BYPASS LINER Viable?
S. Guentherl, A. Dienesthal, J. Stein
Gastroenterology And Clinical Nutrition, DGD Clinics Sachsenhausen, Frankfurt/Main/Germany

Contact E-mail Address: j.stein@em.uni-frankfurt.de

Introduction: The endoscopically implanted DJBL is a 60cm long, impermeable fluoropolymer device which prevents food from making contact with the proximal intestine, thus inducing considerable weight loss and improvement of type 2 diabetes mellitus (T2DM). Both weight and HbA1c levels have been reported to decrease with implantation; however, weight and HbA1c levels decreased one month after re-implantation procedure regardless of the ability of the endoscope practitioner.

Aims & Methods: The aim of this study was to investigate the safety, feasibility and effectiveness of DJBL re-implantation in patients who show a relapse in glucose levels after DJBL explantation. This prospective, observational study was conducted at the Department of Gastroenterology of DGD Clinics Sachsenhausen, Frankfurt (Germany) between 2014 and 2016. Five obese patients was 18 years of age and with a body mass index (BMI) ranging from 35–59 kg/m², who completed follow-up after their first implant and underwent removal of the DJBL after 12 months, were selected for re-implantation after an additional 4 months of follow-up. Weight loss, BMI, and HbA1c were analysed before reimplantation and twelve months thereafter.

Results: In 5 patients, the DJBL was initially implanted and explanted without complications. Re-implantation and re-implantation were also performed without complications. Changes in body weight, BMI and glycaated haemoglobin (HbA1c) are shown in Table 1.

Table 1: Body weight, BMI and HbA1c changes at different timepoints

</tr>
</tbody>
</table>

Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even only 4 months after explantation. After re-implantation, weight and HbA1c levels decreased one month after re-implantation.

P0626 THE COMPARATIVE EFFICACY OF OBESITY TREATMENTS IN YOUNG PEOPLE: A SYSTEMATIC REVIEW AND META ANALYSIS
S. S. Selvendran, N. Penney, N. Aggarwal, A. Darzi, S. Purkayastha
Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: SS6912@i ca.ac.uk

Introduction: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-analyse studies evaluating treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modifications and pharmacological therapy searches were restricted to randomised control trials. Results: 16,372 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more modest impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Conclusion: This is the first systematic review and meta-analysis to comprehensively summarise and quantify the comparative efficacy of BMI reducing treatment options in the obese, young population. Currently, bariatric surgery is rarely considered in this young cohort. However, due to its high efficacy, physicians and patients should have a lower threshold for considering bariatric surgery when lifestyle and pharmacological interventions have failed. The relative effectiveness of surgical interventions provide smaller but statistically significant impacts on BMI reduction. There should be effective communication discussing the relative efficacy of all treatment options and their associated complications between those involved. This knowledge will assist clinicians in determining a holistic, patient-centred treatment programme for obese, young patients.

Introduction: Tumor development is a multistep process, which involves genetic and environmental factors. Diet is among the most important contributing factors and processed and red meat has been classified as carcinogenic for colorectal cancer. MicroRNAs (miRNAs) are functional, ubiquitously present molecules that inhibit translation by binding to the 3’ untranslated region of mRNAs and cause degradation of the target messenger RNA. MicroRNAs (miRNAs) are functional, ubiquitously present molecules that inhibit translation by binding to the 3’ untranslated region of mRNAs and cause degradation of the target messenger RNA. In the present work, we evaluated whether miRNAs are present in various foods, and if miRNAs may be degraded during cooking and other forms of food processing. Furthermore, we tested if short-term vegetarian or meat-rich diet may influence human or plant-derived miRNA in feces and blood. For this purpose, six healthy subjects were asked to adhere to vegetarian or meat rich diet for 5 to 7 days and fecal and blood specimens were obtained at different time points. Plant-miRNAs were further investigated in gastric and colon mucosa. To evaluate the presence of miRNA in food, we selected several common foods prior and after cooking/processing. Quantitative real-time PCR was performed using TaqMan Assay.
P0628 NEUROMEDIN U BLOCS GASTRIC EMPTYING THROUGH VAGAL-DEPENDENT MECHANISMS AND IMPROVES ORAL GLUCOSE TOLERANCE

A. Jarry1, N. Merah1, M. Fiamma2, L. Bodineau1, A. Bado1, J. Le Beyec2, M. Le Gall1

2INSERM U1158, Paris/France

Contact E-mail Address: annel irresistiblejarry@hotmail.fr

Introduction: The gut and brain peptide neuromedin U (NMU) is reported to decrease food intake and body weight, and to improve oral glucose tolerance suggesting it exerts an incretin-like action. NMU is thus considered as a promising candidate for the treatment of obesity and diabetes. However, and in contradiction with previous observations, NMU was recently presented as a “decretin” hormone able to decrease insulin secretion. The pathways through which NMU controls glycemia are thus uncertain and we sought to clarify some of NMU mechanisms of action on glucose homeostasis.

Aims & Methods: Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. Single laparotomy or a transduodenal laparoscopic pyloromyotomy were performed during OGTT. Blood was sampled to measure insulin secretion. [14]C-glucone uptake was assessed in isolated intestinal loops in presence or absence of NMU. Gastric retention of a phenol red gavage and total intestinal transit time were evaluated after an intraperitoneal injection of NMU or PBS. Activation of vagus nerve neurons by intraperitoneal injection of NMU was assessed by cFos immuno-staining on brainstem slides going through the nucleus of the solitary tract (NTS) and the dorsal nucleus of the vagus (DMV). Direct impact of NMU on pyloric emptying was evaluated by isometric chambers. NMU directly induced pyloric contraction in a dose dependent manner (basal contraction +21%, 7% at 0.6-M).

Conclusion: These data demonstrate that a single intraperitoneal injection of NMU blocks gastric emptying directly by inducing pyloric contraction and indirectly via afferent vagal fiber activation. Through the blockade of gastric emptying, NMU reduces intestinal nutrient absorption and thus improves oral glucose tolerance. The gastric emptying blockade induced by NMU could also contribute to its anorexigenic effect.

P0629 LOW FODMAP DIET & PREBIOTIC GALACTOOLIGOSACCHARIDES IMPROVE IRREVERSIBLE BOWEL DISEASE SYMPTOMS: A RANDOMISED CONTROLLED TRIAL

1King’s College London, London/United Kingdom
2University of Liverpool, Liverpool/United Kingdom
3Barts Health NHS Trust, London/United Kingdom
4Guy’s and St Thomas’ NHS Foundation Trust, London/United Kingdom
5Guys and St Thomas Hospital Dept. of Gastroenterology - London/United Kingdom

Contact E-mail Address: bridgette.wilson@kcl.ac.uk

Introduction: Dietary restraint causes the low FODMAP diet (LFD) to be effective at managing symptoms in 50–80 percent of patients with irritable bowel syndrome (IBS). Prebiotic B-galacto-oligosaccharide (B-GOS; HOST-G004) also reduce symptoms in IBS however the combination of the two therapies has not been investigated. We investigated if those who respond to the LFD from those who do not is unclear.

Aims & Methods: This randomised controlled trial aimed to investigate whether: 1) addition of prebiotic B-GOS could improve symptoms of IBS alongside the LFD; and 2) if urinary metabolites, faecal short-chain fatty acids (SCFA) or volatile organic compounds (VOC) could identify factors at baseline that predict response. Sixty-nine adults fulfilling Rome criteria for IBS were recruited to a 3-arm RCT: control (sham diet/placebo), LFD (LFD/placebo) or LFD plus B-GOS (LFD/B-GOS) for four weeks. Questionnaires (global symptom question and gastrointestinal symptom rating scale) assessed GI symptoms (response) and urine and stool samples were collected for analysis at baseline and week 4. To examine the relationship between responders and non-responders, urine metabolomics (700 MHz H-NMR), stool SCFA (gas liquid chro- matography (GLC)) and stool VOC (GC-mass spectrometry) were analysed on samples at baseline and 4-weeks. Urine metabolomics spectra and VOC profiles were analysed using unsupervised principal component analysis (PCA) and supervised pattern recognition methods (orthogonal partial least square discriminant analysis (OPLS-DA) or PLS-DA respectively). Stool SCFA were compared using t-tests, models of prediction were tested using receiver operator characteristic (ROC) curves.

Results: There was a significant difference in response rates (adequate relief) between control (30%), LFD (50%) and LFD/B-GOS (67%) (p=0.046), with post-hoc differences specifically between control and LFD/B-GOS (p=0.015). Individual IBS symptoms improved markedly in the LFD/B-GOS group compared to control. In the LFD group only, there was a significant difference in the urine metabolome between responders and non-responders at both baseline (Q2=0.296 vs randomised ~0.175) and at 4-weeks (Q2=0.485 vs randomised ~0.203). At baseline, there were significant greater stool isobutyrate between responders (51.4 mg/100g) and non-responders (31.9 mg/100g, p=0.04), with ROC curves supporting this as a predictor of response (AUC=0.747, p=0.063). Finally, there was a significant difference in VOC profiles between responders and non-responders to the LFD at baseline (p=0.04), however VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p=0.02).

Conclusion: Addition of B-GOS to the LFD improves symptoms in IBS. Urine metabolomics, stool SCFA and VOC profiling are robust tools for responsive and non-responders to the LFD at baseline (p=0.04). VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p=0.02).

P0630 THE ANALYSIS OF PROTEIN CONSUMPTION PATTERNS IN PATIENTS WITH SIBO

V. Pilipenko, V. Isakov, A. Vlasova

Gastroenterology & Hepatology, Research Institute of Nutrition RAMS, Moscow/ Russian Federation

Contact E-mail Address: pilipenko@rambler.ru

Introduction: Small intestinal bacterial overgrowth (SIBO) is common in patients with gastrointestinal diseases. SIBO symptoms are improved with antimicrobial treatment, but recurrence rate is high (approximately 40% for 9 months). Dietary modification is essential for prevention of recurrence of SIBO however there are no detailed studies of nutrition in SIBO patients. Protein consumption is considered of importance for personalised therapy for patients with IBS.

Aims & Methods: The aim of the study was to assess the protein consumption patterns in patients with SIBO. Three-day food diary was collected from 574 patients, undergoing CH4/H2 lactulose breath test. The photographs used to estimate the size of the portions eaten. According to food product by food groups. Each food group were compared with the normal levels.

Results: All types of SIBO patients consumed less meat than control (no signs of SIBO), however patients with hyperproduction of CH4 only demonstrated highest consumption of fish, and it was a trend in patients with isolated H2-hyperproduction of fish to consume more fish than other groups. There were no differences between groups in consumption of processed meat foods or eggs.

Conclusion: There are specific animal protein consumption patterns related to the type of the SIBO, which can be used for the planning of dietetic interventions in patients for prevention of SIBO recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.
OF FOODS HIGH IN SHORT-CHAIN CARBOHYDRATES, DAILY PRODUCTS, WHEAT, SPICES ETC.

Although some studies indicate increased rectal sensitivity after duodenal lipid administration in patients with IBS and suggest delayed transit after high fat intake, the effects of dietary supplementation with different types of fatty acids in IBS have not been explored so far.

Aims & Methods: The aim of the study was to evaluate the differences in GI motor function and visceral sensitivity in rats exposed to diet supplemented with either medium-chain (MCFAs) or long-chain fatty acids (LCFAs). Male Wistar rats were fed with control diet (A), and diet supplemented with 3.5% coconut oil (B) (abundant with MCFAs) or 3.5% evening primrose oil (C) (abundant with LCFAs) for 4 weeks. The effects of each diet on GI motility were measured radiographically after contrast administration (p.o; X-rays were taken 0–8h before and after feeding, on day 0 and day 28, respectively), and by performing the colon bead expulsion test. Temporal changes in the size of the stomach and caecum of each rat were analyzed based on digitalized X-rays, using an image processor. Visceral sensitivity was assessed with abdominal withdrawal reflex to colorectal distension. Body weight gain and food/water consumption were measured throughout the experiment.

Results: Diet supplementation in neither group B nor group C affected the GI motor function in comparison to control group (A). The number of contractions and the mean time of each contraction in response to colorectal distension measured during each 5min for 40min were higher in the control group (A), when compared to either B or C groups but the differences were not statistically significant. No changes in morphometric measurements of stomach and caecum, the body weight gain and food/water consumption were found.

Conclusion: Diets differing in MCFAs or LCFAs contents did not induce marked effects on GI motility and visceral pain in rats. Available data and the results obtained herein suggest that the amount of FAs intake, rather than the types of FAs may provoke IBS symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0631 LOW FDOMAP DIET IMPROVES SYMPTOMS AND QUALITY OF LIFE IN PATIENTS WITH RADIATION-INDUCED SMALL BOWEL DISEASE: A PILOT STUDY
T. Larsen1, T. Haasken2, S. O. Ystad1, N. Hovdenak1, B. Mueller3, G.A. Lied4
1Department Of Clinical Medicine, University of Bergen, Bergen/Norway
2Haukeland University Hospital, National Centre for Functional Gastrointestinal Disorders, Bergen, Norway

4Center For Nutrition, Clinical Medicine, University of Bergen, Bergen/Norway

Contact E-mail Address: tinelarson92@gmail.com

Introduction: Patients suffering from chronic radiation-induced small bowel disease (RISBD) after cancer treatment have similar symptoms as patients with IBS (irritable bowel syndrome), despite dissimilar pathologic origin. RISBD is a common late effect after pelvic radiation therapy for gastrointestinal (GI), gynecological and urological cancer. The delayed development of ischemia, fibrosis, dysmotility and malabsorption in GI tissue, leads to IBS-like symptoms like abdominal pain, diarrhea, constipation and bloating. The low FODMAP diet is a widespread management strategy for IBS. The aim of the conducted study was to investigate the effects of LFD on symptoms and health related quality of life (HRQOL) for patients with chronic RISBD.

Aims & Methods: In an open pilot study, 11 patients (mean age 46 years) with RISBD related IBS symptoms were instructed to follow LFD throughout a 4-week intervention period. The Severity Scoring System (IBS-SSS) and IBS Symptom Questionnaire (IBS-SQ) were used to assess symptoms. An Ad hoc questionnaire measured grade of tissue damage and typical RISBD complaints (feal incontinence, rectal mucus and rectal bleeding). Short Form Nepean Dyspepsia Index (SF-NDI) and 12-item Short Form Health Survey (SF-12) were used to evaluate HRQOL. A 3-day food record was used to estimate baseline intake of FODMAPs, to reveal dietary changes and to assess adherence to the diet. All schemes were completed at baseline and at 4 weeks. The study included no control group.

Results: FODMAP intake was successfully reduced, and main additional changes in the diet were reduced intake of energy, carbohydrates and fiber. The adherence to the diet was high (mean 94.8%). IBS symptoms improved significantly based on mean total score of IBS-SSS and IBS-SQ, which changed from 310.2 ± 60.7 to 171.4 ± 107.2 (p = 0.001) and 27.4 ± 4.1 to 15.7 ± 10.1 (p = 0.002), respectively. The severity of abdominal pain, abdominal distension, belching/flatusulence, constipation, diarrhea, early satiety, dissatisfaction with bowel habits and interference with life in general, improved significantly. Tendencies of improvement were also measured in comorbidity complaints (nausea, headache, backache, fatigue and muscle pain) and typical RISBD complaints. HRQOL improved based on SF-NDI total score, which changed from 30.5 ± 9.1 to 18.3 ± 8.2 (p = 0.001) and based on mental (p = 0.047) and physical (p = 0.134) component summary score of SF-12.

Conclusion: The low FODMAP diet seems effective in alleviating IBS symptoms, and improving HRQOL in patients with RISBD. High compliance to LFD is possible with adequate diet counseling and continuous guidance. Further controlled studies with larger sample size should be conducted to verify our results and hopefully enable the implementation of LFD as a future management strategy for chronic RISBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0632 DIET SUPPLEMENTED WITH MEDIUM- AND LONG-CHAIN FATTY ACIDS DOES NOT AFFECT LOWER GI MOTILITY AND VISCERAL PAIN IN RATS
P. Mosimina1, M. Martin-Ruiz2, R. Abalo3, J. Fichina3
1Biochemistry, Medical University of Lodes, Lodz; Poland
2Universidad Rey Juan Carlos, Alcorcon, Madrid/Spain

Contact E-mail Address: paula.mosinska@gmail.com

Introduction: Dietary interventions are gaining popularity in terms of alleviating symptoms experienced by patients with functional GI disorders (FGID), especially with irritable bowel syndrome (IBS). Available strategies rely on low intake of foods high in short-chained carbohydrates, daily products, wheat, spices etc. Although some studies indicate increased rectal sensitivity after duodenal lipid administration in patients with IBS and suggest delayed transit after high fat intake, the effects of dietary supplementation with different types of fatty acids in IBS have not been explored so far.

Aims & Methods: The aim of the study was to evaluate the differences in GI motor function and visceral sensitivity in rats exposed to diet supplemented with either medium-chain (MCFAs) or long-chain fatty acids (LCFAs). Male Wistar rats were fed with control diet (A), and diet supplemented with 3.5% coconut oil (B) (abundant with MCFAs) or 3.5% evening primrose oil (C) (abundant with LCFAs) for 4 weeks. The effects of each diet on GI motility were measured radiographically after contrast administration (p.o; X-rays were taken 0–8h before and after feeding, on day 0 and day 28, respectively), and by performing the colon bead expulsion test. Temporal changes in the size of the stomach and caecum of each rat were analyzed based on digitalized X-rays, using an image processor. Visceral sensitivity was assessed with abdominal withdrawal reflex to colorectal distension. Body weight gain and food/water consumption were measured throughout the experiment.

Results: Diet supplementation in neither group B nor group C affected the GI motor function in comparison to control group (A). The number of contractions and the mean time of each contraction in response to colorectal distension measured during each 5min for 40min were higher in the control group (A), when compared to either B or C groups but the differences were not statistically significant. No changes in morphometric measurements of stomach and caecum, the body weight gain and food/water consumption were found.

Conclusion: Diets differing in MCFAs or LCFAs contents did not induce marked effects on GI motility and visceral pain in rats. Available data and the results obtained herein suggest that the amount of FAs intake, rather than the types of FAs may provoke IBS symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Consumption of protein products in SIBO patients.
is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1). GLP-1 is an enteroendocrine L cells (EEC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differentially processed by prohormone convertase 2 (PC2) into glucagon in pancreatic a cells and by prohormone convertase 1/3 (PC1/3) into proglucagon.

Aims & Methods: We hypothesized that, after pancreatectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreatectomy model in C57Bl6 mice. Control (Ct) mice underwent a laparotomy. Post-surgery blood glucose was measured. a cell alpha- and a cell glucagon/insulin mass quantification. Proximal and distal intestinal segments were sampled for morphometric analyses as well as measurement of proconvertase and proglucagon mRNA levels. Colonic segments were incubated in a glucose-enriched medium for one hour and glucose-induced secretions of glucagon and GLP-1 were measured in the supernatant.

Results: As soon as one day post-surgery, pancreatectomized (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in P mice vs 140 mg/dl in Ct mice, P < 0.05, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve >279% in P mice, P < 0.01 vs Ct mice, 1 week post-surgery). During OGTT, intestinal glucose absorption occurred (slope between 0 and 15 min=+69.9% in P mice, P < 0.01). A 1 week post-surgery, glucagonemia increased in fasted pancreatectomized mice (+16.6% in P mice vs P = 0.01 vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (~79.25% in P mice P < 0.05 vs Ct mice, 2 weeks post-surgery). Hypoplasia of the proximal colon to secretes glucagons and GLP1 was observed (+290.6% in P mice P = 0.05 vs Ct mice, 2 weeks post-surgery). In pancreatectomized mice, an hypertrophy of the duodenum was associated with an increase in crypt depth (+77.7%, in P mice P < 0.05 vs control, mice 2 weeks post-surgery) and villus height (+53.3% in P mice P < 0.05 vs control mice, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreatectomy. The upper intestine (duodenum) become hyperplastic and maintain an increased intestinal mass response to a absolute glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglucagonemia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Percutaneous endoscopic gastrostomy placement (PEG) is currently the method of choice for medium- and long-term enteral feeding and is nowadays one of the most common endoscopic procedures performed worldwide. To date, data on complications and mortality rates are generally retrospective and only few prospective studies have been published on small number of patients.

Aim: To establish the overall mortality of patients after PEG insertion or PEG replacement. This is a few prospective studies have been published on small number of patients.

Endoscopic procedure was necessary in 9.7% of cases. The informed consent buried bumper syndrome (0.2%). PEG replacement was carried out in 330 patients. Indications were: dysphagia for cerebrovascular diseases in 64% of patients. Indications were: dysphagia for cerebrovascular diseases in 64% of patients. Indications were: dysphagia for cerebrovascular diseases in 64% of patients. Indications were: dysphagia for cerebrovascular diseases in 64% of patients. Indications were: dysphagia for cerebrovascular diseases in 64% of patients.

Results:
- Thirty-days mortality was 2.4%. Thirty-days mortality was 2.4%. Thirty-days mortality was 2.4%.
- Conclusion: Our data confirm that PEG placement is a safe procedure with a mortality rate at 30 days of 8%. To our knowledge this is the largest prospective study on the use of PEG. Surprisingly in more than 50% of patients the consent form was not properly signed, leading to possible medicolegal consequences. Moreover, in 9/10 of the cases PEG was placed for an early discharge (more than for clinical indication).

P0637 MEDICAL REGISTRAR REPORTING OF CHEST X-RAYS FOR NASOGASTRIC TUBE POSITION: HOW CAN IT BE MADE SAFER?
Nutrition, University Hospitals Southampton, Southampton/United Kingdom

Contact E-mail Address: maeva.tierney@nhs.net

Introduction: Nasogastric tube (NG) feeding is an essential part of in-patient care. Tubes can be placed at the bedside with no need for specific equipment or sedation. However placement of NG tubes is not without risk and avoiding the introduction of substances into the respiratory tract through a misplaced NG tube was highlighted as a UK National Patient Safety Agency alert in 2005. In 2011 the NPSA made this a ‘never event’. The only acceptable methods of checking the position of an NG tube are: pH < 5.3 on aspirate or confirmation from chest x-ray (CXR) by competent medical staff. Reporting a CXR for NG tube position is a frequent request particularly for junior doctors out of hours. Practise varies across the UK - some trusts require NG checking to be done only by senior clinicians (medical registrars or consultants) and some only allow reporting by a consultant radiologist. We assessed documentation of NG position on CXR by medical registrars from the region to find out if documentation was adequate, as would be expected of senior clinicians. NPSA guidance suggests four points should be documented in the medical notes to confirm NG position: 1. Does the tube follow the contours of the oesophagus and avoid those of the bronchi? 2. Does the tube clearly bisect the carina or the bronchi? 3. Does it cross the diaphragm in the midline? 4. Is the tip clearly visible below the left hemidiaphragm? All four criteria were met in only 17.6% of responses and answers were considered incorrect in 20.5%. An aide-memoir sticker with a abbreviated version of the above four points, time, date, doctor signature and whether tube is safe to use or not with Yes/No answers, is used on some wards in Southampton and we assessed whether its use would improve quality of reporting both a correctly placed and misplaced NG tube.

Aims & Methods: Medical registrars from first to final year of specialist training and from various specialties were presented with a CXR showing a correctly sited NG tube and were asked to complete a sticker answering yes or no, to check position and whether it was safe to use. Following this they were presented with a CXR showing an incorrectly sited NG tube and asked to use the sticker to assess position. The CXR was projected and anonymous responses collected after sufficient time for the group to complete both stickers.

Results: 31 complete responses were obtained for the correctly sited tube with 58% stating that it should be used and 42% that they would not use the tube without further review. 10 incomplete responses were obtained and therefore 86% of responses met NPSA guidance for reporting CXR for NG position. 28 complete responses were obtained for the incorrectly sited tube and 100% stated that the tube should not be used.

Conclusion: Use of the sticker increased compliance with NPSA guidance for CXR reporting of NG tube position from 17.6% to 86%. The misplaced tube was correctly reported and not used in 100% of responses. The correctly sited tube was reported as safe to use in 58%. The CXR used was of an anonymous real patient and was slightly rotated to reflect a real-life scenario which meant the tube was slightly off the midline. In this real-life scenario some trainees would be happy to make a judgement considering these factors and others may be cautious and follow the sticker statements exactly prompting further review by radiology or removal of the tube. Overall this increases patient safety and avoids use of a misplaced tube in accordance with the NPSA guidance. We suggest the aide-memoir sticker on all wards which use NG tubes to rapidly improve documentation and patient safety. The other option we may consider is developing a pathway for radiology consultants to report all these CXRs before the NG tube is used; this is likely to take considerable time and is unlikely to be available out of hours.

Disclosure of Interest: All authors have declared no conflicts of interest.

administrative error and has now been seen with micronutrients requested. Two micronutrients checked had them done within the last six months. 6 patients had only recently so did not have results within a year). 32 (61.5%) of those who had of 49 (89.7%) had micronutrients checked within one year (two of the 51 had 57 home parenteral nutrition patients were identified. 51 (89.5%) of

Results: system then the local hospital was contacted for local results if available. A search of the blood results system was performed for all micronutrient results from one full year to the date of the search. Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local trusts do not have the laboratory facilities to check micronutrient levels so they tend to be done in Southampton. If no results were available on the Southampton system then the local hospital was contacted for local results if available.

Results: 57 home parenteral nutrition patients were identified. 51 (89.5%) of these patients had micronutrients checked at some point during their care. 44 of 49 (89.7%) had micronutrients checked within one year (two of the 51 had over recently so did not have results within a year). 32 (61.5%) of those who had micronutrients checked had them done within the last six months. 6 patients had never had micronutrients checked. One had them requested just prior to the time of audit but results were not yet available. Two were out of area and had not been reviewed within a year. One of these commenced PN in 2015 and found it difficult to attend clinic. The other had not been seen in clinic due to an administrative error and has now been seen with micronutrients requested. Two further patients had never had micronutrients checked due to a persistently raised CRP.

Conclusion: Despite a lack of clarity between guidelines about the frequency of monitoring of micronutrients, it is recommended that HPN patients receiving long-term intravenous nutrition should have regular monitoring to reduce risk of deficiency or toxicity. The majority of our cohort of HPN patients had micronutrients checked annually and over half were checked six monthly. This is compliant with ESPEN guidelines; however, we need to aim for 100%. We have introduced a template to use in clinic to trigger review of results and request micronutrients when required. Alongside this we have introduced a virtual ward round to remotely review all out-patients regularly and plan ahead to request blood tests when required. Following the introduction of these measures we will repeat the audit to find out if the situation has improved.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Per-oral endoscopic myotomy (POEM) is a novel treatment modality for achalasia cardia (AC). The studies are limited in paediatric population.

Aims & Methods: In this study our aim was to analyse the feasibility, safety and efficacy of per-or endoscopic myotomy in children We retrospectively evalu- ated the data of all children (<18 years) who underwent POEM at our institution from September 2013 to February 2017. All POEM procedures were performed under general anaesthesia in an endoscopy suit. Technical feasibility, safety and efficacy were analysed. Clinical success was defined as Eckardt score ≤ 3. Objective parasternal ineluding-time barium swallow and high resolution manometry were assessed and compared before and after POEM.

Results: Thirty children (15-boys, 15-girls) with mean age of 14.1 ± 3.22 (4–18 years), underwent POEM during the specified period. The sub-types of AC were type I (6), type II (19) and type III (1). Eight children had prior treatment with pneumatic balloon dilatation. POEM was successfully performed in all children. Anterior myotomy was performed in majority of children 23 (76.7%). Mean total length of myotomy was 10.9 ± 2.25 cm, with 7.9 ± 2.09 cm on esophageal and

P0641 HIGH RATE OF HELICOBACTER PYLORI ANTIBIOTIC RESISTANCE IN ARMENIAN CHILDREN WITH GASTRODUODENAL DISEASE

T. Shahinyan1, G. Amaryan2, M. Hovsepyan3, C. Bragger4
1Chair of Pediatrics, 2, Yerevan State Medical University, Yerevan Arm?enia
2Pediatrics, Arabkir Joint Medical Center, Yerevan/Armenia
3Division Of Gastroenterology And Nutrition, University Children’s Hospital Zurich, Zurich/Switzerland

Introduction: Because of high prevalence of gastric malignancies in the adult population, high H. pylori pylori (Hp) prevalence in Armenia is suspected. Resistance to Hp antibiotic in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.9±4.10). Hp- associated GDD were diagnosed according to clinical, endoscopic and histological criteria. Antral biopsy was cultured on 5% sheep blood Columbia agar and selective Hp media. Antibiotic susceptibility of the Hp strains obtained from children living in Europe. Koletzko S et al. Gut 2012;61:17–25.

Results: Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven Hp-associated GDD were diagnosed in 40 patients out of 47: 37 (92.5%) cultured on 5% sheep blood Columbia agar and selective Hp media. Antibiotic susceptibility of the Hp strains obtained from children living in Europe. Koletzko S et al. Gut 2012;61:17–25.

Conclusion: Hp-associated GDD were diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). P0642 GASTRIC MICROBIOTA OF CHILDREN WITH CHRONIC GASTRITIS

E. Kornienko, N. Parolova, P. Zykov
St. Petersburg State Paediatric Medical University, St. Petersburg/Russian Federation

Contact E-mail Address: da@amamed.ru

Introduction: Children’s gastric microbiota in the presence or absence of H. pylori (HP) has not been studied well.

Aims & Methods: We aim to study the composition of the microbiota in the biopsy material of the antral part of the stomach, according to the 16S-rRNA sequencing, of children with chronic gastritis, in the presence or absence of HP, and also to compare it with the histological data. Biopsy materials of mucous tissue from antral part of the stomach were taken from 16 children aged 10-17 with chronic gastritis and after the preliminary extraction the biopsy materials were examined using the method of sequencing with a pair of oligonucleotide primers, which are specific for the conservative regions of the 16S-rRNA gene, on the Life Technologies Ion Torrent sequencer using the 318v2 chip. Bioinformatic processing was conducted using the QIIME package. The results were compared with the data from the histological examination of the biopsy materials from the same part of the stomach as well as with the results of diagnosis using rapid urease test AMA RUT Expert with digital Reader.

Results: 8 out of 16 patients were identified as HP (+) positive, 2 of them had HP in small amounts, 6 of them – in significant amounts. The dominant types of bacteria in the stomach of all children were Actinobacteria, Bacteroidetes, Firmicutes; in a lesser extent - Actinobacteria, Cyanobacteria, Fusobacteria. 64.1% of HP (+) patients’ microbiome was constituted of HP, among Proteobacteria it reached 75–99%, the amount of other bacteria herewith shor- tened, and the microbiota diversity decreased. Non-helicobacter microbiota of children with small amount of HP was almost identical in composition as HP (+) patients’, the amount of other microbes was more numerous and diverse, also within Proteobacteria. The signs of inflammation in mucous coat of the stomach in patients with HP presence was more pronounced than in HP absence, they corre- lated with the amount of HP.

Conclusion: Microbiome of the children’s stomach is diverse, it is similar to adults’. The infection from HP inhibits another microbiota and it is accompanied with the signs of mucous coat inflammation, which correlates with the amount of HP.

P0643 FEATURES OF CHRONIC GASTRITIS CAUSED BY CO-INFECTION OF HELICOBACTER PYLORI AND EBSTEIN-BARR VIRUS IN PEDIATRIC PATIENTS

E. Spivak, R. Levit
Pediatric, Medical State University, Yaroslav/Russian Federation

Contact E-mail Address: spivak58@mail.ru

Introduction: It is known that co-infection of the gastric mucosa with highly pathogenic Hp strains and the Epstein-Barr virus is a risk factor for the development of severe gastritis and gastric adenocarcinoma. However, the characteristics of such co-infection in children are not sufficiently studied.

Aims & Methods: The aim of this study is to estimate the role co-infection of highly pathogenic strains of Helicobacter pylori and Epstein-Barr virus in pediatric patients with severe gastritis and patients with co-infection (highly pathogenic strains of Hp + VE-B).

Results: Persistent EBV infection was found in 83 children (43.7%) with chronic gastritis of the antral and (or) gastric body areas. Helicobacter pylori strains that possess the virulence factors (cytotoxin-associated gen A (Caga), vacuolating cytotoxin gen A (VacA), induced by contact with epithelium (IceA), and blood group antigen-biding adhesion (BabA)) were detected in 49 patients (25.8%). In most cases, the association of two or more virulence factors in one patient was observed. It was found that 39 pediatric patients had co-infection of the highly pathogenic strains of Hp and EBV. The study revealed no significant effect of the variant of the gastric mucosa infection on the clinical manifestations of gastritis - the nature of intoxication, abdominal and dyspeptic syndromes. At the same time, the endoscopic and morphological data analysis has revealed a severe gastritis with the development of pangastritis and signs of gastric mucosa atrophy observed mainly in the antral region, in patients with co-infection (highly pathogenic strains of Hp + VE-B). In addition, by correlation analysis, we found that the increase and development of the inflammatory process in the gastric mucosa was mostly influenced by the presence of CagA-positive strains of H. pylori in combination with EBV. We found that children infected by EBV without highly pathogenic Hp strains had mild mononuclear and polymorphonuclear cell infiltration without atrophy.

Conclusion: Co-infection with highly pathogenic Hp strains and the Epstein-Barr virus in pediatric patients is significantly associated with severe gastritis. The infection from HP inhibits another microbiota and it is accompanied with the amount of HP.

Aims & Methods: To assess the relationship between H pylori infection and specific immunoglobulin E (Ig E) antibodies to food allergens in children. We conducted a prospective study of 394 symptomatic children (249 girls, age range 6 months-18 years), mostly with uninvestigated dyspepsia requiring an endoscopic evaluation in our unit, from January 2015 to December 2016. All patients were evaluated for H pylori infection by at least two standard invasive tests and for specific immunoglobulin E antibodies to major food allergens (R-Biopharm, Germany). The nutritional status of patients was assessed in all cases by the new World Health Organization (WHO, 2007) growth charts. EPI-INFO version 7 was used for statistical analysis. A two sided p-value less than 0.05 was considered statistically significant.

Results: Active H pylori infection was documented in 246 (62.3%) cases. The allergy sensitization was at least one of the food allergens was identified in 134 of 394 patients (34%). The majority of Ig E positive children (109 of 134; 81.3%) were positive for cow’s milk followed by egg (17.9%), wheat (7.46%), peanut (4.5%), soybean (3.73%). The allergic sensitization to food allergens was associated with abnormal levels of specific Ig E antibodies to common inhalatory allergens in 55 of 134 cases (41.04%). Regarding the association of H pylori infection with an elevated serum Ig E level to at least one of the food allergens tested, there was a significant positive correlation (p = 0.14, 77 of 134 (51.30%) patients positive for food specific Ig E antibodies were H pylori infected and 57 of them (38.55%) were H pylori negative (Fisher exact test = 0.08). The assessment of the patients nutritional profile in relationship with H pylori infection and food allergy not revealed any statistically significant correlation with the two ends of the poor nutritional status (undernutrition and overweight).

Conclusion: The recent decline of H pylori infection is not evident in our study. There was no association between H pylori infection and Ig E mediated food allergy. Undernutrition and overweight were not associated with the H pylori infection and food allergy in our patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0645 CURRENT STATUS OF THE FIRST AND SECOND LINE THERAPY FOR HELICOBACTER PYLORI INFECTION IN SYMPTOMATIC CHILDREN: A SINGLE CENTER STUDY

V. Hurduc, B. Luiza, P. Doina
Pediatric Gastroenterology, Victor Gomoiu Clinical Children Hospital, “Carol Davila” University of Medicine and Pharmacy, Bucharest/Romania

Introduction: Current evidence suggests the decline of the eradication rates of H pylori in children treated with standard first line therapy, partly determined by its antibiotic resistance.

Aims & Methods: To evaluate the effectiveness of current first and second-line therapy for H pylori eradication in children. We conducted a prospective open-label study of 158 symptomatic children (age range 6 months-18 years; 106 girls) who required a first upper digestive endoscopy over the past year. Active H pylori infection was documented in 122 of the 158 investigated children (77.2%). Infected children were randomly assigned to receive either a 7-day triple therapy consisting of clarithromycin (CLA), metronidazole (MET), and omeprazole (OMEX) or a sequential therapy based on metronidazole and clarithromycin (5+5) with amoxicillin (AMO) and clarithromycin (CLA) or metronidazole (MET), either a 7–14 days standard empirical triple therapy consisting of omeprazole (ESO) plus amoxicillin (AMO) and clarithromycin (CLA) or metronidazole (MET), either a sequential therapy for 10–14 days. Bismuth salts are not easily available in our country, therefore the efficacy was assessed by follow-up endoscopy 4–8 weeks after the end of anti-H pylori therapy by at least two different invasive tests. In patients failing to be cured through the first treatment a second approach was applied (a triple therapy based on quinolones or metronidazole either sequential therapy was associated with antibiotic susceptibility testing. The primary and secondary outcomes were the rate of H pylori eradication after the first and second line therapy, by intention to treat (ITT) and per-protocol (PP) analysis. Statistical analysis was performed with EPI INFO 7. The differences between eradication rates were analysed by x² test and the Odds Ratio (p < 0.005 was considered statistically significant).

Results: Patients with H pylori infection were treated with an initial empiric first line standard therapy (n = 52) or a sequential therapy (n = 70). Of the 122 children who required follow-up 74 (61.4%) of them completed the standard therapy and 48 (38.6%) of them completed the sequential therapy. Of the 74 patients who completed the standard therapy, 32 (43.2%) were eradicated in 87/122 children (71.32% for ITT analysis versus 76.96% for PP analysis). The first eradication rates were significantly higher using the sequential therapy (55/70 cases; 78.57% for ITT analysis and 55/64 cases; 85.93% for PP analysis) compared with standard first line therapy (32/52 cases; 61.53% for ITT analysis and 32/49 cases; 65.30% for PP analysis). The ITT and the PP eradication rates were significantly higher with sequential treatment (OR = 0.45; 95% CI: 0.19; 0.97; p = 0.04; x² = 3.42; p = 0.06 for ITT analysis and OR = 0.30; 95% CI: 0.12; 0.77; p = 0.03; x² = 5.55; p = 0.021 for PP analysis). A second-line therapy was recommended in 26 of cases with an overall eradication rate of 80.76% (21/26 cases) for ITT analysis and respectively 87.5% (21/24 cases) for PP analysis. The choice of second line therapy was tailored by antimicrobial susceptibility only in some cases (15/26 cases; 57.7%). The eradication rates for PP analysis were: 90% (25/27 cases) based on MET; 80% (8/9 cases) for triple therapy based on quinolones and 80% (4/5 cases) for sequential therapy.

Conclusion: This endoscopic series reveals a high rate of H pylori infection (77.2%). The sequential therapy achieved a significantly higher rate of eradication than the standard empiric triple regimens regardless of using ITT (78.57% versus 61.53%) or PP (85.93% versus 65.30%) analysis. The eradication rates for the second-line therapy was significantly higher (87.5% for PP analysis) compared with first-line therapy (76.96% for PP analysis).

P0646 GUT MICROBIOTA ALTERATIONS UNDER OLIGOFRUCTOSE-ENRICHED INULIN ADMINISTRATION IN PAEDIATRIC COELIAC DISEASE PATIENTS ON A GLUTEN-FREE DIET: RANDOMIZED CONTROLLED TRIAL

U. Krupa-Kozak1, N. Drabinská1, L. H. Markiewicz2, E. Jarocka-Cyrt3
1Department Of Chemistry And Biodynamics Of Food, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn/Poland
2Department Of Immunology And Food Microbiology, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn/Poland
3Faculty Of Medical Science, Department Of Clinical Pediatrics, University of Warmia & Mazury, Olsztyn/Poland

Introduction: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of coeliac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microflora, are a promising, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.

Aims & Methods: The aim of the present study was to assess the effect of prebiotic oligofructose-enriched inulin (OEI) administration on the quantitative gut microbiota characteristics of CD children following a strict GFD for ≥1 year. A randomized, placebo-controlled 12-weeks dietary intervention was conducted on 34 CD children (62 % female, mean age 10 years) on GFD who were randomly assigned to probiotic (OEI: 10 g/day) or placebo group (maltodextrin; 7 g/day). Before (baseline) and after the intervention, the anthropometric (weight, height) and biochemical blood parameters (C-reactive protein, creatinine, aspartate aminotransferase, alanine aminotransferase), quantitative gut microbiota characteristics (by real-time PCR) and concentration of short-chain fatty acids (by gas chromatography with a flame ionization detector) were assessed.

Results: Thirty CD patients completed the study. After 12-weeks intervention, the biochemical blood parameters remained normative in all CD patients, and the gut microbiota counts within each experimental group did not differ from their counts at baseline. However, in comparison with placebo group, Bifidobacterium counts was significantly (p < 0.01) higher in CD children consuming OEI-supplemented GFD. Moreover, the counts of Clostridium leptum group in children of probiotic group did not show the decreasing tendency along with the time of OEI administration observed in placebo group. These changes were reflected into bacterial number after the intervention that was constant in probiotic group but tended to fall in placebo group. Microbiota counts corresponded well with microbial metabolic activity. In comparison with placebo group, the concentration of short-chain fatty acids (SCFAs) were significantly higher in probiotic group (50.27 vs. 69.95 μg/ml, p < 0.05), mainly due to a significantly higher acetate formation (28.82 vs. 44.06 μg/ml, p < 0.05).

Conclusion: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of coeliac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microflora, are a promising, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.

P0648 EVALUATING GLUTEN IMMUNOGENIC PEPTIDES AS NON-INVASIVE MARKER OF GLUTEN-FREE DIET ADHERENCE IN PAEDIATRIC CELIAC DISEASE

A. Rodriguez-Herrera1, I. Comino1, V. Segura2, J. Díaz2, A. Muñoz-Suano1, A. Cebolla1, C. Sousa1, The Deligs Group2
1Gastroenterology And Nutrition, Instituto Hispalense Pediatria, Seville/Spain
2Departamento de Microbiologia y Parasitologia, Facultad de Farmacia, Universidad de Sevilla, Sevilla/Spain

Introduction: Treatment for celiac disease (CD) is a lifelong gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods
Aims & Methods: Detection of gluten immunogenic peptides (GIP) in stools as a marker of GFD adherence in CD paediatric patients was evaluated and compared against traditional methods of GFD monitoring.

Results: A total of 195 patients met the eligibility criteria for the meta-analysis. The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of adherence to dietary transgression. Anti-tTG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP (anti-DGP) IgA antibodies were measured simultaneously, during basal and follow-up visits at 6, 12, 16 and 24 months. Correlations between fecal GIP and serum antibodies were established by Cochran’s and Friedman tests.

Conclusion: The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of adherence to dietary transgression. Anti-tTG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Introduction: Nowadays food allergy continues to increase, especially in westernized countries and is now recognized as a worldwide problem. Transforming growth factor-β1 (TGF-β1) is a profibrotic cytokine, which plays an important role in promoting the structural changes in food allergy. Also for patients with food protein induced enterocolitis syndrome TNF-α appears to have an important role.

Aims & Methods: The aim was to determine the significance of the Transforming Growth Factor - β1(TGF – β1) and Tumor Necrosis Factor – α (TNF – α) in children with food protein induced enterocolitis syndrome. It was examined 38 patients with FFPIES at the age from 4 months to 3 years, the average age was 19 ±4 months. The control group consisted of 11 healthy children of the same age. The determination of TGF-β1 and TNF-α in serum was performed by an enzymelinked immunoassay kits from Rinder Medsystem (Australia).

Results: The level of TGF-β1 in patients with FFPIES exceeded the norm and was respectively 33.5 ±1.6 ng/ml at norm 20.2 ±2.1 ng/ml, p <0.001. The indices of TNF-α were also increased and amounted to 8.8 ±1.3 ng/ml in comparison with the control group, p <0.001. For statistical evaluation, it was characterized by an increase in specific antibodies IgE to cow’s milk in 18 (47.3%) children. In these patients the index of TGF-β1 increased by 2.64 (p ≥ 0.001).

Conclusion: It is believed that TGF – β1 and TNF-α have a bigger birth weight and increase the risk of newborns’ obesity. Glutathione S-transferase M1 polymorphisms and anthropometrical parameters (p = 0.545 for FFPIES and clinical parameters, p = 0.066 for TST and bacterial infections). The American journal of gastroenterology 107, 730-735, doi:10.1038/ajg.2012.4 (2012).

Conclusion: Mother’s GSTM1 is an independent risk factor for newborn’s W > 3000 gr, while mother’s GWG seems to be a protective factor for W < 3000 gr. Further studies are needed in order to determine the clear role of these polymorphisms in newborns’ obesity risk. This research was supported by the Research Grants of the University of Medicine and Pharmacy Targu Mureş, Romania - “The role of genetic determination of the mother in child’s obesity correlated with measurements of bisepidope and anthropometry” no.275/4/ 11.01.2017. Contact E-mail Address: antihiburt@gmail.com

Introduction: Deficits in lean mass and muscle measures are well described in children with chronic disease e.g. childhood inflammatory bowel disease[1]. Sarcopenia is a poor prognostic biomarker in adults with advanced cancer, liver transplantation and in children with acute lymphoblastic leukaemia [2-4]. Poas muscle cross sectional area (PCA) has been shown to correlate with whole body muscle mass and can be measured from axial imaging [5]. Little is known about sarcopenia in children with intestinal transplantation (IT). Sarcopenia is a poor prognostic biomarker in adults with advanced cancer, liver transplantation and in children with acute lymphoblastic leukaemia. Poas muscle cross sectional area (PCA) has been shown to correlate with whole body muscle mass and can be measured from axial imaging [5]. Little is known about sarcopenia in children with intestinal transplantation (IT).

Aims & Methods: The primary objective was to determine whether children who had IT show differences in total PCA when compared to healthy controls. The secondary objective was to investigate association of PCA and survival after IT. A retrospective, case note review of children who had IT at a single centre since inception in 2009 to May 2016. Controls were identified from abdominal trauma series. Total PCA (mm²) was measured using direct techniques of magnetic resonance imaging in the axial plane at the level of the psoas major. An operator of superior iliac spine. To correct for body size, PCA index was derived for all subjects: PCA divided by height. PCA index was then described according to outcome. Statistical analysis was carried out using Social Sciences (SSPS) version 23.

Results: 16 patients (9 male). The current IT at our centre. Post-transplant axial imaging was available for 12/6 (male), median age 6.2 (range 12.91) years patients in whom the diagnoses (n): Chronic intestinal pseudo-obstruction (3), gastrochisis (3), intestinal ischaemia (1), intestinal lymphangiectasia (1), volvulus (1), progressive familial intrahepatic cholestasis (1), Hirschsprung’s disease (1) and intestinal failure of indeterminate aetiology (9) compared to those who did not (2). Conclusion: Children who underwent IT had sarcopenia of the poas muscle in comparison to healthy controls. Children who died there was a trend toward poas muscle sarcopenia. This study adds to the evidence that body core muscle is consistently deficient in children with chronic disease and is the first to comment about sarcopenia in children with intestinal transplantation (IT).

Introduction: Primary lactose intolerance (PLI) is a frequent condition caused by a genetically programmed and progressive loss of lactase expression. It is considered that PLI is the ancestral variant, while lactase persistence is caused by 2 polymorphisms: the common C/T13910 and G/A22018. Homozygotes (CC or GG) have undetectable lactase levels. In clinical practice only half of people with PLI have symptoms. However, some studies showed that PLI subjects have lower dairy intake.

Aims & Methods: To investigate whether genetic predisposition to PLI influences the quality of life and dairy intake in a group of Romanian children. We conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study population included 87 children aged 6–17 years. We used strip genotyping to identify genetic predisposition to IPL. Subjects were asked to complete a validated questionnaire for quality of life and dairy intake questionnaire. We used Spearman’s to evaluate the correlation between IPL and quality of life and dairy intake.

Results: (51.7%) subjects had a CC genotype, 30 (34.5%) subjects had a GA genotype and 7 (8%) subjects had a GG genotype. Our results were consistent with Hardy-Weinberg equilibrium. We found no correlation between homozgyosity for PLI and dairy intake (CC: r = -0.06, p = 0.54; GG: r = -0.01, p = 0.86). We found no correlation between either CC, or GG genotype and quality of life (r = -0.11, p = 0.3; r = -0.1, p = 0.34).

Conclusion: In our group genetic predisposition to IPL followed European trends. It did not influence quality of life and dairy intake.

Introduction: Fibroblast growth factor-21 (FGF21) and omentin-1 have been recognized as potent antiadipogenic agents, with potential hepatoprotective activity. Aims & Methods: The aim of this study was to evaluate hepatic FGF21 and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGF21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGF21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminant power for FGF21 serum level in differentiation between more and less extensive steato- sis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGF21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGF21 and omentin-1 mRNA levels (r = 0.73; p < 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (r = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In our conclusion our study, which focused on hepatic FGF21 and omen- tin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by biological abnormalities. Increased hepatic steatosis was associated with evident change in serum FGF21 concentration in morbidly obese women with NAFLD. The vast amount of fat, both visceral and subcutaneous in severely obese patients may affect FGF21 and omentin-1 serum levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

(HSCs), which were separated from Sprague-Dawley rat, were treated with dif-
ferent concentrations of Loureirin B. MTT assay was performed to determine whether autophagy dysfunction has been implicated in lipid accumulation related diseases. This was also accompanied by the reduction of neutrophils, which together can reduce inflammation. Upregulated macrophages were associated with the increased expression of GRP78 and p-IRE1α, and the activation of NF-

cy3a10. Western blot analysis showed that the expressions of Wnt receptor Frizzled-4 and secreted protein and Frizzled-4 receptor protein and 

**Aims & Methods:** We aimed to screen BA derivatives for their potential to selectively activate FXR, thus protecting liver cells against free fatty acid (FFA)-induced lipid accumulation and lipotoxicity. Nineteen novel BA derivatives were analyzed in in vitro models for FXR binding activity and further evaluated in human cells using a FXR reporter assay. Assessment of FXR-dependent gene and protein expression was analyzed upon incubation of primary mouse hepatocytes and HepG2 cells with selected BA derivatives. In parallel, BA derivatives were co-incubated with oleic and palmitic acids (2:1) for assessment of cellular cytotoxicity and intracellular lipid accumulation.

**Results:** From the compound library, five BA derivatives showed stronger activation of FXR, comparing with their natural precursors. Incubation of HepG2 cells with FAs led to a ~25% reduction in cell viability and ~35% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly induced FXR, RXR, SHP, BSEP, FGFr19 and VLDLR mRNA levels, and repressed PARP1, LXR, SREBP1-c and CFTR mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to FXR. Furthermore, chenodeoxycholic acid and its structural analogues were found to be activators of FXR at lower concentra-

Scholars Program 2015).

Introduction: Mitochondrial dynamics proteins, like mitofusin-2 (Mfn2) is frequently observed in liver steatosis, inflammation and insulin resistance; as well as progressive steatosis to NASH. mRNA and protein expressions were analyzed by HTqPCR package in Bioconductor. Liver biopsies were obtained from patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure admitted in TUTH. Patients were randomized (in a 1:1 ratio) to either the ‘GCSF + SMT’ (Standard Medical Therapy) group (cases) or the ‘SMT-alone’ (control) group according to computer-generated random numbers. Patients in G-CSF group received G-CSF 300 μg twice daily for 3 days (total 6 doses). Mortality rates at 1 month and CTP (Child Turcotte Pugh) and MELD (total 10 doses).

Results: A total of 49 patients (median age: 49 (range: 27–73) years, 70% males) were included in the study. 24 of them received G-CSF along with SMT and 25 received SMT alone. Baseline characteristics were similar in both the groups. The 3-day G-CSF therapy did not lead to any significant adverse effects. At one month, in GCSF + SMT group, 4 had died whereas in SMT alone group 15 had died and 83% survived in GCSF group whereas only 40% survived in control group (P = 0.002). Also significant improvement in CTP and MELD scores was seen in the group treated with GCSF at one month after therapy. Also, there were fewer complications of sepsis, hepatic encephalopathy and renal impairment in G-CSF group compared to SMT alone group.

Conclusion: G-CSF therapy improves survival and clinical outcome in patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure. It may be useful in patients who do not have access to transplant services and also to the patients awaiting transplantation to prevent worsening during the waiting period. Further studies are needed to explore whether lower doses (total 6 doses) of GCSF are as effective as higher doses (total 10 doses).

Disclose of Interest: All authors have declared no conflicts of interest.

P0663 GRANULOCYTE COLONY STIMULATING FACTOR IN DECOMPENSATED LIVER DISEASE - OUR EXPERIENCE IN A TERTIARY HOSPITAL IN NEPAL

S. Thapaliya
Department Of Gastroenterology, Tribhuvan University Teaching Hospital, Institute of Medicine, Maharajgunj, Kathmandu/Nepal

Contact E-mail Address: sabinthapaliya@gmail.com

Introduction: Alcoholic Hepatitis, Decompensated Chronic Liver Disease and Acute-on-Chronic Liver Failure (ACLF) is a burden of mortality. Mortality is quite high in these presentations despite all the medications currently available in our country. Prednisolone and Pentoxifylline are not up to the mark in terms of both short and long-term outcomes. The only option that remains is liver transplantation which is not readily available in our country, and even if available in the near future, needs at least some months for planning and preparation and is costly. G-CSF (Granulocyte Colony Stimulating Factor) has shown both morbidity and mortality benefit in some studies in these groups of patients1,2. By comparing the outcomes in those receiving and not receiving G-CSF, we can suggest G-CSF therapy to reduce mortality and morbidity in these patients. Although most of the studies done in the role of G-CSF in ACLF (Acute-on-Chronic Liver Failure) and decompensated CLD (Chronic Liver Disease) have used a high dose of G-CSF, our study has used a fixed dosage of 300μg of G-CSF subcutaneously twice a day for a total of 3 days (6 doses).

Aims and Methods: We aimed to study the role of G-CSF in the treatment of alcoholic hepatitis, Decompensated CLD and ACLF. From January 2016 to December 26, a total 49 patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure admitted in TUTH (Tribhuvan University Teaching Hospital) were studied. Patients were randomized in a 1:1 ratio to either the ‘GCSF + SMT’ (Standard Medical Therapy) group (cases) or the ‘SMT-alone’ (control) group according to computer-generated random numbers. Patients in G-CSF group received G-CSF 300 μg twice daily for 3 days (total 6 doses). Mortality rates at 1 month and CTP (Child Turcotte Pugh) and MELD (Model for End Stage Liver Disease) scores at enrollment and at Day 30 were compared in the two groups.

Results: A total of 49 patients (median age: 49 (range: 27–73) years, 70% males) were included in the study. 24 of them received G-CSF along with SMT and 25 received SMT alone. Baseline characteristics were similar in both the groups. The 3-day G-CSF therapy did not lead to any significant adverse effects. At one month, in GCSF + SMT group, 4 had died whereas in SMT alone group 15 had died and 83% survived in GCSF group whereas only 40% survived in control group (P = 0.002). Also significant improvement in CTP and MELD scores was seen in the group treated with GCSF at one month after therapy. Also, there were fewer complications of sepsis, hepatic encephalopathy and renal impairment in G-CSF group compared to SMT alone group.

Conclusion: G-CSF therapy improves survival and clinical outcome in patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure. It may be useful in patients who do not have access to transplant services and also to the patients awaiting transplantation to prevent worsening during the waiting period. Further studies are needed to explore whether lower doses (total 6 doses) of GCSF are as effective as higher doses (total 10 doses).

mononuclear layer containing stem cells is a novel approach for regeneration of liver cell layer in a hepatoprotective therapeutic option for patients.

**Aims & Methods:** To determine the outcome after intrasplenic or intrahepatic injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronic hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; Group I: 20 patients underwent (ABMSC) injected intrasplenic. Group Ia: 10 patients underwent (ABMSC) injected intrasplenic after trans differentiation into hepatocytes with the double amount of growth factor. Group Ib: 10 patients underwent (ABMSC) injected intrasplenic after trans differentiation into hepatocytes using regular amount of growth factor. Group IIb: 10 patients underwent (ABMSC) injected intrahepatic; after trans differentiation into hepatocytes with the double amount of growth factor. Group III: (Control Group); consisted of 20 patients treated with intrasplenic or intrahepatic stem cell transplantation. The aim of this study was to determine to what extent the risk factors of metabolic syndrome has on ultrasonography of fatty liver, especially NAFLD.

**Results:** NAFLD was found in 13.8% of non-obese subjects and 52.3% of obesity subjects. NAFLD was associated with most components of MetS in both obese and non-obese subjects. However, non-obese NAFLD patients had significantly higher PIs for certain components of MetS than did obese patients, especially among women. Body mass index, waist circumference, fasting blood glucose, triglyceride, HbA1C and aspartate aminotransferase, alanine aminotransferase, γ-glutamyl transferase levels all affected NAFLD independently. The prevalence of metabolic syndrome was increased in mild (40.8%) and moderate (57.8%) NAFLD groups. When odd ratio (95% CI) for NAFLD group was compared to the contrast group, there was an increased risk of metabolic syndrome with odd ratio of 12.8 (95% CI, 9.1–17.0).

**Conclusion:** NAFLD and its complications is a close association with MetS and also with each risk factors of MetS. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary. **Disclosure of Interest:** All authors have declared no conflicts of interest.

P0668 THE USE OF THE FATTY LIVER INDEX TO DETERMINE THE PREVALENCE OF FATTY LIVER DISEASE (HEPATIC STEATOSIS) IN AN IRISH POPULATION

L. Reynolds, L. Rabbitt, C. Goulding
Acute Medical Unit, University Hospital Galway, Galway/Ireland

Contact E-mail Address: laura93reynolds@gmail.com

Introduction: Worldwide, the prevalence of fatty liver disease (FLD) is increasing, particularly in countries with rising obesity rates, such as Ireland. Studies suggest that up to 25% of those with FLD can progress to non alcoholic steatohepatitis (NASH) and be at risk of its sequelae, including cirrhosis and hepatocellular carcinoma. Indeed, NASH is now the second most common indication for liver transplantation in the US. Despite this alarming data, there is no prevalence data for Ireland in relation to FLD.

Aims & Methods: We aimed to use a simple screening tool, the Fatty Liver Index (FLI) to identify those at risk of having fatty liver disease (FLD) amongst all comers presenting to an Acute Medical Unit (AMU) and to use this data as an indicator of prevalence of FLD in Ireland.

Methods: In this prospective cohort study, all patients attending the Acute Medical Unit (AMU) were invited to take part. Their height, weight and waist circumference were measured, and triglycerides (TG) were added to their ‘routine AMU blood panel’, which also included measurement of gamma glutamyl transferase (GGT). Exclusion criteria were as follows: known liver disease, excess alcohol intake (>17 units per week for males, >11 units per week for females), age <18 years, pregnancy, active malignancy. The Fatty Liver Index (FLI), an algorithm that identifies a risk threshold score (MTATC) to stratify patients into groups based on risk of having FLD. A FLI score of >60 is highly suggestive of having FLD, a score of 30-60 is indeterminate and a score of <30 is considered low risk for FLD. Ethical approval for this research was obtained from the ethics committees of UHG.

Results: Data was completed on 316 participants; 58 were excluded, the majority due to either a history of alcohol excess or known liver disease. A total of 258 participants were therefore evaluated; 50% were male. One hundred and sixteen (44.8%) of these participants had a FLI >60 on the FLI, 57.3% of which were male. Only 16% of males had a FLI <30, compared with 44% of females. Males had a significantly higher FLI than females; 60.9 vs. 43.12 (p < 0.0001). Those with FLI >60 had a mean weight = 93.5 kg and BMI = 31.5 vs. 64.9 kg and 22.4 respectively for those with FLI <30 (p < 0.0001). There was a statistically significant difference in all parameters measured between all 3 groups (p < 0.0001), apart from height, although there was a trend toward lower height in the FLI >30 group, most likely due to the fact that it was 73% female. When obese females were looked at, there was no height difference between the 3 groups. Those with a FLI >60 were older than those with FLI <30, 54.6 vs. 48 (p = 0.01).

Conclusion: In this study looking at prevalence of fatty liver in Ireland, 45% of participants were found to be at high risk, and 70% were at high or indeterminate risk. Worryingly, only 16% of males fell into the low-risk group. Apart from weight, GGT, TG and BMI this study also showed age and male sex to be significant risk factors for developing fatty liver. This group clearly needs follow up to further evaluate and manage their fatty liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0670 ASSESSMENT OF FATTY PANCREAS IN PATIENTS WITH NON–ALCOHOLIC FATTY LIVER DISEASE

Introduction: The clinical implications of non-alcoholic fatty pancreas disease (NAFPD) are still the topic of debate in human studies. It has been shown that fatty infiltration in pancreas correlates with metabolic risk factors and may represent significant manifestation of metabolic syndrome (MeS) in association with nonalcoholic fatty liver disease (NAFLD). The aim of our study was to determine the association of fatty pancreas (FP) in NAFLD patients with features of MeSand to determine a simple new noninvasive scoring system for FP prediction in NAFLD patients.

Aims & Methods: We conducted across-sectional study that included 143 subjects with NAFLD classified into two groups according to the severity grade of FP as follows: patients with non fatty pancreas and grade I light FP (n = 59) and patients with grade II severely and grade III highly FP (n = 84). Patients were analyzed for diagnostic criteria of MeS, underwent sonographic examination with adiposity measurements and liver biopsy. Liver fibrosis was evaluated semi-quantitative according to the METAVIR scoring system and using non-invasive markers of hepatic fibrosis (NAFLD fibrosis score (NFS), BARD score, Fibrotest, Fibroscan). Statistical analysis was performed through Kruskal-Wallis test and independent t-test.

Results: Of these 143 patients with NAFLD, 84 had criteria for metabolic syndrome (MeS), while there was no significant difference in frequency among FP groups. Out of all clinical and laboratory characteristics, no statistical differences were observed in demographic or lifestyle factors such as age, sex, body mass index (BMI), systolic and diastolic blood pressure, presence of hypertension and dyslipidemia, values of insulin, high density lipoprotein (HDL) and triglycerides. Waist circumference (WC) showed significant difference among groups, indicating WC as a possible marker for higher risk of FP in NAFLD patients (P = 0.018). Diabetes mellitus (DM) was more frequent in patients with severely FP (P = 0.02), with greater portion of patients with HOMA-IR > 3. Higher values of fasting plasma glucose, total cholesterol, serum amyrase and lipase were associated with presence of highly fatty pancreas (P = 0.052, P = 0.007, P = 0.014; P = 0.024, respectively). Values of hemoglobin A1c (HbA1c) > 6% were significantly associated with NAFLD patients with severely FP, highlighting its impaired function in MeS (P = 0.008). While no significant difference was found in the use of statins and hypertensives, higher number of patients with severely FP did not use antidiabetic agents and association was registered among NAFLD patients with use of metformin and glibenclamide and the first FP group (P = 0.035). Out of all visceral fat amounts, only measures of mesenteric fat were associated with severely FP (P = 0.013). Results of our study determined highly significant association of NAFLD and NAFPD. Neither NAFLD noninvasive markers nor histological reports of liver fibroses showed significant association with presence of fatty pancreas.

Multivariate analysis of FP predictors in our study cohort, logistic regression approach was used. Model of predicting occurrence of FP was designed from multivariate logistic regression analysis. The probability was estimated with the equation: 0.627 + 0.640 * 0.593 * glucose (fasting glucose level) – cholesterol level (mg/dL) – HDL cholesterol (mg/dL) + 0.060 * sex + 0.051 * serum lipase * WC. Presence of NASH and high levels of liver steatosis. According to the score values for different cut off levels, best ability in the prediction of severely FP has shown the score value above 6.5.

Conclusion: Our study demonstrated that pancreatic fat infiltration due to its clinical correlation presents possible risk factor for development of MeS manifestations, affects glucose metabolism and severity of NAFLD. Interestingly, significant association was registered among NAFLD patients
with use of antidiabetic agents and the absence of highly fatty pancreas, indicating its potential protective role. Simple noninvasive scoring system was designed from multivariate logistic regression analysis to estimate the occurrence of severe FP in NAFLD with best ability in the prediction in score values above 6.5.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for nonalcoholic fatty liver histology. Mean age of individuals with and without steatosis were 6.69 and 31.8 years respectively (P=0.004). In univariate analysis higher weight, triglyceride, total cholesterol, alanine aminotransferase (ALT), alkaline phosphatase, fasting blood sugar and 1.27 mIU/L) were independent predictors of hepatic steatosis. In regression analysis, higher serum TSH was independently associated with steatohepatitis compared to primary cholangiocytes obtained from a patient without PLD. This indicates in this patient no loss of heterozygosity occurs in cholangiocytes lining the hepatic cysts.

Conclusion: We describe six novel GANAB mutations that can cause PLD in a mixed population of ADPKD and ADPLD patients. These mutations are found in functionally important domains of α-subunit of glucosidase II, which may lead to impaired enzymatic activity of the complex. In contrast to other PLD related genes no loss of heterozygosity was found for GANAB in cyst epithelium.

Introduction: In patients with morbid obesity, dietary treatment and physical activity are the first line of treatment, but if not responding, bariatric surgery is a seriously validated option. The main surgical procedures are the sleeve gastrectomy (SG) and gastric bypass (GBP), and they are choices in function of BMI, age and comorbidity. Both techniques have proven effective in weight loss. It is known that liver fibrosis evaluation with Point Shear Wave Elastography (pSWE) is difficult in these patients.

Aims & Methods: To study the difference between SG and GB and their impact on main clinical and laboratory hepatic metabolic indicators and scores 6 and 12 months after the intervention and pSWE at 12 months. We studied 68 obese subject candidate to bariatric surgery (45 female, 23 male). 28 underwent GBP and 40 GB. Blood tests, physical examination were assessed before surgery, after 6 months (68 patients) and after 12 months (51 patients) and pSWE after 12 months.

Results: In the comparison between GBP vs SG there was a statistically significant difference in the reduction in Fatty Liver Index (61% vs 37%, P = 0.015), waist circumference (26% vs 18%, P = 0.045), BMI (34% vs 28%, P = 0.016), total cholesterol (23% vs 0.5%, P = 0.001), ALT (increased by 15% in GBP, decreased by 27% in SG, P = 0.023) no differences were observed in the other indicators considered. Ferritin level increased (52%) in SG and decreased (25%) in GBP (P = 0.02). No difference was observed for pSWE.

Conclusion: This study showed some significant differences in clinical and laboratory indicators between the two groups of intervention, in GBP seems to have a more powerful effect on weight loss and all related markers: all steatosis scores (FLI, HSI, LAP), BMI, waist circumference. This can be explained by better malabsorptive effect of this intervention and by a lower BMI starting point for reasons related to the intervention technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Polycystic liver disease (PLD) occurs in the setting of 2 different genetic disorders: autosomal polycystic liver disease (ADPLD) and autosomal polycystic kidney disease (ADPKD). These patients may develop hepatomegaly as a result of multiple fluid-filled cysts. It is unclear whether PLD severity differs between ADPLD and ADPKD. Height adjusted liver volume (htTLV) reflects with symptomatic disease and diminished quality of life. We assessed hepatomegaly with htTLV, as an objective parameter, in a large cohort of ADPKD and ADPLD patients.

Aims & Methods: PLD patients, defined by >10 liver cysts on radiological imaging, were included in the international PLD registry. The cases were identified from clinical records at the University Leuven (Belgium), Seoul National University Hospital (South-Korea) and Radboud University Hospital Nijmegen (the Netherlands). In a cross-sectional analysis, we selected patients when height adjusted total liver volume was measured prior to liver reducing therapy. We performed univariate and multivariate analyses to explore risk factors associated with severity of disease.

Results: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 with symptomatic disease and diminished quality of life. We assessed hepatomegaly with htTLV, as an objective parameter, in a large cohort of ADPKD and ADPLD patients. Height adjusted liver volume was measured prior to liver reducing therapy. We performed univariate and multivariate analyses to explore risk factors associated with severity of disease.

Conclusion: In this cohort more ADPKD patients had moderate to severe PLD compared to ADPLD patients. ADPKD patients had higher htTLV compared to ADPLD patients. In total, ADPLD patients had a lower risk of developing severe disease.

Introduction: Non-alcoholic fatty liver disease (NAFLD) affects about 1 billion people worldwide. Those with non-alcoholic steatohepatitis (NASH) among NAFLD patients have increased mortality rates compared to the general population, with cardiovascular diseases being the leading cause of death. Identifying patients at risk of developing cardiovascular events is of major importance, both in terms of prognosis, as in the terms of therapeutic attitude.

Aims & Methods: Our aim was to quantify the risk of developing atherosclerosis as a main cardiovascular risk factor, in NAFLD patients and to identify a screening strategy for those patients. We included patients with NAFLD and metabolic syndrome (MS) into 2 arms: with and without NAFLD, and with and without MS. NAFLD diagnosis was based on clinical, biological and ultrason examination. We used Fibromax for evaluating the hepatic modifications (presence of steatosis and fibrosis), with values of >35% for steatosis and F3-F4 counted as advanced fibrosis). We performed ultrasound measurement of the carotid intima-media thickness (in the common carotid artery, 1 cm before the bifurcation). Values above 0.07 cm were considered pathological and values above 0.12 cm were considered as normal for hepatic (ats) plaques. Routine antropometric and laboratory determinations were performed.

Results: We included 95 patients with NAFLD, from which 53 were with MS and 43 were without MS. In all patients with NAFLD, with and without MS, there was a correlation between the value of intima-media thickness and the presence of NASH (p = 0.025), the degree of steatosis (p = 0.027) and the severity of fibrosis (p < 0.001). Patients with NAFLD and MS had higher values of the intima-media thickness than those with NAFLD, but without MS (p = 0.002).

In all patients with NAFLD, there was a correlation between the presence of ats plaque and NASH (p < 0.001). The sex of the patients (p = 0.638) and the level of total cholesterol (p = 0.438), LDL cholesterol (p = 0.505), HDL-cholesterol (p = 0.438), and triglycerides (p = 0.911) were not correlated with the presence of ats plaque, nor on the entire group of patients or on each arm. In a logistic model for the risk of developing ats plaque, we included presence of NASH, the grade of steatosis, the stage of fibrosis, body mass index, abdominal circumference and creatinine clearance level. In this model, the stage of fibrosis has been shown to be a predictor with a positive effect on the presence of ats plaque (p = 0.004, adjusted OR = 7.19, CI[1.86;27.72]). This model correctly classified 90.9% of patients with ats plaque and 91.7% of patients without ats plaque.

Conclusion: NAFLD patients were found to be atypical for the development of cardiovascular risk. Staging disease severity has proved to be an important diagnostic factor. On the other hand, identifying NAFLD patients with ats plaques might select the patients in which liver biopsy might be indicated for better characterization of the liver disease. Screening and aggressive treatment of cardiovascular risk factors should be done in all NAFLD patients.

Introduction: Liver biopsy is the reference standard for diagnosing and staging non-alcoholic fatty liver disease (NAFLD). Steatosis grade and fibrosis stage are typically reported using semi-quantitative scores. Inter-and intra-observer variability in the current scoring systems may impact upon histological staging, and consequently upon the interpretation of responses to interventions in clinical trials.

Aims & Methods: We developed an automated method for steatosis and fibrosis quantification using biopsy samples of NAFLD patients. We further validated Liver Stiffness Measurements (LSM) and controlled attenuation parameter (CAP) in this group, using quantitative assessment as reference. 246 consecutive patients with biopsy-confirmed NAFLD and transient elastography within 3 months of the biopsy were evaluated. Biopsies were independently scored by two histopathologists and digitalised at 2x magnification. Areas of steatosis and fibrosis were annotated manually using the NDP.view2 to facilitate machine learning. Each image was then analysed by the automated software: fat percentage (fat%) and (Collagen ProportionateArea (CPA) computed by the software were compared with the manual annotation. They were also correlated with LSM and CAP.

Results: There was an excellent concordance between manual and automatic measurements, with inter-class correlation coefficient, ICC = 0.98, (95%CI = 0.96-0.99, p = 0.0001). There was good correlation between fat% and steatosis grade, but with significant overlap between groups. Results were significant between CPA and histological stage. LSM was significantly associated with CPA (Rho = 0.8, p = 0.001). CAP score correlated significantly with fat% (Rho = 0.45, p = 0.002) and effectively diagnosed steatosis > 5% (AUROC 0.82, 95% sensitivity, 60% specificity), but could not distinguish between grades. Conclusion: We have developed an automated software, using low-resolution images to provide a rapid, easily performed, objective assessment of steatosis and fibrosis in NAFLD, with excellent correlation with experts’ annotation. Objective measures would be helpful in the assessment of therapeutic response in clinical trial practice and in clinical trials for patients with non-alcoholic fatty liver disease.

Introduction: Today, nonalcoholic fatty liver disease (NAFLD) is the most prevalent form of liver disease and it is an increasingly frequent cause of cirrhosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.
Aims & Methods: Aim of our study was to compare two non-invasive methods: fibrosis scores based on serum markers and transient elastography (TE). We included 152 patients with NAFLD, 40 males (26.31%) and 72 females with age from 23 to 79 years.35 patients (23.02%) were overweight, 9 patients had normal weight and 24 (15.79%) had severe obesity. In all patients we calculated Fibrosis scores: BARD, Fibro-4 and NAFLD FIBRO-4 and Fibrosis score (NAFLD-FS). Blood samples were collected to determine aminotransferases, glucose, albumin level, platelet count. The abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale of 0–5. TE was also performed by a single physician using the conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when estimated cutoff of F2 was 7.1 kPa, severe fibrosis (F3) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value >12.5 kPa.

Results: 86.84% patients had metabolic syndrome and 51.31% had diabetes mellitus.40 patients had mild steatosis, 59 had moderate and 53 had severe steatosis. After we performed TE 69.07% of patients had no significant fibrosis, 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95% CI: 0.74–0.89). Sensibility and specificity for cutoff 7.1 kPa was 0.74 respectively 0.79 to exclude significant fibrosis. NAFLD-FS correlated statistically significant with TE (p < 0.0001). BARD score did not correlate with TE and NAFLD-FS for significant fibrosis. FIB-4 correlated with TE for high degree of fibrosis (p = 0.004).

Conclusion: NAFLD-FS, FIB-4 and TE can be used together to evaluate the progression of fibrosis in NAFLD and to select the patients for liver biopsy. In our study BARD score was not useful in detection of high degree fibrosis.

difficult due to the unreliable history of alcohol consumption and lack of sensi-ble biomarkers. In contrast, one single-marker feature, an alcoholic liver disease/nonalcoholic fatty liver disease index) was created for a non-invasive determination of fatty liver diagnosis.

Aims & Methods: The aim of this study was to evaluate the reliability of ANI as a non-invasive diagnostic tool for NAFLD from ALD. A retrospective study between 2010 and 2015 in patients with definite diagnosis of NAFLD and ALD based on clinical, biochemical and histological criteria was performed. ANI scor-ing system in the differentiation of ALD and NAFLD was evaluated through the area under receiver-operating curve (AUROC). ANI score was calculated through Mayo Clinic formula.

Results: This study was carried out in 22 patients with ALD and 120 with NAFLD, 87 men (61.3%) with a median age of 51 ± 13 years. NAFLD patients presented a higher body mass index (BMI) of 28.9 ± 5.9 vs 23.9 ± 6 in ALD. ANI showed a sensitivity of 81% and specificity of 79% for the diagnosis of ALD with a cut-off value of ~1.96 [AUROC 0.806 (0.715-0.899), p < 0.001]. ANI greater than ~1.96 indicates a diagnosis of ALD whereas ANI less than ~1.96 indicates a diagnosis of NAFLD.

Conclusion: ANI scoring system is a non-invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for liver biopsy. ANI greater than ~1.96 suggests the diagnosis of ALD and ANI lesser than ~1.96 suggests NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
the CTCAE scale was used. Overweight was detected in 40 patients: BMI = 25–30, and 30 – in 11 (13.1%) patients. Depending on the overweight presence the patients were divided into 2 groups: I (n = 44) – patients with AL with normal body weight, II (n = 40) – patients with AL and overweight.

Results: In AL patients of group I before the start of chemotherapy functional liver tests were significantly different from healthy people. In group II there was an increase of ALT activity in 1.5 times, AST – in 1.2 times, ALP and GGT in 1.4 times compared to the norm (p < 0.05) and reached grade I level, and no change in bilirubin and total protein levels. On the 28th day of treatment in 3 (6.8%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 2.3 and in 2.2 times respectively, GGT and ALP in 1.9 and 2.4 times respectively, the level of total bilirubin increased in 2.1 times (p < 0.05), of which in 17 (42.5%) patients hepatic function was characterized by the increased activity of ALT in 2.6 and in 2.3 times respectively, and AST – in 1.3 times, ALP – in 1.6 times, GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT and AST in 2.6 and in 2.3 times respectively, GGT and ALP in 2.6 and 3.7 times respectively, the level of total bilirubin increased in 3.6 times (p < 0.05), of which in 10 (25%) patients hepatotoxic reactions were of grade I and in 16 (40%) – of grade II level.

Conclusion: The presence of the overweight results in a significant increase in the frequency and degree of hepatotoxic reactions in patients with AL during chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
Severe alcoholic hepatitis (SAH) remains a condition which bears utmost importance. Although serum biomarkers are available (Maddrey Discriminant Function - MDF), the diagnostic of SAH relies on liver biopsy. Adequate selection of patients who would benefit the most from corticotherapy is of utmost importance. Previous metabolomic studies have shown a core metabolic phenotype represented by decreased serum lysophosphatidylcholines (LPC) and increased serum bile acids that occurs relatively early in liver diseases regardless of etiology, and remains stable in their evolution, including liver cirrhosis and hepatocellular carcinoma (1). Our previous work also showed that decreased LPC levels are associated with alcoholic liver disease (ALD).

Aims & Methods: The aim of the study was to assess the metabolic profile of patients with ALD and to identify potential new biomarkers associated with severity. Between December 2015 and September 2016, 64 patients with biopsy proven AH were included (38 with SAH - MDF $\geq$ 32 and 24 with non-severe AH - MDF < 32). Fasting serum was stored at $-80$ degrees after centrifugation at 5000 rpm for 10 minutes. Specific purification protocol metabolic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system, equipped with a Dionex quaternary pump delivery system and a Bruker Daltonics MaXis Impact MS detection equipment (version 2012). Biostatistical analysis The chromatograms obtained were processed using CompassDataAnalysis 4.2 software (Bruker, Germany) and about 3000–4000 molecular masses were identified. Those data were further processed using ProfileAnalysis (Bruker, Daltonics): time alignment, normalization by sum of bucket values in analysis, 80% bucket filter, internal recalibration, etc. The matrix obtained was further processed by MetaboAnalysis, to analyze samples through univariate and multivariate statistical analysis.

Results: Univariate and multivariate statistical analysis by MetaboAnalysis identified 10 potential biomarkers. Among them, LPC (18:0) showed good discrimination for SAH (AUC = 0.804) with significantly lower values as compared with non-severe AH (0.38 fold change, $p = 6 \times 10^{-11}$). SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Severe alcoholic hepatitis (SAH) remains a condition which bears high mortality and morbidity rates, as well as high healthcare costs. This is why adequate selection of patients who would benefit the most from corticotherapy is of utmost importance. Although serum biomarkers are available (Maddrey Discriminant Function - MDF), the diagnostic of SAH relies on liver biopsy. Previous metabolic studies have shown a core metabolic phenotype represented by decreased serum lysophosphatidylcholines (LPC) and increased serum bile acids that occurs relatively early in liver diseases regardless of etiology, and remains stable in their evolution, including liver cirrhosis and hepatocellular carcinoma (1). Our previous work also showed that decreased LPC levels are associated with alcoholic liver disease (ALD).

Aims & Methods: The aim of the study was to assess the metabolic profile of patients with ALD and to identify potential new biomarkers associated with severity. Between December 2015 and September 2016, 64 patients with biopsy proven AH were included (38 with SAH - MDF $\geq$ 32 and 24 with non-severe AH - MDF < 32). Fasting serum was stored at $-80$ degrees after centrifugation at 5000 rpm for 10 minutes. Specific purification protocol metabolic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system, equipped with a Dionex quaternary pump delivery system and a Bruker Daltonics MaXis Impact MS detection equipment (version 2012). Biostatistical analysis The chromatograms obtained were processed using CompassDataAnalysis 4.2 software (Bruker, Germany) and about 3000–4000 molecular masses were identified. Those data were further processed using ProfileAnalysis (Bruker, Daltonics): time alignment, normalization by sum of bucket values in analysis, 80% bucket filter, internal recalibration, etc. The matrix obtained was further processed by MetaboAnalysis, to analyze samples through univariate and multivariate statistical analysis.

Results: Univariate and multivariate statistical analysis by MetaboAnalysis identified 10 potential biomarkers. Among them, LPC (18:0) showed good discrimination for SAH (AUC = 0.804) with significantly lower values as compared with non-severe AH (0.38 fold change, $p = 6 \times 10^{-11}$). SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

P0688 APPLICATION OF THE ICA-AKI CRITERIA IN THE DIAGNOSIS OF ACUTE KIDNEY INJURY IN PATIENTS WITH ACUTE DECOMPENSATION OF CIRRHOSIS

R. Azevedo, J. Pinto, H. Ribeiro, F. Pereira, C. Leitão, A. Caldeira, E. Pereira, R. Sousa, A. Banhudo

Gastroenterology, Amato Lusitano Hospital, Castelo Branco/Portugal

Contact E-Mail Address: richaradazedev013@gmail.com

Introduction: Acute kidney injury (AKI) is a common complication in patients with decompensated liver cirrhosis. Recently, the International Club of Ascites (ICA) defined new diagnostic criteria: the ICA-AKI criteria.

Aims & Methods: This study aims to identify patients hospitalized for acute decompensation of cirrhosis with AKI, according to the ICA-AKI criteria, and to determine if its application leads to greater prognostic accuracy.

Methods: Retrospective analysis of hospitalized patients in a gastroenterology department for acute decompensation of cirrhosis, without acute-on-chronic liver failure, between January 2014 and December 2015. Identification of AKI patients: fulfilling ICA-AKI criteria. Calculation of severity of liver disease and in-hospital and short-term mortality among patients with and without AKI. Compared the accuracy of the conventional criteria vs. ICA-AKI criteria in the prediction of mortality.

Results: 161 patients included, 85.7% male, mean age of 65 ± 10.8 years. Average length of stay of 11.6 ± 9.5 days. 39.8% of patients had AKI on admission or during hospitalization according to the ICA-AKI criteria (60.9% in stage 1, 20.3% in stage 2 and 18.8% in stage 3). Patients with AKI according to ICA-AKI had longer hospitalizations (14.55 ± 9.75 days, p < 0.05), higher severity of hepatic disease quantified by the MELD and MELD-Na scores (17.62 ± 12.83 vs. 12.83 P < 0.005 and higher in-hospital, 28 and 90-day mortality rates compared to patients without AKI 23.4 vs. 6.2% (p < 0.05), 3 vs. 9.3%, p < 0.05, 42.9 ± 23.7%, p < 0.05). There was a statistically significant association between the presence of infection and the development of AKI (p < 0.05). The ICA-AKI area under the curve (AUC) to predict in-hospital, 28 and 90-day mortality was significantly higher than the AUC of conventional criteria (0.682 vs. 0.533; 0.678 vs. 0.588; 0.618 vs. 0.509, p < 0.05).

Conclusion: The ICA-AKI criteria allow the identification of decompensated cirrhotic patients in whom a worse prognosis is predicted. Thus, they constitute a useful tool in daily clinical practice.

Introduction: The pathophysiology of hepatic encephalopathy is not fully understood. A nationwide nested case-control study was conducted to investigate risk factors in the development of hepatic encephalopathy (HE) among patients with liver cirrhosis (LC) in Taiwan.

Aims & Methods: A total of 913 patients with incident HE and 3499 patients without HE (controls) were identified from a cohort of liver cirrhosis (n = 14,428) using the population-based, Longitudinal Health Insurance Database 2000 in 1997–2012. Controls were matched to case patients on age at LC diagnosis (< ±2 years), sex, Charlson Comorbid index score, year of LC and follow-up time at 1:1 ratio. A multivariate logistic regression model for HE was developed to explore the relative contribution of various risk factors, including patient demographics, infections, cirrhosis-related complications (hepato cellular carcinoma, hepato porphyria), and other liver uker bleeding. A Cox regression model for all-cause mortality was performed.

Results: 714 cases of HE and matched to 714 controls were enrolled in the analysis. Infections (adj. OR, 3.41; 95% CI, 2.7–4.31, p < 0.001) and frequency of infections yearly (≥3 ≥3 OR 11.26, 95%CI, 5.7–22.2; 1–3 ≥3 adj. OR 2.82 95%CI, 2.26–3.53) were significantly associated with increased risk of HE. H. pylori infection (13.13% vs. 8.68%, p = 0.0052) and sites of infections such as pneumonia (14.99% vs. 10.50%, p = 0.0111), peritonitis (14.29% vs 2.52%, p < 0.0001), sepsis (25.63% vs 9.52%, p < 0.0001), biliary tract infection (7.14% vs. 3.22%, p < 0.0008) and cholecystitis (11.62% vs. 3.98%, p = 0.0207) increased risk for HE. HE (adj OR 0.90, 95% CI 0.76–1.06, p = 0.02) and infections (adj. OR, 1.13, 95% CI 0.93–1.38, p = 0.23) increased hazards of death but did not reach statistical significance.

Conclusion: This is the first reported case-control study of HE in Taiwan. The study provides further evidence that infections are strongly associated with HE development but other factors play relative roles. Further studies are needed to clarify the relative frequencies and sites of infections. These data provides important information relevant to the prevention and management of cirrhotic patients at risk for HE.

predictors of in-hospital mortality. Patients with Sepsis-3 had higher incidence of acute kidney injury (36 vs 11%; p < 0.001) and severe sepsis (43 vs 26%; p < 0.001) compared to patients without Sepsis-3. Similar findings were found for qSOFA.

Conclusion: Sepsis-3 criteria are more accurate than SIRS criteria in predicting the severity of infections in patients with cirrhosis. qSOFA is a useful bedside tool to assess risk for worse outcomes in these patients. Patients with Sepsis-3 and positive qSOFA deserve more intensive management and strict surveillance.

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol versus propranolol in primary prophylaxis of variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and confirmed by computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal variceal bleeding or death.

Results: During the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49 ± 12.2 years: 33 (68.7%) were males: 60.4% had viral cirrhosis; mean Child-Pugh score was 7.2 ± 2.6 and mean follow up was 12.3 ± 9.1 months (range 1–29 months). All the patients had occlusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, P = 0.062), bled related mortality (9.5% vs. 11.1%, P = 0.027) and overall mortality (23.8% vs. 22.2%, P = 0.044) respectively. Adverse events in carvedilol group were hypotension (n = 2), requiring cessation of therapy, while and dyspnea (n = 3) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 atrio-ventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to propranolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Retrospective uncenter study, including consecutive adult patients with cirrhosis admitted for UGB between January 2011 and November 2015. Clinical, analytical and endoscopic variables were assessed and ALBI, CP and MELD scores at admission were calculated. Statistical analysis was performed using SPSS v21.0 and MedCalc v.16.4.3, and a two-tailed p value < 0.05 was defined as indicating statistical significance.

Results: Included 111 patients with a mean age of 57 ± 12 years, 76.6% were males. Liver cirrhosis was most frequently alcoholic (89.2%) and the most common cause of cirrhosis was viral cirrhosis; mean Child-Pugh score was 7.2 ± 2.6. According to ALBI score, 23 patients (20.7%) had stage A, 69 (62.1%) stage B, and 29 (26.2%) stage C. During the first 30 days of follow-up 12 patients (10.8%) died, and during the 1st year of follow-up another 10 patients died (1st year mortality of 19.8%). When comparing the three scores, regarding in-stay and 30 days mortality, only ALBI score showed statistical significant results, with an area under the curve (AUC) of 0.82 (p < 0.001) for both outcomes. Regarding 1st year mortality, AUC for ALBI, CP and MELD scores, were 0.71 (p = 0.01), 0.64 (p < 0.05) and 0.66 (p = 0.02), respectively, while for global mortality AUC were 0.75 (p < 0.01), 0.72 (p < 0.01) and 0.72 (p < 0.01), respectively. When comparing the AUC of the three scores, no significant differences were found regarding 1st year mortality and global mortality.

Conclusion: In our series, ALBI score accurately predicted both in-stay and 30 days mortality (AUC= 0.82 (p < 0.001)), while CP and MELD scores weren’t able to predict these outcomes. All scores showed a fair prognostic prediction performance regarding 1st year and global mortality. These results suggest that ALBI score is particularly helpful in the assessment of short term outcomes, with a better performance than the most commonly used scores, and may assist the clinician in the stratification of care at admission and maybe even in the referral to liver transplant.

P0695 PROTON PUMP INHIBITORS IN CIRRHOTIC PATIENTS: IT’S URGENT TO RETHINK THEIR USE!
T. Cardia Gonzàlvez1, S. Monteiro1, S. Xavier1, M. Barbosa1, P. Boal Carvalho1, J. Magalhães1, C. Marinho2, J. Cotter2
1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães/Portugal
2Dept. Of Emergency And Organ Transplantation, Gastroenterology Unit, Bari/Italy

Introduction: It’s urgent to rethink their use!

Results: From the 179 patients with a first hospitalization for DC, 6% had ascites on admission, 45.8% had upper gastrointestinal bleeding, 38.5% had jaundice, and 28.5% had hepatic encephalopathy. Regarding medication, 29.6% of the patients were taking proton pump inhibitors (PPI), 22.3% had beta-blockers prescribed, and 1.7% were on prophylactic antibiotic. In those 53 patients with proven infection, spontaneous bacterial peritonitis was the most common infection (34%), followed by urinary tract infection (30.2%) and pneumonia (15.2%). Infected patients presented with jaundice (p = 0.03), severe ascites (p = 0.09), use of PPI (p = 0.003) and acute-on-chronic liver failure (p = 0.006) more frequently than those without infection. Additionally, infected patients presented with significantly increased values of C-reactive protein (p < 0.001), INR (p = 0.04), creatinine (p = 0.04), and MELD scores (p = 0.001). Mortality rates were higher in infected patients at 30-day (4.0% vs. 9.4%), 3 months (7.9% vs. 18.9%), 6 months (12.7% vs. 24.5%) and 1 year (22.2% vs. 26.5%). In the multivariate analysis, the use of PPI was independently associated with an increased risk of infections (OR = 2.3, 95% CI 1.05–5.173).

Conclusion: Almost a third of patients will develop infections right at the first hospital admission for decompensated cirrhosis, which are associated with higher short and long-term mortality rates. As PPI more than double the risk of infections, the indication for the use of these drugs should be strictly reviewed and their interruption considered in cirrhotic patients.

3Pathology, Jeroen Bosch Hospital, ‘s-Hertogenbosch/Netherlands

Introduction: The Fontan circulation causes some degree of hepatic congestion by its nature of anatomical reconstruction. This may lead to liver fibrosis or even cirrhosis, but to what extent is unknown. A profound hepatic evaluation, incorporating several non-invasive and invasive modalities, in an asymptomatic Fontan patient cohort may further elucidate this.

Aims & Methods: Consecutive patients with a Fontan circulation are prospectively included for scanning of liver fibrosis. This screening consists of a blood sampling for liver biomarkers, liver stiffness using ultrasound, transient elastography ( Fibroscan), contrast-enhanced liver MR or CT-scan and liver biopsy. Liver biopsies were systematically scored with the Fontan specific fibrosis score.

Conclusion: Infected patients presented with jaundice (p = 0.03), severe ascites (p = 0.09), use of PPI (p = 0.003) and acute-on-chronic liver failure (p = 0.006) more frequently than those without infection. Additionally, infected patients presented with significantly increased values of C-reactive protein (p < 0.001), INR (p = 0.04), creatinine (p = 0.04), and MELD scores (p = 0.001). Mortality rates were higher in infected patients at 30-day (4.0% vs. 9.4%), 3 months (7.9% vs. 18.9%), 6 months (12.7% vs. 24.5%) and 1 year (22.2% vs. 26.5%). In the multivariate analysis, the use of PPI was independently associated with an increased risk of infections (OR = 2.3, 95% CI 1.05–5.173).

3San Camillo Hospital, Manfredonia (Foggia), Italy, Gastroenterology Unit, Foggia/Italy

Introduction: Prebiotics has been recently used to treat cirrhotic patients with any grade of acute or chronic hepatic encephalopathy (HE). Herein, we evaluated the efficacy of Lactobacillus Rhamnosus GG (LRGG) on the treatment of minimal HE (mHE) in compensated cirrhotics.

Aims & Methods: 134 patients were screened by critical flicker frequency (CFF) to diagnose mHE. Among them, 41 patients were CFF+ (≤39Hz) and were
randomized to placebo or LRGG treatment, for 2 months. In all intention to treat and per protocol patients, demographic characteristics, laboratory test, were analyzed. In addition, the regulatory mechanism of HSCs was also investigated.

Contact E-mail Address: liuyun2008294@126.com

Introduction: Th17 cells are involved in liver fibrosis by activating hepatic stellate cells (HSCs). We aimed to investigate whether HSCs could regulate the function of Th17 cells and the relevant mechanism.

Aims & Methods: Sixty-five patients diagnosed with chronic hepatitis B (CHB) were enrolled in this study. To unravel the effect of HSCs on T cells, naïve CD4⁺ T cells and Th17 cells were sorted from CHB patients and cultured with IL-17A, IL-23R, RORC, CCL20 and CCR6, and meanwhile, they could activate the primary HSCs. The co-culture experiment indicated that activated HSCs dramatically promoted the proliferation of CD4⁺ T cells and Th17 cells with the expression of IL-17A, IL-23R, RORC, CCL20 and CCR6, while naïve CD4⁺ T cells and Th17 cells were more pathogenic via the expression of IL-17A, IL-23R, RORC, CCL20 and CCR6, and could activate the primary HSCs. The co-culture experiment indicated that activated HSCs dramatically promoted the proliferation of CD4⁺ T cells and Th17 cells which had a more pathogenic phenotype. Moreover, activated-HSCs-mediated induction of Th17 cells might depend on IL-18 and IL-6 release as well as COX-PGE2 pathway.

Conclusion: Th17 cells cooperated with HSCs in a proinflammatory feedback loop provide us a more understanding of the pathogenic role of Th17 cells in the chronicity of HBV infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Direct antiviral agents (DAAs) have led to high sustained virological response (SVR) rates in HC1 patients. However, genotype 3 patients respond to treatment in a suboptimal way.

Aims & Methods: This study aims to identify which of the several treatment schedules, for genotype 3, would constitute the best option.

Twenty-four Italian centers were involved in this real-life study where HCV genotype 3 patients treated with DAAs. To expand the number of cases, we conducted a systematic review of literature on the outcome of genotype 3 patients treated with DAAs.

Results: A total of 233 patients with HCV genotype 3 were enrolled. Cirrhotic patients accounted for 83.7%. Overall, the SVR12 rate was achieved by 205 subjects (88.0%); the SVR rates were 78.8% after sofosbuvir/ribavirin, 92.5% after sofosbuvir/daclatasvir+ribavirin, and 100% after sofosbuvir/ledipasvir (Ppatients). No difference of rate of SVR was observed in cirrhotic and non-cirrhotic patients (92.2%/94.4%) using a combination regimens of NSSA and NS5B inhibitors. The systematic review of literature provided data of 3311 patients: the mean weighted SVR12 rate was 84.4% (C1.70.4–87.8%); the rates varied from 79.0% (C1.70.9–85.3) with sofosbuvir/ribavirin, to 83.7% (C1.62–93.1) with sofosbuvir/ledipasvir, and to 88.2% (C1.83.3–91.7) with sofosbuvir/daclatasvir.

Conclusion: Our results reinforce the concept that HCV genotype 3 should no more considered difficult to treat individuals. The optimal therapeutic regimens for these patients appears to be the combination sofosbuvir/daclatasvir, with a reduced rate of RBV in non-cirrhotic patients in cirrhosis the meta-analyses approach suggests to extend therapy at 24 weeks.

P0704 IMPROVEMENT OF LIVER STIFFNESS VALUES MEASURED BY TRANSITION ELASTOGRAPHY AFTER CHRONIC HEPATITIS C TREATMENT WITH DIRECT ACTION ANTIVIRALS AND EVOLUTIVE CORRELATION OF THROMBOCYTOPENIA AND PRESENCE OF ESOPHAGEAL VARICES

M. Perez Ferrer1, I. Maestro Prada2, A. Mcgee3, J.L. Castro Urda1, L.A. Castillo Herrero1, C. Garcia Ramos1, 2, 3
1Gastroenterology, Hospital Severo Ochoa, Leganes/Spain
2Epidemiology, University Hospitalario Mostoles, Mostoles/Spain

Contact E-mail Address: miguelpferrer@gmail.com

Introduction: An improvement in liver stiffness (LS) measured by transient elastography (TE) has been observed in patients with chronic hepatitis C treated with direct action antivirals (DAA).1 – 3 The Baveno VI guidelines 1– 3 propose that patients with compensated advanced chronic liver disease (cACLD), LS measurement <20 kPa and a platelet count >150000/μL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant oesophageal varices (EV). These findings have been validated recently.1 – 3

Aims & Methods: The aim of this study was to quantify LS regression both (quantitatively (measured in Kilopascals) and qualitatively (Stages of F0–F4 fibrosis) in a stationary phase after the sustained virological response (SVR) in patients with cACLD (14). The secondary objective was to assess whether this improvement in LS measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI criteria.

Results: 84 patients (49 men and 35 women) with cACLD were included in the study. Median TE on baseline (BL) prior to DAA treatment was [mean range], 11.23 (8.19–15.75) kPa and decreased to [mean range], 15.4 (8.4–7.5) kPa at SVR 24 and [mean range], 16.19 (9.6–7.2) kPa at SVR > 54. Both were statistically significant, showing a decrease in LS about 30% between BL and SVR24 and about 33% between BL and SVR > 54. We did not find statistically significant differences between SVR24 and SVR > 54. Regarding the probability of qualitative improvement of the LS (improve from F4 to F3 or less) the AUC was 0.84 with 17.9 kPa as the cut-off point which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12, PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15 kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV).17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with big EV). There were only 3 cases of EV misdiagnosed by Baveno VI Criteria. We did not find any significant differences in platelet levels or in the regression of varices.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0705 8 VERSUS 12 WEEKS OF LEDIPASVIR/SOFOSBUVIR REGIMEN IN PATIENTS WITH CHRONIC HEPATITIS C GENOTYPE 1 INFECTION

Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Portugal, Lisbon/Portugal

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: The therapeutic regimens for chronic hepatitis C are now tending to be shorter and ribavirin free, more cost-effective and with fewer adverse effects. Aims & Methods: We aimed at comparing the 8 weeks versus the 12 weeks regimen of ledipasvir plus sofosbuvir in patients with hepatitis C virus (HCV) genotype 1 infection without cirrhosis, treatment naive, HCV RNA <6000000 UI/mL. We included 281 patients (pts) with genotype 1 and HCV RNA <6000000 UI/mL treated with ledipasvir plus sofosbuvir in the recommended dose: 120 pts - 8 weeks (group 1) and 161 pts - 12 weeks (group 2). The fibrosis stage was evaluated by transient elastography (Fibroscan®, Echosens, Paris) considering F4 > 12.5 kPa. Patients with undetectable RNA after 12 weeks of treatment were considered cured – sustained virologic response (SVR).

Results: No significant demographic and clinical differences were found between the two groups with the exception of the fibrosis stage (table). Two hundred and forty-four patients concluded the treatment; the SVR was 99% in group 1 and 100% in group 2, without differences between the two groups (p = 0.275). Thirty three patients are still in follow up: group 1-15 pts and group 2-18pts. The reported adverse effects were mild in both groups (fatigue, insomnia, headache and pruritus) but more frequent in group 2 (p = 0.046).

Patients characteristics 8 weeks n = 120 12 weeks n = 161 p
Average age (years) 50.4 (20-81) 53.6 (19-86) 0.473
Male sex, n (%) 52 (51.7%) 89 (55.3%) 0.548
Genotype (n) 1a 74 94 0.579

Mild adverse effects, n (%) 7 (6%) 21 (13%) 0.046

* Patient retreated with ledipasvir + sofosbuvir + ribavirine during 12 weeks with SVR

Conclusion: In patients with chronic HCV genotype 1 infection and RNA <6000000 UI/mL, the 8 weeks regimen of ledipasvir plus sofosbuvir without ribavirin has similar high cure rates with less adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.
virological response (SVR) [1]. However, the impact of DAAs on the occurrence of hepatocellular carcinoma (HCC) and HCC recurrence after curative hepatic resection of HCC has been recently discussed [2, 3], but remain unclear.

Aims & Methods: The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and March 2017 were reviewed to clarify the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

Results: SVR was achieved in 21 patients treated with interferon (IFN)-based regimens and in 16 patients with DAAs at hepatocytectomy. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: −123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 33 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatocytectomy, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatocytectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.3% and 83.0% in patients after SVR treated with DAAs (n = 251). 90.9% and 71.8% in patients with IFN-based regimens (n = 26) and 57.8% and 19.7% in patients without SVR (n = 46), respectively, regardless of the timing of hepatocytectomy, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR (p < 0.001), but was not markedly different according to the antiviral treatments (p = 0.594).

Conclusion: While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

P7070 SOFOSBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS. AN EXPERIENCE FROM TERTIARY CARE HOSPITAL
A. A. Langhah
Gastroenterology Section, Medical Unit Iv, Jinnah Postgraduate Medical Centre, Karachi Pakistan
Contact E-mail Address: dralaikbar12@gmail.com
Introduction: Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advant of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the corner stone in treatment of (HCV). Most trials have been conducted in HCV genotype 1 and data for Interferon free regimen in genotype 3 (GT-3) is limited especially in cirrhotics.
Aims & Methods: We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RBV) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response after 6 months of completion of treatment. Adverse events were recorded on designed proforma on serial follow-up visits.
Results: The cohort consisted of 9 1 consecutively patients out of which 41 were compensated cirrhotics and 50 had decompensated cirrhosis. The mean age was 53.4 ± 11 years. Males were 47 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84.5%) treatment naïve patients compared to treatment experienced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naïve patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 gm/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.
Conclusion: Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

Introduction: Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HrQoL) burden.
Aims & Methods: The aim of this study was to assess HrQoL impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACT- F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched for age and sex with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.
Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACT- F utility scores (43.2±3.85 vs 49.5±4.95, p < 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6 % (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2, p < 0.05) compared to the study group.
Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HrQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

P0708 EFFICACY AND SAFETY OF SOFOSBUVIR AND RIBAVIRIN IN HCV POSITIVE PATIENTS WITH RENAL IMPAIRMENT
M.O. T. Butt
Gastroenterology And Liver Transplant, Shifa International Hospital, Islamabad, Islamabad/Pakistan
Contact E-mail Address: mosamabutt2016@gmail.com
Introduction: Hepatitis C virus infection is a leading cause of chronic liver disease affecting more than 170 million people worldwide. HCV infection in the setting of renal impairment is uncommon. Despite the major developments in the treatment of HCV, treatment of this sub group of patient with impaired renal function is still a challenge.
Aims & Methods: The aim of this study is determine the efficacy and safety of sofosbuvir and ribavirin in HCV positive patients with renal impairment. All consecutive patients of HCV related liver disease with creatinine clearance less than 30 ml/min were included in the study. Data was collected for tolerability, efficacy and on treatment adverse events. All the patients received Sofosbuvir and dose adjusted Ribavirin according of CrCl. Virological response was checked in 1 month (RVR), 3 months (MVR) and at the end of treatment.
Results: A total of 31 patients were included in the study were 31 out of which 17 (54.8%) were male. Mean age was 52.23 ± 17.6 years while the mean BMI was 25.0 ± 4.3kg/m2. 10 (32.25%) patient were on regular hemodialysis. 26 (83.9%) patients had CTP-A while 5 (16.1%) had CTP-B disease. Majority of the patients 22 (71 %) were genotype 3 while 7 (22.6 %) were genotype 1. 24 (77.4 %) patients were treatment naïve, while those who were treatment experienced. 3 patients received each Interferon and Peg interferon treatment. Treatment was stopped in 2 (6.5%) patients because of disease decenpensation while 3 (9.7%) were lost to follow up. ETR was achieved in 25 (96.1%) out of 26 patients who completed treatment. Similarly 12 (80 %) out of 15 patients have achieved SVR-12 so far. During the therapy 10 (32.3%) patients had adverse events, 6 (19.4 %) suffered from depression while 4 (12.9 %) developed grade II anemia.
Conclusion: In resource constraint population where newer DAAs are not available an combination of sofosbuvir and low-dose ribavirin in patients with renal impairment seems to be better tolerated and efficacious in terms of achieving the virological response.
Disclosure of Interest: All authors have declared no conflicts of interest.
4. Reig M, Merino Z, Perello C, . Unexpected high rate of early tumor recurrence following DAA treatment (60%) than in those with hepatic resection (33%), and the lowest risk was 29%, higher in males (40%) than females (18%), higher in patients treated with TACE (40%) than in those with hepatic resection (33%), and the lowest risk of recurrence was reported in 19/21 as per protocol analysis (90.5%). Recurrence rate of HCC was 29%, higher in males (40%) than females (18%), higher in patients treated with TACE (33%) than in those with hepatic resection (29%), and the lowest risk of recurrence was reported in 19/21 as per protocol analysis (90.5%).

Introduction: Intraluminal ultrasonic imaging (IVUS) is performed in EGV evaluation between January 2011 and July 2016 were included (no varices, n = 89). Virtual Touch Quantification (VTQ) was used for measurements of LS and EWV, n = 340, esophagus only, n = 107; stomach only, n = 14; esophagus and stomach, n = 29. Regression analysis using the leave one out method were: Residual attenuation coefficient (RAC = slope of the mean echo level (MU)); MU; slope of the Signal to noise ratio; and the lateral speckle size. AUC for LS was found to be 0.93 (n = 71) with a sensitivity and specificity of 87% and 85% respectively. AUC for SSI in line with previously performed studies. 87% of the included patients were found to have NASH with fibrosis. However, no significant correlations of the CAUS parameters to a pure fibrosis stage was found. No significant correlations of the CAUS parameters to a pure fibrosis stage was found.

Results:

Conclusion: CAUS is able to classify steatosis accurately and does not suffer from the presence of fibrosis, making CAUS a feasible tool for screening and evaluation of hepatic steatosis.

Introduction imaging technology has been reported as useful for radiofrequency ablation (RFA) and various models of ultrasound equipment have been developed to include fusion imaging systems. The 3D Sim-Navigator (HITACHI) is a navigation system that can be used in real-time vascular ultrasound imaging and navigating the 3D position of electrodes. As an addition, the 3D Sim-Navigator is now equipped with a new system that shows the predicted ablative area. This function indicates the electric field that occurs around the electrodes as the predicted ablative area on MPR images. The E-field Simulator (E-field) can manage various electrodes, such as monopolar and bipolar RF systems. E-field can be used to predict the ablative areas from not only a single electrode but also multiple electrodes, which was difficult to do in the past. We therefore examined the accuracy of E-field on 3D Sim-Navigator.

Aims & Methods: We evaluated 10 nodules treated using a bipolar RF system (CelonPOWER; Olympus Medical Systems) with multiple electrodes and 72 nodules treated using a monopolar RF system (VIVARF system; STARMed) between April 2016 and March 2017 prospectively. We compared the degree of major and minor axes of maximum ablative area for 72 nodules ablated by the monopolar RF system on both E-field and post-RFA contrast-enhanced computed tomography (CT). We then compared ablative volumes of 10 nodules ablated by the bipolar RF system on E-field and on post-RFA contrast-enhanced CT.

Results: On the evaluation of maximum ablative area by monopolar electrodes, major and minor axes were smaller on E-field than on CT, but these differences were not significant. On the evaluation of ablative volume by bipolar electrodes, correlation coefficient for all lesion of CEUS for the E-field was significantly greater than the E-field greater than 0.96. On comparing treatment efficacy based on the grading system using the grading system, the degree of agreement between E-field and CT was 0.691 and the weighted kappa coefficient was 0.929.

Conclusion: Ablative volume on E-field correlated well with that on post-RFA contrast-enhanced CT. Furthermore, good agreement was observed between the treatment efficacy on E-field and post-RFA contrast-enhanced CT. E-field can be used to predict the ablative area from not only a single electrode, but also multiple electrodes, which was difficult to do in the past. The present results suggest that contrast-enhanced CT may become unnecessary for confirming therapeutic effects in the future.

P0715 ATTENUATION COEFFICIENT MEASUREMENT (ACM) AS NOVEL REAL TIME ULTRASOUND ALTERNATIVE TO CAP (FIBROSCAN)

Contact E-mail Address: nazariikobyliak@gmail.com

Introduction: The presence of fat droplets in the hepatocytes (micro- or macrovesicular hepatic steatosis) under condition of chronic diffuse liver disease (CDDL) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM) patent UA No2014111234. Aims & Methods: From total of 327 patients who underwent to comprehensive abdominal examination in our clinic: 95 patients were diagnosed with non-CDDL liver disease according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement on SoneusP7 device (Ultrasign, Ukraine), with a 1–6 MHz convex transducer in the right and left lobes. For diagnostic accuracy assessment (used CEUS is an accurate and reliable method as a first step in the evaluation of focal liver lesions. Liver cirrhosis does not influence significantly CEUS performance.

P0717 CUX1 IN LIVER CANCER: EXPERIMENTAL STUDY IN HYPOXIA MODEL

Contact E-mail Address: sophie.bluemel@gmx.de

Introduction: CUXI (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe. It favors the expression of oncogenes and survival factors, especially in stress condition, thus supporting tumorigenesis.

Aims & Methods: Here, we show CUXI activity during hypoxia in liver cancer cells. CUXI was knocked down and its targets were analysed by RT-qPCR in Hep3B cells under hypoxic and/or normal culture condition. The hypoxia induction was established by 24h treatment with 150 µM CoCl2 or with 0.5% O2 atmosphere. Hypoxia markers and CUXI were analysed by RT-qPCR.

Disclosure of interest: All authors have declared no conflicts of interest.

Aims & Methods:
S-Adenosylmethionine (SAMe) is a kind of common liver-protective medicine. Recent studies have shown that SAMe has the inhibitory effects on hepatic tumor cells (HCC). But the specific mechanism has not been elucidated.

Aims & Methods: Here, we examine the effects and relevant mechanism of SAMe on human hepatic tumor cells HepG2 and mouse hepatic tumor AML12. RNA sequencing (RNA-Seq) was used to identify the differentially expressed genes between HepG2 cells which were treated with SAMe or not. And we used qRT-PCR to confirm the results of these genes. MTS and flow cytometry-based assays were carried out in response to SAMe treatment.

Results: A total of 472 SAMe-related genes were identified by RNA-Seq. We found that differentially expressed genes were enriched in cell cycle related signaling pathways significantly by the KEGG and GO Pathway enrichment analysis. Through the construction of protein-protein interaction network, we observed the module associated with cell cycle is in the middle of the whole network. All these results implied that cell cycle pathway may play a very important role in the regulation of SAMe effects on HepG2 cells. Then the RNA-Seq characterized genes involved in cell cycle (MCM3, MCM4, and E2F1) were confirmed by Western blot and qRT-PCR in HepG2 and AML12 cells. MTS analysis showed that SAMe could diminish cell proliferation. And flow cytometry-based assays indicated that treatment with SAMe altered cell cycle kinetic significantly.

Conclusion: Altogether, our data enforce the evidence of SAMe possessing of antiproliferative action in liver cells, capable of up-regulating MCM3, MCM4, and E2F1. SAMe interfered with cell cycle, and provide an important theoretical basis for the clinical chemoprevention and treatment in HCC of SAMe.

P0720 PROGNOSTIC ROLE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN HEPATOCELLULAR CARCINOMA (HCC)

Sahloul, Sousse/Tunisia

Contact E-mail Address: Elleuchghorbel.nour@yahoo.fr

Introduction: Inflammation may play an important role in progression, and a high neutrophil-to-lymphocyte ratio (NLR) has been reported as a poor prognostic indicator in several malignancies. Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepatogastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33–87 years). The sex ratio was 3.22 (M/F = 58/18). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice (P < 0.05). Otherwise, high NLR was significantly correlated with the presence of vascular invasion (P = 0.002), lymph node metastasis (P = 0.04), tumor multinodularity (P = 0.01) and higher incidence of AFP ≥ 200 ng/ml (P = 0.04).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0722 SURGICAL OUTCOME OF PATIENTS WITH FIBROLAMELLAR HEPATOCELLULAR CARCINOMA. DOES IT DIFFERS FROM COMMON HEPATOCELLULAR CARCINOMA?

E. El-Hanafy

Facultu Of Medicine, Mansoura University, Gastroenterology Surgical Center, Cairo/Egypt

Contact E-mail Address: dr.ehah_elhanafy@yahoo.com

Introduction: Fibrolamellar hepatoellular carcinoma (FL-HCC) has conventionally been considered to be a histologic variant of hepatocellular carcinoma (HCC), with distinct clinicopathologic features. It is a rare primary hepatic malignancy that was first described as a pathological variant of HCC by Edmondson in 1956 [1]. The etiology of FL-HCC remains unclear. It typically occurs in normal livers without underlying liver fibrosis or cirrhosis [2]. In contrast to HCC which usually found in the presence of cirrhosis or chronic hepatitis [3]. FL-HCC has been reported to occur in association with focal nodular hyperplasia (FNH) a type of benign liver lesion. Many series have mentioned that FL- HCC is less aggressive than conventional HCC [4]. However, other studies have failed to confirm the observation of a better outcome in FL-HCC [5]. Other studies reported that the survival was similar between common HCC and FL- HCC, and that may be related to the higher resectability rate which improve the survival of patients with FL-HCC [6].

Aims & Methods: The aim of this study was to evaluate the clinicopathological features and the surgical outcomes of patients with FL-HCC who were referred to our tertiary referral center over a 15-year period. This is a retrospective study including 22 patients with a pathologic diagnosis of FL-HCC who underwent hepatectomy over a 15-year period. Tumor characteristics, survival and recurrence were evaluated.

Results: There were 11 male and 11 female with a median age of 29 years (range from 21 to 58 years). Two (9%) patients had hepatitis C viral infection and only 2 (9%) patients had alpha-fetoprotein level > 200 ng/ml. The median size of the tumors was 12 cm (range from 5–20 cm). Vascular invasion was detected in 5 (23%) patients. Four (18%) patients had lymph node metastases. The median follow up period was 42 mo and the 5-year survival was 65%. Five (23%) patients had a recurrent disease, 4 of them had a second surgery with 36 mo median time interval. Vascular invasion is the only significant negative prognostic factor.

Localized resection 2 (9%)

Stage I 10 (45%)

II 5 (23%)

III 7 (32%)

IV 0

Nodal metastases 4 (18%)

Vascular invasion 5 (23%)

Positive safety margin 2 (9%)

Repeated hepatectomy 4 (18%)

Factor No. (%) Overall survival (month) p. value

Age (year)

<40 16 (73%) 86

≥40 6 (27%) 72 0.4

Gender Female 11 (50%) 84

Male 11 (50%) 79 0.6

Tumor size (cm)

<10 8 (36%) 82

≥10 14 (64%) 76 0.3

Number

<1 19 (86%) 89

≥1 3 (14%) 77 0.2

Hepatic resection Hepatocetomy 16 (73%) 86

(continued)
Conclusion: FL-HCC has a favorable prognosis than common HCC and should be suspected in young patients with non cirrhotic liver. Aggressive surgical resection should be done for all patients. Repeated hepatectomy or excision of recurrent disease should be considered for these patients as it has a relatively indolent course.

P0724 MICROWAVE VERSUS RADIOFREQUENCY THERMAL ABLATION OF HEPATOCELLULAR ADENOMA: SAFETY AND EFFICACY
H. El Alfy1, T. Besheer2, K. Farid3, A. Mohammad El Sayed Ahmed El Nakib1, A. El Shabrawi1, A. Elbaddawy2, A. El Morsy1, K. Zalata3, M. Abd El_Aziz1

Introduction: Hepatocellular adenoma (HCA) is a rare benign tumor of the liver that typically presents in women within their reproductive years. The recent increase in the HCA prevalence is noticeably associated with the rising prevalence of obesity and the metabolic syndrome. Because of high risk of complications such as hemorrage, rupture and malignant transformation, appropriate treatment strategy should be considered. Given the success of image-guided ablation in treating malignant hepatic tumors, there is increased interest in treating benign masses with percutaneous ablation.

Aims & Methods: To investigate the efficacy and safety of Microwave versus Radiofrequency Ablation in management of HCA. Of 320 Patients presented with hepatic focal lesions over 1 year, data of 15 patients diagnosed to have HCA were collected retrospectively. The diagnosis of HCA in those patients was based on radiological findings using triphasic pelvi-abdominal CT, dynamic MRI or cytopathological examination of FNAC for those whose radiological findings were not conclusive. The size of the all tumors was ranged between 2.5 to 3.4 cm. Tumors were selected for treatment by percutaneous ablation after multidisciplinary discussion of multiple factors, including patient preference, number and location of tumors impacting the extent of a possible liver resection and hepatic reserve and the decreased morbidity compared with surgery. The patients were divided into 2 groups: GroupA included 7 patients (5 females, 2 males) underwent Radiofrequency Ablation. GroupB included 8 patients (5 females, 3 males) underwent Microwave Ablation. Follow up was performed every 3 months over a period of 1 year.

Results: Microwave and Radiofrequency thermal ablation had the same safety and efficacy in management of HCA with no evidence of residual tumor, tumor recurrence nor complications but Microwave thermal ablation was superior in large size tumors and needed only single skin puncture while Radiofrequency ablation needed more than single puncture in the same session.

Conclusion: Percutaneous ablation of HCA using Microwave or Radiofrequency thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA. Of note Microwave ablation is much more efficient in treating larger lesions through single puncture in contrast to Radiofrequency which needs more than one puncture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the natural history of HCC patients is not established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.LI.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hypertriglyceridemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features showed lower percentage of HCC diagnosis on surveillance (p 0.021), larger tumors (p 0.038), better liver function (higher percentage of patients with Child-Pugh A [p 0.007] and MELD < 10 [p 0.003]), higher percentage of metastases (p 0.024), and lower percentage of portal vein thrombosis (p 0.010). The BCLC stage and treatment options were similar among the 3 groups, with the exception of a less frequent access to locoregional therapies for BCLC stage B patients with 3–5 features (p 0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups. Diabetic patients showed a lower survival (p 0.046). MELD score, HCC
morphology, nodule size, BCLC stage, portal vein thrombosis and metastases were 1 epidemiologic factors of lead-time for sorafenib-treated patients with HFS may have prolonged the administration period, improving the prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0726 LIVER VOLUME AS A PREDICTOR OF RISK FOR HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS C PATIENTS

N. Kang1, J.W. Chung, J. Kim
Internal Medicine, Seoul National University Bundang hospital, Seong-Nam city/Korea, Republic of
Contact E-mail Address: namkyunym@gmail.com

Introduction: Chronic hepatitis C virus (HCV) infection pose risk for development of hepatocellular carcinoma (HCC), even after viral eradication with effective antiviral therapy. Therefore, risk prediction is clinically important for effective surveillance of chronic hepatitis C (CHC) patients, but it is not known whether decreased liver volume predicts the HCC risk in CHC.

Aims & Methods: The aim of this study was to assess the significance of liver volume in the prediction of HCC risk in CHC patients. A retrospective cohort of 101 CHC patients who received 4-phase dynamic CT imaging studies during surveillance was analyzed for liver volume and outcome of surveillance. Liver volumes were measured on portal venous phase of CT image and corrected for body weight and height: liver volume index (LVI) = ratio of the expected standard volume to the measured liver volume. Kaplan–Meier analysis with the log-rank test used to compare HCC Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with lower liver volumes. Presence of liver cirrhosis was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 6.35, CI: 1.24-1244.28, P < 0.001; HR: 3.10, CI: 1.26-751.2, P = 0.12, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0727 HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB

M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hirai
Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact E-mail Address: masaochiph@gmail.com

Introduction: Sorafenib is a multi-thyrosine kinase inhibitor classed as a neo-vascularization inhibitor. A previous study indicated that the administration of a thrombolytic drug, etamsylam, significantly prolonged the survival of patients with dermal disorder1. However, few studies have reported the efficacy of sorafenib administration in patients with hand and foot syndrome (HFS).

Aims & Methods: In this study, we investigated the prognosis of sorafenib-treated patients with HFS. HFS grading was conducted according to the Common Terminology Criteria for Adverse Events (CTCAE) v.4.0. Patients with grade 1 or higher dermal disorder were regarded as having HFS, and grade 0 patients as not having HFS. For HFS evaluation, a double-check system was adopted: primary evaluation based on a specific evaluation sheet at the Pharmacists’ Outpatient Clinic and final evaluation by physicians at the outpatient clinic. We examined the influence of HFS on the effects of treatment after the introduction of sorafenib in 42 patients with a history of multidisciplinary treatment, such as transcatheter arterial chemoembolization (TACE), between May 2009 and March 2017.

Results: Grade 1 or higher HFS was observed in 22 patients (53%), and it was absent in 20 (47%). Overall, the median sorafenib administration period was 2.1 months. In the HFS-free and HFS groups, it was 0.9 and 2.7 months, respectively (p < 0.001). Survival analysis was performed using the Kaplan-Meier method. Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively (p = 0.001). Multivariate analysis showed that HFS was an independent predictor of HCC (hazard ratio: 0.41; 95% CI: 0.19 to 0.88; p = 0.023) and administration period (hazard ratio, 0.45; 95% CI, 0.20 to 0.98; p = 0.045) were significant predictive factors. The following were not significant predictive factors: age, BCLC staging, dosage, and tumor markers.

Conclusion: The prognosis of hepatocellular carcinoma patients receiving sorafenib treatment was closely related to the presence of HFS and administration period. HFS was a predictor of outcome in patients with hepatocellular carcinoma treated with sorafenib. This study indicated that a multi-thyrosine kinase inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated for cetuximab. HFS reduces the quality of life (QOL), and is a sorafenib administration-inhibiting factor. In our hospital, a system for patients to initially consult the Pharmacists’ Outpatient Clinic, followed by the feed-back of grade-based control strategies to physicians at the outpatient clinic, was established.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0729 UNUSUAL METASTASIS OF HEPATOCELLULAR CARCINOMA

I. Nakihada, J. Benelbarhadi, F.Z. Ajana
1Service Medicine C Rabat Maroc, Hospital Ibn Sina Rabat, Rabat/Morocco
2Rabat, Ibn Sina Hospital, Rabat/Morocco

Contact E-mail Address: Ibtissammakihada@gmail.com

Introduction: Hepatocellular carcinoma is the most common primary tumor of the liver and is estimated to cause more than a quarter of a million deaths each year throughout the world. Extraphaeretic metastasis of HCC occurs in about 30-50% of patients, and it depends on HCC stages.1 The most frequent site is lung, followed by lymph node, bone, and adrenal gland.2 In our previous study, we observed some patients with unusual metastatic sites from HCC.3 In this study, we set to evaluate epidemiological features and overall survival of histologically proven advanced HCC patients in a Japanese population.

Aims & Methods: We carried out a retrospective study of 16 patients with unusual metastatic sites from hepatocellular carcinoma out of 1047 cases of HCC treated at the hepatogastroenterology department "Medicine C" of the IBN SINA University Hospital during the past 22 years. The diagnosis was suspected based on clinical signs and imaging data, and confirmed by histology when the biopsy of the metastasis was possible, were excluded from this study, patients with lung metastasis, lymph node and portal thrombosis.

Results: Our study included 16 patients, 10 men and 6 women with a mean age of 58.5 years ranging from 37 years to 75 years. 13 patients had cirrhosis due to hepatitis C virus, 1 patient had a cirrhosis due to viral B infection and 2 patients had HCC with anacoricotic liver. All patients had one or more HCC, ranging in size from 2 to 10 cm. The AFP was normal in 11 cases and elevated in 4 cases (>200 ng/ml). We collected 4 cases of adrenal metastases, 5 costovertebral metastases, 2 gastric metastases, 2 brain metastases, 1 cranial metastasis, 1 caval metastasis, 1 ovarian metastasis, 1 nasopharyngeal metastasis, and a case of hepatocellular carcinoma metastases to lung, brain and adrenal gland.4 Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively (p = 0.041). The difference was not significant (p = 0.08).

Conclusion: The incidence of unusual and extraphaeretic metastasis of HCC diagnosed during clinical course was not frequent. The diagnostic procedures for extraphaeretic metastasis have been standardized, however considering the substantial advances in treatment of HCC, the detection of extraphaeretic HCC is crucial for patients to receive appropriate therapy, which ultimately determines patient survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0730 EPIDEMIOLOGICAL STUDY OF HISTOLOGICALLY PROVEN ADVANCED HEPATOCHELONGIACARCINOMA: AN AGED MULTICENTER RETROSPECTIVE STUDY IN FRANCE

Introduction: Hepatocelholangiocarcinoma is a rare primary hepatic tumor combining features of both, cholangiocarcinoma and hepatocellular carcinoma (CHC-C). Few data concerning the epidemiology of hHCC-ICC have been published, mainly from surgically treated Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of historically proven advanced CHCC patients in a French population. Data from patients treated for historically proven CHCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients were included (76.6% of men, median age 64 years [extreme 37-88]. Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively.
Aims & Methods: The aim of this study was to evaluate the clinical manifesta-
tions, risk factors, and prognosis of patients with hepatocellular carcinoma with hepatic involvement. We conducted a retrospective study of patients diagnosed with hepatic lymphoma at our center between 2005 and 2016.

Results: During the 12 years, 36 hepatic lymphomas were identified, 27 primary hepatic lymphomas and 9 with secondary hepatic involvement. The mean age at diagnosis was 53.5 ± 14.6 years and 50% were males. Only one patient had hepatitis B and none had hepatitis C. The majority (94.4%) had symptoms at the time of diagnosis, with fatigue (83.3%), night sweats (61.1%) and loss of weight (52.8%) being the most common. The imaging presentation was that of a single mass in 47.2% of cases, multiple masses in 30.6% and infiltrative mass in 22.2%. The most common lymphoma subtypes were diffuse large B-cell lymphoma (52.8%), MALT lymphoma (11.1%) and Hodgkin’s lymphoma (11.1%). Survival at the end of one year was 63.8% and 27.8% at 5 years. Age > 60 years (p = 0.004) was the only factor that was significantly associated with higher mortality.

Conclusion: Hepatic lymphomas are rare entities that may occur in different ways, with diffuse large B-cell lymphoma being the most common subtype. They presented a 3-year survival of only 27.8% and the age over 60 years was the only factor significantly associated with mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0734** **MIRNA-21 IS OVEREXPRESSED IN PRIMARY BILIARY CHOLANGITIS AND MEDIATES LIVER INJURY AND NECROPTOSIS IN EXPERIMENTAL CHOLESTASIS**

M. B. Afonso1, P. M. Rodrigues1, A. L. Simão2, M. M. Gaspar1, T. Carvalho2, P. Borralho1, J. M. Banules1, R. E. Castro1, C. M. P. Rodrigues1

1Research Institute for Medicines (Med.U.Lisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon; Portugal
2Histology and Comparative Pathology Laboratory, Institute of Medicine Molecular, Lisbon; Portugal

**Introduction:** Inhibition of microRNA-21 (miR-21) prevents necroptosis in the mouse pancreas. In turn, we recently showed that necroptosis contribute to hepatic necro-inflammation in the common bile duct ligation (BDL) murine model.

**Aims & Methods:** We aimed to evaluate the role of miR-21 in mediating deleterious processes associated with cholestasis. The functional crosstalk between miR-21 and necroptosis was investigated in vitro.

**Results:** miR-21 and necroptosis was investigated in vitro. miR-21 expression was evaluated in the liver of primary biliary cholangitis (PBC) patients. C57BL/6 wild-type (WT) or miR-21-deficient (miR-21−/−) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

**Conclusion:** miR-21−/− primary mouse hepatocytes established a functional link between miR-21 and necroptosis through cyclin dependent kinase 2 associated protein 1 (CDK2AP1). miR-21 expression increased in the liver of PBC patients in comparison with that of mice at both 3 and 14 days. Notably, under BDL, miR-21−/− mice displayed decreased serum levels of liver injury markers compared with WT mice, accompanied by reduced hepatocellular degeneration, oxidative stress and pro-fibrogenic gene expression. Hallmarks of necroptosis were depressed in the liver of BDL miR-21−/− mice, via relieved repression of CDK2AP1. Further, miR-21−/− mice displayed improved adaptive response in the expression of bile acid homeostasis-associated genes.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0735** **IS COMPLETE STONE REMOVAL FOR CHOLEDOCHOLITHIASIS ALWAYS NECESSARY IN EXTREMELY ELDERLY PATIENTS?**

Gastroenterology, New Tokyo Hospital, Chiba; Japan

**Aims & Methods:** The aim of this study was to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTC failed and when deemed feasible by a dedicated multidisciplinary team including a hepatopancreato-biliary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

**Results:** Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transaction of the bile duct (type D) and 16 (5.8%) were diagnosed with incomplete transaction (type E). Primary success rate of RV was 94% (44/47 patients). Reasons for failure (N = 3) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to
P0739 TRANRECTAL GALLBLADDER PRESERVING CHOLECYSTOLITHOTOMY AND POLYPECTOMY BY PURE NOTES
B. Liu
Gastroenterology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou/China
Contact E-mail Address: 3217265358@qq.com
Introduction: Transcolonic and transrectal NOTES in human cases was greatly restricted by the fact of fecal contamination. We developed a detachable intracolic balloon to help keep the colon sterile by blocking the colonic lumen. Although cholecystectomy is widely used for treating gallbladder polyps and gallstones, there is still a controversy about whether or not the gallbladder should be preserved. However, postcholecystectomy syndromes, such as bile duct injury and the correlation with colon cancer, remind us of the importance of gallbladder preservation.
Aims & Methods: Approved by the Independent Ethics Committee, we’ve completed 8 transrectal gallbladder preserving cholecystolithotomy (TRGP) and 3 transrectal gallbladder preserving polypectomy (TRGPP) and 2 combined cases by pure NOTES. Moreover, 1 case of TRGPP was done by hybrid NOTES. As the figures show, the balloon was placed in the transverse colon to block the colonic lumen, and the distal colon cavity was disinfected with povidone-iodine solution. An incision was made on the anterior rectal wall 12–17 cm from the anus. The endoscope was advanced into the peritoneal cavity with liver and gallbladder identified. The bile was aspirated before an incision on the gallbladder wall was made. Stones and/or polyps were found inside of the gallbladder. Stone extractor and biopsy forceps were used to take out the stones. The polyps were coagulated and removed by electric biopsy forceps. The muscular layer and the adventitial layer were successively closed with endoclips. Peritoneal cavity lavage was performed with sterile saline. The rectal incision was closed with endoclips and endoloops tightly. At the end of the procedure, the balloon was pulled out after being deflated.
Results: The mean operation time (from incision making till the last clipping) was 180.5 min. (89–467 min.), 6 hours after anesthesia, the patients could drink water, and liquid diet was resumed 24 hours later. Postoperatively, 4 of the 14 patients fed mild abdominal distention which disappeared within 12 hours when they were able to get off the bed. For 1 patient with acute cholecystitis, a hybrid NOTES with laparoscopy was performed. Moreover, gallbladder drainage and peritoneal lavage were used, and the abdominal pain relieved soon. All the patients were discharged without any adverse events and all felt good during the follow-ups.
Conclusion: The usage of the detachable balloon can prevent the operative field from fecal contamination effectively. TRGPP and TRGP by pure NOTES are suitable for both males and females. Transrectal route provides a novel alternative approach for the treatment of gallbladder polyps and gallstones. To our knowledge, this is the first human case series of transrectal gallbladder preserving cholecystolithotomy and polypectomy by pure NOTES. However, multi-centered, prospective, controlled researches with more cases are needed in the future.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0740 KML001, AN ORAL ARSENIC COMPOUND, AS PALLIATIVE CHEMOTHERAPY IN ADVANCED BILIARY TRACT CANCERS AFTER FAILURE OF GEMCITABINE-BASED CHEMOTHERAPY
Department Of Internal Medicine And Institute Of Gastroenterology, Yonsei University Health System Dept. of Internal Medicine Dept. of Gastroenterology, Seoul/Korea, Republic of
Contact E-mail Address: woforce@naver.com
Introduction: Sodium metarsenite (NaAs203; code name KML001) is an orally bioavailable arsenic compound with potential anti-cancer activity. However, the effect of KML001 has not been evaluated in patient with biliary tract cancers. We investigated the potential of KML001 as palliative chemotherapy in patients with advanced biliary tract cancers who non-respond to gemcitabine-based chemotherapy.
Aims & Methods: The study was designed to evaluate safety, tolerability and effectiveness of KML001 as palliative chemotherapy in advanced biliary tract cancer. Inclusion criteria were 1) inoperable or metastatic cholangiocarcinoma and gallbladder cancer, and 2) previous history of failure to gemcitabine-based chemotherapy. Exclusion criteria were 1) naïve patient to chemotherapy, 2) ECOG PS >3, and 3) history of decompensated congestive heart failure, uncontrolled arrhythmia, and QT prolongation (QTc > 480 ms). KML001 (Kominos, Komipharm International Co., Ltd.) was administered as 7.5 mg daily to eligible subjects. Every two months, patient took response evaluation by biliary CT scan.
Results: A total of 44 patients (21 females and 23 males) were enrolled prospectively between November 2011 and October 2014. Mean age of the patients was surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojejunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N=4.7%). No life-threatening adverse events and no 30-day mortality occurred.
Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.
Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: drain 1 or more segments, depending on the number of segments drained, in function of the number of segments drained. The aim of our study was to evaluate the efficiency of hilar stenosis. Our policy is to try to drain the most possible segments of the liver in unilateral or bilateral palliative drainage. Therefore, for this kind of drainage we need to decide the plan of the drainage and to evaluate efficiency and quality of the drainage. All drainages were performed under general anesthesia in a ICU. All patients had been operated for hilar stenosis, and median overall survival from hilar stenosis was 2.5 months (IQR 1.4–4.9 months). During treatment, 25 patients (55.6%) could maintain tolerable general condition without increasing ECOG PS, and 35 patients (79.6%) could maintain or decrease the requirement for morphine as pain killer. During treatment, there were 12 cases (12/44, 27.3%) of grade 3 adverse events (AE), and no cases of grade 4 AE. Most common AE was ALT/AST elevation, which was followed by anemia (10/44, 22.7%). The major causes of the drop outs from study were due to disease progression or patient’s death (30 cases, 66.7%), and there were only 5 cases (11.1%) who dropped out due to adverse drug reactions or severe AE.

Table 1: Treatment outcomes

| Study period, mean, mo (IQR) | 1.5 (1.0–10.0) |
| Progression free survival, mo (IQR) | 1.7 (0.8–2.3) |
| Survival from study-enroll, mo (IQR) | 2.5 (1.4–4.9) |
| Best response, n (%) | SD 3 (6.8%), PD 23 (52.3%) |
| Not evaluated | 18 (40.9%) |
| ECOG, n (%) | |
| Increased | 19 (43.2%) |
| Maintained | 24 (54.5%) |
| Morphin requirement, n (%) | increased 8 (18.6%), maintenance 31 (72.1%), decreased 4 (9.3%) |
| Adverse event, n (%) | Grade 1 16 (36.4%), Grade 2 29 (65.9%), Grade 3 12 (27.3%), Grade 4 0 (0%) |
| Drop out cause, n (%) | Drug reaction 1 (2.3%), Adverse event 4 (9.1%), Patient’s death 7 (15.9%), Disease progression 22 (50.0%), Withdrawal consent 5 (11.4%), Loss of follow-up 2 (4.5%), Poor general condition 3 (6.8%) |

Conclusion: KML001 was safe and well tolerated in respects of adverse events. KML001 was also shown promising result in disease control and pain control. KML001 can be another palliative treatment option for patients with advanced biliary tract cancers who non-respond to gemcitabine-based chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0741 ENDOSCOPIC DRAINAGE OF MALIGNANT STENOSIS OF THE BILIARY CONFLUENCE: HOW MANY SEGMENTS SHOULD BE DRAINED TO IMPROVE THE PATIENT SURVIVAL?

F. Caillol1, E. Bories2, C. Zemmour3, C. Pesenti1, J.P. Ratone1, M. Giovannini1

Introduction: ESGE stated in 2012 that more than 50% of the liver had to be drained in case of unresectable hilar liver stenosis, however it remains unclear if unilateral or bilateral palliative drainage has to be performed for this kind of stenosis. Our policy is to try to drain the most possible segments of the liver in function of the number of segments drained. The aim of our study was to evaluate the efficiency of hilar stenosis. The drainage was performed by removing the biliary stenoses and the percutaneous drainage. The choice of the technique was left to the appreciation of the operators. All drainages were performed under general anesthesia in a ICU. All patients had been operated for hilar stenosis, and median overall survival from hilar stenosis was 2.5 months (IQR 1.4–4.9 months). During treatment, 25 patients (55.6%) could maintain tolerable general condition without increasing ECOG PS, and 35 patients (79.6%) could maintain or decrease the requirement for morphine as pain killer. During treatment, there were 12 cases (12/44, 27.3%) of grade 3 adverse events (AE), and no cases of grade 4 AE. Most common AE was ALT/AST elevation, which was followed by anemia (10/44, 22.7%). The major causes of the drop outs from study were due to disease progression or patient’s death (30 cases, 66.7%), and there were only 5 cases (11.1%) who dropped out due to adverse drug reactions or severe AE.

Table 1: Treatment outcomes

| Study period, mean, mo (IQR) | 1.5 (1.0–10.0) |
| Progression free survival, mo (IQR) | 1.7 (0.8–2.3) |
| Survival from study-enroll, mo (IQR) | 2.5 (1.4–4.9) |
| Best response, n (%) | SD 3 (6.8%), PD 23 (52.3%) |
| Not evaluated | 18 (40.9%) |
| ECOG, n (%) | |

Introduction: Approximately 0.6% to 4% of cholecystectomies are for gallbladder polyps. The decision to perform cholecystectomy is based on presence of gallbladder polyp on transabdominal ultrasound (TAUS) or endoscopic ultrasound (EUS), or both. This decision is also influenced by whether the polyp is malignant or not. True polyps are neoplastic, either benign (adenoma) or (pre)malignant (dysplastic polyp/carcinoma). True polyps usually need surgery, as they are thought to have malignant potential through the adenoma-carcinoma sequence. (Pre)malignant lesions should be operated sooner than benign lesions. There has been no systematic review and meta-analysis on the accuracy of TAUS and EUS in the diagnosis of gallbladder polyps, true gallbladder polyps and (pre)malignant polyps.

Aims & Methods: The aim was to determine and compare the accuracy of TAUS and EUS for diagnosis of gallbladder polyps, differentiating between true and pseudopolyps and differentiating between (pre)malignant and benign polyps.

Results: A total of 17 studies were included in this review. For diagnosis of gallbladder polyps six studies on TAUS were included. The sensitivities and specificities of the studies ranged from 0.45 to 1.00, and 0.91 to 0.98 respectively. There were no studies on EUS for this topic. For differentiating between true and pseudopolyps, seven studies were included. All seven studies reported on TAUS, four studies also reported on EUS. The sensitivities and specificities of the studies ranged from 0.47 to 1.00 and 0.51 to 0.98 for TAUS, and from 0.63 to 1.00 and 0.84 to 0.96 for EUS. For differentiating between (pre)malignant and benign polyps, five studies were included. Four studies reported on TAUS and three studies on EUS. The sensitivities and specificities of the studies ranged from 0.09 to 1.00 and 0.46 and 1.00 for TAUS and from 0.69 and 0.92, and 0.87 to 0.95 for EUS. There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.77 (0.65–0.88). There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.77 (0.65–0.88).

**Introduction:** In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigators have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubbles contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

**Aims & Methods:** The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polyoid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Perfluorobutane-based contrast agent and high MI contrast mode was used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement. Subsequently, patients were stratified according to lesion size at the largest diameter, and the diagnostic accuracy for gallbladder cancer in B-mode and CEUS were assessed.

**Results:** Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than in B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity (p < 0.01). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) (p < 0.01). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/17), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (33/36) on CEUS, and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

**Conclusion:** CEUS in high mechanical index contrast mode was a useful modality for differentiating gallbladder cancer and benign PLGs.

Introduction: Recent studies have been conducted to investigate the association between obesity and survival in cancer patients. Cancer has a significant influence on the nutrient status of patients and obesity can affect on the pharmacokinetics of anti-cancer drugs. The impact of obesity on survival is known to vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence.

Aims & Methods: We performed this study to investigate the association between BMI and overall survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows; underweight, <18.5 kg/m²; normal, 18.5-22.9 kg/m²; overweight, 23-24.9 kg/m²; obese, ≥25 kg/m².

Results: Median OS was 12.1 months for underweight patients, 10.5 months for normal patients, 16.1 months for overweight group, 13.6 months for obese patients, respectively. (p = 0.047) Univariate analysis showed that BMI, local status and disease, operation and radiotherapy and ECOG performance were significantly associated with better survival. Compared with normal patients, overweight patients (BMI 23-24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.491, CI 0.334–0.721; 95% p = 0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival.

Conclusion: Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Meier curves, and calibration curves revealed good predictive abilities. The risk score identified patients with a 1-year survival probability ranging from 15% to 73%.

**Conclusion:** We developed a prognostic score to predict overall survival for PHC patients using eight independent poor prognostic factors available at presentation. This score may help to inform patients and guide individualized treatment decisions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**THE OUTCOMES OF ERCP FOR THE PALLIATION OF MALIGNANT JAUNDICE IN ENGLAND BETWEEN 2001 AND 2015**

P. Harvey1, S. Baldwin1, J. Myttor2, F. Evison2, P. Petal2, N. Trudgill1

Contact E-mail Address: philipharvey@nhs.net

**Introduction:** Malignant biliary obstruction has a poor prognosis unless secondary to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

**Aims & Methods:** The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

**Results:** 49055 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%) followed by liver and intraductal bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.6% for 7 day, in hospital and 30 day respectively. In multivariate analysis male gender (OR 1.14, (95% CI 1.08–1.20) p < 0.001); increasing age 61–70 (1.34, (1.23–1.47) p < 0.001), 71–80 (1.57, (1.44–1.72) p < 0.001), 81–90 (1.83, (1.68–2.00) p < 0.001), p < 0.001); increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16), p < 0.001), 6 to 10 (1.12, (1.06–1.12) p < 0.001), 11 to 15 (1.14, (1.33–1.66), p < 0.001), 16 to 20 (1.92, (1.80–2.07), p < 0.001); advancing year of ERCP 2013/14 (0.76, (0.68–0.90), p < 0.001), 2014/15 (0.85, (0.74–0.98) p < 0.028); and previous renal failure (1.92, (1.77–2.09), p < 0.001) were associated with increased 30 day mortality. Asian ethnicity (OR 0.82, (0.67–0.99), p = 0.036), presence of anastomotic and unspecified parts of biliary tree (0.60, (0.55–0.65), p < 0.001) and upper tertile of unit ERCP activity (>230) per annum (0.86, (0.80–0.93), p < 0.001) were negatively associated with 30 day mortality.

**Conclusion:** Short-term mortality in subjects with malignant biliary obstruction following ERCP was high. A better prognosis was observed in high-volume ERCP units, Asian ethnicity and extrahepatic primary cancers. Male gender, advancing age, increasing co-morbidity score, previous renal failure and mortality were examined by logistic regression.

**EARLY DEVELOPMENT OF NONALCOHOLIC FATTY LIVER DISEASE IN GENETICALLY PREDISPOSED CHILDREN: WHAT IS THE NUMBER OF LIVER STIFFNESS MEASUREMENTS NEEDED FOR A HIGH QUALITY EVALUATION?**

K. Karnebeck1, J. Plat2, A. Vreugdenhil1

1Department Of Pediatrics, Maastricht University Medical Centre, Maastricht/United Kingdom

2Health Informatics, University Hospital Birmingham, Birmingham, United Kingdom

Contact E-mail Address: kkarnebeck@mumc.nl

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738499) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver pancreatic and cardiometabolic disturbances coincide in PNPLA3 and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

**Aims & Methods:** One hundred and seventy-four children (49% boys) from the Centre for Overweight Adolescent and Children’s Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 I148M and TM6SF2 E167K. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

**Results:** Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in PNPLA3 G allele carriers as compared to the C allele carriers (ALT; CC 21, (0.10–0.60) vs GG 26, (0.34, 0.50); GG 27, (0.21, 0.00–0.40, 00); GG 30, (0.26, 0.00, 36, 00) p < 0.004). The odds ratio for having ALT levels above the cut-off values increased for every PNPLA3 G allele, with an OR of 2, 51 (1, 22, 58; p = 0,015) for the PNPLA3 G homozygote compared to the CC genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers. The TM6SF2 T allele carriers also showed a tendency towards increased transaminase levels, but a significantly healthier cardiometabolic profile compared to non-carriers. Despite significantly higher liver transaminase levels and a positive correlation between ALT levels and triglyceride and fasting insulin concentrations in PNPLA3 G allele carriers, these children did not have a more deteriorated cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Contact E-mail Address: cpienan@gmail.com

**Introduction:** Pediatric chronic liver diseases are becoming a public health issue. Ultrasound based elastographic techniques have emerged as non-invasive methods of pediatric liver fibrosis assessment. The most recent are two dimensional shear wave techniques. While they are proved to be highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation.

**Aims & Methods:** We aimed to investigate the number of liver stiffness measurements (LSM) needed for a high-quality evaluation using 2D SWE technique. We conducted a prospective study which included 73 children (age range: 3–17 years, mean age 11.73 ± 3.55 years, 37% girls, mean body mass index (BMI) 25.12 ± 7.38 kg/m2). We used the 2D-SWE. GE (Logiq E9, GE Healthcare, Chalfont St Giles- UK), with a c5-1 probe. One examiner performed 10 LSM for each child. We randomly extracted 1 LSM, 2 LSM, 3 LSM and 5 LSM from all and calculated their respective medians. We employed the Friedman test to compare the medians of 1, 2, 3, 5 and 10 LSMs. We used the interclass correlation coefficient (ICC) to assess the agreement between the medians of 1, 2, 3, 5 and 10 LSMs.

**Results:** Medians calculated from 1, 2, 3, 5 and 10 LSMs were similar (ICC = 0.91 kPa, 4.25 kPa ± 0.99 kPa, 4.25 ± 1.03 vs 4.2 ± 0.99 kPa vs 4.19 ± 0.99 kPa, p = 0.94). Furthermore, the agreement between medians calculated from 1, 2, 3, 5 and 10 LSMs was excellent (ICC = 0.960, 95% confidence interval: 0.944-0.974).

**Conclusion:** We suggest obtaining 5 LSM for a high-quality evaluation using this 2D SWE technique.

**Disclosure of Interest:** S.A. Popescu: I hereby confirm that I have received financial support (congress travel grants, speaker fee) from: Philips, General Electric, Abbvie, Astrazeneca, Zentiva All other authors have declared no conflicts of interest.

**PERCUTANEOUS EMBOLIZATION OF VISCERAL ARTERY PSEUDO-AneURYSMS – A TERTIARY CENTER EXPERIENCE**

R. Chavan1, J. Singh1, Z. Nabi1, R. Kalapala1, D.N. Reddy1

1Gastroenterology, 2Institute of Anaesthesiology, 3Hyderabad, 4Hyderabad, India

Contact E-mail Address: drradhikachavan@gmail.com

**Introduction:** Visceral artery pseudo-aneurysms are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreaticitis. Angioembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.
Aims & Methods: We aimed to assess the technical feasibility, safety and effic-acy of percutaneous embolization as an alternative treatment option for visceral pseudo aneurysms. We retrospectively evaluated the data of patients who underwent percutaneous embolization at our institution from Feb 2007 to March 2017. All procedures were performed under ultrasound (US) guidance. Embolization technique, safety and efficacy of percutaneous embolization were analysed. At 30 days follow up US with color Doppler/dual phase computed tomography was done to see for recurrence of pseudoaneurysm.

Results: 23 patients(18-male) with mean age of 34.47 ± 2.28 (7–72) years, under- went direct percutaneous embolization for visceral pseudoaneurysm. Most common aetiology for pseudoaneurysm was pancreatitis (16) followed by trauma (3), paracentesis (3) and surgery (1). The site of pseudoaneurysm was splenic artery (13), left gastric artery (3), hepatic artery (3), inferior epigastric artery (3) and gastroduodenal artery (1). Mean size of pseudoaneurysm was 1.8 ± 0.6 (1–3.5) cm. Reasons for choosing percutaneous approach over trans-catheter embolization included - technical difficulties in 11 patients, excess collat- erals to feeding artery in 5 patients, and recurrence after pre- vious embolization in 6 patients. Agents used for embolization- glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3 ± 2.11 (8–16) minutes and fluoroscopy exposure time was 2.4 ± 1.14 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success–100%). Mild adverse events included - local site pain in 19 (80%) patients. Moderate adverse event included - splenic infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 910 days (30–3186) there was no recurrence of pseudoaneurysm (clinical success-100%).

Conclusion: Percutaneous embolization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding trans-catheter approach.

Introduction: Various forms of pancreatitis (e.g. severe acute pancreatitis, auto-immune pancreatitis type 2) are characterized by an infiltration of neutrophil granulocytes. Yet, despite sharing the feature of granulocytic infiltration, these diseases take opposing natural courses of disease. A novel function of granulo- cytes, the formation of aggregated neutrophil extracellular traps (aggNETs), has been described and called for a reevaluation of the specific role of neutrophils in pancreatitis. We were interested in the specific function of granulocytes in various models of pancreatic inflammation.

Aims & Methods: Experimental models of pancreatic inflammation were employed including caerulein-induced pancreatitis and a novel model of IL-17A-induced pancreatitis. The outcome of disease was characterized by immuno- histochemistry, RNA expression and flow cytometric analyses.

Results: Transgenic systemic delivery of IL-17A alone can induce granulocytosis and neutrophil infiltration to the pancreas. Interestingly, neutrophils do not remain in the interstitium, yet enter the pancreatic ducts and form aggregates in the duc- tular lumen. Our experimental models further indicate that peptidyl arginine deiminate 4 (PAD4) is critical for intraductal aggregate formation and that PAD4-deficiency abrogates disease progression. Mechanistically, we identify the pancreatic juice as a strong instigator of neutrophil extracellular matrix formation. Characteristic single components of pancreatic juice, such as bicarbonate ions and calcium carbonate crystals, induce aggregated NET formation.

Conclusion: Granulocytes aim to contain an inflammatory focus and enter pan- creatic ducts with potentially detrimental consequences to dependent areas of the organ.

Introduction: Mitochondrial dysfunction is a hallmark of several disease patho- genesis including acute pancreatitis (AP). Our results suggest that mitochondrial damage is crucial in bile acid induced inhibition of pancreatic ductal HCO3− secretion, however the details of mitochondrial function and dysfunction in pan- creatic ductal epithelial cells (PDEC) is not known yet.

Aims & Methods: The aim of our study was to characterize the mitochondrial function and function in PDEC under physiological and pathophysiological conditions. Guinea pig and Cyclophilin D WT and knock out (KO) mouse pancreatic ducts were used. Mitochondrial distribution was studied by electron microscopy (EM). Mitochondrial membrane potential (ΔΨm) was measured by confocal microscopy and pancreatic ductal HCO3− secretion by microfluorometry.

Results: EM measurements revealed that the mitochondrial density is signifi- cantly higher on the apical side of the guinea pig PDEC compared to the middle or the basal segment in HEPES solution. The apical mitochondrial den- sity increased further in CO2/HCO3− buffered solution, or during the adminis- tration of 5 μM forskolin. It was also confirmed by ΔΨm measurements as we detected increased TRM3 fluorescence on the apical side of the PDEC during stimulation. The genetic KO of cyclophilin D significantly reduced the loss of ΔΨm and protected pancreatic ductal HCO3− secretion during the adminis- tration of 500 μM chenodeoxycholic acid.

Conclusion: Our results revealed that mitochondrial function has a central role in the function of PDEC presumably by providing ATP for fluid and ion secretion. On the other hand the opening of MPTP seems to be crucial in the bile acid induced toxicity offering a potential therapeutic target in AP.

Introduction: Infectious complications are main causes of mortality in severe acute pancreatitis. Most infections in AP are intestinal origin (2). The Nucleotide oligomerization domain 2 (NOD2) is a NOD-like receptor family that senses and responds to bacterial wall peptides (3). Guenther et al. reported that p.R702W mutation was found to be associated with multipl organ failure and mortality in patients with AP (4). We aimed to investigate whether there is a correlation between NOD2 variants and AP severity in this study.

Aims & Methods: Group 1 (n = 27) was healthy. Group 2 (n = 36) and Group 3 (n = 32) were composed of mild and severe pancreatitis patients according to the Atlanta 2012 classification (5). Four NOD2 variants and serum interleukin-6 (IL-6), Tumor Necrosis Factor-α (TNF-α) and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007S variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NOD2 variants between Groups. Serum IL-6, TNF-α and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NOD2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.

P0757 A LUMEN APPEARING METAL STENT WITH ANTI-REFUX VALVE FOR ENDOSCOPIC ULTRASOUND-GUIDED DRAINAGE OF PSEUDOCYST AND WALLED-OFF NECROSIS

Department Of Internal Medicine, Yongsei University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: inn0428@yuhs.ac

Introduction: Pancreatic pseudocyst (PC) and walled-off necrosis (WON) are frequent complications of acute pancreatitis. Drainage procedure is required when complications and complications such as pain, bilateral obstruction and infection occur. With technological advances, endoscopic ultrasonography (EUS)-guided drainage replaced surgical treatment and has become the standard treatment. We developed a novel fully-covered lumen-apposing metal stent (LAMS) with anti-reflux valve for the purpose of preventing complications such as stent migration or reflux of bowel contents while improving the stent patency. The aim of this study is to investigate the efficacy and the rate of complications of EUS-guided drainage using novel LAMS with anti-reflux valve for PC and WON.

Aims & Methods: We compared the treatment outcomes and the rate of complications of EUS-guided drainage using LAMS with EUS-guided drainage using plastic stents. Ten patients underwent EUS-guided drainage using the novel LAMS (LAMS group) and eighteen patients using conventional plastic stents (plastic stent group) from December 2013 to October 2016. A novel LAMS used in this study was designed to have bilateral flare ends, 4 anti-migration flaps (at each side) and a pair of 2 anti-reflux valves (inside the lumen). Technical success is defined as a successful placement of the LAMS, and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Results: Among 10 patients treated with LAMS, 4 patients had complicated PC and 6 patients had WON. In plastic stent group, 15 patients had complicated PC and 3 patients had WON. The median size of fluid collection before treatment was 69.5 mm (range, 48-214 mm) in LAMS group and 92.0 mm (56-253 mm) in plastic stent group. Median duration of stent placement was 47 days (1-355 days) in LAMS group and 55 days (1-216 days) in plastic stent group. Treatment outcomes of the LAMS group were not inferior despite the significantly higher proportion of WON patients in the LAMS group compared to the plastic stent group. There were no statistically significant differences in the technical success rate (90%; versus 94.4%; p = 0.95), clinical success rate (70% vs. 77.8%; p = 0.491), resolution rate (76.8% vs. 80.7%; p = 0.705), complication rate (40% vs. 50%; p = 0.456). In LAMS group, 3 patients experienced mild fever and 1 patient showed peritonitis due to immediate stent migration. In plastic stent group, mild fever was developed in 4 patients, all patients had nausea and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Conclusion: Among 10 patients treated with LAMS, 4 patients had complicated PC and 6 patients had WON. In plastic stent group, 15 patients had complicated PC and 3 patients had WON. The median size of fluid collection before treatment was 69.5 mm (range, 48-214 mm) in LAMS group and 92.0 mm (56-253 mm) in plastic stent group. Median duration of stent placement was 47 days (1-355 days) in LAMS group and 55 days (1-216 days) in plastic stent group. Treatment outcomes of the LAMS group were not inferior despite the significantly higher proportion of WON patients in the LAMS group compared to the plastic stent group. There were no statistically significant differences in the technical success rate (90%; versus 94.4%; p = 0.95), clinical success rate (70% vs. 77.8%; p = 0.491), resolution rate (76.8% vs. 80.7%; p = 0.705), complication rate (40% vs. 50%; p = 0.456). In LAMS group, 3 patients experienced mild fever and 1 patient showed peritonitis due to immediate stent migration. In plastic stent group, mild fever was developed in 4 patients, all patients had nausea and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has been shown to be a safe and effective minimally invasive treatment for walled-off necrosis (WON). However, in some cases, simple drainage is not sufficient to manage the symptoms of WON and step up approaches such as direct endoscopic necrosectomy (DEN) and surgical necrosectomy may be required. The association with the outcome of endoscopic treatment for WON remains unclear.

Aims & Methods: This study tried to retrospectively correlate the clinical characteristics of WON with the outcome of endoscopic transmural drainage. 49 patients (38 males; mean age 60.79 ± 13.44) with symptomatic WON treated by an attempted EUS-TD initially were enrolled in this study. The relationship between the outcome of treatment and the clinical characteristics including morphology and extent of WON was investigated.

Results: The mean size of WON was 126.63 ± 46.79 mm. EUS-TD was technically successful in 48/49 (97.9%) patients and 26 (54.2%) improved with EUS-TD alone while step up approach was needed in 19 patients. DEN, percutaneous drainage and surgery were done in 2, 4 and 3 patients, respectively. All patients with step up approach had successful outcomes. Three patients died before step up approach was performed, but death was not related with the procedure itself. The patients who needed step up approach had multi-local (p = 0.05) and large size WON (p = 0.02) as compared to patients treated with EUS-TD alone. The extent of WON correlated significantly (p = 0.001) with the type of treatment. Gas bubbles sign within necrotic tissue on the abdominal CT imaging early after EUS-TD were significant necessity of necrosectomy during the treatment (p < 0.01). Bleeding as adverse events was observed in 3 patients (6.2%). Two patients improved with conservative therapy and 1 patient underwent transcatheater arterial embolization.

Conclusion: The step up approach is safe and effective for the treatment of WON. Multi-local, large size and extensive WON were important predictors for performing a step up approach. Gas bubbles sign within necrotic tissue after EUS-TD may help to perform necrosectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.
admission to hospital. A receiver operating characteristic (ROC) analysis was built at day 0 for the prediction of severity. Later, a multiple discriminant analysis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to severity and mortality.

Results: ROC curves showed that IL1 cytokines Il6, IFN-g and TNF-α can be measured for the prediction of severe AP, while TH2 cytokines IL4, IL13, GM-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL13 and IFN-g were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks’ lambda = 0.855, p < 0.0001; Wilks’ lambda = 0.747, p < 0.0001, respectively). We calculated the IL13/IFNg index. This ratio was significantly higher in patients with mild AP when we compared between groups (p = 7.36 × 10–8). This difference was also observed between severe AP and the rest of the patients (p = 0.007). The ROC curve was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity.

Conclusion: AN IL13/IFNg ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13/IFNg ratio at hospital admission is associated with a good prognosis of AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0763 CORRELATION BETWEEN POST-ERCP SERUM AMYLASE LEVELS AND CT FINDINGS IN ERCP-INDUCED PANCREATITIS: A PROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

Introduction: According to the diagnostic criteria by Cotton et al.1, post-ERCP acute pancreatitis is defined as the persistence of serum amylase levels three times or higher than the upper limit of the standard for 18 ± 6 h after ERCP with persistent upper abdominal pain for 4 h or longer. However, the criterion of three times or higher than the upper limit was mostly based on retrospective studies, and has not been necessarily supported by imaging diagnosis. In this study, using CT findings as the gold standard of ERCP-induced pancreatitis, we investigated the serum amylase level that suggested ERCP-induced pancreatitis in a prospective multicenter study.

Methods: In a high-volume center, 2078 patients examined by ERCP between April 2015 and May 2016 were prospectively followed. CT was performed in patients whose serum amylase level exceeded the institutional upper limit on the day after ERCP (after 12–20 h) to investigate the presence or absence of pancreatectasis. Two expert radiologists evaluated the diagnostic images blinded and judged the presence or absence of pancreatitis based on the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed with acute pancreatitis, had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed with acute pancreatitis, had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed with acute pancreatitis, had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed with acute pancreatitis, had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed with acute pancreatitis, had a difficult imaging evaluation due to the presence of the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed with acute pancreatitis, had a difficult imaging evaluation due to the presence of the Balthazar grade.

Results: Amylase levels increased on the following day in 402 (21.5%) of the 1868 patients included, and 340 patients examined by CT were included in the analysis. ERCP-induced pancreatitis was diagnosed based on imaging in 204 patients (10.9%). The cutoff amylase level for judging the presence or absence of pancreatitis on the following day was 2.73 times higher than the institutional upper limit (sensitivity: 73.3%, specificity: 91.1%, positive likelihood ratio: 2.24, negative likelihood ratio: 0.68) with an area under the curve (AUC) of 0.855. The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69). The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69). The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69). The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69). The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69). The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69). The cutoff amylase level for judging the presence or absence of pancreatitis on the day following ERCP was 2.75 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 45.6%, positive likelihood ratio: 1.99, negative likelihood ratio: 0.69).

Conclusion: The clinical characteristics of the patients and their WONs are shown in Table 1. In the cohort, the deployment of LAMS (AXIOS: 15 ± 10 mm, n = 38; 10 × 10 mm, n = 8) was technically success in 45 (97.8%, 3 cases required 2nd attempt for proper deployment) cases while one case required to switch over to a fully-covered metal stent due to the lengthy insertion tract. 28 (60.9%) cases were managed with necrosectomy (median 1, IQR 2) in which 15 (32.6%) of them had concurrent necrosyic drainage prior to each procedure. 43 (93.5%) patients were treated successfully while two refractory cases required superimposed insertion of a fully-covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases; three were managed by local injection of adrenaline, one managed by arterial embolization. Both the bleeding site and one with uncontrolled bleeding due to disseminated intravascular coagulopathy and then died of multiple organ failure. Ten cases were reported to have stent migration during management in which two cases were dissolved during necrosectomy while the others were found during follow-up.

Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13-50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 0.5 to 1%, among them, one case managed by a fully-covered tubular metal stent (n = 10 mm)8: diverted to nasocystic drainage (n, %) 15(32.6). Spontaneously migration 8, Stent revision 12(26.1), Lumpy/mass content 18(39.1). Gram positive 7(15.2) 5, healthercancer, post ERCP (n = 1); idiopathic (n = 3); Enterococcus spp (n = 5); early: within 48 h; early mild 14(30.4); lumen-apposing metal stent-assisted drainage with high technical and clinical success rate. Bleeding and stent migration are the two major adverse events during the management that can be managed accordingly.

cohort study based on the anonymous computerized database of hospital discharges in Veneto Region (North-East of Italy). The primary diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto population was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG) were the endpoints of interest. Admissions to hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied. Results: During the analysed period, 23,389 overall hospitalizations for AP, annual hospitalizations of 32 patients/100,000 inhabitants and in-hospital mortality of 3.2% were observed. Characteristics of the patients were: mean age: 62.2 ±/−19.3y, 54% Males (M); Female (F) mean age: 65y±/−19.3y, male mean age: 59.4±/−19.3y (p = 0.05). Hospitalizations was higher in males (M: 35.4: F: 28.4, OR 1:24 (95% CI: 1:20−1:27, p < 0.05) and it increased in a stepwise progression from youngest to oldest patients (from 44:4 to 151:2 p < 0.05); a similar trend was observed when considering in-hospital mortality (from 0.5 to 10.3%, p < 0.05). From 2001 to 2015, hospitalization (32.4 to 29.5, p = 0.04), in-hospital mortality (1.41 to 0.79, p < 0.05) and need for surgery (NFS: 5.6% to 3.0%, p < 0.05) trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 34 to 63, p < 0.05) and Gastrointestinal (GI) Units (from 14 to 29, p < 0.05). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality (OR: 0.37, CI 95%: 0.28−0.49, p < 0.001) whereas ICU requirement was seen in significantly more patients in AP group (59; 37%) than in ACP (5; 11%) and RAP (0; 0%) (p < 0.001). RAP, 26% of AP, 2 (4.4%) of ACP, but none of patient with RAP needed ventilatory support (p < 0.001), while 13 (8%) of AP patients, 1 (2.2%) of ACP and none with RAP required dialysis (p < 0.05). Mortality in AP, ACP and RAP was 29 (18%), 2 (4.4%), 0 (0%) respectively (p < 0.05).

Conclusion: During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a best outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0767 COMPARISON OF CLINICAL COURSE AND OUTCOME OF ACUTE PANCREATITIS, RECURRENT ACUTE PANCREATITIS, ACUTE ON CHRONIC PANCREATITIS
N. Berry, D. Sharma, J. Samanta, N. Dhaka, S. K. Sinha, K. J. Lee
Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India
Contact E-mail Address: dibhya.sharma@yahoo.com
Introduction: Recurrent acute pancreatitis (RAP) and acute on chronic pancreatitis (ACP) are likely to have less severe disease and local complications in comparison to acute pancreatitis (AP) possibly due to underlying chronic changes of fibrosis. However there is lack of literature regarding comparative studies between the natural course of disease and outcome of patients of AP vis-à-vis that of RAP and ACP.
Aims & Methods: This study was conducted to compare the clinical course and outcomes of patients with AP, RAP and ACP. 248 consecutive patients with diagnosis of AP, RAP or ACP were included during study period. Outcome measures studied were severity, organ failure (OF), persistent organ failure (POF), need for ICU stay, ventilator and hospital stay, need for percutaneous catheter drain (PCD), surgery and mortality.
Results: Out of 248,158 (64%) patients had AP, 45 (18%) patients had RAP and 43 (18%) patients had ACP. 86 (54%) of AP, 4 (9%) of ACP and none of patients in RAP group had severe AP according to revised Atlanta classification (p < 0.001). On comparison of OF, 101 (63%); of whom 54% had POF of AP, 6 (13%); of whom 9% had POF of ACP and none of RAP patients developed OF (p < 0.001). PCD and surgery requirement were seen in 89 (56%) & 9 (6%) of AP, 5 (11%) & 4 (9%) of ACP and none of RAP patients respectively (p < 0.001) as compared to RAP (18.80±14.5±8.82±11.2±3.3±6±4.4, p < 0.001)

P0768 ACUTE PANCREATITIS IN PATIENTS WITH IPMNS: RETROSPECTIVE STUDY OF 346 PATIENTS OBSERVED FROM 2009 TO 2016
L. Brozzi 1, A. Amadio 2, F. De Marchi 3, R. Teresa Marzai 1, I. Breoni 3, P. Campagnola 1, S. F. Cirolo 4, A. Gabbrielli 5, L. Frulloni 5
1 Medicine, AOUI Verona-Pancare Center, Verona/Italy
2Gastroenterology, University of Verona, Verona/Italy
Contact E-mail Address: lorenzo.brozzi89@gmail.com
Introduction: In literature the frequency of acute pancreatitis (AP) in patients with IPMNs varies between 12 and 65%, but most of studies are from surgical series and often pancreatitis occurred after surgery was included. Furthermore, most of the studies includes in the diction of "symptomatic IPMNs" the presence of less severe disorders, such dyspeptic symptoms, making series unclear.
Aims & Methods: The aim of this study was to investigate the correlation between the presence of IPMN and acute pancreatitis, and the frequency of different characteristics from asymptomatic IPMNs patients, evaluate the possible differences between type and localization of IPMNs in occurrence of acute pancreatitis and his disease severity. A retrospective analysis was performed on all observed patients with IPMN-MD, IPMN-BD and mixed type at Gastroenterology Unit in the period between January 2009 and March 2016. In the study patients an instrumental or histological diagnosis of IPMNs were included. Results: Studied 346 patients (164 males and 182 females, mean age at the first report 61.6±12.2 years). At the time of radiological diagnosis, 45% were asymptomatic, 51% had had symptoms, while 4% of the data were missing: the frequency of AP (excluding biliary etiology) of all 346 patients with IPMN was 26%. AP was edematous in 85% of patients and necrotic in 15%. We found increased frequency in patients with PA with IPMN of the main pancreatic duct (MD and mixed), and unifocal type. The localization to the body seems to be more correlated with the presence of AP. The number of cysts (for IPMN-BD and mixed type) was significantly lower in patients who have had AP.
Conclusion: Our medical extraction series confirms that the PA is an event that occurs in 26% of patients with IPMNs, with a prevalence of the male sex, it is associated with an IPMN central and mixed type, predominantly localized to the body. The pancreatitis is not associated with malignancy in resected patients.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0769 APOLIPOPROTEIN B AND A-I RATIO PREDICTS SEVERE ACUTE PANCREATITIS
J. Kin, K. J. Lee
Internal Medicine, Yonsei University Wonju College of Medicine Dept. of Internal Medicine, Wonju/Korea, Republic of
Contact E-mail Address: jawkim96@yonsei.ac.kr
Introduction: Severe acute pancreatitis (SAP) has a considerable mortality and morbidity rate. Although many indices have been developed to classify the severity of acute pancreatitis (AP), there is no ideal method for predicting SAP. The ratio of apolipoprotein B to A-I (apoB/A-I) is associated with metabolic syndrome and inflammatory status.
Aims & Methods: This study aims to investigate the association between severity of AP and serum apoB/A-I ratio. Patients with AP were prospectively enrolled at Yonsei University Wonju College of Medicine from March 2015 to August 2016. The severity of acute pancreatitis was assessed according to the revised Atlanta classification criteria (Atlanta 2012).
Results: Of 191 patients with AP, 134 (70.2%) were classified as mild AP, 42 (22%) as moderately severe AP, and 15 (7.9%) as SAP. The apoB/A-I ratio was highest in patients with SAP compared with those with mild and moderately severe AP (P =0.0001). The apoB/A-I ratio positively correlated with Atlanta classification, computed tomography severity index, and Bedside index for severity of AP. The apoB/A-I ratio showed the highest ability to predict SAP in patients with AP compared with apolipoprotein B or apolipoprotein A-I alone. Conclusion: Serum apoB/A-I ratio appears to have value in predicting SAP in patients with AP.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Scandinavian-Baltic-Pancreatic-Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

Aims & Methods: We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNHEIM diagnostic-criteria were included. Structural changes were graded according to the M-ANNHEIM-classification. A subgroup was also scored by the modified Cambridge score. Clinical data on disease-duration, nutrition, exocrine function, pain, alcohol/smoking habits and frequencies of malnutrition and diabetes were collected. A grouping of the M-ANNHEIM score (A: Normal = 0, B: Minimal change = 1 2 and C: Moderate/marked = 3 4) was performed for correlation to the clinical data.

Results: The database contains 932 patients (623 men). The M-ANNHEIM-score was present from 446 subjects and both imaging scores from 93 subjects. Correlation of the imaging scores: The imaging-scores demonstrated equivocal (22.9%), 2: Mild (12.1%), 3: Moderate (17.9%) and 4: Marked (51.7%). According to M-ANNHEIM subjects were graded as 0: Normal (8.1%), 1: Minimal change (20.3%), 2: Mild (20.3%), 3: Moderate (25.6%) and 4: Marked (25.6%). The correlation to clinical data was poor. Poor agreement in normal/minimal-change groups may reduce the value of grading to the clinical data.

Conclusion: Subjects with marked structural changes had the highest lifetime smoke-doses. There was poor correlation of structural changes to the clinical features. The two imaging scores demonstrated acceptable correlation and agreement. Poor agreement in normal/minimal-change groups may reduce the value of the scores where they are most needed. The results are presented on behalf of the SBPC study group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0771 OSTEOPATHY IS COMMON IN PATIENTS WITH CHRONIC PANCREATITIS, BUT IS NOT RELATED WITH VITAMIN D AND FECAL ELASTASE LEVELS (P-BONE STUDY)

Introduction: In patients with chronic pancreatitis (CP) malabsorption of vitamins D and K, alcoholism, smoking and inflammatory status contribute to low bone mineral density (BMD). A recent meta-analysis estimated the prevalence of osteoporosis (25%) and osteopenia (40%) in CP and highlighted limitations of the reviewed studies.

Aims & Methods: To evaluate the prevalence of osteoporosis and osteopenia in patients with CP and to investigate the correlation between BMD and CP features, and vitamin D and PEI. This is a multicentre cross-sectional study (P-BONE, A Pancreas 2000 project) on prevalent CP patients. The Diagnosis and severity of the disease was defined according to the M-ANNHEIM classification. Clinical information and biochemical variables were recorded; PEI was assessed by fecal elastase. Standardised Osteodensitometry was performed by dual-energy x-ray absorptiometry (DEXA). Categorical variables were analysed by means of Fisher's exact test, and continuous variables by t-test. A logistic regression analysis was performed to identify risk factors for osteoporosis or osteopenia. The relationship between continuous variables was assessed with Pearson correlation coefficient.

Results: 211 consecutive CP patients were enrolled at 6 Centres (67% M; mean age 60 ± 13 years). Osteopenia was diagnosed in 42% and osteoporosis in 22% of cases. Aetiology was alcoholic in 43%, and 18% had severe CP. 56% of patients had PEI. The mean value of vitamin D was 20ng/ml and 56% of cases had vitamin D insufficiency. There was no correlation between vitamin D levels, or elastase levels and t-score at either spine or femur. Alcoholic aetiology was associated with higher risk of having low levels of fecal elastase (p<0.02) and with lower level of vitamin D (p<0.01) but not with osteoporosis or osteopenia. Female sex and older age seems to be associated with a higher risk of developing osteoporosis (OR 4.5 95%CI 2–9.8 p<0.001; OR 1.09 95% CI 1–1.3 p<0.01) while a higher BMI is associated with a reduced risk of its occurrence (OR 0.8 95% CI 0.77–0.94 p<0.001).

Conclusion: The present data confirm a high rate of osteoporosis in CP patients. However, there was apparently no correlation between BMD, pancreatic exocrine function, severity of the disease or vitamin D levels. Other factors, such as vitamin K might deserve investigation for their possible relationship with bone mineral density in CP patients.

Contact E-mail Address: nelly.muller@aphp.fr

Introduction: SPINK1 is a gene coding for the inhibitor of the cationic trypsino- gen. Heterozygous mutations prevalence is estimated at 2%. They are recognized as a risk factor for chronic pancreatitis. However few data are available regarding the natural history and the risk of complications in these patients.

Aims & Methods: A prospective monocentric study was carried out from 2000 to 2016 to describe the natural history of SPINK1 mutation related pancreatitis. All patients referred for idiopathic acute and/or chronic pancreatitis with a SPINK1 mutation, were included and followed annually. Epidemiological, genetic, clinical and morphological data were collected.

Results: We included 158 patients. Mutations of SPINK1 were: heterozygous (65%), homozygous (8%) N34S, others (27%). Median age at first symptoms was 40 years (23–73) and 9 years (3–76). During follow-up (median length:7.4 years), clinical manifestations were pancreatic pain (73%), pseudo-cyst (15%), acute pancreatitis (77%), cholestasis (6%), exocrine pancreatic insufficiency (EPI) (33%), diabetes (15%) and pancreatic adenocarcinoma (n = 6.4%). Calculations and duodenal abnormalities were found in 56% and 62%. Endoscopic treatment and surgery were performed for 16% and 14% of the patients. Four patients died including 3 due to pancreatic cancer). The risk of pancreatic cancer at 55, 60, 70 and 75 years was 9.4%, 14.7%, 28.9% and 46.7%. Risk factors of cancer were calculations (p = 0.03) and EPI (p = 0.04).

Conclusion: SPINK1 mutations should be searched for in young patients with idiopathic pancreatitis. Risk of pancreatic cancer is probably underestimated.
P0773 EXOCRINE FUNCTION, NUTRITION AND ENZYME TREATMENT IN THE SCANDINAVIAN BALTIC PANCREAS CLUB DATABASE - PRELIMINARY DATA

Contact E-mail Address: friedemann.erchinger@helse-bergen.no

Introduction: The Scandinavian-Baltic-Pancreas-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal, B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes.

Clinical parameter (A) (B) (C) Proven
Exocrine pancreatic function (%)

| 33 | 16 | 51 |

Faecal Elasticity (μg/g) (mean (SD)) < 0.001

| 368 (161) | 128 (144) | 51 (69) |

Nutrition: BMI (kg/m2) (mean (SD)) < 0.005

| 24.6(4.9) | 23.7(4.3) | 22.6(4.3) |

Frequency BMI < 18.5 (%) < 0.005

| 5 | 16 |

Vitamin D: Frequency <25nmol/L (%) (I vs II) < 0.005

| 7.4 | 23.7 | 17.6 |

Enzyme Treatment (lipase-units/day) (median [IQ range]) < 0.005

| 00-75000 | 120000 |

Hemoglobin: (median [IQ range]) < 0.05

| 11.8(2.7-3.0) | 10.7(2.8) |

Faecal Elastase and disease duration (years)**

| <10: 143(175) | >10: 91(118) |

p < 0.001. 9% received <50000 lipase-units/day. 14 subjects having FE > 200 received enzymes, 48 subjects with FE < 100 received no enzymes.

**no age/sex differences in EPF

Conclusion: In our material frequency of EPI is higher than reported in the NAPS2 study (31%). Consequences of EPI were lower BMI, more frequent underweight, higher enzyme-doses and lower haemoglobin. Need for vitamin D supplements was highest in the group with mild EPI not receiving enzymes. Exocrine function was correlated with disease duration, but neither with age nor gender.

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ducal alkaline fluid (which is regulated mostly by the anion exchanger and CFTR) is diminished in CP.

Aims & Methods: In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO3− secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water by a smoking machine. Intracellular Ca2+ concentration and pH were evaluated by microfluorometry. Fluid secretion was measured by video microscopy. CFTR currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO3− secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO3− secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na+/H+ exchanger and Na+/HCO3− cotransporter and also forskolin-stimulated Cl− current of CFTR Cl− channel. CSE incubation altered the pattern of carbachol-induced Ca2+ signal in pancreatic ducts suggesting that some of the inhibitory effects may be regulated by calcium signalling.

Conclusion: Cigarette smoking and CSE inhibits pancreatic ductal fluid and HCO3− secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKp.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignant lesions are limited, which shows an evident need to understand the pathomechanism leading to PDAC and find a suitable marker for early detection. Initial processes in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins found primarily in the stomach where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KrasG12D Ptf1aCre (KC) mice, a mouse model with predisposition to pancreatic cancer, revealed strikingly high gastrokine expression. We will further analyze the involvement of GKNs in the development and progression of PDAC and explore the possibility to use them as biomarkers.

Aims & Objectives: GKN2 expression was confirmed by qPCR in human and mouse pancreas samples. The presence of GKN1 was verified by western blot and immunohistochemistry (IHC) in mouse pancreas. Mouse pancreatic juice and serum were analyzed by proteomic analysis. To investigate the role of GKNs in pancreatic carcinogenesis in vivo, we established mouse models by introducing KC mice with Gkn1−/− and Gkn2−/− mice respectively. The capacity of acinar cells lacking Gkn1 and Gkn2 to transdifferentiate into ductal lesions in vitro was tested.

Results: GKNs were upregulated during early stages of pancreatic carcinogenesis in mouse and peri-tumoral human pancreas. GKNs were absent in healthy pancreas and tumor tissue. IHC showed specific GKN1 expression in premalignant PanIN lesions, while GKN2 positive cells were also localized in the stroma. ELISA and proteomic analysis in mice confirmed the secretion of GKNs into pancreatic juice. Preliminary results from the first timepoint of analysis showed accelerated tumor development in Gkn1−/− and Gkn2−/− mice respectively. The capacity of acinar cells lacking Gkn1 and Gkn2 to transdifferentiate spontaneously, and in higher number of ADMs.

Conclusion: We identified for the first time specific gastrokine expression in pre-neoplastic lesions in human and mouse pancreatic tissue. The secretion into pancreatic juice during carcinogenesis could make gastrokine a potential biomarker for the detection of early pancreatic premalignant lesions. With our mouse models we will provide in vivo evidence on the role of GKNs as potential tumor suppressors in the pancreas.

Introduction: Intra- and extra-cellular involvement are lacking and their relationship with the caxxhia is not known. Ezrin is involved in intracellular signaling and adhesion, by linking in the PI3K/Akt pathways.

Aims & Methods: The goal is to assess the significance of activin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n = 124). The plasma levels of Activin A were analyzed using western blot. The t test was used to determine the difference between the two groups. Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: Ezrin protein expression was more frequently in PDAC compared to controls (p = 0.001), and has been closely related to advanced clinical stage (stage III-IV), tumor size, location and with the presence of metastasis (p < 0.05). Activin expression was higher in patients with type 2 diabetes (p = 0.04). No relationship between activin level and the patients age, sex or tumor size, was noted. Patients with activin high expression had a shorter survival time than PDAC patients with activin low expression (Log-rank = 4.35; p = 0.03).

Conclusion: Activin pathway is related to cachexia and the local spread of PDAC, metastasis, the presence of diabetes and survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: FOLLIRINOX (FFX) or nab-paclitaxel plus gemcitabine (GnP) and standard regimens in patients with advanced pancreatic cancer. However, chemotherapy can impair quality of life (QoL) due to adverse events. Because the life expectancy of this population is typically short, QoL is as important as the actual length of life.

Aim(s): The aim of this study was to assess QoL during chemotherapy in patients with advanced pancreatic cancer. Twenty-one Japanese patients with unresectable advanced pancreatic cancer and performance status 0–1 were included in this study. All patients were treated with FFX or GnP as first-line chemotherapy. QoL was assessed using the Japanese Organization for Research and Treatment for Cancer Quality of Life Core Questionnaire (EORTC QLQ- C30), and anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) at baseline and 2 weeks every month after initiation of chemotherapy. Changes at score at baseline and median score after chemotherapy were compared using Wilcoxon signed-rank test. Continuous variables are presented as median (range).

Results: Thirteen male and 8 female patients were included, with a median age of 65 years and BMI of 22.1 kg/m2. The chemotherapy regimens were FFX in 5 men and 2 women, modified-FFX in 4 men and 4 women, and GnP in 4 men and 2 women. Eight patients took opioids for pain, and 4 received celiac plexus neurolysis. Regarding global health status (GHS) and functional scale in QLQ-C30, baseline scores were: GHS: 50 (17–92)%; physical, 87 (53–100)%; role, 83 (33–100)%; emotional, 67 (33–100)%; cognitive, 83 (33–100)%; and social, 67 (11–100)%.

Aim(s): The aim of this study was to assess QoL during chemotherapy in patients with advanced pancreatic cancer. Twenty-one Japanese patients with unresectable advanced pancreatic cancer and performance status 0–1 were included in this study. All patients were treated with FFX or GnP as first-line chemotherapy. QoL was assessed using the European Organization for Research and Treatment for Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30), and anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) at baseline and 2 weeks every month after initiation of chemotherapy. Changes at score at baseline and median score after chemotherapy were compared using Wilcoxon signed-rank test. Continuous variables are presented as median (range).

Results: Thirteen male and 8 female patients were included, with a median age of 65 years and BMI of 22.1 kg/m2. The chemotherapy regimens were FFX in 5 men and 2 women, modified-FFX in 4 men and 4 women, and GnP in 4 men and 2 women. Eight patients took opioids for pain, and 4 received celiac plexus neurolysis. Regarding global health status (GHS) and functional scale in QLQ-C30, baseline scores were: GHS: 50 (17–92)%; physical, 87 (53–100)%; role, 83 (33–100)%; emotional, 67 (33–100)%; cognitive, 83 (33–100)%; and social, 67 (11–100)%.

After chemotherapy, role function scale was decreased significantly (p = 0.04), and nausea (p = 0.02) and diarrhea (p = 0.049) were more frequently observed, while global health status (p = 0.002). In analysis according to patients’ background, a lot of evaluation in patients with BMI < 21 kg/m2 tended to be worse than in those with BMI ≥ 21 kg/m2 after chemotherapy. Regarding HADS at baseline, 5 patients reported depression, 7 borderline depression, 5 anxiety requiring intervention, and 5 anxiety requiring follow-up. There were no significant changes in HADS after chemotherapy.

Conclusion: In patients with advanced pancreatic cancer, GHS and mental status had already deteriorated at baseline. Although pain scale might be improved due to analgesic treatment, role function scale, nausea and diarrhea became worse during chemotherapy. In particular, QoL tended to deteriorate in lean patients. These results indicate that pain as well as QoL factors should always be considered to manage chemotherapy properly in patients with advanced pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
treated by EUS-CPN. Clinical information was obtained retrospectively from the medical charts of patients reporting symptoms associated with the pain until the patient died or was lost to follow-up. Between November 2014 and March 2017, 70 patients with PC pain were enrolled. We performed EUS-CPN by injection of 5 ml of bupivacaine mixed with 15 ml of pure ethanol on the celiac trunk. A contrast endoscopic ultrasound-guided fine needle aspiration needle. Treatment response was assessed by self-reported pain relief and change in the daily dose requirement of morphine. Treatment response was defined as to decrease or stay of the same amount of morphine consumption after EUS-CPN, or achieve morphine dosage level within 4 weeks after EUS-CPN if morphine consumption temporarily elevated because of the delayed response of EUS-CPN. Pain evaluation was conducted at 1 week, 4 weeks, 12 weeks after EUS-CPN and tumor disease progression. Response rate was 81.4% (57/70). The median duration of pain relief was 4 months. 10 patients required a second EUS-CPN due to pain relapse, and 90% (9/10) showed response to the repeat procedure. Of the 44 patients who showed response to the initial EUS-CPN during chemotherapy, the median follow-up after the diagnosis of PC relapse was 16 (14:46) months. Among the response group and non-response groups, there were significant differences in the prevalences of liver metastasis (47 vs. 92%, P = 0.001) and metastasis to the pancreas (20 vs. 37%, P = 0.029). The difference in the serum levels of CEA (median: 6.7 vs. 17.1 ng/ ml, P = 0.017), CA19-9 (median: 617.2 vs. 3519 U/ml, P = 0.009), CRP (median: 0.61 vs. 1.91 mg/dl, P = 0.029) and albumin (median: 3.4 vs. 3.8 g/dl, P = 0.029). Univariate analysis revealed a significantly smaller percentage of patients with CRP level elevation over 3.0 mg/dl from baseline within 4 weeks after EUS-CPN (11 vs. 38%, P = 0.01). The overall survival after EUS-CPN was also significantly longer in the response group compared to the non-response group (median: 5.8 vs. 1.0 months, P = 0.01). Conclusion: Our study demonstrated that EUS-CPN had therapeutic effect on intractable pain in unresectable PC in the long follow-up. Repeat EUS-CPN was also effective in patients who showed a treatment response to the first EUS-CPN. Patients who benefited from EUS-CPN had stronger cancer inflammation and aggressiveness, indicative of higher CRP, CA19-9 and lower albumin levels, and the higher frequencies of liver metastasis.

Treatment efficacy and adverse events of gemcitabine plus nab-paclitaxel used for metastatic pancreatic cancer: a retrospective cohort study

Department Of Internal Medicine, Yonsei University College of Medicine, Seoul Korea, Republic of

Contact E-mail Address: irnae428@yahoobl

Introduction: Pancreatic cancer is a lethal disease and the fifth most common cause of cancer-related death in Korea. Pancreatic cancer patients show dismal prognosis with a 5-year survival rate less than 10%, because the majority of patients are diagnosed in advanced stage. Since the late 1990s, gemcitabine-based chemotherapy has been used as a mainstay of metastatic pancreatic cancer (mPC) treatment and various combination therapies (such as combination with capetebine or erlotinib) had been attempted to improve the patients’ survival, so far. Recently, MPACT trial, a randomized phase III trial showed that combination of gemcitabine and nab-paclitaxel had statistically significant survival benefit compared with gemcitabine monotherapy. Based on the results of this trial, gemcitabine with nab-paclitaxel combination therapy is currently being used as a standard therapy for pancreatic cancer patients. However, only 2% of the MPACT trial study population was Asian, and other researches on Asian population group are also lacking. Therefore, we investigated treatment efficacy and safety of gemcitabine plus nab-paclitaxel combination therapy for mPC treatment in Korean population.

Aims & Methods: Total 66 metastatic pancreatic cancer patients treated with gemcitabine (1000mg/m²) and nab-paclitaxel (125 mg/m²) regimen (on day 1, 8, 15 of a 28-day cycle) as the first line chemotherapy from February 2016 were identified using the Severance Hospital Pancreatic Cancer Cohort Registry. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate) and treatment-related adverse events (AE) of patients (occurrence rate, severity grade and dose intensity) were analyzed.

Results: The median follow-up period was 7.4 months (range 1.5–14.9 months); during this period, 21 (31.8%) patients died. Median cumulative dose of gemcitabine and nab-paclitaxel were 13,000 mg/m² and 1487.5 mg/m². The median OS, PFS and objective response rate were 12.0 months (95% confidence interval [CI] 9.515–14.485), 7.8 months (95% CI 5.021–10.579) and 48.5%, respectively. The incidence of neurotoxicity was 54.5% and 12 (18.2%) patients experienced grade ≥ 3 neurotoxicity. 30 (45.5%) patients showed grade ≥ 3 neutropenia and 10 (15.2%) patients had febrile neutropenia. Grade ≥ 3 gastrointestinal AE was observed in 11 (16.7%) patients and 26 (42.4%) patients experienced dermatological AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

Conclusion: These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in East-Asian population group. Similar to previous studies, this combination therapy showed remarkable neurotoxicity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

Impact of preoperative EUS-FNA on peritoneal recurrence and survival in patients with pancreatic cancer

Gastroenterology, Samsung Medical Center, Seoul Korea, Republic of

Contact E-mail Address: ilonaelona@hanmail.net

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is a useful and safe method for tissue confirmation of malignancy. This method has improved the tumor needle placement along the needle track or within the peritoneum by preoperative EUS-FNA.

Aims & Methods: The aim of our study was to estimate the risk of peritoneal recurrence and the impact on long-term outcomes by preoperative EUS-FNA in resected pancreatic cancer. The records of patients diagnosed with pancreatic cancer who underwent curative resection between 2009 and 2013 were reviewed retrospectively. A total of 394 patients were included: 78 patients with preoperative EUS-FNA (EUS-FNA group) and 316 without preoperative EUS-FNA (Non-EUS-FNA group). Peritoneal recurrence was diagnosed based on images findings.

Results: Median length of follow-up was 23 months (range 1–94 months). A total of 82 patients had peritoneal recurrence; 34.6% (27/85) in EUS-FNA group vs. 28.2% (89/316) in Non-EUS-FNA group (P = 0.26). Cancer-free survival and overall survival were not different between the groups: median cancer-free survi- val in EUS-FNA group was 10.8 months compared with 10.6 months in Non-EUS-FNA group (P = 0.83), and median overall survival in EUS-FNA group was 56.4 months compared with 56.7 months in Non-EUS-FNA group (P = 0.93).

Conclusion: Preoperative EUS-FNA for pancreatic cancer was not associated with an increased rate of peritoneal recurrence and mortality. Our study suggests that EUS-FNA is a safe method for obtaining tissues of pancreatic masses.

Disclosure of Interest: All authors have declared no conflicts of interest.

hENT1-positive patients (MST: 25 versus 25, respectively). We suspect that genetic factor may contribute to this observation variability.

Aims & Methods In the present study, we evaluated hENT1 and dihydroxyri-
dine dehydrogenase (DPD: enzyme involved in the degradation of tegafur) expression in EUS-FNAB samples for evaluating and predicting the clinical efficacy of 5-FU treated patients. EUS-FNAB samples were obtained prior to GS-CRT administration. In total, 95 formalin-embedded PDAC speci mens were obtained. In the samples determined to have sufficient material remaining following cytological/histological examination (n = 76), hENT1 expression was evaluated via immunohistochemical (IHC) examination. An additional DPD analysis was performed in those samples determined to have sufficient material remaining (n = 58).

Results By reusing the EUS-FNAB specimens after diagnosis of PDAC, hENT1 and DPD expression could be successfully assessed in 79.2% (76/95) and 61.1% (58/95) of these cases, respectively. In those sufficient for hENT1 testing, 67.1% (51/76) were found to be positive. And in those sufficient for DPD testing, 27.6% (16/58) were found to be positive. MST was significantly longer in hENT1-positive patients (MST = 33.4 months, P < 0.001), compared to hENT1-negative patients (MST = 15.5 months, P < 0.001). As for DPD, MST was significantly longer in DPD-negative patients (33 months versus 14 positive, P < 0.001). In the multivariate model including pretreatment clinical factors (age, sex, tumor location, tumor size, UICC-T classification, hENT1 expression, and DPD expression) and the clinical response after GS-CRT (response of GS-CRT, reduction rate in serum CA19-9 level, and distant metastasis after GS-CRT), only hENT1 expression (HR = 3.51; 1.545–7.981, P = 0.003) and DPD expression (HR = 0.232, 0.108–0.496, P < 0.001) were found to be significant independent prognostic factors.

Conclusion hENT1 and DPD expression observed in EUS-FNAB samples can be useful clinical predictors in PDAC cases treated with GS-CRT.

Introduction: Intraductal Papillary Mucinous Neoplasms (IPMN) require a close follow-up with early detect worrisome features, which imply a pejorative evolution towards dysplasia and surgery. However, some patients are symptomatic including post-prandial pancreas related abdominal pain (PPAP) or recurrent acute pancreatitis (RAP). An accurate diagnostic is currently not done if no symptoms are risk factor of cancer in IPMN, and there are no data about the efficacy of endoscopic sphincterotomy (ES) to manage them.

Aims & Methods This was a retrospective multi-centered observational study in 4 tertiary endoscopy units of 27 patients that underwent ES for symptomatic IPMN without worrisome features nor surgical indication were considered. Six were excluded (4 lack of data; 1 pseudocyst; 1 adenocarcinoma), thus 21 were analyzed. Age, sex, medical history, time of follow-up, characteristics of IPMN and ERCP procedure, clinical success, evolution and need for surgery was recorded. The primary endpoint was to assess the efficacy of ES for improving the symptoms of pain related to IPMN. The efficacy was defined as the resolution or the decreasing > 50% of the symptoms’ frequency. The secondary endpoint was to document the need for a second ES, the occurrence of WF during follow-up, the need for surgery and its indications.

Results There were 10 men and 11 women involved, with a mean age of 66 years old [45–87] and a mean total follow-up of 105 months [17–276]. Their symptoms were PPAP in 6 patients and RAP in the 15 others (5 being severe AP), with a mean of 3.6 episode/year [1–12]. The delay between diagnosis and ES was 41 months [1–192] and the patients were followed by MRI (81%), EUS (95%) CTscan (36%) or by alternating (MRI and EUS) for 45%. The IPMN were involved in a pancreatico-biliary duct in 11 patients (52.4%), a main pancreatic duct < 7 mm. The mean number of cysts was 3.5 [1–10], the largest measuring 12.7 mm [5–25] mean. They were located for 59% in the head, 17% in the body or tail, and they were diffuse in 24%. None patient had a normal endoscopy- ERC performed in 13 cases (95% of the cases with 5 pancreas divisum, 2 pre-cut required), associated with a biliary ES in 33% of the cases. A prophylaxis with NSAIDS was carried out in 38% of the cases and a plastic stent placement in 33%. There were 4 post-ERC benign pancreatitis, and the mean follow-up after ES was 54 months [13–167]. The clinical efficacy rate as defined after one session was 81% (17/21). Among them, one had a late recurrence (41 months) and underwent a second ES session with final success, whereas 4 have been operated (2 for initial pain, 2 for WF). Among the patients whom failed (4/21), one had a second ES with final success (2 months after surgery), thus 5 finally had surgery. The two groups were comparable in terms of age, sex, mean follow-up time, and characteristics of IPMN. The final efficacy of ES was 86% (19/21). In total seven patients were operated after a mean of 19 months of follow-up, 24% if success of ERCP and in 75% if failure. The indications (e.g., RAP WF (n = 4) or pain (n = 3)). The histopathology showed four low-grade dysplasia, one high-grade dysplasia, and two no dysplasia (=surgery for pain). No patients evolved towards adenocarcinoma in the follow-up.

Conclusion ES for symptomatic IPMN without WF is effective in 81% of the cases. The number of ES is to be considered for an efficacious indication for surgery, since no patients developed with cancer after a follow-up greater than 5 years.

Aims & Methods: In this study, we aimed to overcome the subsampling issue and to establish a more reliable framework for quantification of rare tumor cell-derived mutant alleles for non-invasive diagnosis of gastrointestinal cancer. To establish more reliable ddPCR protocol for quantification of low-frequency alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight clinically relevant mutant KRAS variants was examined using a Bio-Rad QX200 droplet digital PCR platform. Plasma samples from patients with colorectal cancer (n = 10) and pancreatic cancer (n = 9) were evaluated, and cfDNA from healthy volunteers (n = 30) was utilized to calculate reference intervals.

Results: Limited cfDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of rate mutant alleles by ddPCR. To overcome the subsampling issues and concurrent chemo-radiation therapy (CCRT), we applied the technique of long pre-amplification cycles followed by a second-run ddPCR to sufficient approximatively 5000–10,000 target alleles/ng cfDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background presented by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant KRAS was determined to be ~0.09% based on samples from healthy individuals.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic KRAS, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Introduction: Benefit of second line chemotherapy (SL) after failed first-line chemotherapy in advanced pancreatic cancer has not yet been established. We intend to identify prognostic factors and ultimately devise a model of clinical parameters for decision of SL versus basic supportive care (BSC) after failure of FL chemotherapy.

Aims & Methods: 408 patients who received gemcitabine-based first-line chemotherapy for advanced pancreatic adenocarcinoma at Yeouido University Hospital between January 2010 and December 2014 were retrospectively reviewed. Significant clinical parameters regarding second line related survival were identified using predictive factor models.

Results: 161 of 408 (39.5%) received SL therapy. Median overall survival from the beginning of SL (OS2) was 20.0 weeks (14.0 – 34.0). Significantly more SL patients presented higher body mass index (BMI) (p = 0.001) and ECOG 0 – 1 (p = 0.003) at diagnosis, lower rate of lung metastasis (p = 0.001) and longer duration of FL (p < 0.001). More SL patients had received gemcitabine-based concurrent chemo-radiotherapy (CCRT) (p = 0.029) compared to FL only patients. Prognostic factors significant to OS2 were BMI at diagnosis (p = 0.019, HR = 0.870), duration of FL therapy (median duration 16weeks (8.0–28.0) p = 0.004, HR = 0.986), presence of peritoneal metastasis (p = 0.002, HR1.732) at diagnosis, malignant thrombotic event during first-line chemotherapy (p = 0.001, HR = 0.428). Experience of CCRT was also a significant prognostic factor (p = 0.001, HR = 2.245); initial staging of the CCRT group was TNM stage3, which might be the ultimate factor impacting OS2.

Conclusion: Study suggests that SL chemotherapy may be beneficial for patients with longer duration of FL chemotherapy, higher BMI at diagnosis, patients without peritoneal metastasis at diagnosis, no malignant thrombosis event during chemotherapy and patient initially TNM stage3, who received Gemcitabine based CCRT.

and antifibrotic properties. Increasing evidences point out MSC action via subcellular extracellular vesicles (EVs). MSC EVs recapitulate the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in the Duodenal Mucosal Resurfacing (DMR) procedure in a single-arm, open-label, multicenter study.

Aims & Methods: In this endoscopic DMR procedure, the duodenal mucosa was treated with hydrothermal ablation using a patented balloon catheter. Efficacy was analyzed in a modified intent-to-treat cohort (mITT, patients who received ≥1 ablation) stratified into baseline alanine aminotransferase (ALT) level tertiles — lowest (ALT < 28 U/L), middle (28 ≤ ALT < 37 U/L), and upper (ALT ≥ 37 U/L). For each subgroup, HOMA-IR, HbA1c, and ALT reductions were compared to baseline. All results are expressed as mean (95% CI).

2AMC-UvA Dept. of Vascular Medicine, Amsterdam/Netherlands

Introduction: Type 2 diabetes mellitus is a common disease with a high prevalence and mortality. Fatty liver disease are highly prevalent, often overlapping metabolic disorders where upstream insulin resistance is thought to be a common pathogenic driver. Simultaneous treatment of both conditions has been reported with insulin sensitizing interventions including lifestyle, medications, and endoscopic procedures. Here we report the 12-month follow-up of a single procedure duodenal mucosal resurfacing (DMR) for patients with type 2 diabetes.

Peroral administration of rebamipide in addition to proton pump inhibitor (PPI) was reported to be effective to promote ulcer healing after endoscopic submucosal dissection (ESD). In this pilot study, we assessed the efficacy and safety of a novel rebamipide solution as a submucosal injection agent for ESD using in vivo porcine models.

**Aims & Methods:** The protocol was approved by the ethics review board of our animal experimental laboratory in advance (13055 -(0)). ESDs of about 30 mm in diameter were performed at four sites in the stomachs of three pigs. An endoscopic submucosal dissection (ESD). In this pilot study, we assessed the efficacy and safety of a novel rebamipide solution as a submucosal injection agent for ESD using in vivo porcine models.

**Introduction:** ESD is the standard treatment for early gastric cancer and less invasive procedure compared with gastrectomy. Proton pump inhibitors (PPIs) have been widely used for the treatment of ESD-induced gastric ulcers. Many studies have reported that it is critical for ESD procedure to prevent postoperative bleeding. Vonoprazan, a potassium-competitive acid blocker (P-CAB), has a strong and continuous inhibition of gastric acid secretion, and is expected to improve effectively ESD-induced gastric ulcerations compared to the treatment with PPIs.

**Aims & Methods:** To determine whether vonoprazan can ameliorate more effectively ESD-induced gastric ulcerations and can reduce the incidence of postoperative bleeding than PPIs, we compared healing rate of ulcerations and bleeding incidence in the patients treated with vonoprazan with those treated with PPI. 139 patients who underwent ESD between January 2015 and December 2016 were enrolled in Nippon Medical School Hospital. 11 patients who were injected triamcinolone into mucosa preventing stricture of the prepylorus were excluded. 59 patients were treated with P-CAB for 4 weeks (P-CAB group) and 69 patients were treated with PPI (4 omeprazole, 22 esomprazole, 11 lanoprazole or 32 rabeprazole) for 4 weeks (PPI group), and subsequently underwent endoscopic evaluation for evaluation of ulcer size and intra gastru muscle area. The ulcer areas were approximated by multiplying the length (mm) by the width (mm).

**Results:** The results of vonoprazan and PPIs were different significantly (p = 0.0189) different between P-CAB and PPI groups. The post-ESD bleeding incidence (6.8%) in the P-CAB group were not significantly different (p = 0.0189) different from that (5.8%) in the PPI group. The intra gastric pH at 4 weeks after ESD in the P-CAB group was significantly higher than that in the PPI group (6.9 ± 1.0 vs 6.1 ± 1.9, respectively, p = 0.0028).

**Conclusion:** Vonoprazan is superior to PPI in acid suppression, but there were no significant differences in ulcer healing and bleeding incidence between the two groups.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**INTRODUCTION:** Endoscopic submucosal dissection (ESD) permits en bloc resection for large lesions. The number of the patients taking anti-thrombotic agents including low-dose aspirin (LDA) has increased. The Japanese guidelines recommended endoscopic procedures without interruption of LDA therapy in patients at high risk of thrombotic events who use LDA alone. And, bile acid reflux is known to cause gastric mucosal damage though the exact mechanisms are still unclear.

**Aims & Methods:** In this study, we aimed to clarify whether LDA treatment and gastric bile acid contents synergistically affect on postoperative bleeding and histopathology of ulcer after ESD procedure. A total 224 patients with gastric neoplasms were treated with ESD at Nippon Medical Hospital, between January 2013 and June 2016. To investigate whether anti-thrombotic agents increase the delayed bleeding rate, we retrospectively investigated the delayed bleeding rate in 153 patients receiving antithrombotic therapy with 512 patients without that. Furthermore, we compared the delayed bleeding rate in the patients taking antithrombotic therapy with that in the patients with cessation of antithrombotic therapy or with heparin bridge therapy. The patients who were discontinuing antithrombotic agents were treated with continuation of aspirin or clopidogrel. The cessation period of antithrombotic therapy before ESD followed the guidelines for therapeutic endoscopy in antithrombotic agents-users from Japan Gastrointestinal Endoscopy Society. We defined delayed bleeding as a hematemesis, a melena, or a decrease of Hb > 2 g/dl.

**Results:** The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7% (29/512)) (p = 0.0007). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.4 ± 4.6 days and 7.0 ± 6.8 days, respectively, without significant difference (p = 0.48). Of 153 patients taking aspirin (A), 147 continued antithrombotic therapy (A and all of them were antiplatelet drugs) during ESD (continuation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference (p = 0.63). The delayed bleeding rate of continuation group was not different from cessation group (p = 0.57). The delayed bleeding rate of heparin bridge group seemed to be high (20.0%), but there was no significant difference compared to that of total number of cessation and cessation group (13.1% (16/122), p = 0.24). Deep vein thrombosis was observed in one patient in the cessation group.

**Conclusion:** Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients continuing antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy. Therefore, it is inappropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** LDA increased gastric bile acid contents, which delayed the ulcer healing and increased the bleeding after ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

esophageal squamous cell carcinoma at the endoscopic center of Xinqiao Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal tissues were immediately placed on a ‘ulcer surface’ by hemoclips and then fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

Results: En bloc ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophageus mucosa were successfully transplanted to ‘ulcer surface’ using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median of 8.6 days with a graft survival rate at 93.06%. Postprocedural stricture accompanied by dysphagia occurred in seven patients on post-procedure day 24.7 (range, 18–34 days). The median sessions of EBD and intraluminal steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as immediate bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: Transplantation of autologous esophageus mucosa appears to be a safe means of relieving the severity of esophageal stenoses following circumferential ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

2. Hochberger J, Koehler P, Wedi E, Gluer S, Rothstein RI, Niemann H, 2012; and after endoscopic procedure (n = 1). Location of the fistulas: cardia (33%), gastroesophageal junction (33%), cardia (16%), antrum (8%), esophagus-jejunal anastomosis (6%) and duodenal bulb (6%). Overall clinical success rate was achieved in 72.2% (n = 13). Fistulas were successfully closed in both non-surgical cases. Regarding post-surgical fistulas (n = 16), 50% (n = 8) were after bariatric surgery. There was a clinical success rate of 68.8% (n = 11). The median time between surgery and the endoscopic intervention was 20.5 (2–550) days. There was no association between clinical success and the time between surgery and the endoscopic intervention (p = 0.624) or the location of the fistula (p = 0.334). In 1 case, endoscopic re-intervention with placement of OTSC was required due to persistence of fistula. In 5 (31%) cases the OTSC was not effective, requiring endoscopic re-intervention with stent placement (n = 2) or surgical intervention (n = 3). The overall recurrence rate was 11% (n = 2).

Conclusion: OTSCs can be safely and effectively used in patients presenting with post-surgical fistulas or perforations and, when feasible, may be more advantageous and less costly than surgery. Further research is required to characterize the determinants of long-term success and risk factors for failure. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early neoplastic lesions in Barrett’s Esophagus (BE) can be effectively and safely removed by endoscopic resection (ER) using multi-band mucosectomy (MBM). Recently a new MBM device became available, designed for improved visualization, easier passage of accessories, and better suction power compared to other marketed MBM devices.

Aims & Methods: This study aims to document performance of the new MBM device for ER of early neoplastic lesions in BE.

This is a company sponsored, international, multicenter, single-arm, prospective registry study enrolling 300 subjects with early neoplasia in BE. Primary endpoint is successful ER defined as complete resection of the delineated target area in one procedure. Secondary outcomes: adverse events, procedure time.

Results: To date 259 subjects have been enrolled at 14 centers (Europe 10, US 3, Canada 1). Mean age was 67 ± 9 years, with 87% males. In these 259 subjects, a total of 301 lesions were removed using the new MBM device, with a mean of 2.5 ± 1.9 resections per procedure. Indication for ER was high-grade dysplasia (HGD) in 65%, early adenocarcinoma in 20%, visible lesion with low-grade dysplasia in 10%, and a visible lesion suspicious for neoplasia without pre-treatment histology in 5%. The primary endpoint of successful ER of a target lesion

United European Gastroenterology Journal 5(5S)
was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 ER procedures (1.01%). CI 0.21% – 3.89%. Two perforations were closed with clips, all three patients received intra-venous antibiotics and were admitted to hospital for 2, 3 and 9 days. Bleeding requiring intraprocedural hemostasis occurred during 15% of procedures. Significant post-procedural bleeding requiring intervention was seen in 5 cases (2%). Dysphagia requiring endoscopic dilatation occurred in 7 patients (3%), after ER with a mean number of 4 ± 2.9 resected pieces. Mean total procedure time for ER using the new MBM device was 33 ± 17.1 minutes.

Conclusion: The new MBM device used in this study proved to be effective for resection of early neoplastic lesions in BE: successful ER was achieved in 96% of procedures. Perforations were seen in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

Disclosure of Interest: All authors have declared no conflicts of interest.

towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remained unclear whether endoscopic management of FBs under general anaesthesia could improve endoscopic outcomes when compared with topical pharyngeal anaesthesia.

**Aims & Methods:** The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anaesthesia methods of endoscopic intervention in population with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

**Results:** Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31–63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency dysphagia (415 cases, 32.1%), foreign body sensation (340 cases, 26.3%) and sore throat (267 cases, 20.1%). The duration of FB impaction ranged from 4 hours to more than 2 years with a median time of 1.63 (3.3) days. Pony FBs, jubae pt, food bolus and dentulous pros thesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n = 1025, 85.9%), especially in the upper oesophagus (n = 702, 59.5%), followed by stomach (n = 95, 8.1%), duodenum (n = 36, 3.0%) and pharynx (n = 24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (356 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 29.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased (p < 0.001). Furthermore, complication rate significantly increased with time (p < 0.001). Age (OR = 1.15, 95%CI: 1.20–1.91, p < 0.001), type and location of FBs (OR = 4.51, 95%CI: 2.95–6.90, p < 0.001; OR = 2.26, 95%CI: 1.48–3.46, p < 0.001), anaesthesia methods (OR = 1.35, 95%CI: 1.05–1.75, p = 0.02) and duration of FB impaction (OR = 1.74, 95%CI: 1.50–2.0, p < 0.001) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anaesthesia could not improve FB detection rate (p = 0.181) or success rate of endoscopic management of FBs (p = 0.135), as well as decrease the complication rate when compared with topical pharyngeal anaesthesia (52.3%. VS 47.5%, p = 0.033).

**Conclusion:** FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with topical pharyngeal anaesthesia. Overall, Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0810 CLINICAL OUTCOMES AFTER ENDOSCOPIC RESECTION FOR ESOPHAGEAL SQUAMOUS CELL CARCINOMA COMPARING THE CASES WITH MM AND SM1 INVASION**

S. Yoshinuzu1, T. Yoshio2, K. Namikawa2, A. Ishiyama2, T. Tsuchida3, J. Fujisaki2

1Cancer Institute Hospital, Tokyo/Japan

**Introduction:** Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SM1 invasion. As MM/SM1 invasive cancer is reported to have 8–20% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For these patients, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients’ condition.

**Aims & Methods:** To know the difference of metastatic risk and long time outcomes, we retrospectively studied 121 cases of ESCC with pathological MM/SM1 invasion (MM/SM1:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

**Results:** Enrolled cases included 112 males and 9 females and their median age was 66 (39–86). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by re-EMR and 1 case by APC, resulting in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 12 cases (10.0%). Additional therapy was performed in 15 cases (15.5%) (ope/CRT/RT/9/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SM1, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 9 cases (37.5%) (ope/CRT/RT/chemotherapy: 3/4/1/1). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different for each other. The frequency of LVI was significantly higher in SM1 than in MM (p < 0.05) and the frequency of DI was higher in SM1, although not significant (p = 0.161). The metastatic recurrence was observed significantly frequent in SM1 than MM (16.7% vs 2.1%; p < 0.001). The 5-year overall survival (OS)/disease specific survival (DSS)/relapse free survival (RFS) were 81.7%/100%/94.1% for MM and 62.9%/87.9%/91.7% for SM1. OS and RFS were not different for each other, however, CSS was superior in MM than in SM1 (p < 0.01).

**Conclusion:** ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SM1 invasion, although we treat MM/SM1 in the same way. Additional therapy should be considered more positively in cases of SM1 than in cases of MM, considering metastatic risk and patients’ conditions.

**P0811 GASTRIC ESD IN AN ANIMAL SURVIVAL MODEL USING THE ANUBIS-SYSTEM**

J. Bernhardt1, H. Steffen2, P. Koehler2, S. Schneider-Kortath2, K. Ludwig2

1Dept. Of Endoscopy, Klinikum Suedstadt Rostock, Rostock/Germany
2Dept. Of Endoscopy, Klinikum Suedstadt Rostock, Rostock/Germany

Contact E-mail Address: joern.bernhardt@kliniksued-rostock.de

**Introduction:** ESD in general is still under evaluation. The one-piece resection of lesions larger than 2 cm has many advantages against piece meal resection. One problem in ESD is to lift and prepare the specimen simultaneously. We used the ANUBIS-system for intragastric ESD.

**Aims & Methods:** The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubisscope (Carl Storz, Germany). After insertion of the scope insufflations were made with the two arms of the scope using a gaspaser and a hook-knife. After the opening of the valves at the tip of the scope, an area of 5 cm in diameter was selected for resection. Injection was done through the working channel with a hyperosmolaric solution added with blue colour. After circle incision, preparation was done with the two arms of the scope using a gaspaser and a hook-knife. Also the gaspaser could be used for coagulation. The specimen was removed with the scope after closing its valves.

**Results:** The procedure was successful in all animals with operation time ranging from 102 to 189 minutes with a learning curve. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent healing with a star-like scar.

**Conclusion:** The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER**

T. Morinushi

Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatsu@yahoo.co.jp
Introduction: Narrow band imaging with magnifying endoscopy (NBI-ME) is used for gastric cancer; however, whether NBI-ME is as a screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

Aims & Methods: We aimed to determine the usefulness of NBI-ME as a screening test for gastric cancer. We retrospectively studied 3515 patients who had undergone screening upper gastrointestinal endoscopy between April 2013 and March 2014. We excluded patients with advanced gastric cancer and those who had undergone gastrectomy. Thus, we studied 1080 patients who received NBI-ME and 2435 patients who had undergone conventional endoscopy. We classified the degree of atrophy of the background gastric mucosa using the Kimura-Takemoto classification. Severe atrophy was noted in 1620 patients (Group S), and mild atrophy in 1895 patients (Group M). We evaluated the biopsy rate, the detection rate of gastric neoplasms, and the accuracy of biopsy using NBI-ME compared to conventional endoscopy.

Results: The biopsy rate of NBI-ME and conventional endoscopy in Group M was 5.4 and 7.7%, respectively, while in Group S it was 14.9 and 14.8%, respectively. The biopsy rate did not differ significantly between those who received NBI-ME and those who had undergone conventional endoscopy. The detection rate of gastric neoplasms using NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S (p < 0.01). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S it was noted to be 36.4 and 14.1%, respectively. Thus, the rate of biopsy using NBI-ME is significantly superior to conventional endoscopy in Group S (p < 0.01).

Conclusion: NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

cardiovascular diseases [5]. Thus, the verified risk prediction model of post-ESD bleeding may be able to determine preventive therapeutic options and restarting date of antplatelet agents.

Aims & Methods: The aim of this study is to develop the predictive risk model of post-ESD bleeding. A total of 3574 patients, who were taken ESD from January 2007 to December 2017 in a Korean tertiary hospital, were included in this retrospective study. To avoid overfitting of the prediction model, we divided the patients randomly into two groups, either a derivation group or a validation group. Preoperative and procedural-related variables were selected via univariate and multivariate analysis. A risk score was calculated to assess the bleeding prediction model of a patient in the derivation group and was discriminated in the validation group.

Results: Post-ESD bleeding occurred in 248 patients (6.9%). In the derivation group, the model showed good discrimination (C-statistic = 0.72). In the validation group, the model also showed good discrimination (C-statistic = 0.67). In the validation group, the model also showed good discrimination (C-statistic = 0.67). In the validation group, the model also showed good discriminatory power (C-statistic = 0.58; 95% CI, 0.53–0.62). Based on the scoring system of odds ratio, bleeding risk was 4.1% in the low risk set (score ≤ 4), 7.0% in the high risk set (score > 4, P = 0.003) (validation set).

Conclusion: Our study investigated a prediction scoring system of estimating the bleeding risk, including the patient, endoscopist factors. A risk score can be calculated before the procedure and the endoscopists can predict bleeding potency before the gastric ESD. Based on the scoring system, endoscopists may alter therapeutic plans such as prolongation of admission dates or medicare schedules.

Introduction: Endoscopic diagnosis of early gastric cancer (EGC) is essential for ESD. However, it was difficult to diagnose EGC precisely using blue light imaging. Therefore, we determined the diagnostic efficacy of blue light imaging used for ESD using a novel light source. We compared diagnostic accuracy to LED-BLI-ME, the LED blue light imaging system for endoscopic diagnosis of early gastric cancer.

Methods: We prospectively evaluated whether blue light imaging with another light source (LED-BLI-ME) could be as efficient for diagnosis of EGC as blue laser imaging with magnifying endoscopy (BLI-ME). 43 patients with 45 tumorous lesions including 28 well-differentiated adenocarcinomas, two moderately differentiated adenocarcinomas, six poorly differentiated, and five adenosquamous were enrolled in this study. Our study was conducted at Department of Gastroenterology, Osaka City General Hospital, Osaka, Japan from July 2017 to November 2017.

Results: The diagnostic accuracy of LED-BLI-ME for EGC was 85.1% (95% CI: 76.7–91.1) and that of BLI-ME was 91.1% (95% CI: 85.2–95.1) (P = 0.36). The diagnostic accuracy of LED-BLI-ME for EGC was 91.1% (95% CI: 85.2–95.1) and that of BLI-ME was 91.1% (95% CI: 85.2–95.1) (P = 0.36). The diagnostic accuracy of LED-BLI-ME for EGC was 91.1% (95% CI: 85.2–95.1) and that of BLI-ME was 91.1% (95% CI: 85.2–95.1) (P = 0.36). The diagnostic accuracy of LED-BLI-ME for EGC was 91.1% (95% CI: 85.2–95.1) and that of BLI-ME was 91.1% (95% CI: 85.2–95.1) (P = 0.36).

Conclusion: LED-BLI-ME was as efficient as BLI-ME for diagnosis of early gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0818 RISK FACTORS OF COMPLICATION RELATED TO ENDOSCOPIC MANAGEMENT OF FOREIGN BODIES IN THE ESOPHAGUS: A PROSPECTIVE STUDY IN 595 CASES FROM MULTIPLE CENTERS IN CHINA**

L. Wang, L. Wang
The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Contact E-mail Address: wanglj76@hotmail.com

Introduction: Foreign bodies (FBs) ingestion is a common medical emergency accounting for 4% of all emergency endoscopies, secondary only to the GI bleeding. 70% – 75% of FBs are located in the esophagus[3]. The need of endoscopic management reached up to 63 – 76%[4,5,13] with 3% – 20% of incidence of complications[3]. According to the latest guidelines from ESGE, emergent endoscopy is recommended for the impaction of sharp-pointed objects within 24 hours[4,5]. However, there were still different opinions on the endoscopic methods with different FBs.

Aims & Methods: The study was performed from October 2015 to August 2016 among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.

Results: 1) The most common types of foreign bodies were fish bones (34.0%), chicken bones (22.1%), fruit nucleus (17.1%) and food bolus (14.6%). The majority of them were short objects (< 2.5 cm), 74.0% subsequently followed by middle objects (2.5 – 6.0 cm, 24.5%) and long objects (> 6 cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (19.6%) and distal segment (8.9%) of esophagus. 2) 96.3% of all cases had obvious clinical symptoms. Clinical symptoms occurred more often in the proximal segment of the esophagus (98.1%) than any other segments of the upper gastrointestinal tract (92.6%) (P < 0.001). 3) The successful removal rate through endoscopy was 94.5%. It was even higher with general anesthesia (99.3%) than without it (92.7%) (P < 0.01). 4) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects (P < 0.001). The rate was increased by 2.2- and 6.1-folds after impacted for over 48 hours as compared with less than 24 hours. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97–5.74). In particular, the incidence of bleeding[5] was difficult compared to 0-IIa in WLI, IC and BLI-brt mode. However, LCI color enhancement of the diffuse redness by LCI was useful for the diagnosis of infection. Therefore, we expected that LCI facilitate the endoscopic recognition of early gastric cancer and gastric adenoma by enhancing its color difference between normal and atypical mucosa.

**P0819 BIOPSY STRATEGIES FOR ENDOSCOPIC SCREENING OF PRE-MALIGNANT GASTRIC LESIONS**

Z. Neng
Department Of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China

Contact E-mail Address: zm1990morphone@163.com

Introduction: GA and IM are detectable precursor lesions of most gastric carcinomas. Early endoscopy examination may potentially result in early detection and treatment of advanced precursor lesions and cancer. The annual incidence of GA and IM in China, Europe, for GAs IM was 0.1% and for IM was 0.25%.[4,5] The histological assessment and biopsy sampling protocol has been standardized in the updated Sydney system and the recommended five gastric biopsies were widely applied in the staging system for gastric cancer risk stratification[6,7]. Some believe that the GA risk screening requires consideration of the cost, suffering of patients as well as rational utilization of medical resources, so adopt five biopsy may be presumably less appropriate in large-scale population gastric cancer risk screening. In this study, we evaluated the OLGA and OLGIM staging in a standardized five biopsy protocol through screening patients underwent endoscopy with abdominal pain and discomfort. In order to identify a more optimal biopsy strategy with quite high consistence with the standardized five biopsy protocol in OLGA and OLGIM staging and less number of biopsies during cancer risk assessment, we re-evaluated OLGA and OLGIM staging adopting different biopsy combinations (evaluated the appropriate biopsy locations and number of biopsies).

Aims & Methods: Gastric atrophy (GA) and intestinal metaplastic (IM) are precursor lesions of gastric cancer (GC), the extent and severity of which was intimately correlated with the occurrence of GC. Operative Linkon Gastritis Assessment (OLGA) and Operative Linkon Gastric Intestinal Metaplasia Assessment (OLGIM) with five biopsy samples are superordinate stages system during gastric risk stratification. We analysis the degree of GA and IM in these five locations and screen out an more representative, simple and convenient biopsy samples composition for gastric risk screening.

Methods: 368 patients with abdominal pain and other discomfort undergoing endoscopy were enrolled in the study. Five biopsy pieces (two from antrum, namely lesser to the left of the pubes, and larger curvature of corpus, larger and lesser curvature and one from incisura angularis) were acquired and graded by senior gastrointestinal pathologists according to the updated Sydney system. Gastric risk stratification was calculated by adopting OLGA and OLGIM staging system.

Aims & Methods: GA and IM are the most frequently acquired in the incisura angularis mucosa than the both lesser and larger curve of antrum and corpus respectively (P <0.05), especially the moderate and severe degree. More GA and IM alternations happened in the lesser curve of the antrum and corpus than in the corpus (P < 0.05) in the composition of incisura angularis (antrum and corpus, angular biopsy) with quite accurate consistence with five biopsy pieces protocol using OLGA and OLGIM staging (94.0% and 92.9%), together with a rather low omission diagnostic rate of OLGA and OLGIM III + IV (5.8%) and 7.2%)

Conclusion: The incisura angularis with more moderate and severe GA and IM should be recommended as conventional biopsy site during endoscopy. The three most common location (antrum and corpus, angular biopsy) with quite high consistence, more convenience and less cost comparing with five biopsy pieces protocol using OLGA and OLGIM staging system, and thus could be recommend in the further gastric risk screening applying OLGA and OLGIM staging.

P0824 ENDOSCOPIC SUBMUCOSAL TUNNEL DISSECTION FOR LESSER GASTRIC CURVATURE SUPERFICIAL NEOPLASMS
D. Shi, R. Li, W. Chen, X. Wang, C. Ma, D. Zhang
Gastroenterology, the First Affiliated Hospital of Soochow University, Suzhou/China

Contact E-mail Address: hrhcsz@163.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used for resection of gastrointestinal neoplastic lesions, but there are still technical challenges in treating large ones especially located in lesser gastric curvature. In the tunnel technique, incisions at the lower and upper lesion edges are joined by a submucosal tunnel and then lateral incisions are made. The mucosa is thereby easily separated from the muscular layer. We report our experience of endoscopic submucosal tunnel dissection (ESTD) in lesser gastric curvature.

Aims & Methods: To estimate the safety and efficiency of endoscopic submucosal tunnel dissection (ESTD) for lesser curvature superficial neoplasms. 47 patients with lesser curvature superficial neoplasms undergoing endoscopic resection were analyzed retrospectively. 26 patients underwent ESTD and 21 received endoscopic submucosal dissection (ESD). Operation time, security, En bloc resection rate and complications were compared between the two groups. The major difficulty separated from the muscular layer. We report our experience of endoscopic submucosal tunnel dissection (ESTD) in lesser gastric curvature.

Results: The differences between the two groups in the age of the patients and the diameter of the lesions had no statistically significant (P > 0.05). En bloc resection rate was 100% in the study group and 90.5% in the control group (19/21), and the difference was statistically significant (P < 0.05). The intraoperative bleeding rate of the study group was 57.7% (15/26), the control group (2/21), and the difference was statistically significant (P < 0.05). The incidence of perforation was 0% in the study group and 9.5% in the control group (2/21), and the difference was statistically significant (P < 0.05). There was 1 case of delayed bleeding after operation in the two groups, there were no postoperative perforation, and the difference was not statistically significant (P > 0.05). There were no cases of peritoneal metastasis in 2 groups after operation.

Conclusion: ESTD for lesser curvature superficial neoplasms can obviously shorten the operation time and have a higher security, compared with the traditional ESD operation.

Contact E-mail Address: thorsten.brechmann@rub.de

Introduction: Propofol is recommended for sedation in gastrointestinal endoscopy (GE) [1], but preliminary data suggests additive potentials in animal models [2, 3] and healthy volunteers [4]. There is an increasing number of reports of propofol addiction in physicians and nurses associated with high mortality up to 4% within the first year. [5-7] Some patients and medical laymen developed propofol addiction and feigned an indication for endoscopy to receive propofol [8, 9]. Survivors after propofol abuse reported that the abiding memory of the intense relaxation many years ago was a major reason to abuse propofol years thereafter [10]. However, it is unknown how many patients develop a euphoric drug reaction after endoscopy.

Aims & Methods: The primary objectives were to define the frequency of a euphoric reaction pattern under propofol sedation, to evaluate the remissiveness of a re-treatment and to investigate the superposition of the respective propofol-induced euphoria. Eighty-two patients undergoing elective GE under propofol-sedation in an ambulatory setting were enrolled in a prospective observational study. The grade of anxiety, expectation or belief about the endoscopy’s result and affective state in terms of cheerfulness, relaxation, activation, sedation and anxiety were surveyed using a numeric rating scale (1 to 10) immediately before (t1), after GE (t2) and seven days (t3) later. Statistics: hierarchical cluster analysis, heat map, q2 test and paired t-test.

Results: Mean propofol dosage was 264 ± 120 mg. The average indices of cheerfulness, relaxation and activation increased significantly (t1 to t2 to t3), whereas sedation and anxiety decreased. Two clusters of mood changes emerged (t1 vs. t2). One (n = 46, 56.1%) was characterized by an unease reaction pattern with equal values regarding cheerfulness, relaxation, anxiety and wellbeing, while the other showed a euphoric reaction pattern (n = 36, 43.9%) with markedly increased cheerfulness, relaxation and decreased anxiety. Despite similar endoscopy results, euphoric cluster patients rated these more positively. No association between cluster and personal traits, prior use of psychotropic drugs, alcohol consumption or smoking habits were found.

Conclusion: Propofol induces euphoria in nearly half the patients undergoing elective GE with persisting, even enhanced remissiveness. Consequently, endoscopists should be aware of a potential risk of addiction in vulnerable subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Submucosal tumours (SMT) in the upper gastrointestinal tract (UG) impose diagnostic and therapeutic challenges. They may have malignant potential and endoscopic ultrasound (EUS) guided diagnosis is often inadequate. A substantial proportion may not involve the muscularis propria (MP) and thus may be amenable to endoscopic excision. Snare-based techniques are usually unable to completely excise such lesions, though without complete excision ongoing endoscopic surveillance may be necessary. Endoscopic submucosal dissection (ESD) offers the possibility of complete resection and definitive
Aims & Methods: A prospectively collected ESD database was analysed to identify patients with SMT of the UGI. All lesions underwent EUS assessment with the aim to exclude MP involvement prior to resection, and in the case of neoplastic endoscopic tumours (NET) blood tests and Octreotide PET scan were performed.

Results: Over 42 months, 32 ESDs for SMT lesions were performed. The median age was 62 years with 19 male patients (69%). Mean lesion size was 18 mm. Twenty-five patients (83.3%) had completely resected lesions. Four patients (13%) had involvement of the MP which was identified during the resection, and one patient (3%) had MP injury which precluded complete resection. Three of five lesions of the incompletely ESD procedures were in the proximal body of the stomach, however only two lesions of the completely resected lesions were in the proximal body (P=0.004). Otherwise, there were no significant differences between the patients and lesions characteristics. The histology of the SMT lesions were 9 NET, 6 leiomyoma, 5 Granular cell tumours, 4 inflammatory fibroid polypl, 2 GIST, 2 dysplastic Lipoma, one myofibroblastic tumour and one Warthin’s like tumour. Nineteen patients had completed surveillance endoscopy (SE) without an endoscopic and histological recurrence (Median follow up 18 months). Six patients are pending SE. The four patients with deep MP involvement were referred for surgery.

Conclusion: ESD for selected UGI SMT is an effective treatment. Long-term endoscopic follow-up confirmed the absence of recurrence endoscopically and histologically. MP involvement cannot be reliably excluded by prior EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

P0027 COMPARING APPROACHES TO SELF-EXPANDING METALLIC STENTS INSERTION

L. Mooney1, N. Church2, R. Sinha1, C. Basquill1
1Centre For Liver And Digestive Disorders, NHS Lothian, Edinburgh/United Kingdom
2Centre For Liver And Digestive Disorders, NHS Lothian, Edinburgh/United Kingdom

Contact E-mail Address: leanne.mooney@nhs.net

Introduction: The incidence of oesophageal cancer has increased significantly over the past two decades. The majority of these cancers are incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expanding metallic stents (SEMS) have a well-recognised role in the palliative management of patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscopy (FAE). There is little evidence to compare outcomes between these approaches.

Aims & Methods: The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation in oesophageal cancer via different approaches (EC or FAE) at the Royal Infirmary of Edinburgh (RIE). A retrospective observational study was conducted between May 2014 to April 2016; a total of 62 SEMS. The approach to stent insertion was subject to operator choice and availability of fluoroscopic assistance, and as such can be akin to randomized study. We compared early and late complications associated with two techniques. Early complications included pain, vomiting, bleeding, perforation and tachyarrhythmia. Late complications included tumour overgrowth, oesophagitis, oesophageal stent migration and stent migration. We also compared morbidity, the need for repeat procedures and the number of additional stents required following each approach.

Results: Forty-seven stents where inserted by EC and fifteen by FAE. The median age among the two groups were comparable at 75 and 69 years respectively. There was male predominance in both the groups (70% and 67%). Adenocarcinoma was the most common malignancy (56%), followed by squamous cell carcinoma (35%) among the study subjects. We observed a higher frequency of technical difficulties with EC placement (13%) to FAE (0%), however no malposition was observed in the EC group. Early complications were comparable in both groups, however chest pain (21%) was more frequently observed no malposition was observed in the EC group. Early complications were comparable in both groups, however chest pain (21%) was more frequently observed.

Conclusion: Our results are comparable to findings of other authors (1, 2), in that neither approach is superior. Both FAE and EC techniques have similar early and late complications and comparable median survival. EC offers the advantage of stent placement with direct visualization, however a learning curve must be acknowledged. FAE insertion is a time-consuming procedure and exposes both patients and endoscopy staff to radiation. In conclusion, the approach used should be based on individual characteristics including operator experience, tumour characteristics and previous endoscopic interventions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0028 CAUSTIC INJURIES OF THE SUPERIOR GASTROINTESTINAL TRACT: 15 YEARS OF EXPERIENCE

M. Rocha, T. Moreira, M. Salgado, L. Maia, S. Barrias, I. Pedrso Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: martalemosrocha@gmail.com

Introduction: Ingestion of caustic substances is relatively frequent and can cause serious lesions in the upper gastrointestinal tract, carrying important morbidity and even mortality.

Aims & Methods: We aimed to characterize the population assisted for caustic ingestion, the therapeutic approach, complications and risk factors for severe oesophageal lesions.

Retrospective cohort of adults presenting due to caustic ingestion between 2000 and 2015. Demographic and clinical data were collected. The endoscopic Zargar classification was applied. We analysed risk factors for severe oesophageal lesions, defined as Zargar 2b-3. Statistical tests Mann-Whitney, Spearman (significance level 5%).

Results: Overall 72 patients were included, with a mean age 53 ± 17 years, 65.3% female. Ingestion was voluntary in 49.3% of the cases, 33.3% had previous suicide attempts. Alkaline substance in 90.4%. Most common symptoms at admission: 60.3% odynophagia, 41.1% epigastic pain, 32.9% vomiting. Oropharyngeal lesions in 41.1%. In 79.5% endoscopy was performed in the first 12 hours. Oesophageal lesions were present in 46.6% of patients (Zargar classification: 1-2.7%, Ha-23.3%, Hb-5.5%, Hs-6.8%, Hn-8.2%). Gastric lesions in 58.9% and duodenal lesions in 13.7%, 53.4% were hospitalized, 51.3% in intensive/intermediate care units. The mean length of hospital stay was 14.9 days. Medical treatment prescribed: 76.7% proton pump inhibitors, 15.1% corticoids, 15.1% prophylactic antibiotics. Parenteral feeding was initiated in 28.8% of patients. Eight patients required invasive ventilation and two were tracheo-terminted. Early complications: infections in 12 patients (16.4%), perforations in 2 (2.7%); late complications: stenosis in 7 (9.6%): dilation in 6, surgery in 3. One patient died from gastric perforation after voluntary ingestion of acid. Severe oesophageal lesions were associated with increased inflammatory parameters, tachycardia and/or hypotension at admission and motivated longer hospital stays, requirement of intensive care and further complications (p<0.002). The ingestion of acidic substances (100% of voluntary intake) was associated with severe oesophageal damage in 3/7 (42.9%) patients, severe gastric lesion in 5/7 (71.4%), acidemia in 5/7 (71.4%), complications in 5/7 (71.4%) and 100% hospitalization.
Introduction: A value of the combination of magnifying endoscopy of and image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diagnosis for the early gastric neoplasm. That method is useful, but in order to master it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm Co). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combination of light provides more information about the vasculature and architecture on the mucosal surface than that obtained with typical white-light imaging. When we use acetic acid indigocarmine indigo-carmine (AIM) with LCI mode, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects are 120 lesions of 115 patients with gastric neoplasm. We are indicated the endoscopic submucosal dissection (ESD) and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy with the BLI mode and diagnosed using VS classification system. Secondly we observed the lesions by magnifying endoscopy with LCI+AIM method and diagnosed using VS classification system. Furthermore, we classified tumor differentiation into high differentiation, moderately differentiated, and poorly differentiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We carried out ESD and compared the image with the histopathology.

Results: By the pathology results, 92 lesions were gastric cancer and 28 lesions were non-cancer adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the BLI mode and the LCI+AIM methods. Diagnosis of differentiation of gastric cancer was correct in 87 of 92 cases (94.6%). In the classification of visualization ability, 32 lesions were Clear, 44 lesions were Visible, 44 lesions were Invisible by BLI mode. On the other hand, 45 lesions were Clear, 64 lesions were Visible, 11 lesions were Invisible and classified by AIM method. In the visualization ability of the surface fine structure, LCI+AIM method is significantly clearer than BLI mode (p < 0.001).

Conclusion: When we use AIM, indigocarmine accumulates in pit of the duct, and duct structures become clear by the acetic acid. By LCI mode, we can observe the vascular pattern of the lesion clearly. So by the combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this method, we can compare histopathology with an endoscopic image intuitively, so we believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled even if we do not use various confusing classifications.

Results: The patients’ mean ages were 87 (Group A) and 71 years (Group B), and the male-to-female ratios were 30/29 (Group A) and 6/46 (Group B). No significant differences were found in the mean tumor size for Group A (15 mm) and Group B (20 mm). Regarding histopathological findings, the prevalence rates of tubular adenoma were 28.3% (21/71; Group A) and 33.8% (26/76; Group 805; Group B); intramucosal carcinomas, 51.2% (37/71; Group A) and 53.8% (433/805; Group B); shallow submucosal invasive carcinomas (<500 mm), 7.0% (57/805; Group A) and 6.5% (52/805; Group B); and deep submucosal invasive carcinomas (>500 mm), 11.3% (8/71; Group A) and 6.6% (53/805; Group B). Once again, the groups showed no significant differences. The en bloc resection rates were 94.7% (67/71; Group A) and 92.9% (748/805; Group B), and the curative resection rates were 78.6% (56/71; Group A) and 86.3% (695/805; Group B). Among the non-curative cases, 13 (86.6%) of the 15 patients in Group A and 14 (46.3%) of the 31 patients in Group B were resection mismatches. Furthermore, we classified tumor differentiation into high differentiation, moderately differentiated, and poorly differentiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We carried out ESD and compared the image with the histopathology.

Results: By the pathology results, 92 lesions were gastric cancer and 28 lesions were non-cancer adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the BLI mode and the LCI+AIM methods. rate of complex LNPCPs with features suggestive of increased malignancy risk was 2.0% (14 cases). Breakdown of Outcomes (n = 53) *(Primary endoscopic therapy, (n = 27) -23 excised with curative intent -21 cases with no recurrence at 1 y -2 cases with recurrence (8.7%) both <1 cm and managed endoscopically -4 required secondary surgery -2 failed endotherapy -2 proved to be malignant *(Secondary surgical management, n = 23) -10/21 malignant lesions (43.5%) -9/23 subject to transanal surgery (39.1%) *(Conservative management, n = 3) Breakdown via High risk features of malignancy (SMSA3/SMSA4) (n = 53) *(High risk features of malignancy (any SMSA score) (n = 27) - endoscopically managed 14.0% (2/23) (6 cases both managed with pEMR) malignant -13 endoscopically surgical (4/13; 30.8%); transanal surgery -9 malignant (69.2%) -1 managed conservatively *(SMSA 4 (n = 25) -12 managed endoscopically -2 surgically managed (due to technical considerations) -5/12 malignant (25%) -1 managed conservatively *(SMSA 3 (n = 7) -4 managed endoscopically -2 management surgically (both lesions originating from within appendix) -1 managed conservatively.

Conclusion: 61 complex LNPCP cases were managed via the MDM with 8 excised from analysis (7; managed prior to MDM referral, 1; MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and 2 due to a finding of malignancy. 12 month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSC/AGCPKGI PBI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection rate of complex LNPCPs with features suggestive of increased malignancy risk was 71.4%.

United European Gastroenterology Journal 2015; 2015: 144; 54.3%) and rectum (n = 1; 0.8%); stomach (n = 5; 1.8%); sigmoid colon (n = 14; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size was 38.6 ± 18.5 mm. Median duration of the procedure was 105 min. (8 ± 375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258; 97.3%) both situations, duration >3 h and a piecemeal resection, were noted in 21 (8.1%) patients. Duration >3 h in 25 cases (9.7%) and unsuccessful en bloc

Introduction: ESD is a complex procedure, mainly in non-Asian countries where the learning process is not well established. Results may be improved in Western societies with a careful selection of lesions for ESD and avoiding those with greater chance of technical difficulty. Factors predicting technically difficult ESD when it is performed by non-Asian endoscopists should be clarified.

Aims & Methods: We aimed to identify the potential risk factors that are associated with a higher technical difficulty during ESD in a Western European setting where there are no available Asian experts. We prospectively recorded consecutive ESD cases performed by members of the ESD Working Group of the Spanish Society of Digestive Endoscopy. Demographic and clinical characteristics of the patients, location and morphology of the lesions, and technical factors were collected. We defined difficult ESD as those aborted procedures, time-consuming (duration >180 min.) or when changing the technique to piecemeal resection was needed to remove the tumor. Analyses were carried out using IBM SPSS software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous variables are reported as the mean ± standard deviation (SD). A Kolmogorov-Smirnov test was used to evaluate normal distribution. Categorical variables are reported as either frequencies or percentages. Statistical differences between the groups were analyzed using a chi-squared test for categorical data. The meaningful variables with a p value <0.1 in the univariate analysis were included in the logistic regression model. Multivariate analysis was performed using binary logistic regression methods. Odds ratios (ORs) and 95% confidence intervals (CI) were calculated to assess the strength of the influence of each individual variable.

Results: We included 265 lesions in 265 patients [mean age ±SD: 69 ± 10 (15; males 56.6%)]. They were recruited in 15 Spanish University Hospitals between January 2016 and March 2017. Location of the lesions were: esophagus (n = 7; 2.6%), cardia (n = 5; 1.8%); stomach (n = 48; 18.1%); duodenal bulb (n = 1; 0.3%); colon (n = 144; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size was 38.6 ± 18.5 mm. Median duration of the procedure was 105 min. (8 ± 375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258; 97.3%) both situations, duration >3 h and a piecemeal resection, were noted in 21 (8.1%) patients. Conclusion: The factors independently associated with technically difficult ESD (abortive procedures, time-consuming or finished with a piecmeal resection) were: lesion size >30 mm, poor manoeuvrability, recurrent lesions and intraprocedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curves.

P0834 EPOCH-MAKING TECHNIQUE OF FULL-THICKNESS RESECTION FOR THE COLORECTAL TUMOR BY USING LAPAROSCOPY ENDOSCOPY COOPERATIVE SURGERY (LECS)

Introduction: We established the Laparoscopy Endoscopy Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal endoscopic submucoosal dissection (ESD). This procedure is a local full-thickness resection of the combined procedure of laparoscopy assisted colectomy (LAC) and ESD procedure. Also, it is the method that is epoch-making for minimal invasive treatment that kept an intestinal function.

Aims & Methods: The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1376 colorectal tumors in 1341 patients (male: female 777:564; mean age, 66.1 years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: female = 7:4; mean age, 63.5 years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR and is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastasis does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be as follows: 1) Intramucosal carcinoma (Tis) and adenoma with high-grade atypia involved appendix or diverticulum. We examined the clinicopathological outcomes of the mentioned 11 cases.

Results: Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The reasons that we judged as the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticulum, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. An operative time was an average of 195.8 minutes (127 to 332), and the perioperative bleeding was an average of 8.9 g/dl (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.7(6 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10-60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesions, we followed favorable course.

Conclusion: We developed a LECS procedure to overcome the limit of ESD, and completed full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

Reference
The interviews provided an in-depth understanding of patient experience of GI procedures. 6 over-arching and inter-linking themes emerged across all procedures: anxiety, expectations, choice/control, communication/information, comfort and embarrassment/dignity. Relation of themes was seen e.g. if the procedure appointment was sooner than expected, patients were anxious about the potential outcome. Choice was important in terms of appointment, endoscopist and choice of pre-medication, however it was highly individualised. Communication prepared patients and managed expectations, with one patient describing poor endoscopist communication affecting the whole experience. Patients described embarrassment related to changing and waiting areas; sensitive nature of the test; exposure and physical reaction. Discomfort during the procedure was attributed to instrument and air insertion.

Conclusion: Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for patient experience emerging. This work will be used to develop PREMs for patient experience.

Introduction: Rheological properties of the submucosal cushion solu-

tions are crucial to avoid complications secondary to endoscopic resection.

Electrical resistance (R) of a substance is a measure of the difficulty to pass an electric current through that solution. The higher the R, the resection will be quicker, easier and safer, with less temperature increase. Our group has developed a new solution to perform submucosal injection (TriBio).

Aims & Methods: To analyse the electrical (R) and rheological (temperature, viscosity, height and lasting of the cushion) properties of different submucosal solutions in an ex vivo model of porcine stomach. Tested solutions were: saline (S), Glicolic® (GC), Hyaluronic acid (HA), Distilled water (DW), Platelet-rich plasma (PRP), Glucosated serum 10% (GS), Gelaspan (GP), TriBio (TB) and PRP + TB. Measurements were done at time 0 and 30 minutes.

Results: The solutions that showed the best basal R were: PL, HA, GS, TB and PRP + TB. At 60 minutes, the best R were: PRP, TB, PRP + TB, HA and GS. The best durability at 60 minutes was for TB, PRP, TB + PRP and PL that maintained the height at around 80% of its original in comparison to the other substances with were at around 60%. During the resection the solutions that underwent a lower temperature increase were: TB + PRP, PL, and TB.

Contact E-mail Address: sara.bjoblom@vgregion.se

Introduction: Patients with chronic diseases, such as inflammatory bowel disease, experience a lower degree of being involved in health care than others. Compared with other countries Swedish patients report lower possibility to be involved in their care and receive less information about care (1).

Aims & Methods: To investigate the perception of written and oral information given before and after a colonoscopy, the perceived knowledge of planned follow-up and preference to be more involved in decisions/participate in their care in different patient groups. Outpatients (>18 y) undergoing colonoscopy (all indications) were consecutively included (n = 862). Before the procedure patients completed questionnaires regarding sociodemographic data and the written information about bowel preparation and examination. After the procedure patients reported their perceptions about the information provided regarding the colonoscopy and the follow-up.

Results: Data from 862 patients were analyzed (447 females) (mean age 52; 18–90 y) A large number of patients (n = 740, 87%) rated the written information sent home before the colonoscopy as distinct, while a subset (n = 110, 13%) rated it as indifferent/very indistinct. When questions of importance were asked to the medical staff during the colonoscopy most patients were content with the answers from the physician or nurse. A small proportion of patients (n = 57, 7%) stated that they received too little information or that they did not understand the information about the colonoscopy results; these patients were mainly younger (< 50 y) (p < 0.001). The majority of the patients (n = 602, 74%) reported thorough knowledge about the follow-up, while 26% (n = 207) lacked this knowledge. More than 1/3 (n = 275) of the patients wished to be more involved in decisions regarding their care and treatment. Desire for a higher degree of involvement were more pronounced in patients < 40 y (p < 0.05) and in patients with IBD (p < 0.05) compared to patients with other indications for colonoscopy.

Patients referred from outpatient clinics in the hospital desires a higher degree of involvement than patients referred from primary care (p < 0.01).

Conclusion: The majority of the patients undergoing colonoscopy reported that they received satisfactory information about the procedure and preparation. However, there is room for improvement regarding follow-up information and patients’ involvement in their care and treatment. Specifically, improvements seem warranted for younger patients and patients with chronic diseases, such as IBD.

THE INCIDENCE OF SYNCHRONOUS ADVANCED NEOPLASIA OF RECTAL LATERALLY SPREADING TUMORS WITH A SKIRT

Department Of Gastroenterology, Saku Central Hospital Advanced Care Center, Saku, Nagano/Japan

Contact E-mail Address: shou0122@hotmail.com

Introduction: A "skirt" is a slightly elevated flat lesion with wide pits occasionally observed at the margin of laterally spreading tumors (LSTs), and rectal LSTs had significantly more skirt lesion in comparison to colonic LSTs. Although the clinicopathological, endoscopic, and molecular characteristics of LSTs with a skirt have been reported [1], there are no reports concerning the incidence of synchronous neoplastic lesions of rectal LSTs with a skirt.

Aims & Methods: The aim of this retrospective study was to clarify the incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt. A total of 13,116 cases underwent colonoscopy in our hospital between January 2012 and June 2016. Of these, 101 consecutive rectal LSTs were examined to assess the incidence of synchronous AN detection rate and the number of AN according to the location, there were significant differences in the right colon (8.0% vs 29.9%, p < 0.01) between LSTs with and without a skirt. In contrast, there was no significant difference with respect to the rectum (6.0% vs 6.6%, p = 0.41). The incidence of synchronous AN in rectal LSTs with a skirt (n = 7; right colon: 2, left colon and rectum: 5) was significantly lower compared with rectal LSTs without a skirt (n = 36; 47.4%, p = 0.02). As for the analysis of AN detection rate according to the location, there were significant differences in the right colon (8.0% vs 29.9%, p = 0.03) and the left colon (4.0% vs 27.3%, p = 0.03) between LSTs with and without a skirt. In contrast, there was no significant difference between LSTs with and without a skirt (n = 25; 20.0% vs 27.1 mm) had 22 high-grade dysplasia, 45 high-grade dysplasia, and 23 submucosal carcinomas, respectively. The overall AN detection rate in rectal LSTs with a skirt (20.0%) was significantly lower compared with rectal LSTs without a skirt (46.8%, p = 0.02). As for the analysis of AN detection rate according to the location, there were significant differences in the right colon (4.0% vs 27.3%, p = 0.01) between LSTs with and without a skirt. In contrast, there was no significant difference with respect to the rectum (6.0% vs 6.5%, p = 0.41). The total number of AN in rectal LSTs with a skirt (n = 7; right colon: 2, left colon: 2 and rectum: 3) was significantly lower than in rectal LSTs without a skirt (n = 74; right colon: 35, left colon: 34 and rectum: 5). There were significant differences in the right colon (p = 0.03) and the left colon (p = 0.04), while, there was no significant difference between these groups with respect to the rectum.

Conclusion: The rectal LSTs with a skirt had a significantly lower synchronous advanced neoplasia than rectal LSTs without a skirt, especially in the right and left colon. Our results may suggest that rectal LSTs with a skirt have different characteristics compared with rectal LSTs without a skirt in terms of the incidence of synchronous neoplastic lesion.

Introduction: Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hialuronic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

Aims & Methods: To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomly assigned to receive one of the following shields onto the lesions: PRP + TriBio, PRP and TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Results: Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; p < 0.05). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio

Conclusion: The use of a combination of two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon.

Introduction: Colonscopic procedures have become massive in the last years since colorectal cancer (CRC) is becoming a prevalent disorder. The next frontier of this technique will be to provide an active substance in a precise site of the colon (targeted therapy). This has many advantages (targeted therapy, dose adjustment, limiting side effects, assessment of mucosal healing, etc.); however, this selective and direct administration of drugs is not possible nowadays, but it is a true challenge. Following these evidences we have developed drug eluting platform to locally treat CRC lesions.

Aims & Methods: To evaluate the efficacy of intratumoral injection of our drug-eluting platform with different combinations of these antitumoral drugs (alfubect-cept 2 mg/mL, etuximub 16 mg/mL, panitumumab 6 mg/mL, irinotecan 3.5 mg/mL and bevacizumab 5 mg/mL) in a rat model of azoxymethane-induced colorectal cancer. Rats underwent endoscopic follow-up at 1 and 2 weeks after endoscopic therapy. Afterwards, animals were sacrificed and tumors were excised and macroscopically and histopathologically evaluated.

P0844 A THREE-DIMENSIONAL IMAGING SYSTEM IMPROVES THE ENDOSCOPIC VISIBILITY OF NON-POLYPYID COLORECTAL NEOPLASMS

Department Of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba City, Japan

Contact E-mail Address: matsumur919@yahoo.co.jp

Introduction: Three-dimensional (3D) imaging techniques have been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colonic lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colorectal neoplasms compared with conventional 2D endoscopy. We endoscoped the colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasm was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35 ± 0.58 for 2D endoscopy and 3.75 ± 0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy (p < 0.01). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p < 0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.30 ± 0.53 for 2D endoscopy and 3.87 ± 0.55 for the 3D system, p = 0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient’s needs. Colonoscopy is by many patients considered as a painful and strenuous procedure. Results: Data from 785 patients has been collected, mean age 52 (18–90) years; 46% of patients had a history of pain during colonoscopy. Approximately 8% of patients reported pain during a sub-group of 14% were not adequately relieved. This subgroup reported severe, very severe or extremely severe pain. 90% of the patients were given analgesics and sedation during the investigation. For patients who reported, “severe, very severe or extremely severe pain” (n = 111), pain was underestimated by physicians and nurses in 58% of all assessments. This was most commonly seen among the youngest patients, 18–29 years (n = 99), where pain was underestimated in 25.5% among the group. There was also a difference according to gender; physicians underestimated pain in 60% of men who reported “moderate pain” (n = 66) while the nurses underestimated pain in 27% among the same group of men. Women’s pain was overestimated by caregivers in 26% (n = 188) of all cases with mild pain. Patients undergoing colonoscopy for the first time (n = 331), and reporting “moderate pain”, were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety (p < 0.001). Presence of anxiety and a high level of agitation among the group who reported moderate pain, was significantly higher than the expert, non-expert and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p < 0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.30 ± 0.53 for 2D endoscopy and 3.87 ± 0.55 for the 3D system, p = 0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: Agreement between caregivers’ and patients’ pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients.

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD. However, characterization of colonic lesions in IBD remains challenging even by using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]).

Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic lesions, and to validated by international experts (Frankfurt Advanced Chromoendoscopy IBD LESions-FACILE Group). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel pattern, signs of inflammation (table). A library of 60 colonic lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariable analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: The 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/Ps and 12 (20%) pseudopolyps. Across the experienced academic raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 92%, 91%, 40%, 72%, sensitivity, specificity, PPV, NPV, accuracy, for predictions made with high confidence were 72%, 90%, 97%, 46%, 76%, which were significantly more accurate compared with a low confidence of diagnosis (76% vs 65%; p < 0.001). Univariate analysis showed that the non polypoid lesions, irregular, and vessel architecture and signs of inflammation within the lesion were predictive of dysplasia. Subsequent multivariate analysis confirmed that of these endoscopic findings non polypoid lesion OR 11.6 (95% CI 6.71–20.2), surface pattern
OR 0.31 (95% CI 0.17–0.54), vessel architecture OR 5.1 (95% CI 2.7–10.2), sign of inflammation within the lesion OR 0.39 (95% CI 0.18–0.85) were independent predictors of dysplasia, with vessel architecture and morphology being the best predictors. The sensitivity, specificity, PPV, NPV and accuracy at the multivariate analysis stage were 94% (95% CI: 90–96%), 51% (95% CI: 43–58%), 88% (95% CI: 82–92%), 69% (95% CI:62–75%), 85% (95% CI: 79–90%). Inter-observer agreement of the raters improved from the pre-test (Kappa = 0.27 CI: 0.19–0.38) to post test (Kappa = 0.34 CI: 0.23–0.45; P = 0.02) but was moderate.

**Conclusion:** We developed and validated the first endoscopic classification using all imaging modalities (HD, VCE, DCE) to characterize and differentiate dysplastic from non-dysplastic lesions in IBD. Non polypoid lesions, irregular surface and vascular pattern as well as inflammation within the lesions were predictive of dysplasia. The inter-observer variability of the score was moderate. The classification will be further refined based on the multivariate analysis and a prospective study is ongoing.

(continued)
with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Is) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered "pseudopolyps" had a 8 mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

**Conclusion:** This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0849 THE SAFETY AND EFFECTIVENESS OF COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION USING A SCISSORS-TYPE KNIFE IN ELDERLY PATIENTS

T. Kuwai1, T. Yamaguchi1, H. Imaigawa1, S. Funaki2, K. Taro1, R. Miura1, T. Takasago1, Y. Shimada1, Y. Miyasako1, A. Yamaguchi1, H. Kouno1, H. Kohno1, S. Ishaiq2
1Gastroenterology, Kure MC & Chagoku CC, Kure/Japan
2Gastroenterology, Dudley Group Hospitals, Birmingham City University, Birmingham/United Kingdom

Contact E-mail Address: toshiokuwai@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr: Akita Sumitomo Bakeiki, Japan) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Aims & Methods: The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥75 years in comparison with those in younger patients. We evaluated 291 lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at Kure Medical Center and Chugoku Cancer Center. The patients were divided into two groups, an elderly group (group A: age, ≥75 years; 95 patients, 97 lesions) and a non-elderly group (group B: age, <75 years; 176 patients, 194 lesions). We evaluated the en bloc resection rate, complete resection rate, curative resection rate, resected tumor size, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

Results: The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.4% (70/194); Tub. 39.2% (38/97) and 44.8% (87/194); Tla, 10.3% (10/97) and 10.3% (20/194); and Tlb, 13.4% (13/97) and 8.8% (17/194) in groups A and B, respectively, showing no significant difference. The mean resected tumor size was 33.9 ± 16.6 mm in group A and 34.7 ± 15.2 mm in group B, and the median procedural time was 75.6 min (range, 10–420 min) in group A and 75 min (range, 10–533 min) in group B, showing no significant difference. The en bloc resection rates were 96.9% (94/97) and 99.0% (192/194); the complete resection rates, 94.8% (92/97) and 94.8% (184/194); and the curative resection rates, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and delayed bleeding occurred in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period: group A, 523 ± 469 days; group B, 628 ± 582 days), the 3-year overall and disease-specific survival rates were respectively 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of colorectal cancer (2.6%, 5/194) during other diseases in group B, while one patient (1.1%, 1/95) died of other diseases in group A.

Conclusion: ESD performed with SB Knife Jr is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms in elderly patients. The safety and efficacy of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0850 QUALITY IN COLONOSCOPY; HAVE YOU REALLY GOT TO THE CAECUM?

S. Buddhul
Department Of Endoscopy, Nottingham University Hospitals, Nottingham/United Kingdom

Contact E-mail Address: shivbuddul@yahoo.co.uk

Introduction: Poor quality and incomplete colonoscopy is associated with missed diagnosis and failure to prevent interval cancers.1 Caecal intubation rate is the most frequently used Quality Indicator of colonoscopy. British Society of Gastroenterology guidelines recommend obtaining “clear images of caecal landmarks or terminal ileum” while the European and American guidelines suggest “acceptable photo documentation preferably a panoramic view of the ileocecal valve and caecum”.2 In this retrospective study we aimed to assess colonoscopists’ practice in photo documentation of colonoscopy completion.

Aims & Methods: Colonoscopy reports for colonoscopies performed at an endoscopy unit over a University Hospital over a period of three months from 01/01/2014 to 31/03/2014 were retrieved from the Trust’s Endoscopy database. Photo documentation from the reports were then analysed for caecal landmarks and terminal ileum images.

Results: A total of 292 colonoscopies were performed by 21 endoscopists (5 Colorectal Surgeries (24%), 3 Nurse Endoscopists (14%), 3 Specialist Registrar Gastroenterology (14%) and 10 Consultant Gastroenterologist (48%). Caecal intubation was achieved in 248 cases (85%). In 8(3%) cases the anastomosis was reached. The ileo-caecal valve was photographed in 172(70%) cases, the appendix in 102(41%) cases, the caecum in 83(33%) cases and a panoramic view was achieved only in 43(17%) patients. Terminal Ileum was intubated in 53 cases (21%) and images were recorded in 25 cases (40%). In the case of anastomosis, 7 images (88%) of the anastomosis were obtained. In some of the reports images were labelled and in a number of reports no photos were recorded at all.

Conclusion: This study shows that photo documentation is poor and needs to be improved in order to adhere to national and international guidelines. Evidence of caecal intubation is imperative as it can protect against medicolegal implications.3 Obtaining clear images of caecal landmarks will ensure definite caecal intubation and efforts towards recording them will prompt the endoscopist to attain adequate mucosal view. In order to achieve excellence we suggest colonoscopists obtain images of all caecal landmarks including the ileum (when intubated), label photographs and where possible record video clips of caecal intubation.

Contact E-mail Address: iacuccim@yahoo.it

Introduction: Sessile Serrated polyps (SSA/Ps) are pre-malignant lesions that may lead to colorectal cancer in accelerated manner. These lesions are easily missed by endoscopists as these are difficult to detect in IBD patients. We aimed to assess the prevalence, detection rate and endoscopic findings of SSA/Ps in long standing IBD patients prospectively undergoing surveillance colonoscopy using dye (DCE) or virtual electronic chromoendoscopy (VCE) or high definition white light imaging (HD-WLE) colonoscopy.

Aims & Methods: A total of 270 randomized patients (55% men; age range 20–77 years, median age 49 years) with long-standing IBD (median duration of the disease 14 years) undergoing surveillance colonoscopy were assessed by HD-WLE (n=90), VCE (n=90) or DCE (n=90). Surveillance colonoscopy with High Definition (HD) alone, or with iSCAN VCE or DCE was performed. Endoscopic features were recorded in each group with regard to location, morphology (polypoid/non polypoid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification and Paris classification. The histology was reported by modified Vienna classification.

Results: Thirty -three SSA/Ps were detected in 20 (11UC; 9 CD; 11 female, age range 34–72 y, median age 61 years) patients out of the 270 patients with IBD enrolled (12.2%). The endoscopic features of SSA/P lesions were: non-polypoid appearance (51.5%), predominant localization in the proximal colon (vs distal) (87%), ≥5 mm in size (48.4%), Kudo pit pattern modified type I (77%). Kudo pit pattern modified type I had a sensitivity of 79% and specificity of 62% for diagnosing SSA/Ps at surveillance colonoscopy in IBD patients. There was no difference in detection rates of SSA/P using HD-WLE, DCE or VCE.

Conclusion: SSA/Ps are not an infrequent finding at surveillance colonoscopy in IBD. There are prevalent in the right colon location and these generally have Kudo pit pattern of I/O. SSA/Ps can be recognized endoscopically by Kudo pit

Abstract: P0851
pattern even in IBD patients. Further studies are needed to evaluate the natural history and management of the SSA/Ps pathways in IBD patients.

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic accuracy. However, the individual acuity of the endoscopists ranged from 66% to 76%. The lack of recourse to magnification may have contributed to these results.

Aims & Methods: To evaluate the in vivo histological prediction acuity of colorectal polyps <10 mm in diameter vs adenoma in WLE (White light endoscopy) and using FICE technology, comparing both modalities. Propospective evaluation, using WLE and FICE, of colorectal polyps <10 mm in patients submitted to colonoscopy between 12/2016 and 02/2017 by four inexperienced endoscopists in FICE, except for a previous 20-minutes interactive session. Polyps were evaluated using the FICE classification (tubular or oval crypts (adenoma), round crypts or featureless appearance (hyperplastic polyps), indicating their confidence level (low <90% vs high >90%). Statistics: SPSS v23.

Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic and 1 serrated adenoma. From the global assessment of all polyps and observations, the use of the FICE classification for prediction of adenomas showed a high positive predictive value identical to WLE (100%, 62.5%, 60% and 100%, respectively). Overall, diagnostic acuity in histological prediction was identical in both modalities (76%). The individual acuity of the endoscopists ranged from 66% to 77% (31.8%). A sub-sore classification was not associated with a higher probability of correct classification, both in WLE (77% vs. 75%) and FICE (75% vs. 80%), p > 0.05.

Conclusion: The use of FICE technology by inexperienced endoscopists in the histological prediction of colorectal polyps has no advantage over WLE, having both suboptimal acuities. The lack of recourse to magnification may have contributed to these results.

PO853 POLYP DETECTION RATES IN COLONOSCOPIES PERFORMED UNDER GENERAL ANAESTHETIC COMPARED TO CONVENTIONAL SEDATION

B. Perren1, A. S. Bancel1, A. G. Lim1, P. You1, J. S. Moodie1, P. Patel1, Medicine, Epsom and St Helier University Hospitals, London/United Kingdom

Contact E-mail Address: ben.perren@doctors.org.uk

Introduction: Colonoscopies are performed under general anaesthesia (GA) for various reasons. This may be due to previous episodes being poorly tolerated with normal sedation. During the procedure, the endoscopist must be aware of the patient’s comfort levels and reactions to endoscopic manoeuvres. Polyp detection rate (PDR) is a well-recognized indicator of colonoscopy. We have demonstrated that use of sedation increases the quality of colonoscopy11. We hypothesised that complete removal of the patient factor may increase the detection rate of polyps further.

Aims & Methods: The study was undertaken retrospectively at a district general hospital. Results were analysed for all colonoscopies performed under GA between February 2016 and February 2017 to identify whether polyps had been detected, the number of polyps detected, and the site of polyp detection. Sedation records for a period of one year were retrospectively evaluated for IBD and inflammatory bowel diseases. All patients were excluded. The age and gender of each group was also analysed to identify possible confounding factors.

Results: 40 colonoscopies were performed under propofol sedation within the defined criteria; 40 colonoscopies performed using conventional sedation were randomly selected to use for comparison. A significant increase in rate of polyp detection was found in GA studies (45% vs non-GA studies 30%, p = 0.0384). GA studies identified a mean of 1.275 polyps per study, compared to a mean of 0.325 polyps when conventional sedation was used (p = 0.0001). There was an insignificant (p = 0.175) difference in age between the GA group (59.7±8.2) and non-GA (64.7±14.2). There was a significant (p = 0.0005) difference in gender between groups; there was an even distribution of gender in the conventional polyps, whereas 77% of patients were female. For propofol sedation, 70% of patients were female.

Conclusion: Use of propofol sedation during colonoscopy provides a statistically significant increase to both the rate of detection of polyps, and the number of polyps identified when compared to procedures performed for similar indications using conventional sedation. This may be an indication of the patient factor. The implications of this are unclear and thus further larger comparison studies are needed. It is not practical for all colonoscopies to be performed under GA due to capacity issues, anaesthetic requirements and time allocated to lists. However, it may be a clinically effective tool for high-risk patients, such as those being screened for hereditary colonic malignancies or IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO854 PATIENT AND PHYSICIANS RELATED FACTORS ASSOCIATED WITH A HIGH ADENOMA DETECTION RATE IN ROUTINE COLONOSCOPY

2IGR, Villejuif/FRANCE
3Digestive Endoscopy Unit, Clinique de Bercy, Chartier-le-Pont/FRANCE

Contact E-mail Address: m.cavichi@wanadoo.fr

Introduction: Adenoma and polyp detection rates are correlated to the risk of interval colorectal cancer and is consequently considered as a quality benchmark in routine colonoscopy. We propose to evaluate these factors in our daily practice, involving all the endoscopists of our endoscopy unit.

Aims & Methods: 6027 colonoscopies were performed between 01/2016 and 31/12/2016 by 30 physicians. Regarding patients, the following data were prospectively collected: age, gender, indication for colonoscopy, preparation procedure and time, and quality of preparation (assessed by the Bowel Score). Regarding physicians, age, gender, number of colonoscopies and mean withdrawal time (c). We performed a univariate analysis (using unpaired t-test for two groups, the χ2-test or Fisher’s exact test for categorical data). A multivariate analysis (stepwise logistic regression) was performed with the significant variables identified in the univariate analysis.

Results: We enrolled 2719 Male patients (45.1%) and 3308 Female patients (54.9%). Among them, 1370 (45.1%) were under 50 year-old or more. A sub-optimal preparation (defined as a Bowel scale score < 3 or at least one sub-score < was observed in 61.9% of the patients. Caecal intubation rate was 99%. 21 endoscopists were Male and 10 were under 50 year-old. The median number of colonoscopy per physician was 140 (range: 10–720). 2054 colonoscopies detected 3914 lesions or polyps: 2914 tubular/villous adenomas, 496 serrated adenomas, 242 hyperplastic polyps (hyperplastic polyps located in the rectum and sigmoid colon were not considered as at risk for cancer and were excluded), 212 other histology leading to a Malignancy. Of the Number of Polyps (MNP) had an MNP of 0.65 and a Polyp Detection Rate (PDR) of 34.1%. 1935 colonoscopies detected at least one adenoma (adenoma detection rate, 32.1%). Large Polyp Detection Rate was 7.9% with detection of 538 polyps > 1 (13.7% of polyps), in 477 patients. Neoplasia Detection Rate was 3.6% (300 neoplasias in 220 patients). Among the endoscopists, the median PDR was 32.5% (range 14–62%). Among them, 4 had a PDR < 20, 17 had a PDR between 20 and 39% and 9 had a PDR > 40%. Mean withdrawal time was 490 seconds (range 228–831). 10 physicians had a mean withdrawal time <420 seconds, 16 had a mean ADR >420 seconds. 34 physicians compared to 34% for polyps, withdrawal time of more than 420 seconds (p > 0.05). In the univariate analysis, a high PDR was significantly associated with patient-dependent factors: age, Male gender, a familial history of polyp/cancer, screening or positive faecal immunochemical test (FIT+) and quality of preparation. Regarding physician-dependent factors, a high PDR was significantly associated with Male gender, high volume (> 140 colonoscopies per year) and withdrawal time. In the multivariate analysis, the only factor associated with a high PDR were: familial history of polyp/cancer, FIT+ and patient age.

Conclusion: In this large series of routine colonoscopies, we found medically-relevant polyps in more than one third of the patients, irrespectively of age and indications. In multivariate analysis, a high PDR was significantly associated with familial history of polyp/cancer, FIT+ and age of the patient. This may suggest that the Male gender is no longer a risk factor for polyps. In addition, even if there are still discrepancies regarding PDR among physicians, we found no significant physician-dependant factor associated with a high PDR in the multivariate analysis.

Acknowledgement to all the endoscopists and nurses of the Clinique de Bercy.

Introduction: Fecal immunochemical test (FIT+) has progressively replaced the guaiac test for colorectal screening in average risk population in France since May 2015. With a high sensitivity and a good specificity, it is supposed to increase colonic cancer-risk detection. However, its efficiency has not been described in routine colonoscopy.

Aims & Methods: Among 6027 colonoscopies performed between 01/2016 and 31/12/2016 in our endoscopy unit, 391 were performed for a positive FIT (FIT+)}
PO857 TWO LITERS OF POLYETHYLENE GLYCOL (PEG) WITH 15 MG OF BISACODYL VERSUS 4 LITERS OF PEG FOR BOWEL PREPARATION TO COLONOSCOPY, PROSPECTIVE RANDOMIZED STUDY. PRELIMINARY RESULTS

1Hepatogastrenterology, CHU Med VI Oujda, Oujda/Morocco
2Avicenne, Faculty of medicine Oujda, Oujda/Morocco

Contact E-mail Address: mekamine@hotmail.com

Introduction: Adequate bowel preparation is one of the most important quality factors of colonoscopy. Several formulations of bowel preparation have been evaluated for their ability to have a clean colon and be well tolerated by patients. Currently, PEG 4L solution is the preferred method of bowel preparation to colonoscopy. This preparation has the disadvantage of being poorly tolerated by patients. Furthermore, recent studies have shown that a low-volume PEG solution (2L) plus bisacodyl for bowel cleansing is as effective and better tolerated as a large volume PEG (4L).

Aims & Methods: This study aims to assess the efficacy and tolerance of the new regimen (bisacodyl) compared to the classical regimen (4L of PEG).

Materials and methods: A prospective comparative randomised study comparing the tolerance, acceptability and efficacy of a protocol A based on 4L of PEG and a protocol B corresponding to 2L of PEG + 15mg of Bisacodyl. Using the Boston Bowel Preparation Scale (BBPS) by endoscopists, who did not know bowel preparation type, to evaluate the quality of preparation.

Results: Sixty-six patients were included (35 in group A and 31 in group B), with a sex ratio = 1. The average age of patients was 52 ± 15 years (17-86 years) with a median of 51.5 years, 19 patients in the first group found that the preparation was difficult or moderately difficult vs 3 in group B (p = NS) with mild to severe side effects 54% of group A and 29% of group B (p = 0.03) and A mean side effect per patient was 2.26 vs. 1.89 (p = NS). Nausea and vomiting were respectively (34% and 19%) of patients in group A and B. However, 5 patients in group A had sleep disorders vs only one case in group B. Four patients who received 4L of PEG had expressed their refusal to resume the same preparation if necessary while 2 patients in group B had refused. A score greater than or equal to 7 was recorded 61% of patients in group A (n = 21) vs 19% of patients in group B (p = 0.03). Overall, the overall score obtained was 6.49 versus 7.32, respectively. This score (BBPS) tended to be better in protocol B than in protocol A in the right segment (2.55 vs 2.17), transverse colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). This same trend was recorded in relation to the number of patients with hyperplastic polyps (9.9%) with 4 patients in group B and no patient in group A. Seven patients refused to repeat the test even if indicated. This refusal was secondary to the lubrication in 4 cases (2 cases of each group). Abdominal pain and post-endoscopic distension were respectively (62.8% and 65.7% vs 32% and 22.5%) (p = 0.016 and p < 0.001).

Conclusion: Preliminary results from our study suggest that the low-volume 2 L PEG with bisacodyl does improve patient tolerability with a tendency to be better for Good Bowel Preparation as compared to the traditional 4 L PEG. We continue our study to have a more significant number of patients view these results.
Results: 1382 LSL in 1243 patients were analysed. 1155/1243 (92.9%) patients had a solitary LSL. The majority of patients with multiple LSL had two (77.3%) or three (15.9%) lesions. 889/1382 (64.3%) of LSL were G LSL, were more likely to be solitary (87.0%) than NG LSL (77.5%, p < .001). G LSL were more commonly large (>40 mm in size) (49.5%) than NG LSL (26.0%, p < .001) and were more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, p = .034). In 88 patients with multiple LSL the dominant LSL was G (49/88 [55.7%]). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, p = .029.

Table 1: The morphology of the dominant (largest) laterally spreading lesion (LSL) predicts the presence and number of synchronous LSL. Morphology of the dominant lesion did not predict the others would be of the same morphology (p = .697). The dominant LSL was large in 43.2% of cases. Size of the dominant LSL predicted size of the other LSL (p = .001). 58.0% of dominant LSL were located in the right colon. In 65.9% patients all LSL were in the same colonic segment; this was not predicted either by the location of the dominant LSL (p = .860) or its morphology (p = .228).

Conclusion: 7% of patients will have more than one LSL. In these patients the dominant lesion morphology predicts the presence and number of additional LSL (the Colonic Mucosal Phenotype). More than 20% of NG LSL are associated with an additional NG lesion whereas G LSL are predominantly large and solitary. Practitioners of endoscopic resection should be aware that NG LSL may be multiple and ensure full examination of the colonic mucosal surface, particularly since they are higher risk for SMIC than G LSL.

P0860 WIDE-FIELD PIECEMEAL COLD SNARE POLYPECTOMY OF LARGE SESSILE SERRATED POLYPS WITHOUT A SUBMUCOSAL INJECTION IS SAFE
D. J. Tate, H. Awadie, F. Buhin, L. Desomer, R. Lee, S. Heitman, G. Goodrick, M. Bourke
Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney, Australia/NSW

Contact E-mail Address: dtate@gmail.com

Introduction: Large series suggest endoscopic mucosal resection is safe and effective for the removal of large sessile serrated polyps ≥10mm (large SSP) but it exposes the patient to the risks of electrocuturety, principally delayed bleeding.

Aims & Methods: We aimed to examine the feasibility and safety of piecemeal cold snare polypectomy (pCSP) for the resection of large SSP. Over 12 months sequential large SSP without endoscopic evidence of dysplasia referred to a tertiary endoscopy centre were considered for pCSP. The technique for pCSP was standardised. The lesion and its margins were assessed using high definition endoscopic imaging. Snare resection commenced at one margin including a 2–3 mm rim of normal tissue. A thin-wire snare was used in all cases. Firm downward pressure and suction of luminal gas aided tissue capture. Submucosal injection was not performed. High-definition imaging of the defect margin was used to ensure the absence of residual serrated tissue. Adverse events were assessed at 2 weeks and surveillance was planned between 6 and 12 months.

Results: 41 SSP were completely removed by pCSP in 34 patients. 7 patients had two lesions removed. The median size of SSP was 15 mm (IQR 14.5–20), range 10–35 mm. The median duration of procedures was 4.5 minutes (IQR 1.4–6.3). There was no evidence of perforation or significant intra-procedural bleeding. There were no significant adverse events at 2 week follow up including delayed bleeding and post polypectomy syndrome. 8/41 lesions underwent first follow-up at median 6 months with no evidence of recurrence.

Table 1: Baseline characteristics and outcomes of the 34 patients and 41 SSP that underwent piecemeal cold snare polypectomy (pCSP). IQR – interquartile range, SC1 - first surveillance colonoscopy.

Conclusion: There is potential for pCSP to become the standard of care for non-dysplastic large SSP. This may reduce the burden on patients and healthcare systems of removing SSP, particularly by avoidance of delayed bleeding.

P0861 THE PROSPECTIVE OBSERVATION STUDY FOR OVER 10MM COLORECTAL LESIONS ENDOSCOPICALLY RESECTED USING BIPOLAR SNARE
Gastroenterology And Endoscopy, National Cancer Center Hospital East, Kawasaki, Japan

Contact E-mail Address: hirosnak@east.ncc.go.jp

Introduction: Polypectomy of adenomas reduces death due to colorectal cancer; therefore colonoscopy is the gold standard to detect and treat adenomatous lesions. Most adenomatous lesions are less than 20 mm in size. Therefore, these are not indication for endoscopic submucosal dissection (ESD). Recently, there are some reports about cold snare polypectomy (CSP). CSP is effective and easy to remove lesions of less than 5–10 mm in size. On the other hand, in over 10 mm lesions, most endoscopists would remove it by endoscopic mucosal resection (EMR) with monopolar snare. It is expected that the bipolar snare would decrease the incidence of perforation because of electric current flow peculiar to bipolar snare that does not flow through the wall of colon. So, by using bipolar snare, hot snare polypectomy (HSP) that can be easily resected in a short time may be safely performed for over 10 mm colorectal lesions. However, there is no report about them.

Aims & Methods: We aimed to clarify removal method, procedure time and complications for over 10 mm colorectal lesions endoscopically resected using bipolar snare. Consecutive patients with over 10 mm colorectal lesions endoscopically resected using bipolar snare in National Cancer Center Hospital East between September 2016 and March 2017 were enrolled in this study, prospectively. The removal method rate of these lesions, each procedure time, complete resection rate, bleeding rate and perforation rate, and pathological finding were assessed.

Results: A total 92 lesions in 67 patients were analyzed. 47 patients (70%) were male, and the median age was 67 years (range: 44–88). The median lesion size was 15 mm (range: 10–30). The macroscopic type was 33 (36%) polyoid lesions and 59 (64%) flat lesions. The location was 55 (60%) lesions in right colon, 31 (34%)
in left colon and 6 (6%) in rectum. Pathological diagnosis was 22 (24%) hyperplastic polypl or SSA/P, 42 (46%) low grade dysplasia (LGD), 23 (26%) high grade dysplasia (HGD), and 11% submucosal invasive cancer. In the removal methods, HSP was 71 (77%) lesions and EMR was 21 (23%). The median procedure time of HSP and EMR was 37 seconds (range: 7–430) and 167 seconds (range: 60–450) (p < 0.001). The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–26) (p < 0.001). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (33%) (p = 0.009). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p < 0.001). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polypl or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

Conclusion: Of over 10 mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Outcomes after endoscopic mucosal resection at the initial procedure, 2 weeks and subsequent surveillance procedures.

Introduction: The SMSA polyp scoring system is an objective method for stratifying the difficulty of polypectomy based on expert consensus opinion. The score is simple, intuitive and has previously not been evaluated in a large multicentre setting.

Aims & Methods: We aimed to determine the ability of the SMSA polyp score to predict robust endpoints after endoscopic mucosal resection (EMR) of colorectal laterally spreading lesions. The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMS over eight years. This score describes the complexity of polypectomy with respect to four major domains (table 2) and is subsequently divided into four levels. Standardized inject and resect EMR procedures were performed with detailed patient, procedural and outcome data recorded prospectively over the study period including all features of the SMSA. In patients who had multiple lesions resected the largest lesion was for analysis. The primary endpoints were correlation of SMSA score with completion rate, adverse event rate and adenoma recurrence.

Results: 2305 lesions in 2305 patients (47.4% M, 45, 2% right colon) underwent EMS. The majority of lesions were SMSA 4 (50.2%) with a median lesion size of 30 mm (range 20–160 mm). Failed single session EMR occurred in 97 (4.2%) and this was predicted by increasing SMSA (p < 0.01). Intra-procedural bleeding was significantly more common with increasing SMSA (SMSA 2, 19,229 [8.3%] versus SMSA 4 291,1185 [25.1%], p < 0.001). Clinically significant post-EMR bowel perforation was more common as SMSA increased with 412% in the SMSA 2 group and 90% (7.6%) in the SMSA 4 group, p < 0.001. Intra-procedural perforation and delayed perforation were not different between the groups. After EMS surgery at 2 weeks was more common in the SMSA 4 group (p < 0.001).

Of those patients that underwent their first surveillance colonoscopy (SC1), endoscopic recurrence (EDR) was more common in the SMSA 4 group than in the SMSA 2 group, 206 [23.7%] as compared to 9 [5.4%], p < 0.001. The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p < 0.001). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polypl or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

Conclusion: Of over 10 mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sessile serrated adenoma/polypl (SSA/P) has been accumulated increasing attention since its risk for developing to cancer had been clarified. These polyps are difficult not only to detect but also to determine their precise malignancy after detection especially in right side colon. Such a difficulty leads high recurrence rate after endoscopic resection. Magnifying function and narrow band imaging (NBI) is reported to be useful for evaluation of SSA/P but it needs special equipment, extra time, and expertise. Easier, uncomplicated, and non time consuming method is desired. The use of acetic acid or acetic acid-indigo carmine mixture have been introduced into endoscopic diagnosis in Barrett’s esophagus, early gastric cancer, and colorectal early cancer. However, there have been no reports on using this agent as aid for the optimal diagnosis of the margin of SSA/P. If this rather cheap agent were helpful for realizing the precise margin of SSA/P, it could decrease insufficient removal of the polyp and recurrence after that.

Aims & Methods: The aim of this pilot study is to assess whether the acetic acid mixture could facilitate the recognition of the margin of SSA/P. We used acetic acid as a mixture with indigo carmine and compared it to conventional evaluating methods; narrow band imaging (NBI) and indigo carmine. From December 2016 to February 2017, patients in whom SSA/P more than 10 mm were found in right side colon in daily practical colonoscopy by single endoscopist in our institute were included. We used the standard scope without magnifying function. First we observed lesions with conventional white light and NBI. Second, we recorded pictures with indigo carmine (IC) spray on it. Finally, we sprayed the mixture of acetic acid and indigo carmine mixture (AIC) directly through the endoscopic working channel without using catheter onto lesion. Using recorded pictures during these procedures, ability for recognizing the margin of polyps were compared between IC and AIC, or NBI and AIC by 3 endoscopists, and the concordance rate of diagnosis among these three were assessed as Kappa statistics.

Results: 9 SSA/P lesions in 7 patients were investigated. In all cases, AIC was helpful to recognize the margin of polyps without causing any obstructive effect. We also observed disappearance of mucous on the surface, diluted crysps caused by acid contact, and aceto-whish reaction on the serificial glands in all lesions. In comparing the ability for recognizing the margin of the lesions, 6.3 in 9 lesions (mean among 3 practitioners) were thought to be as AIC better than IC, and
similarly 7.3 in 9 were better than NBI. Kappa value for all participants was 0.66 (p < 0.001). All polyps were removed endoscopically after examination. All lesions were histologically diagnosed as SSA/P without dysplasia.

Conclusion: Acetic acid was useful and promising to facilitate the endoscopic recognition of the precancerous margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill.

Introduction: Preoperative localization or tattooing is essential for minimally invasive surgery. Although preoperative endoscopic tattooing using India ink or indocyanine green is widely used, clinical evidence and safety profile supporting the use of these agents is lacking.

Aims & Methods: We assessed the efficacy and safety of preoperative endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopic tattooing or India ink tattooing were included in this study. From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospective reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattooing in the peritoneal cavity and relation adverse events.

Results: Endoscopic tattoos produced using India ink were visible in 38 (95%) patients, and tattoos created using autologous blood were visible in 36 (90%) patients. In the autologous blood group, the tattoo could not be identified in four patients due to excessive peritoneal fat, bleeding tendency, congenital anomaly, and tattooing in an inadequate depth. Eight (20%) patients in the India ink group and four patients (10%) in the autologous blood group experienced endoscopic tattooing-related adverse events.

Conclusion: Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colonic lesions.

Contact E-mail Address: heithemso9am@hotmail.com

Introduction: Luminar tumors (LSTs) are defined as lesions > 10 mm with a low vertical axis and lateral extension. They are separated in 2 groups with 2 subclasses for each of them: granular LST (LST-G) with or without large nodule; and non-granular LST (LST-NG), separated into flat lesions (Ht) and depressed lesions (Ht + Hc). Every subclass has been associated with a higher risk of cancer and submucosal invasion (T1sm) 

Results: A total of 631 lesions were included in our study. The average age was 67.7 years old. The mean size of lesion was 40.6 mm. LST were located in the right colon, the left colon and the transverse colon in 44.5%, 32.6%, 14.0% and 8.8%, respectively. The resection technique used was a monobloc EMR in 15.4%, piecemeal EMR (pEMR) in 42.9%, ESD in 27.3% and assisted ESD in 14.5%. ESD was associated with a significant low risk of recurrence after 1 year (4.9% against 18.1%). Considering the LST classification, there were 27.0% LST-G with large nodule, 28.4% LST-G with large nodule, 35.5% flat LST-NG Ht and 9.0% LST-NG with depression Ht + Hc. The overall rate of adenocarcinoma was 19.7% and 9.0% with submucosal invasion. The rates of adenocarcinoma and the rates of submucosal invasion in every subtype of LST are reported in table 1. They were higher for LST-G with large nodule (34.5% and 15.9% respectively) and for LST-NG with depression (35.3% and 20.6%). Regarding the prediction of submucoeal cancer by the endoscopist, we report a low sensitivity, and positive predictive value (respectively 64.7% and 32.8%). However, we had a good specificity and negative predictive value (86.0% and 96.0%). Endoscopic predictors of submucosal cancer were invasive pit pattern (HR 33.0; p = 5.76e-07) and depression (HR = 11.86; p = 0.049).

Conclusion: Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

Introduction: Evidence on an international variation of pathological types and anatomical distribution of colon polyps is beneficial for early detection and management but limited.

Aims & Methods: To characterize differences in colonoscopy findings by ethnicity, a random sample of patients aged at least 50 years without colonic symptoms or history of colonic diseases who underwent colonoscopy were reviewed. Of 25,508 subjects, 2651 were randomly selected. Of 1300 subjects who met the inclusion criteria, abnormal findings were identified in 878 cases (67.54%), of which 452 cases had 940 polyps and 7 cancer lesions were found in 6 cases. Of 452 patients with polyps, half had only one polyp (53.76%) and were Asian (54.63%), followed by Caucasian (26.99%), Middle Eastern (15.71%), and other ethnic origins (26.25%) (Figure). Ethnicity-specific polyp prevalence were 36.26%, 38.05%, 27.24%, and 34.15%, respectively. Polyps of Caucasian subjects tended to be smaller (4.52 mm) whereas 8.19% were large (≥ 5 mm) whereas 8.19% were large (> 20 mm); hyperplastic polyp, tubular adenoma (TA), and tubulovillous (TVA) adenoma were identified in 43.19%, 53.83%, and 2.34%, respectively. Preliminary (TA + TVA) polyps were found in 56.08%, 50.19%, and 64.23% of the polyps of Asian, Caucasian, and Middle Eastern patients, respectively. Preliminary lesions were found in 52.91% of small polyps.

Conclusion: The findings suggested that number, size, distribution, and pathological type of colonic polyps vary across ethnic groups. As more than half of small polyps were a tubular adenoma, we propose that polyps of all sizes should be removed when feasible.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection represents the standard of care for large superficial colorectal neoplasms in Japan. In Europe, only few studies related to performing ESD results, especially in the rectal location. Colonic ESD is more technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is also more risky because perforations are mostly non-clinically significant in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD.

**Aims & Methods:** Retrospective bicentre study of all cases of colonic ESD performed between 01/2016 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and extended curative resection rate (Curative resection + non-curative due to positive horizontal margins and without recurrent disease on endoscopic control). Secondary endpoints were to compare these results with results of rectal ESDs performed during the same period.

**Results:** 87 ESDs were performed in two French centers between 01/2015 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. During the same period 93 rectal ESDs were performed for superficial pre-cancerous or cancerous neoplasms. **Descriptive results:** male 54 (67%), mean size of the specimen 49 mm, mean duration of procedure 125.1 min, mean speed of ESD: 18.9 mm²/min, perforation rate: 9 (10.3%), post procedural bleeding rate: 2.3%, secondary surgery 13 (15.3%) (3 (23%) for a perforation; 10 (77%) for a failure or non-curative due to positive horizontal margins and without recurrent disease). There was a significant difference between two groups (p < 0.001). The frequency of colorectal neoplastic was 66.8% (119/178 patients) in the case group and was significantly higher than control group of 24.2% (86/356 patients) (p < 0.001). The median number and size of neoplasm were 2.44 and 4.74 mm in the case group and 1.77 and 3.89 mm in the control group. There was a significant difference between two groups (p = 0.001). The distribution of neoplasm in the control group vs in the control group was 12.6% vs 12.6% in cecum, 30.3% vs 36% in ascending colon, 21.4% vs 26.5% in transverse colon, 15.1% vs 10.5% in descending colon, 66.4% vs 40.7% in sigmoid colon, and 31.9% vs 19.8% in rectum. The incidence of neoplasm in sigmoidal region had a significant difference in two groups (the case group 80.7% vs the control group 55.3% (p < 0.001). In terms of neoplasm larger than 5 mm, the frequency was 34.5% (61/178 patients) in the case group and 7.6% (27/356 patients) in the control group (p < 0.001). In addition, as for neoplasm larger than 10 mm, that was 15.2% (27/178 patients) and 2.2% (8/356 patients) respectively (p < 0.001). The number of neoplasm resected by endoscopy was 71 lesions (24.5% of all) in the case group and 5 lesions (16.4%) in the control group. The pathological examination in the case and control group showed eight and one had hyperplastic polyops, 2 and zero had sessile serrated adenoma/polyp, 3 and zero had inflammatory polyop, 48 and 19 had low grade neoplasms, 10 and 1 had high grade adenoma and carcinoma, 5 and 2 had carcinoma respectively. There were no significant differences between two groups in the limited cases of high grade adenoma and carcinoma.

**Conclusion:** This study showed the acromegalic patients had an increased risk of colorectal neoplasia especially in the sigmoidal region. It is important to be performed colonoscopy at the diagnosis of acromegaly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** It is well known that acromegolys have been at an increased risk of colorectal neoplasm. However, there has been few reports of them in Japanese patients with acromegaly. In this study, we attempted to elucidate the risk of colorectal neoplasm in Japanese patients with acromegaly comparing with healthy controlled patients.

**Aims & Methods:** Between April 2008 and September 2016, a total of 745 patients were underwent Hardy operation in our institute. Among them, a total of 178 patients were performed colonoscopy in our hospital during perioperative period and were enrolled in the case group. In contrast, a total of 356 patients were selected randomly from those who were performed colonoscopy in our medical check-up in the same period by means of being matched to cases of the age and gender. The incidence, size, location and histology of colorectal neoplasm were investigated.

**Results:** As background, 84 patients (47.2%) were men and 94 patients were women, and the median age was 47.5 years old (18 to 75) in the case group. The median height/weight was 165.5 cm/65.1 kg in the case group and was significantly larger than the control group (163.4 cm/60.1 kg) (p = 0.038, p < 0.001 respectively). The median Body Mass Index (BMI) were 23.4 in the control group and 22.5 in the case group and was significantly different between two groups (p < 0.001). The frequency of colorectal neoplasm was 66.8% (119/178 patients) in the case group and was significantly higher than control group of 24.2% (86/356 patients) (p < 0.001). The average number and size of neoplasm were 2.44 and 4.74 mm in the case group and 1.77 and 3.89 mm in the control group. There was a significant difference between two groups (p = 0.001). The distribution of neoplasm in the case group vs in the control group was 12.6% vs 12.6% in cecum, 30.3% vs 36% in ascending colon, 21.4% vs 26.5% in transverse colon, 15.1% vs 10.5% in descending colon, 66.4% vs 40.7% in sigmoid colon, and 31.9% vs 19.8% in rectum. The incidence of neoplasm in sigmoidal region had a significant difference in two groups (the case group 80.7% vs the control group 55.3% (p < 0.001). In terms of neoplasm larger than 5 mm, the frequency was 34.5% (61/178 patients) in the case group and 7.6% (27/356 patients) in the control group (p < 0.001). In addition, as for neoplasm larger than 10 mm, that was 15.2% (27/178 patients) and 2.2% (8/356 patients) respectively (p < 0.001). The number of neoplasm resected by endoscopy was 71 lesions in the case group and 5 lesions in the control group. The pathological examination in the case and control group showed eight and one had hyperplastic polyps, 2 and zero had sessile serrated adenoma/polyp, 3 and zero had inflammatory polyop, 48 and 19 had low grade neoplasms, 10 and 1 had high grade adenoma and carcinoma, 5 and 2 had carcinoma respectively. There were no significant differences between two groups in the limited cases of high grade adenoma and carcinoma.

**Conclusion:** There were no significant differences between two groups in the limited cases of high grade adenoma and carcinoma.

**Contact E-mail Address:** rasmusklump1974@gmail.com

**Introduction:** Colonoscopy in ulcerative colitis (UC) is performed as first diagnosis and during screening for dysplasia and disease flares. It is an invasive procedure with a burden of discomfort and possible complications. To overcome discomfort and complications due to colonoscopy an Italian high-tech start-up (Endots, Paccioti, Italy) developed a soft, self-propelled, disposable robotic colonoscope (R), approved with CE mark.

**Aims & Methods:** We wanted to compare diagnostic performance and tolerability of R with those of standard white light colonoscopy (S) in patients with ulcerative colitis (UC). Consecutive patients referred for colonoscopy to our endoscopy department with clinically mild to moderate ulcerative colitis that signed the informed consent for both procedures were studied first with R and then with S (Olympus CF-145), by two different operators, blinded to previous observations. R had the following technical specifications: 17 mm outer diameter, rest position length probe 30 cm; maximum length of probe 54 cm; working length 210 cm; NTSC CMOS analog camera. Conscious sedation with midazolam was administered as
Disclosure of Interest:

We recorded endoscopic diagnostic accuracy according to Baron criteria, time to reach the caecum, patient's pain/discomfort and operator's difficulty.

Results: We studied 12 patients (7M:5F), mean age 41 yrs and disease duration 5.33 yrs. 53 colonic segments out of the 54 evaluated had the same assessment of disease activity (absent = 0 points, mild = 1 pt, moderate = 2 pts and severe = 3 pts). The diagnostic accuracy score with R was 0.33 pts (SD 0.60) with S, without significant difference. The caecum was reached in 11/12 cases by S in an average of 29.42 min (SD 28.94), and in 10/12 cases by R, in an average of 46.67 min (SD 24.98 min), with a mean difference of 17.25 min., not statistically significant. Incomplete colon explorations with R clustered in Milan, probably because of smaller experience. An average of 1.45 (SD 0.79) mg of midazolam were used during S while 0.41 (SD 0.38) mg during R. Mean pain/discomfort on a 0–10 scale was 2.08 (SD 1.67) for R and 4.17 (SD 1.74) for S, with a statistically significant difference (p=0.06) favouring R. Mean perceived operator’s difficulty on a 0–10 scale was 4.44 (SD 1.78) for R, and 4.08 (SD 1.44) for S, with a mean difference of 0.42 pts favouring S, not statistically significant.

Conclusion: R appears to be a promising method for disease staging in patients with ulcerative colitis, because of comparable accuracy and reduction in pain and discomfort. A tool channel to obtain biopsies and perform therapeutic endoscopy, together with images of higher definition (CMOS digital Camera HD ready) and virtual chromo-endoscopy, useful for follow-up and screening for dysplasia in patients with long duration of disease are now available in the latest version of R. The “column” connected to the latest version of the robot is the size of a portable suitcase, and suitable for remote operation. Further developments with new versions of the robot are needed to assess role of this technology from an economic point of view and in special settings like failed colonoscopies, dysplastic lesions in UC, bedside colonoscopy, colonoscopy in rural areas.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0870 WHAT IS THE CONCORDANCE FOR THE DIAGNOSIS OF LATERALLY SPREADING-TYPE LESIONS (LST) AMONGST WESTERN AND JAPANESE EXPERT ENDOSCOPISTS?

Aims & Methods:

Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-M malignant) were by 6 expert endoscopists; 3 from Japan and 3 from the West. We studied 12 patients (7M/5F), mean age 41 yrs and disease duration 6.27 yrs (45.4%), Western diagnosed more LST-G than Japanese (54.6 vs. 37.3%; p=0.007). The interobserver agreement of the LST classification amongst Western & Japanese experts. Aims & Methods:

A total of 40 endoscopic video clips depicting LSTs (10% margin) was scored by 6 expert endoscopists; 3 from Japan and 3 from the West. Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-NG flat, LST-NG pseudodepressed), Paris classification, invasiveness, treatment suggestion and mean size of lesion. We calculated the interobserver agreement with weighted kappa and Chi square. Results:

Japanese endoscopists diagnosed more lesions as LST-G than Western (62.7 vs. 45.4%), Western diagnosed more LST-NG than Japanese (54.6 vs. 37.3%; p=0.007). The interobserver agreement of the LST classification amongst Western & Japanese experts was good with a weighted Kappa of 0.61 (IC 95% 0.45–0.78) for Japanese, and moderate at 0.45 (IC95% 0.27–0.64) for Western. Difference in concordance between the two cohorts was not statistically significant (p=0.22). When only two categories were considered (LST-G vs NG), agreement was very good for Japanese (weighted Kappa of 0.81; 95% CI 0.65–0.97) and good for Western endoscopists (0.65; 95% CI 0.46–0.85). Again, difference in concordance was not statistically significant (p=0.22). Piecemal Endoscopic Resection was suggested in 34, 7% cases by Western, but never by Japanese endoscopists, whereas Endoscopic Submucosal Dissection was recommended in 50.4% and 16.1% cases by Japanese and Western experts respectively (p < 0.0001).

Conclusion: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

DISSECTION OF LARGE NON-PEDUNCULATED COLORECTAL LESIONS: A MULTICENTER STUDY FROM THE SPANISH ENDOSCOPY SOCIETY ENDOSCOPIC RESSECTION GROUP

We studied 12 patients (7M/5F), mean age 41 yrs and disease duration 6.27 yrs (45.4%), Western diagnosed more LST-NP than Japanese (54.6 vs. 37.3%; p=0.007). The interobserver agreement of the LST classification was good in the Japanese cohort and moderate in the Western. Again, difference in concordance was not statistically significant (p=0.22). When only two categories were considered (LST-NP vs LST-NG), agreement was very good for Japanese (weighted Kappa of 0.81; 95% CI 0.65–0.97) and good for Western endoscopists (0.65; 95% CI 0.46–0.85). Again, difference in concordance was not statistically significant (p=0.22). Piecemal Endoscopic Resection was suggested in 34.7% cases by Western, but never by Japanese endoscopists, whereas Endoscopic Submucosal Dissection was recommended in 50.4% and 16.1% cases by Japanese and Western experts respectively (p<0.0001).

Conclusion: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

calculated the SMSA score of difficulty and assessed the ability of SMSA to identify 5 outcomes: 3-month recurrence, 1-year recurrence, global recurrence (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using chi-squared tests and complemented with logistic regression models.

**Results:** The SMSA scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 399 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak (κ = 0.33). 255 patients (19.9%) had 3-months recurrence after EMR, 84 (11.6%) had recurrence at 1 year, 78.5% suffered delayed bleeding and 35.1% underwent perforation. The level 4 polyps had significantly higher rates of recurrence at 3 months and 1 year (p < 0.001 in both cases) and delayed bleeding too (p = 0.006), but not for perforation.

**Conclusion:** The SMSA grading tool is a predictor of outcomes or recurrences and bleeding following resection of LNPCI. However, in our multi-center sample, it does not appear to overcome the utility of a subjective indicator of difficulty used by the endoscopist during the EMR. It seems that this score can be used to facilitate planning, training or competency assessment, but efforts should be focused on validating the scoring system in a real situation, adjusting the score of variables or including new ones.

**P0872 NARROW BAND IMAGING GUIDED BIOPSY IMPROVES THE YIELD OF HISTOLOGY FOR THE DIAGNOSIS OF GASTROINTESTINAL TUBERCULOSIS (GITB)**
Gastrointestinal, Postgraduate Institute of Medical Education and Research, Chandigarh/India

**Contact E-mail Address:** sarojk.sinha@hotmail.com

**Introduction:** Accurate diagnosis of gastrointestinal tuberculosis (GITB) is challenging due to pauci-bacillary nature of disease and poor sensitivity of histopathology. Role of tissue acquisition using narrow band imaging magnification (NBI-M) to improve yield of histopathology over high-definition white light endoscopy (HD-WLE) has not been assessed.

**Aims & Methods:** Utility of narrow band imaging with magnification versus high-definition white light imaging guided endoscopic biopsy for diagnosis of gastrointestinal tuberculosis. In this prospective study from July 2015 to November 2016, adult cases of clinically suspected GITB were recruited. All patients underwent NBI-M test, contrast enhanced computed tomography of abdomen, esophagogastroduodenoscopy and colonoscopy using both HD-WLE and NBI-M and guided biopsies using both were taken. Histopathological examination was done by two independent pathologists. A final diagnosis of GITB was made if acid-fast bacilli were seen in tissue or grown in culture, histopathology showed caseous necrosis with granulomatous inflammation or clinical/radiological and endoscopic features were suggestive of tuberculosis and patient had clinical response to antitubercular therapy.

**Results:** A total of 35 cases of clinically suspected GITB were recruited. A final diagnosis of tuberculosis was made in 32 cases (duodenal n = 4, ileocolic n = 28). Concomitant evidence of active or healed pulmonary tuberculosis was seen in 21% of cases. The mean age, haemoglobin and erythrocyte sedimentation rate of patients with tuberculosis were 36.1±4.16 years, 10.2±2.4 g/dl, 37.8±15.53 mm/hour respectively. The mean duration of symptoms was 10.9 months. The most common symptoms were pain abdomen (78%), weight loss (62.5%), and loss of appetite (40.6%), fever (37.5%), vomiting (34%) and diarrhoea (22%). Mantoux test was positive in 40.6% cases. The most common endoscopic findings were ulcerations (75%), nodularity (46.8%), distorted ileocecal valve (28%) and strictures (21.8%) (Table 1). The most common radiological findings were mural wall thickening (65.6%), mesenteric lymphadenopathy (56%) and strictures (40%) (Table 1). NBI-M guided biopsy confirmed the diagnosis of GITB in 46.8%, while HD WLE guided biopsy confirmed diagnosis of GITB in 28.12% (P, 0.04). The two sets of biopsies together confirmed diagnosis of GITB in 53.1%. The area under curve for NBI-M plus HDWLE, NBI-M alone and HDWLE alone were 0.77 (0.63–0.87) 0.73 (0.60–0.85) and 0.64 (0.50–0.77) respectively. Patients were started on anti-tubercular therapy for nine months. Four patients underwent surgery for intestinal obstruction while on anti-tubercular therapy. Twenty eight completed full therapy and improved.

**Conclusion:** NBI-M guided biopsy improved the yield of histology for diagnosis of GITB.

**Introduction:** Colorectal cancer is a leading cause for cancer related mortality. Adenomatous polyp, the precursor, can usually be endoscopically resected to prevent cancer. Currently, there are no criteria for surgical vs. endoscopic resection and decision is individually made by the treating physician.

**Aims & Methods:** We aimed to evaluate factors associated with short-term efficacy and safety of endoscopic resection of large (≥20 mm) and giant (≥40 mm) adenomas. Consecutive cases that underwent endoscopic resection of adenomas larger than 20 mm were included. Endoscopic, clinical and histological details of polyps and of the endoscopic procedure were recorded as well as the need for surgical resection.

**Results:** Total of 351 resections were included. Average diameter was 30.34±10.66 mm. Surgery was indicated in 21 (5.98%) cases. In a multivariate analysis for efficacy, two variables were independent risk factors for surgery: adenoma size (OR 95%CI 1.08 (1.04–1.12) and cecal location (OR 95%CI 1.06 (1.02–1.10). In a multivariate analysis for safety, independent risk factors for post-polypectomy complications were: bleeding (OR 95%CI 0.33 (0.16–0.67), perforation (OR 95%CI 1.66 (1.04–2.65) and minimal discomfort up to early termination of procedure (OR 95%CI 1.43 (1.03–1.98)). Only 21 (6.0%) developed serious complications requiring further hospitalization. In multivariate analysis for safety, independent risk factors for post-polypectomy complications were: adenoma size (OR 95%CI 1.04 (1.01–1.06), polyph morphology (OR 95%CI 2.55 (1.45–4.51), flat OR 95%CI 2.40 (1.04–5.52) and submucosal adrenaline injection (OR 95%CI 1.87 (1.11–3.10)). Every increment of 1 mm in adenoma diameter above 20 mm, increased the need for surgery by 8% and the risk for complications by 4%.

**Conclusion:** Resection of large or giant adenomas is generally a safe procedure when performed by an experienced endoscopist. Although adenoma size is the most significantly related to efficacy and safety, each case of giant adenoma should be evaluated in a referral center for feasibility of endoscopic resection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Prophylactic mucosal defect closure was effective in reducing delayed bleeding.

Results: 269 articles were initially screened; 5 were RCTs, 4 of them were pooled in the quantitative analysis. A total of 555 patients and 557 resected lesions (proximal colon: 220; distal: 337) were included. Endoscopic procedures: 459 loop polypectomies and 98 submucosal dissections. A total of 298 lesions were randomized to PC versus 259 to non-closure (NC). Number of events on PC group: delayed bleeding (n = 3), PSF and perforation (n = 61). Number of events on NC group: delayed bleeding (n = 13), PSF and perforation (n = 14). Prophylactic mucosal defect closure was effective in reducing delayed bleeding risk (OR = 0.036 95%CI: 0.004–0.77% p = 0.001; I² = 0.0%; 3 RCT and 165 lesions included). There was a non-significant trend for PSF/perforation risk reduction after PC (OR 0.349 95%CI 0.114–1.070, p = 0.066; I² = 0.0%; 2 RCT and 374 lesions included).

Conclusion: Prophylactic closure of mucosal defects after EMR of flat or sessile colorectal lesions ≥10 mm reduces de risk of delayed bleeding. Further studies are needed to evaluate the effect on PSF/perforation prevention.Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: ESD is feasible and efficient in very old patients. However, En bloc resection and R0 resection are less frequent than in younger patients probably due to more challenging lesions (more frequent cancer on the pathological analysis). ESD should be the treatment of choice for large rectal superficial neoplasms of the rectum in very old patients in view of its oncological efficiency and its safety in comparison to the surgical alternative.

P0875 COLORECTAL MUCOSAL DEFECT CLOSURE FOLLOWING ENDOSCOPIC MUCOSAL RESECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Palma1, P. Marques Da Costa2, A. O. Ferreira1
1Gastroenterology Department, Hospital Beatriz Angeló, Loures/Portugal
2Gastroenterology And Hepatology Department, Hospital de Santa Maria, Lisboa/Portugal

Contact E-mail Address: palmecarolina@gmail.com

Introduction: Clinical delay or small perforating defects are the most frequent adverse event following endoscopic colorectal mucosal resection. Observational and interventional studies on the efficacy of prophylactic closure (PC) following endoscopic mucosal resection (EMR) showed conflicting results.

Aims & Methods: The primary objective of this review is to evaluate the effectiveness in preventing bleeding and post-polypectomy syndrome (PPS) or perforation of PC of colonic mucosal defects following endoscopic resection. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) from MEDLINE.

Results: A total of 344 patients were included, 53% were male, mean age of 61.8 ± 13.6 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of patients had good bowel cleansing quality in patients from a district hospital. This was an exploratory observational study of patients who underwent total colonoscopy between jun/2016-mar/2017 with polyethylenoglycol bowel preparation before and after SD protocol implementation. Bowel cleansing quality was assessed prospectively (using Boston Bowel Preparation Score) and compared between SD and PD groups. Tolerance was assessed using a patient questionnaire.

Conclusion: A total of 344 patients were included, 53% were male, mean age of 61.8 ± 13.6 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of colonoscopies occurred in morning shifts. Mean interval between finishing bowel preparation and colonoscopy was 4h50 (SD) and 8h09 (PD). Adequate bowel cleansing was found in 81% of patients (SD 83% vs. PD 79%; p = 0.34). There was an association between adequate bowel cleansing and a shorter interval between finishing preparation and colonoscopy (5h40 vs. 7h15; p = 0.010). Split-dose preparation was associated with a better cleansing in the right colon (2.17 ± 0.69 vs. 2.03 ± 0.65; p = 0.047) and a trend for better overall cleansing (6.70 ± 1.87 vs. 6.32 ± 1.90; p = 0.067). On morning shifts, there was a significant association between SD preparation and better overall cleansing (p = 0.030) and also right colon cleansing (p = 0.034). After adjusting for morning shifts, we found an association between SD preparation and better bowel cleansing (risk difference 0.406; 95%CI –0.023–0.834; p = 0.063). There was no difference between groups on bowel urgency (SD 2.6% vs. PD 1.7%; p = 0.718). SD preparation was associated with worse sleep quality (SD 25% vs. DA 7%; p = 0.004).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0876 COLORECTAL MUCOSAL DEFECT CLOSURE FOLLOWING ENDOSCOPIC MUCOSAL RESECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

P0877  EQUAL ADENOMA DETECTION RATE IN COLORECTAL ESD CONVERSION TO EMR AT A WESTERN REFERRAL CENTER IN DAILY PRACTICE

A. Perez-Cuadrado-Rohles, H. Piessevaux, T. Moreels, P.H. Deprez
Gastroenterology Department, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Contact E-mail Address: akikenurca@gmail.com

Introduction: There are limited data concerning risk factors and consequences of colorectal endoscopic submucosal dissection (ESD) conversion to en-bloc resection (EMR) in western centers.

Aims & Methods: Hospital-based frequency-matched case-control retrospective study. All patients were identified from a database of 223 consecutive dissections between 2013 and 2017. The cases were those with ESD conversion to EMR for a cancer already installed, especially with the presence of clinical signs.

Results: A total of 1059 colonoscopies were performed; 10.3% were indicated for people older than 70 years. The mean age was 74.15 years with a median age of 75 years and a maximum age of 91 years. The prevalence of males was 51.10%, 15.5% of cases (n = 10) were diabetic, 12.5% (n = 12) hypertensive, 12.5% (n = 12) with ischemic heart disease. 8.4% (n = 8) had either obesity and 9% (n = 9) had a digestive neoplasia. Colonoscopy was indicated for hematocrit 40% (n = 38), transit disorders in 33.6% (n = 22), abdominal pain in 14.7% (n = 14), BMI of 3.1% (N = 3), radiographic abnormalities in 13.6% (n = 13), iron deficiency anemia in 2.4%, and for patients with a family history of colorectal cancer in 1% of cases. Colonoscopy was abnormal in 83% (n = 93), with polyps in 48.5% (n = 45), suspected lesions of malignancy in 16.1% (n = 15), Diarrhea in 19.3% (n = 18), IBD in 19.3% (n = 18), IBD with complications in 12% (n = 11) and rectal erosions in 2.1% (n = 2). The rate of malignant lesions diagnosed by colonoscopy was 53.3% of females (n = 8) versus 46.7% of males (n = 7) (p = 0.26), 13.5% (N = 2) with hematocrit <20% and 86.7% (n = 13) with altered general status (n = 4) versus conserved general status (n = 11) (p = 0.07). The evolution of 46.6% of patients diagnosed with malignant tumor pathology showed that 33.5% of patients underwent surgery and 13.3% of patients had died.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0878  RISK FACTORS AND PRACTICAL CONSEQUENCES OF COLORECTAL ESD CONVERSION TO EMR AT A WESTERN CENTER

Introduction: Acute iatrogenic perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the mortality.
burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting surgery as a first line treatment, and failure of endoscopic treatment. Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute iatrogenic perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 764 studies were identified. 28 studies, in human, met our inclusion criteria and were analysed. A total of 474 endoscopic closures were attempted in these studies. The overall technical success rate was 93.1% (n = 451/474, 95% CI: 90.6%–95.4%), clinical success was 89.7% (n = 431/474, 95% CI: 85.5%–93.9%), and complication rate was 1.3% (n = 7/474, 95% CI: 0.3%–2.3%). Technical success for endoclamp closure was 96.6% (95% CI: 94.2%–98.2%), and clinical success was 93% (95% CI: 87.1%–97.2%), and complications in 9% (95% CI: 80.6%–99.5%). For OTSC (Over the scope clip device), technical success was 83.8% (95% CI: 63.9%–96.6%), clinical success was 77.9% (95% CI: 56.8%–93.3%), and complication rate was 4.1% (95% CI: 2.4%–5.6%). The technical success rate for Self-expanding metallic stent (SEMS) is 100% (95% CI: 71.5%–100%), clinical success is 91% (95% CI: 74.1%–108%), and complication rate of 9.1% (95% CI: 78%–112%). Only one study for endosuturing met our criteria, with technical and clinical success rate of 100%, and without any complication. Factors predicting failure of endoscopic closure and need for further surgery included large size, severe peritoneal free air, necrotic or soft inflammatory margins, unfavourable anatomical site, stool contamination, and failure of endoscopic closure.

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations. Several factors have been suggested as predictors of need for surgery as a first line treatment. The study is limited by the low methodological quality of most studies included, indicating the need for further research.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0882 "O-RING SIGN" AS A NOVEL COLONOSCOPIC FINDING WITH NARROW-BAND IMAGING FOR DETECTING DEPRESSED-TYPE COLORECTAL LESIONS

T. Fuji, R. Gallo
Dept. Of Gastroenterology, TF Clinic Dept. of Gastroenterology, Tokyo/Japan

Introduction: In recent years, colorectal cancer (CRC) has become a focus of attention as likely representing “missed” or “rapidly-growing” lesions in colonoscopy screening for colorectal cancer (CRC). Currently, lesions thought responsible for CRC include sessile serrated adenomas/polyps or flat and depressed-type lesions occurring on the right side of the colon, and there is an increasing need for endoscopic modalities to prevent overlooking these lesions. Colonoscopic screening using narrow-band imaging (NBI) during colonoscopy withdrawal from the cecum, which was started at our clinic since November 2008, suggested that NBI colonoscopy was superior to white-light imaging (WLI) colonoscopy in detecting flat and depressed-type lesions (1). With NBI, the depressed area of a lesion is recognized as “whitish” and the surrounding ring-like mucosa as “brownish”, which constitutes the “O-ring sign”.

Aims & Methods: We aimed to evaluate the incidence and characteristics of the “O-ring sign” in depressed-type colorectal lesions. A total of 227 endoscopically resected and histologically confirmed depressed lesions (Ha + Ic, 156, Ha, 71) were included for analysis. The colonoscopic images of these lesions were retrospectively examined for “O-ring sign” positivity and intensity (grade 0, negative; grade 1, mildly to moderately positive; and grade 2, highly positive). Of these, 16 were excluded as unvaluable and a total of 211 evaluable lesions were analyzed. Results: Of the 211 lesions (Ha + Ic, 141; Ic, 70) analyzed, 84 (Ha + Ic, 68; Ic, 24), 105 (Ia + Ic, 69; Ic, 36), and 22 (Ia + Ic, 12; Ic, 10) were found to be in grades 0, 1, and 2, respectively, with 60.2% of these shown to be “O-ring sign” positive (127/211), with Ha + Ic and Ic accounting for 57.4% (81/141) and 65.7% (45/67), respectively, of these lesions. While an examination by tumor size and location revealed no clear tendency in “O-ring sign” positivity, an examination grade revealed a higher “O-ring sign” positivity rate among those with high-grade dysplasia (84.6%, 11/13) than those with low-grade dysplasia (59.2%, 116/196).

Conclusion: NBI colonoscopy screening for the “O-ring sign” as an index appears to improve the detection of depressed-type colorectal lesions.

Introduction: Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to susceptibility to erosions, as well as to the occurrence of adverse events such as bleeding during the treatment. With liver cirrhosis can tolerate ERCP to treat their biliary tract or pancreatic diseases. Patients with liver cirrhosis are three times more susceptible to cholecholangitis, compared to non-cirrhotic patients. Patients with liver cirrhosis have an increased risk of complications of upper gastrointestinal and other diseases and that is why ERCP is increasingly performed for patients with cirrhosis. Endoscopic sphincterotomy (EST) has become a standard step in management of CBD stones and introduction of both mechanical lithotripsy (ML) and large balloon dilation (LBD) facilitated extraction of the large CBD stones. Despite the increasing use of both techniques, a head-to-head comparison among therapeutic benefits and complications between mechanical lithotripsy and large balloon dilation after sphincterotomy in patients with liver cirrhosis. Ninety eight cirrhotic patients suspected higher rates of adverse events especially bleeding diathesis. Patients with liver cirrhosis patients Child A or B with clinical and laboratory proved obstruction jaundice, presence of large bile duct stones and deep selective cannulation of the bile duct. Exclusion criteria included: Known allergy to the used contrast material, Child C cirrhosis, the Need for needle knife puncturing in order to achieve bile duct cannulation, Selective bile duct cannulation achieved after multiple transpancreatic or transgastric papillotomies. All patients were subjected to thorough history taking, complete clinical examination. Pancreatic enzymes concentrations were measured 4 hours before and 24 hours after the procedure, complete blood count and liver function tests were performed before and after the procedure. Before and during ERCP, stone size and number were verified. Diagnosis of common bile duct stones was confirmed either by pre-ERCPC investigations including abdominal ultrasonography (US), CT, MRCP or at the time of ERCP. Large CBD stone: Is defined before ERCP by a bile duct stone 12 mm or more (transverse diameter of the largest stone) by US, CT or MRCP and during cholangiography showed large filling defect more than 12 mm that could not be extracted using a standard balloon catheter. 

Results: There were no dropouts and all subjects remained in the study till the end of the study. Initial, middle, late period, respectively. In the operation time, there was a significant difference in the operation speed of endoscopist C among each endoscopist.

The reported complications in both groups

Conclusion: In conclusion endoscopic sphincterotomy plus LBD is a safe and effective treatment for endoscopic removal of large common bile duct stones in cirrhotic patients when compared with endoscopic sphincterotomy plus ML. Despite the increasing use of both techniques, a head-to-head comparison among therapeutic benefits and complications between mechanical lithotripsy and large balloon dilation after sphincterotomy in patients with liver cirrhosis. Ninety eight cirrhotic patients suspected higher rates of adverse events especially bleeding diathesis. Patients with liver cirrhosis patients Child A or B with clinical and laboratory proved obstruction jaundice, presence of large bile duct stones and deep selective cannulation of the bile duct. Exclusion criteria included: Known allergy to the used contrast material, Child C cirrhosis, the Need for needle knife puncturing in order to achieve bile duct cannulation, Selective bile duct cannulation achieved after multiple transpancreatic or transgastric papillotomies. All patients were subjected to thorough history taking, complete clinical examination. Pancreatic enzymes concentrations were measured 4 hours before and 24 hours after the procedure, complete blood count and liver function tests were performed before and after the procedure. Before and during ERCP, stone size and number were verified. Diagnosis of common bile duct stones was confirmed either by pre-ERCPC investigations including abdominal ultrasonography (US), CT, MRCP or at the time of ERCP. Large CBD stone: Is defined before ERCP by a bile duct stone 12 mm or more (transverse diameter of the largest stone) by US, CT or MRCP and during cholangiography showed large filling defect more than 12 mm that could not be extracted using a standard balloon catheter.

Introduction: Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to susceptibility to erosions, as well as to the occurrence of adverse events such as bleeding during the treatment. With liver cirrhosis can tolerate ERCP to treat their biliary tract or pancreatic diseases. Patients with liver cirrhosis are three times more susceptible to cholecholangitis, compared to non-cirrhotic patients. Patients with liver cirrhosis have an increased risk of complications of upper gastrointestinal and other diseases and that is why ERCP is increasingly performed for patients with cirrhosis. Endoscopic sphincterotomy (EST) has become a standard step in management of CBD stones and introduction of both mechanical lithotripsy (ML) and large balloon dilation (LBD) facilitated extraction of the large CBD stones. Despite the increasing use of both techniques, a head-to-head comparison among therapeutic benefits and complications between mechanical lithotripsy and large balloon dilation after sphincterotomy in patients with liver cirrhosis. Ninety eight cirrhotic patients suspected higher rates of adverse events especially bleeding diathesis. Patients with liver cirrhosis patients Child A or B with clinical and laboratory proved obstruction jaundice, presence of large bile duct stones and deep selective cannulation of the bile duct. Exclusion criteria included: Known allergy to the used contrast material, Child C cirrhosis, the Need for needle knife puncturing in order to achieve bile duct cannulation, Selective bile duct cannulation achieved after multiple transpancreatic or transgastric papillotomies. All patients were subjected to thorough history taking, complete clinical examination. Pancreatic enzymes concentrations were measured 4 hours before and 24 hours after the procedure, complete blood count and liver function tests were performed before and after the procedure. Before and during ERCP, stone size and number were verified. Diagnosis of common bile duct stones was confirmed either by pre-ERCPC investigations including abdominal ultrasonography (US), CT, MRCP or at the time of ERCP. Large CBD stone: Is defined before ERCP by a bile duct stone 12 mm or more (transverse diameter of the largest stone) by US, CT or MRCP and during cholangiography showed large filling defect more than 12 mm that could not be extracted using a standard balloon catheter.
received anesthesiologist-directed BPS, required bag-mask ventilation and the ERCP was aborted due to sedation effects. There was no mortality from any cause within 24 hours of ERCP. All patients were discharged from the advanced endoscopy suite without adverse events.

Conclusion: Endoscopist-directed BPS appears feasible, safe and efficacious for ASA I-III patients requiring inpatient care after ERCP.

PO887 DUODENOSCOPES AND LINEAR ECHOENDOSCOPES ARE NOT INFECTED BY THE SAME MICROORGANISM:
NATIONWIDE PERSISTENT HIGH PREVALENCE IN THE NETHERLANDS

1Gastroenterology & Hepatology, Erasmus MC University Medical Center, Rotterdam/Netherlands
2Medical Microbiology And Infectious Diseases, Erasmus MC University Medical Center, Rotterdam/Netherlands
3Staff Office Medical Devices, Erasmus MC University Medical Center, Rotterdam, the Netherlands, Rotterdam/Netherlands

Contact E-mail Address: a.rauwers@erasmusmc.nl

Introduction: Recent studies describe multiple outbreaks of multi-drug resistant organisms caused by contaminated duodenoscopes, used for endoscopic retrograde cholangiopancreatography (ERCP) procedures. Contamination of duodenoscopes is attributed to their complex design, which includes a ball-valve Y-connection, forceps elevator and elevator wire channel. Linear echoendoscopes (LEs), used for endoscopic ultrasound (EUS) procedures, have a similar design with an additional balloon channel. Previously, we found that contamination of duodenoscopes was widespread in the Netherlands. It is unclear if the increased awareness of contamination and associated outbreaks has improved reprocessing outcomes of duodenoscopes and linear echoendoscopes (DLEs).

Aims & Methods: This cross-sectional study was conducted to determine the prevalence of bacterial contamination of all reprocessed DLEs in The Netherlands. All 75 Dutch ERCP/EUS centres were invited to sample all DLEs using centrally distributed kits, according to uniform sampling methods and video instructions. Local staff sampled four to six sites per DLE depending on endoscope type, including swabs (protection cap, forceps elevator), flushes (biopsy, suction, air/water and forceps elevator channel) and brushes (biopsy, air/water and balloon channel). Samples were centrally cultured. Cultures were interpreted using standard culture and culture interpretation were consistent with Dutch guidelines. Contamination was defined as AM20: any microorganism with ≥20 colony forming units (CFU)/20 mL, and MGO: presence of microorganisms with gastrointestinal or oral origin, independent of CFU count.

Results: Between October 2015 and April 2017, 62 (85%) Dutch ERCP/EUS centres responded with 1130 samples of 215 DLEs (158 duodenoscopes and 57 LEs). Fifteen different DLE types from three distinct manufacturers were sampled. In total 29.62 (47%) centres had at least one AM20 or MGO contaminated DLE, similar to the prevalence (31.66 centres; 47%) in our previous study (p = 0.98). Twenty-eight (13%) DLEs from 19 (31%) centres were AM20 contaminated. Thirty-two (15%) DLEs from 23 (37%) centres were contaminated with MGO, including Enterobacteriaceae, Pseudomonas aeruginosa and Candida albicans. Of 19 patients with cholangiocarcinoma, success rate of SpyDS guided biopsy was 100% (19/19). M.J. Bruno: Prof. Dr. Marco J. Bruno received personal fees from Boston Scientific, personal fees from Cook Medical and grants from Pentax Medical outside the submitted work. PO888 TECHNICAL EVOLUTION OF A NEWLY-DEVELOPED DIGITAL CHOLANGIO/ Pancreato-scopy (SpyGlass DS) FOR INTERVENTIONAL EVALUATION OF PANCREATOBILIARY NEOPLASM

Gastroenterology, Sendai City Medical Center, Sendai/Japan

Contact E-mail Address: keito@openbor.or.jp

Introduction: Although a newly digital cholangio/pancreato-scopy (SpyDS) has been reported to be useful for therapeutic purpose in patients with biliary diseases, clinical application for diagnostic purpose of pancreateobiliary neoplasms remains unclarified.

Aims & Methods: To evaluate the usefulness and safety of cholangio/pancreato-scopy using a SpyDS for preoperative evaluation of pancreateobiliary neoplasms. Patients and methods: Between October 2015 and Feb 2017, consecutive 26 patients (19, cholangiocarcinoma; 7, IPMN) who underwent cholangio/pancreato-scopy using a SpyDS for preoperative evaluation were included in this study. Diagnostic accuracy of malignancy and tumor extent evaluation by cholangio/pancreato-scopy guided biopsy/cytology and adverse event after the procedure were retrospectively investigated.

Results: Of 19 patients with cholangiocarcinoma, success rate of SpyDS guided mapping biopsy was 83% (16/19) and diagnostic accuracy of adenocarcinoma was 77.8% (15/19). Of 7 patients with IPMN, diagnostic accuracy of malignancy was 85.7% (6/7).
tumor extent using SpysDS plus mapping biopsy was 92%. One patient developed mild cholangitis after the procedure. As for IPMN, pancreatoscopy using a SpysDS could visualize intraductal papillary tumors in all patients, and SpysDS guided biopsy/cytology was successfully performed. Diagnostic accuracy of malignancy was 100% without any adverse event after the procedure.

**Conclusion:** Preoperative evaluation using a SpysDS plus histological evaluation for pancreaticobiliary neoplasm was found to be useful and safe. Further study is needed to establish evidence about the usefulness of this technique.

### P0889 ACUTE PANCREATITIS AND HYPERAMYLASAEMY DEVELOPMENT AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY – CHALLENGES AND PREVENTION

**P. Petrov**1, B. Petrov1, T. Vukova2

1-University hospital “Sofiamed” - Sofia, Sofia, Bulgaria
2-Excitable Structures, Institute of Biophysics and Biomedical Engineering - Bulgarian Academy of Sciences, Sofia, Bulgaria

**Contact E-mail Address:** dr.p.petrov@gmail.com

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

**Aims & Methods:** To analyze the frequency of probable causes of asymptomatic hyperamylasaemia and acute pancreatitis after ERCP and their prevention. Two groups of patients were covered: a retrospective (340) and prospective (154) group. Patients had evidence of bile ducts impaired passability of varying etiology. In these cases ERCP is the final stage in the diagnostic and therapeutic algorithm. All ERCPs were carried out by one expert endoscopist. Patients from the prospective group were administered intramuscularly with Diclofenac (75 mg) before and after the manipulation. The methods used in the study were: demographic data; history and physical examination; laboratory data; imaging methods; ERCP; clinical course and statistical methods for processing data received.

**Results:** The most common indication for ERCP in all patients was choledocholithiasis (88.1%). In a minority of patients ERCP was purely diagnostic (6.1%), while at 93.9% it was also therapeutic. Of all patients at 47 of cases (9.5%) hyperamylasaemia was observed, and at 12 or 2.4% - acute pancreatitis was observed. Patients who developed acute pancreatitis were found to have a lower level of alkaline phosphatase and ES and higher values of leucocytes on the 72nd hour. The univariate logistic regression analysis identified the following risk factors for developing hyperamylasaemia: cholelithiasis; sclerosing papilloditis of ERCP; normal values of serum total bilirubin and elevated CRP levels in receiving. In order to establish a predictive model a multiple logistic regression analysis was performed. The model includes: average total bilirubin at entry and cannulation of the pancreatic duct more than 3 times. The estimated true percentage for predicting lack of hyperamylasaemia with this predictive model is very good - 97%. Univariate logistic regression analysis identified the following risk factors for the development of acute pancreatitis: cannulation of the pancreatic duct and the presence of calculous cholecystitis when entering.

**Conclusion:** We detected a low incidence of asymptomatic hyperamylasaemia (9.5%) and acute pancreatitis (2.4%) in the group of patients which were subjected to ERCP. Clinical and laboratory parameters characterizing the patients who developed these complications, and risk factors for acute pancreatitis and asymptomatic hyperamylasaemia were determined. The effect of intramuscular Diclofenac administered before and after ERCP has no effect.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0890 MOST ADVANCED ENDOSCOPY TRAINEES DO NOT MEET COMPETENCE FOR NATIVE PAPILLAE CANNULATION IN ERCP: RESULTS FROM A PROSPECTIVE MULTICENTER STUDY

**S. Wani**1, M. Hall1, V. Simon1, S. Han1, D. Early2, R. Keswani3

1-University of Colorado Anschutz Medical Center, Aurora/United States of America
2-Washington University in St. Louis, St. Louis/United States of America

**Contact E-mail Address:** sachin.wani@ucdenver.edu

**Introduction:** Advanced endoscopy trainees (AETs) achieve ERCP competency at variable rates and specific case volumes do not ensure competence. However, training and credentialing guidelines continue to utilize an absolute procedure volume to determine competence. There are limited data on whether current training composition and volumes ensure ERCP competence in the US.

**Aims & Methods:** (i) To define ERCP learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERCP training in AETPs. ASGE-recognized AETPs were invited to participate and AETs were graded on every ERCP after completion of 25 hands-on ERCP exams. Grading was performed using our previously developed and validated tool [The EUS and ERCP Skills Assessment Tool (TEESAT)] which assesses technical and cognitive competence in a continuous fashion. Grading for each skill was done using a 4-point scoring system: 1-no assistance, 2-minimal verbal cues, 3-multiple verbal cues or hands-on assistance and 4-unable to complete. A comprehensive data collection and reporting system was built using REDCap, a web-based data collection software, and SAS to create learning curves using cumulative sum (CUSUM) analysis for overall and individual technical and cognitive components of ERCP. Individual results and comparison to peers were sent to AETs and trainers quarterly. Acceptable and unacceptable failure rates were set as a skill score of 1 or 2. Individual and combined graphs to assess change in cannulation success rates were constructed and the Cochran-Armitage trend test was used to assess improvement in success rates.
Disclosure of Interest:

Results: Of the 62 programs invited, 20 AETs participated and 20 AETs were included in the final analysis. At the end of training, median number of ERCPs performed/AET was 350 (15–500). Overall, 2649 ERCP exams were graded; the majority were ASGE biliary grade 1 (77%) and only 14% for pancreatic indication. Among biliary ERCP cases, AETs attempted native papilla cannulation and sphincterotomy in 1199 (53%) and 901 (40%) cases, respectively. The mean time allowed for cannulation was: overall - 4.0 min (SD 4.3), native papilla - 5.7 min (SD 4.8), and AET failed cannulation cases - 6.2 min (SD 5). There was no change in the time allowed for native papilla cannulation during the 1-year period (p = 0.28). AETs were involved in a small proportion of cases requiring advanced cannulation techniques such as double-wire technique, placement of pancreatic duct stent and precut sphincterotomy (6%). Learning curves for individual endoscopists, overall technical and cognitive aspects noted substantial variability. Majority of AETs achieved overall technical (60%) and cognitive (100%) competence at the end of training. While there was a statistically significant improvement in overall and native papilla cannulation rates (both p < 0.001), only 18% of AETs achieved competence for native papilla cannulation (Table 1).

Conclusion: The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence.

Patient & procedural characteristics

Female: 71; 53.8% 79; 66.9%
Median age: 63.5 63
History of Spieltic of Oddi dysfunction: 0 0
History of Perccp: 0 0
History of chronic pancreatitis: 1; 0.8% 1; 0.8%
Trainee involvement: Normal Lfts: 21; 16.5% No data for 5 patients 11; 10% No data for 8 patients
Non-dilated bile ducts: 39; 29.5% 18; 15.3%
Pancreatic duct wire/contrast: 19; 15% Excludes 5 unsuccessful cannulations 30; 25.9% Excludes 2 unsuccessful cannulations
Precut sphincterotomy: 4; 3% 9; 7.6%

Results: A total of 250 procedures were audited. E1 performed 132 procedures (54% female; median age 63.5) and A1 performed 118 procedures (67% female; median age 63). The rates of PERCPP in E1 and A1 were 2.3% (3 patients) and 1.7% (2 patients) respectively. One 84-year-old patient of E1 with a presumed malignant common bile duct (CBD) stricture had PERCPP and died 17 days after ERCP, having opted for palliation. The remaining 4 patients had uneventful conservative management of PERCPP. E1 had one patient with immediate bleeding post-sphincterotomy controlled with a CBD stent whilst A1 had 2 patients requiring adrenaline injection for haemostasis. In addition, E1 had one patient with retroduodenal perforation managed conservatively and A1 had one patient with CT evidence of intraduodenal haematoma which was uneventful. Both E1 and A1 had one case each of uncomplicated hyperamylasaemia. A summary of complications, with patient and procedural characteristics, is listed in Table 1.

Conclusion: In our observational study, which was not intended or powered for statistical analysis, there was no overt difference in the rates of PERCPP when comparing between endoscopist- or assistant-controlled wire-guided CBD cannulation. The overall complication rate was similar and although there were some differences in procedural characteristics between the two endoscopists, there were no characteristics predisposing to PERCPP overtly skewed towards either endoscopist's case load. Further randomised trials, or a crossover study, provided the endoscopists and assistants are equally competent in both methods of wire cannulation, are needed to clarify the safety profile of either technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

Our AHP didn’t reduce the incidence of PEP or its severity. Indeed, PEP was mild. There were no complications related to AHP. We didn’t find any patient remaining 3 were mild. In the AHP group, 3 PEP were moderate and 4 were severe. Between both PEP incidences was not significant. Despite our study didn’t show the AHP group presented more PEP than the SH group, although the difference was not significant after the ERCP. One (94 years old, male) was in the F group and the other (81 years old, male) was in the non-F group. The distributions of used benzodiazepines (midazolam/diazepam) were not different (Fisher’s test: p-value = 0.05). The patient number who got aspiration pneumonia were 102/13/0 and 122/9/1 in the F group and the non-F group, respectively (Fisher’s test: p-value = 0.05). There were no significant differences of patient characteristics between both groups. The mean procedure times were 36.7±7.0 minutes in the F group and 30.3 minutes in the non-F group, respectively. The details of procedures for the major papilla (endoscopic sphincterotomy/endoscopic papillary balloon dilation/others) were 40/13/5/56 in the F group and 25/2/3/41 in the non-F group, respectively. The distributions of endoscopic biliary drainage or stenting/none were 94/21 in the F group and 59/16 in the non-F group, respectively (Fisher’s test: p-value = 0.85). There were no significant differences of procedure characteristics between both groups. 3) Two patients (1.05%) developed aspiration pneumonia after ERCP. One (94 years old, female) was in the F group and the other (81 years old, female) was in the non-F group (Pearson’s Chi-squared test p-value = 1). Both of them were over 80-year old. The patients who were given oxygen during ERCP were 1/3 in the F group and 19/12 in the non-F group, respectively (Fisher’s test: p-value = 1). Conclusion: Flumazenil did not have any preventive effect on aspiration pneumonia related to conscious sedation after ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Gastroenterologia, Hospital Espírito Santo de Évora, Évora/Portugal

Contact E-mail Address: irina.mocanu.24@gmail.com

Introduction: Extra-hepatic biliary tree strictures are caused by a variety of malignant and benign diseases. The brushing of stenosis during ERCP is safe and easy to perform, however, its low sensitivity, ranging from 30 to 50%. Efforts to improve cytology yield include dilution of the stricture prior to brushing and multiple brush passages, both without significant success. In 2011, US Endoscopy introduced the Infinity® cytology brush - a 14Fr (4, 75 mm) device that combines soft and stiff bristles in order to improve acquisition of cytology samples.

Aims & Methods: We aimed to determine if a new-design brush can improve the diagnostic yield of biliary cytology. From February 2015 until December 2016, we evaluated 192 patients undergoing ERCP in a single center. All patients with malignant or benign strictures were included in this prospective study. A classical 8Fr biliary brush (e.g. Boston, Boston Scientific, Endocath) was used as a control. The new Infinity® brush was used in all cases for ERCP cytology. The yields of both brushes were compared with histological controls, where a classical 8Fr biliary brush was used.

Results: Thirty-five new brush cases were compared with 52 historical controls. There was no significant difference between gender (57% Vs. 52% male; p > 0.05), age (mean 70.4 Vs. 74 years; p > 0.05), location of stricture (common bile duct 77% Vs. 84%; p > 0.05), length of stricture (between 1–3 cm in 38% Vs. 84%; p > 0.05) or dilation prior to sampling (71% Vs. 57% p > 0.05). The sensitivity, specificity, positive predictive value and negative predictive value were 66.6% Vs. 80% (p = 0.05), 81% Vs. 82% (p > 0.05), 0.61 Vs. 0.65 (n.s) and 0.54 Vs. 0.58 (n.s) respectively. There was no significant difference between the cases (31%) and controls (27%), either for pancreatic cancer (20% Vs. 24%; p > 0.05) nor cholangiocarcinoma (56% Vs. 50%; p > 0.05). The Infinity® brush was used in all cases of ERCP cytology. These were compared with histological controls, where a classical 8Fr biliary brush was used. In both groups, at least two passages were made, with transfer to a thin prep solution, as per prior protocol. Follow-up data, namely clinical course, radiological data or other histological results were collected for a definitive diagnosis.

Conclusion: There were significantly more samples with adequate cellularity for the new Infinity® brush than for the control brush (86% Vs. 100%, p < 0.05). The sensitivity of new design brush and the control brush were 86% Vs. 100%, respectively. There was no difference between the new designed and control brush (86% Vs. 100%, p > 0.05) or dilation prior to sampling (71% Vs. 57% p > 0.05) between the two groups. Physicians’ impression of malignant stricture during ERCP was more frequent in new brush cases, and with statistical significance (91% Vs. 75%; p = 0.052). The Infinity® brush was used in all cases of ERCP cytology. These were compared with histological controls, where a classical 8Fr biliary brush was used. In both groups, at least two passages were made, with transfer to a thin prep solution, as per prior protocol. Follow-up data, namely clinical course, radiological data or other histological results were collected for a definitive diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Early precut is as efficient as pancreatocutaneous duct cannulation initially by chance, the patients were randomized into early precut (Group A) or usual early precut sphincterotomy with pancreatocutaneous duct (Group B). In Group A, pancreatocutaneous duct cannulation within 5 times and attempted precut papillotomy with or without cystic duct puncture. If Group B, from the precut stent was inserted and then precut with an incision over a pancreatocutaneous duct was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

Results: From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 24 (95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the Group A and 14.8 minutes in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B (P < 0.001).

Conclusion: In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidewire was more effective in pancreatic duct cannulation and the success rate but also promise low incidence of post-ERCP pancreatitis. In experienced hands, utmost early precut technique can dramatically reduce the trauma of ampulla and risk of PEP compared with conventionally persistent cannulation attempts.

P0900 PROSPECTIVE STUDY ON METHODS AND SUCCESS OF BILIARY CANNULATION OF 458 VIRGIN PAPILLAS - QUALITY ASSURANCE OF ERCP AT OUR DEPARTMENT

Gastroenterology, Medical Centre, Hungarian Defence Forces, Budapest, Hungary

Contact E-mail Address: tiborgyokeres@freemail.hu

Introduction: The cannulation of a virgin papilla is the most difficult and high-risk step in ERCP and it requires significant experience to maximize the success and to minimize poor outcomes. Cannulation rate is one of the accepted quality indicators of ERCP. It is mandatory to regularly assess quality indicators of endoscopic procedures to maintain and improve endoscopic service.

Aims & Methods: We prospectively collected data about cannulation details of all patients with virgin papilla and post-ERCP complications from April 2016 to April 2017. Results: During this 12-month period we have performed 1102 ERCPs, in 458 of them we had virgin papilla. All ERCPs had therapeutic intentions and all of the patients were followed up. In 13 patients papillae were never approached due to duodenal stenosis (10) or postoperative situations (3/10). In two of them the indication was ceased (because the biliary obstruction resolved spontaneously), 11 patients got percutaneous transhepatic drainage (PTD). The primary cannulation success rate of accessible papillae was 88.5% (394/445) while the overall cannulation success was 96.6% (430/445). 56.1% of primary successful cannulations were achieved by conventional method, in 14.2% we used pancreatic guidewire assisted technique, in 20.1% we used early precut sphincterotomy, and in the last 5.6% we used combined techniques. In 51 primary unsuccessful cases we repeated ERCP attempt 4 days on average and successfully cannulated 70.5% (36/51) of them at the second or third attempts. 27 of them were achieved by conventional method, 7 of them after extending the precut, one case was achieved by pancreatic guidewire technique, and we used profilaic pancreatic stent in one patient, as well. Out of the 15 patients with finally unsuccessful cannulation, we performed precut without deep cannulation in 10 cases. 7 of them resolved after precut, 2 of the 10 patients got PTD and one patient refused further intervention. In 4 patients out of the 15 unsuccessful cannulations the obstruction resolved without any further intervention and one patient got PTD. We had in sum 3.4% (15/445) post-ERCP pancreatitis, 7 of them were mild, and 8 moderate, we had no severe one. We observed endoscopic signs of biliary tract disease in 34 cases that necessitated some endoscopic interventions (infiltration/coagulation/stenting), of them 7 (1.6%) required blood transfusion. Three patients suffered perforation during ERCP. One of them got biliary stent and was discharged uneventfully on the 8th day. We had 2 sphincterotomy related perforations. 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Conclusion: Quality assessment of ERCP performance is essential. Our overall cannulation rate was acceptable. We used pancreatic guidewire technique just after the failed deep cannulation of pancreatic duct. In our opinion, this is an important phase of process to avoid long lasting traumaisation of the papilla. Our complication rate of post-ERCP pancreatitis was good while the post-sphincterotomy perforations, 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Introduction: The procedures related to endoscopic retrograde cholangiopancreato- graphy (ERCP) play a major role in the diagnosis and treatment of pancreato-biliary disease. However, post-ERCP pancreatitis (PEP) remains the most common and severe complication of ERCP. The incidence rates of and risk factors for PEP have mainly been reported from retrospective studies.

Aims & Methods: This study aimed to identify the incidence rate of and risk factors for PEP in a prospective large cohort study. This is a prospective cohort study of all patients who underwent ERCP-related procedures at 5 high-volume centers between February 2015 and May 2016. Patients who presented with acute pancreatitis, post biliary reconstruction, and failure to reach the papilla were excluded. The incidence rates of PEP and its severity were examined. Multivariate analysis was used to identify the risk factors for the development of PEP. Patients who presented with at least two of the following complications were diagnosed with PEP: 1) elevated levels of serum amylase, 2) abdominal pain lasting more than 24 hours, and 3) abnormal findings of acute pancreatitis on computed tomography. An increase in serum amylase level of at least three times greater than the normal upper limit at approximately 18 h after the procedure (the next morning) was regarded as significant. The severity of PEP was graded according to the severity assessment of the Japanese Ministry of Health, Labour, and Welfare.

Results: A total of 1932 patients were finally analyzed. PEP occurred in 142 patients (7.3%); it was mild in 117 patients (6.0%) and severe in 25 patients (1.3%). Univariate analysis showed that female gender, naive papilla, surgically altered gastrointestinal anatomy, no coexistence of acute cholangitis, diagnostic ERCP, and elective ERCP, procedure time after reaching the papilla, number of cannulation attempts, precut sphincterotomy, intraductal ultrasonography, pancreatic duct injection, insertion of guidewire into the pancreatic duct, and placement of prophylactic pancreatic stent were significant risk factors. In the multivariate analysis, female gender (OR 2.273; 95%CI 1.570–3.291), naive papilla (OR 3.024; 95%CI 1.805–5.066), surgically altered gastrointestinal anatomy (OR 2.607; 95%CI 1.378–4.931), precut sphincterotomy (OR 2.297; 95%CI 4.933–5.324), and intraductal ultrasonography (OR 1.620; 95%CI 1.015–2.585) were independent risk factors.

Conclusion: The incidence of PEP was similar to those reported in previous studies. These risk factors are important as predictors of PEP. A shorter procedure time and avoidance of unnecessary pancreatic duct injection are important for prevention of PEP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0902 USEFULNESS OF AMY MEASUREMENTS AT 2 HOURS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PREDICTING THE SEVERITY OF POST-ERCP PANCREATITIS: A MULTICENTER PROSPECTIVE STUDY, SOSUI

K. Takumi1, T. Suzuki1, H. Sato1, N. Yoshiida1, Y. Nakai2, K. Kasusoto2, Y. Itohoku5, A. Suzuki5, B. Endoh2, K. Chikugo5, O. Inatomi5, S. Bamba3, Y. Mizumoto3, K. Tanaka1

Introduction: The severity of post-ERCP pancreatitis (PEP) is a major problem because of occasional lethality. However, no predictor of the severity has been identified. In the present multicenter prospective study, SOSUI, we investigated the potential predictors of severity.

Aims & Methods: Of 2078 subjects who underwent ERCP between February 2015 and May 2016 at 5 high-volume centers, 1932, excluding those who had been complicated by pancreatitis, undergone biliary tract reconstruction, or had papilla not reached, were included. Of the 1932 patients, 163 who developed PEP were compared between the mild and severe cases to examine potential predictors of severity. PEP was diagnosed based on two or more of the following three conditions: (1) serum amylase elevation (above the upper limits of each center) on the following day, (2) abdominal pain lasting for longer than 24 hours, and (3) acute pancreatitis on CT. The severity was assessed based on the criteria of the Ministry of Health, Labour and Welfare. For continuous variables, the Mann-Whitney U test was employed. For binomial comparison, univariate analysis was conducted using a chi-square test.

Results: Twenty-five severe (1.3%) and 138 mild (7.1%) PEP patients were included. Patient and procedural factors were examined, demonstrating that the AMY values at 2 hours after ERCP were significantly higher in the severe cases than in the mild ones (P = 0.005). ROC analysis was conducted on the AMY values at 2 hours as a predictor of severe PEP, demonstrating that the cutoff value was 3.7 times higher than the upper limits of each center (sensitivity: 64%; specificity: 70%; and AUC: 0.65). In multivariate analysis using logistic regression by dividing the AMY values at 2 hours after ERCP into higher or lower than 3.7 times the reference threshold for each center, abdominal pain immediately after ERCP and AMY values at 2 hours after ERCP were identified as independent factors.

Conclusion: Severe PEP should be diagnosed as early as possible for intervention. However, it may take a long time to assess clinical courses or examine findings after examination. In the present study, abdominal pain immediately after ERCP and AMY values at 2 hours were identified as predictors of severity, being useful for facilitating early therapeutic intervention.

Aims & Methods: The aim of this study was to evaluate the transduodenal tractcholecystectomy technique in the treatment of gallbladder disease without cholecystectomy be patient with cholesterol gallstones and high surgical risks were enrolled between January 2015 and March 2017. Endoscopic ultrasound (EUS)-guided cholecystoduodenostomy by deploying a double-flanged fully covered metal stent with hot stent delivery was performed and endoscopic sphincterotomy (EST) was also performed during this procedure for those patients with accompanying common bile duct stones. One or two weeks later an forward-viewing endoscope was advanced into the gallbladder via the stent, and cholecystolithotomy or polypectomy was performed. After the stents were removed, a pigtail-type nacolo-cholecystic drainage catheter was inserted into the gallbladder over the guide wire and removed 2 days later. Four weeks later gallbladder was assessed by abdominal ultrasound.

Results: EUS-guided cholecystoduodenostomy with double flanged mental stent deployment was successfully performed in all of 26 patients (Male:Femal., 11:15; mean age, 61 ± 16.19yrs). After the procedure, fistulas had formed in each of the patients and the stones of 7 patients expelled themselves completely. Endoscopic sphincterotomy (19) and polyectomy (2) were performed simultaneously through the stents, and then the stents were removed. Common bile duct stones were also successfully removed in 6 patients. EGD showed all the fistula closed completely after 3 days. The ultrasound examination of the gallbladder 4 weeks later showed no stones remaining and also showed satisfactory functioning of the gallbladder. The mean follow-up period was 11 months (range: 1-27months). Cholesterol gallstones recurrence were not detected in any patient during follow-up.

Conclusion: The EUS-guided placement of a novel metal stent with hot stent delivery is a safe and simple approach for performing an endoscopic cholecysto-duodenostomy, which can subsequently allow procedures to be performed for treating biliary disease, including cholecystolithotomy.

Introduction: Determining the cause of suspected biliary strictures is always challenging in clinical practice. Although EUS-guided tissue sampling (EUS-TS) revealed a better diagnostic yield in suspected malignant biliary obstructive lesions comparing to ERCP-guided tissue sampling (ERCP-TS), there were few studies for which techniques are better dependent on primary tumor.
Aim and Methods: In our study, we compared the diagnostic yields between EUS-TS and ERCP-TS in patients with suspected malignant biliary obstructive lesion according to primary tumor sites. By reviewing medical records, we enrolled patients who underwent same-session examination of EUS and ERCP for the evaluation of suspected pancreaticobiliary obstructive lesion.
For cytopathologic diagnosis, endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) or biopsy (EUS-FNB) and ERCP-TS using brush cytology and/or forceps biopsy were performed. The diagnostic performances were compared between two techniques according to primary tumor sites.
Results: From January 2011 to September 2016, we enrolled 125 patients and 32 patients were excluded due to the following reasons: loss of follow up in 8, ERCP-TS from pancreatic duct in 23, and ERCP-TS from peripancreatic biopsy in 4. Among the enrolled patients (93 patients; 62 males, mean age 65.8 years, 86 (92.5%) had malignant tumor such as cholangiocarcinoma in 39, pancreatic cancer in 37, and other malignant tumors in 10 patients. And 7 (7.5%) had nonmalignant lesions. Rates of diagnostic accuracy comparing to ERCP-TS (82.8% vs. 60.2%, p = 0.001).
Depending on primary lesions, the diagnostic accuracy for pancreatic lesions was statistically higher in EUS-TS than ERCP-TS (84.4% vs. 51.1%, P = 0.003). Conclusion: EUS-TS is superior to ERCP-TS for the evaluation of suspected malignant pancreaticobiliary obstructive lesions. Especially, if the biliary obstruction was caused by pancreatic lesions, EUS-TS would need to be a priority for cytopathologic diagnosis

P0907 PREVALENCE OF POSTERIOR MEDIASTINAL LYMPHADENOPATHIES IN PATIENTS UNDERGOING ENDOSCOPIC ULTRASOUND-FINE NEEDLE ASPIRATION-MALIGNANT INDICATIONS: A PORTUGUESE SINGLE-CENTRE PROSPECTIVE STUDY
J. Veloso Du, Carmo, S. C. Marques, M. Bispo, C. Chagas
Gastroenterology, Hospital Egas Moniz - Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal
Contact E-mail Address: joanavcarmo@gmail.com
Introduction: Significant heterogeneity in geographic distribution in the prevalence of mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasonography (EUS) to rule-out malignant neoplasms (PCNs).
Aims & Methods: 1. To document the prevalence and characteristics of mediastinal lymphadenopathies in patients submitted to EUS for non-malignant extra-thoracic disease. 2. To identify predictive factors for the presence of mediastinal lymphadenopathies. A prospective, unicentric study was performed between July and December 2016. Mediastinal stations 9, 8, 7, 6, 5, 4L and 2 were systematically evaluated using a linear echoendoscope in all patients undergoing EUS due to benign extra-thoracic pathology, without history of oncologic disease.
Demographic, clinical and EUS features were analysed, including location, number, shape, dimensions and echogenicity of the lymphadenopathies.
Results: We analysed 75 patients: M:F, 32/43; Mean age: 63 years. The majority (72%) of the patients presented lymphadenopathies in at least one mediastinal station and 88% were found in at least 2 stations. Only 6% of these had short axis diameter >10 mm, most were oval (59%) or triangular (37%) and 40% had a hyperechogenic center. The prevalence of lymphadenopathies was higher in smoker patients (83% vs 64%, p=0.024), with a higher average number of lymphadenopathies per patient in this group (2.1 vs 1.6, p=0.017). Similar findings were documented in patients with relevant occupational or environmental respiratory exposure (prevalence 83% vs 71%; average number 3 vs 1.7). By logistic regression analysis, none of the variables analysed were independently associated with the presence of mediastinal lymphadenopathies.
Conclusion: This prospective Portuguese study documented a higher prevalence of mediastinal lymphadenopathies than previously reported in northern Europe,1, in particular concerning the site of oncologic disease. This higher prevalence, mostly in smokers or patients with relevant occupational exposure, may negatively influence the specificity and positive predictive value for malignancy of mediastinal lymph node (N) staging by EUS, with particular relevance in esophageal and pulmonary cancer staging.

Introduction: Recent studies documented the positive impact of neoadjuvant treatment for gastric adenocarcinoma ≥ 2 and/or N+.
Aims & Methods: We aimed to assess the accuracy of endoscopic ultrasound in the selection of patient with gastric adenocarcinoma for neoadjuvant therapy. A unicentric retrospective analysis of patients with the anatomopathological diagnosis of gastric adenocarcinoma between 2011 and 2016, who performed endoscopic ultrasound for staging and underwent surgery without prior neoadjuvant treatment. The concordance (kappa) and accuracy [sensitivity (S) and specificity (S)] of the endoscopic ultrasound for T ≥ 2 and/or N + (criteria for neoadjuvant treatment) was assessed using the anatomopathological staging of the resected surgical specimen.
Results: The final sample included 144 patients (64.6% male) with a median age of 68.5±12.2 years. In most cases (80.6%), the neoplasia was distal (antrum, incisura angularis and body). The neoplasia was of the intestinal type, diffuse and mixed in 65.3%, 18.8% and 16% of the cases, respectively. After examination of the resected surgical specimen, 53.5% of patients had criteria for neoadjuvant treatment (T ≥ 2 and/or N+). The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥ 2 and/or N + were 0.702 (p < 0.001), 85.2% (95% CI: 75.6–92.1%) and 87.3% (95% CI: 76.9–94.4%), respectively. The overall kappa, sensitivity and specificity of the endoscopic ultrasound for T ≥ 2 and/or N+ were higher in proximal lesions (cardia and JEG) (k = 0.924, S = 94.4% and E = 100%) compared with distal lesions (k = 0.671, S = 82.5% and E = 84.9%) and in intestinal type lesions (k = 0.765, S = 84.9% and E = 92.7%) compared with diffuse type lesions (k = 0.682, S = 88.4% and E = 80%) or mixed (k = 0.566, S = 81.8% and E = 75%).
Conclusion: In one of the largest series of patients, we showed that endoscopic ultrasound was an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fine needle aspiration (FNA) and pancreatic cystic lesions (PCNs) require initial imaging characterization and frequently follow-up. Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) for CEA measurement and cytology of cystic fluid is the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA with cyst fluid analysis in follow-up of PCNs is not clear.
Aims & Methods: To determine if patients with pancreatic cysts with a second repeated EUS-FNA for cyst fluid analysis for CEA and cytology had a change in cyst classification or on clinical decision. Retrospective analysis of a EUS database, with 284 patients who had EUS-FNA for pancreatic cyst evaluation from 2007–16, of which 35 had 2 EUS procedures, and of these, 22 had 2 consecutive EUS-FNA procedures.
**P0910 DETERMINATION OF INTRACYSTIC GLUCOSE CONCENTRATIONS IN THE DIFFERENTIAL DIAGNOSIS OF PANCREATIC CYSTS: A PROSPECTIVE STUDY**

**Introduction:** Despite advances in imaging techniques, differential diagnosis of pancreatic cysts still remains challenging. There has been an increasing interest in new pancreatic cyst biomarkers as a way to differentiate different cyst subtypes and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a promising marker. The aim of this prospective study was to verify this early finding.

**Aims & Methods:** We enrolled in the study all the patients who underwent EUS-FNA for pancreatic cyst aspiration. Informed consent was obtained from all patients. A total of 53 cysts were sampled, and 32 cysts for cytology and 21 cysts for histology. Diagnostic criteria were: (i) Mean glucose concentrations in mucinous cysts were significantly lower than in non-mucinous cysts (p < 0.0001). The diagnosis of mucinous cysts was based on the presence of cells with intracytoplasmic mucin and reduction in the presence of normal pancreatic acinar cells. (ii) A correlation was found between intracystic glucose concentrations and the diagnosis of mucinous cysts. In conclusion, intracystic fluid glucose is a promising marker for the differential diagnosis of pancreatic cysts.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0911 ANTIBIOTIC PROPHYLAXIS AFTER PANCREATIC CYST PUNCTURE – LESS IS MORE? ONE-TIME VERSUS EXTENDED CIPROFLOXACIN PROTOCOL**

**Introduction:** EUS-FNA is a standard practice due to the possible risk of pancreatic infection. The aim of this study was to compare a one-dose prophylaxis (PCL) with two protocols: group 1: Ciprofloxacin 200 mg iv, one-dose, immediately before EUS-FNA; and group 2: Ciprofloxacin 200 mg iv, one-dose, immediately before EUS-FNA plus three days of oral Ciprofloxacin 500 mg, bid. Results: There was no statistical difference between the two protocol groups regarding the morbidity rate (0–2%), Nevertheless, peri-procedural and even several days after EUS-FNA antibiotic prophylaxis has been the standard practice due to the possible risk of pancreatic infection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

---

**Results:** In our series, 16/22 females (75%), mean age = 58 ± 13 years old (29–77). Mean follow-up, 2 years, from 60 to 34months (6–116). Cyst location: head/body/tail: 11/8/3. Mean size in 1st EUS-FNA: 3 ± 1 cm, 1 (1–2 cm) vs 2nd EUS-FNA: 3, 1 ± 1 cm, 9 (1–2.1 cm); with both EUS-FNAs with 36% cysts > 3 cm. Mass/mural nodule present:7/22 vs 8/22 on 2nd EUS-FNA. Repetition of EUS-FNA did not lead to change or increase in size. Mean interval between the two subsequent EUS-FNAs: 35 months (3–117). Cysts with CEA level > 192/ g/mL (7 vs 10 patients) and acellular cystic fluid samples (62% vs 59%), between the 1st and the 2nd EUS-FNA, not statistically significant. There were 4 patients operated that had previously a repeated EUS-FNA (2nd EUS-FNA 3, 4, 7 and 10 months after the 1st EUS-FNA). Surgical pathology (respectively): Intraductal papillary mucinous neoplasm, mucinous cystic neoplasm, solid pseudopapillary neoplasm and a neuroendocrine tumour. Comparing the group of patients who had surgical interventions with patients in one cystic group, there was a statistical difference in cystic size > 3 cm and the presence of a mural nodule or mass in the surgery group, but no significant differences in age, CEA value or a diagnostic cytology between the two groups. The mean time between the two EUS-FNA procedures was significantly shorter in the surgical patients group. In the diagnosis of pancreatic cysts still remains challenging. There has been an increasing interest in new pancreatic cyst biomarkers as a way to differentiate different cyst subtypes and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a promising marker. The aim of this prospective study was to verify this early finding.

**Aims & Methods:** We enrolled in the study all the patients who underwent EUS-FNA for pancreatic cyst aspiration. Informed consent was obtained from all patients. A total of 53 cysts were sampled, and 32 cysts for cytology and 21 cysts for histology. Diagnostic criteria were: (i) Mean glucose concentrations in mucinous cysts were significantly lower than in non-mucinous cysts (p < 0.0001). The diagnosis of mucinous cysts was based on the presence of cells with intracytoplasmic mucin and reduction in the presence of normal pancreatic acinar cells. (ii) A correlation was found between intracystic glucose concentrations and the diagnosis of mucinous cysts. In conclusion, intracystic fluid glucose is a promising marker for the differential diagnosis of pancreatic cysts.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Results:** Significant material rate of cytological evaluation was 96.6% in all enrolled specimens (282/292). 10 insufficient materials were obtained from PC in 2 cases, 4 in 2nd EUS-FNA and 2 in PNET. In seven of the 10 cases with insufficient materials, sampling error occurred because sufficient material was not confirmed using rapid onsite evaluation. Accuracy of cytology, histology, and combination of cytology and histology were 84.4%, 72.9%, and 90.0%, respectively. In the study of patients with malignant diseases, the sufficient material rate of cytology and histology and were 99.1%(223/225) and 89.3%(201/225). Positive predictive values of cytology and histology are 81.7%(184/225) and 67.6%(152/225). 65.8%(48/73) of pathologically non-diagnosed cases could be diagnosed by endoscopic ultrasound (EUS) and histology. In 26 specimens, when cytology and histology were not available, in 23 of the 26 specimens (88.5%) and ICC was available in all specimens. In the three specimens, ICC was not available owing to pathological insufficiency. In conclusion, for pancreatic cysts obtained by EUS-FNA may be useful for reducing insufficient material rate and conducting ICC as well as in samples in other medical fields.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
prophylaxis is mandatory during EUS-FNA of PCLs, since it does not seem to have a protective effect. Moreover, the risk in antibiotic resistance and possible adverse effects related to their use should be balanced against the very low infectious complication rate of EUS-FNA. One limitation of our study is its retrospective nature, with a significant delay between the EUS-FNA and the time to inquiry, which could have biased the patients' answers.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:

Introduction: The current classifications of non-metastatic GIST are based on post-operative pathologic criteria and are used to help in the decision of postoperative recurrence and determine the value of adjuvant Imatinib. The proposed pre-treatment classification currently recognized risk factors as tumor diameter, mitotic rate and site (gastric vs non-gastric). EUS-guided tissue samples remain the mainstay for pathological diagnosis of GIST, but previous studies showed that EUS-FNA with standard 19 or 22 gauge needles does not reliably reflect GIST's proliferation and size.

Aims & Methods: We aimed to investigate the EUS-FNB diagnostic yield for GIST and to evaluate whether EUS-FNB samples reflect prognostic criteria obtained from resected GISTs. A prospectively maintained database was retrospectively reviewed to identify consecutive patients with surgically resected subepithelial lesions who received a diagnosis of GIST at a previous EUS-FNB with a 19 or 22 gauge core-needle (EchoTip® ProCore™, Cook Medical). Size from EUS examination and mitotic/proliferative indexes obtained from EUS-FNB samples were compared with surgical specimens.

Results: Between November 2012 and December 2016 18 patients were studied (11 males, mean age 71.6 years, range 44-88 yo). The tumour site was the stomach in 15 out of 18 patients and the duodenum in 3 out of 18 patients. Agreement between EUS-FNB and surgical pathology was 100% with respect to the diagnosis of GIST (18/18). Proliferative indexes (Ki67/MIB1) were determined in 14/18 (77.7%) samples versus all cases (as expected) in resected specimens. In our series Ki67/MIB1 were generally underestimated. We found only 2 patients with the required number of 50 HPFs for mitotic count examination. They showed a mitotic index <5/50 HPFs comparable to surgical specimens. No mitotic figures were seen in core biopsy specimen from any of the remaining 16 patients. In these patients the number of HPFs for mitotic count examination ranged from 1 to 22. In their corresponding surgical specimen we found mitoses in 16/16 patients, ranging from 1 to 50 per 50 high-power fields (5-50 HPFs). The size of the surgical specimens exceeded (>5 tumor EUS-size in 11 out of the 18 investigated cases (66.6%) and was equal (±5 mm) in 6 cases (33.3%).

Conclusion: In our experience, EUS-guided tissue core biopsy have an extremely high diagnostic accuracy for GIST diagnosis, but underestimates the proliferation indexes and rarely allows for a reliable mitotic count. The main reason responsible for these results is the uneven distribution of the mitotic figures throughout the lesion, which can bias the biopsy to miss the most mitotically active areas. Furthermore, EUS examination generally underestimates the size of the lesions; this limit is fundamentally linked to the “bidimensional” evaluation of lesions obtained by ultrasound. In addition, the underestimation of the size is greater for large lesions because of the low depth of field evaluated by high frequencies used in EUS. Our data obtained with EUS-FNB are similar to previous studies with FNA and constitute a major limitation for developing a possible pre-treatment and biopsy-based risk classification of GIST. Alternative parameters (such as genotype profiling) must be validated on pre-surgical biopsy samples from GISTs for prognostication purposes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic cancer (PC) remains a disease with overall poor prognostic indexes and rarely allows for a reliable mitotic count. The main reason responsible for these results is the uneven distribution of the mitotic figures throughout the lesion, which can bias the biopsy to miss the most mitotically active areas. Furthermore, EUS examination generally underestimates the size of the lesions; this limit is fundamentally linked to the “bidimensional” evaluation of lesions obtained by ultrasound. In addition, the underestimation of the size is greater for large lesions because of the low depth of field evaluated by high frequencies used in EUS. Our data obtained with EUS-FNB are similar to previous studies with FNA and constitute a major limitation for developing a possible pre-treatment and biopsy-based risk classification of GIST. Alternative parameters (such as genotype profiling) must be validated on pre-surgical biopsy samples from GISTs for prognostication purposes.

Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of the FNA needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

Aims & Methods: We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive PC patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS needle pre-loaded with 2 gold markers with knurled design. After the 2 markers were deployed, the EUS fiducial needle insert was exchanged out for a second pre-loaded EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and complications. The primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

Results: Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n = 6), neck (n = 2), and the body (n = 2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, p = 0.002). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

Conclusion: EUS-guided fiducial placement with a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

Introduction: Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE).

Aims & Methods: Our aim was to develop and to validate a computational algorithm, which would evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as “scarce in” or “abundant in” bubbles. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as “scarce in” or “abundant in” bubbles. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as “scarce in” or “abundant in” bubbles.

Results: Our aim was to develop and to validate a computational algorithm, which would evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as “scarce in” or “abundant in” bubbles. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as “scarce in” or “abundant in” bubbles.

Conclusion: A GLCM detector strategy has high diagnostic performances to categorize “scarce in” or “abundant in” bubbles SB-CE frames. This algorithm is of interest for clinical use (i.e. quality in CE reporting) and for research (providing an objective comparison tool of different preparations, including anti-bubble agents).

Introduction: Capsule endoscopy has been demonstrated to be a first-line tool for small bowel visualization. However, it has some limitations such as incomplete examinations - i.e: the capsule does not reach the cecum - leading to missing lesions.

Aims & Methods: To evaluate those factors that can predict incomplete examinations, to identify those patients at risk for incomplete procedures and to define those approaches that may improve the efficiency of the examination reducing the time of the diagnostic process as well as the need to repeat procedures. A total of 1918 patients who underwent capsule enteroscopy at our center between 2008 and 2015 were retrospectively analyzed. We evaluated variables such as age, sex, anthropometric parameters, comorbidity, drugs, outpatient care, analytical parameters, indication of the test and transit times. Initially, a univariate analysis and then, a multivariate analysis using a logistic regression model were carried out.

Results: In the univariate analysis, the following variables showed a statistically significant association with the rate of incomplete examinations: age, gender, indication of procedure, outpatient care, history of abdominal surgery, heart disease, capsule ingestion posture, hemoglobin levels, renal failure and both gastric and small bowel transit times. These variables were included in the multivariate analysis were age > 65 years (OR = 1.99, 95% CI: 1.34–2.95), gastric transit time > 41 minutes (OR = 2.60, 95% CI: 1.72–3.93) and small bowel transit time > than 286 minutes (OR = 3.52 95% CI: 2.26–5.48) showed a statistically significant association with the risk of incomplete examination.

Conclusion: Incomplete capsule endoscopy is predictable. Patients older than 65 years and/or a gastric emptying greater than 42 minutes are independent predictive factors for incomplete procedures. In these clinical scenarios, pharmacological preventive measures or endoscopic introduction should be taken into account to avoid incomplete examinations.

PROCEDURE ACCURACY?
P0920 COLON CAPSULE ENDOSCOPY: HOW DOES IT WORK?

All other authors have declared no conflicts of interest.

Disclosure of Interest: (no systemic delivery) therapy for IBD and cancer.

tions in the colon. A wide variety of drugs can accurately be delivered to their intended destinations and on line algorithms can determine colonic entrance and identify exact locations in the colon. Which incorporates a diffused gas sensor that allows for an accurate sensing of colon entrance; as well as a 3D real time positioning system that allows for an accurate, programmable, localized, and in colon drug delivery system.

Aims & Methods: Data was collected from 14 patients that swallowed capsules in a multi-center clinical trial using an x-ray imaging capsule (GUT 2016). The patients were sent home to continue their normal life routine while the capsule naturally traveled in the gastrointestinal tract until excretion. (Subjects signed informed consent forms and the study was performed after local IRB approval). The capsules contained electronics and software that allowed for live communication between the capsule and a recording device that is placed directly on the patient’s back. This device tracks the position of the capsule and communicates with it, receiving diffused gas pressure from the capsule sensor and fusing this information with 3D position information from the capsule. The capsule system exhibited position accuracy of ±1 cm and the ability to detect movements in real time, as well as potential of ~1 ml of payload for drug containment.

Results: The average total transit time of the capsule was 43 hours (range: 15-68 hours). The average transit time to cecum was 13.8 hours, and the average time across the colon was 12.8 hours (range 6-25). The position tracking and the RF communication between the capsule and the recorder showed >90% coverage in all cases, even in obese patients. No adverse events were reported. Figure 1 illustrates the recorder placement on the patient back. Figure 2 is a typical averaged capsule position trace in the colon.

Conclusion: A capsule with accurate position tracking, 2-way communication, and on line algorithms can determine colonic entrance and identify exact locations in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic (no systemic delivery) therapy for IBD and cancer.

P0920 COLON CAPSULE ENDOSCOPY: HOW DOES IT WORK?

Introduction: Colon Capsule Endoscopy (CCE) procedure requires a preparation regimen, which provides a clean colon, clear capsule images and promotes capsule propulsion through the entire colon. A four-point cleansing grading scale system (poor, fair, good and excellent) has been used to describe the quality of colon preparation. “Poor” and “fair” are considered inadequate cleansing, while “good” and “excellent” – adequate for polyp detection. Adequate cleansing has been associated with significantly higher diagnostic accuracy, when compared with inadequate cleansing (72% vs. 28% respectively).[1]

Aims & Methods: Evaluate the relation between CCE procedure cleansing and accuracy – with an emphasis on inadequate cleansing. This is an additional post study analysis[2], including 767 screening population participants, from 17 sites in the United States and Israel, who underwent CCE procedure followed by a blinded colonoscopy. Capsule preparation included 12 mg Senna, 4 liters split dose of sulfate-free polyethylene glycol (PEG), with 6 and 3 oz of oral sulfate solution – for capsule propulsion. The CCE video was reviewed by 1 of 5 highly experienced CCE gastroenterologists. These physicians assessed colon cleansing on a “poor” to “excellent” scale. Incomplete studies were included in the analysis. Polyps were considered a match, if the size measured by the capsule (~±30%) range overlapped the size measured by the colonoscopy (~±50%) range, and polyp location estimates by the 2 methods were in the same or adjacent segments[2].

Results: The mean age of the analyzed cohort was 57.1 (SD 5.8) with 342 males (48.6%).

Conclusion: This analysis indicates, that when utilizing 4 liter PEG and oral sulfate solutions for CCE procedure preparation, current cleansing assessment scale and methodology may need to be re-evaluated - to better correlate with polyp detection. Currently, “fair” cleansing may not indicate inadequate cleansing for polyp detection.

P0921 COLON CAPSULE ENDOSCOPY MAY REDUCE COLONOSCOPY MISS RATE – A MULTICENTER STUDY

S. Perek1, N. Schwartz1
1Medicine A, Rambam Health Care Campus, Haifa/Israel
2HaEmek Medical Center, Afula/Israel

Contact E-mail Address: shayperek@gmail.com

Introduction: Colonoscopy miss rate is an area of intense focus, as it directly correlates with colorectal cancer incidence rate. Previous studies reported a colonoscopy miss rate of 2%-22%, depending on polyp size and histology [1].

Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas [2]. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient’s CCE report was assessed. Based on the findings in this report, the colonoscopy physician decided whether or not to immediately follow up with a second colonoscopy. 70 of the CCE findings were detected by the second colonoscopy. These 70 polyps were compared with 683 polyps detected by blinded colonoscopy, using logistic regression model. Adjusted Odds Ratios (Adj.OR) and corresponding Confidence Intervals (CI) were estimated.

Results: Of the 70 polyps missed by first colonoscopy and detected by second colonoscopy, 20 (29%) were 6 mm or larger (based on colonoscopy size estimation), 19 (27%) were either adenomatous or sessile serrated lesions and 16 (23%) were described as either flat or sessile-flat by colonoscopy performing physician. Stratification of polyps based on location:

Abstract: P0920

Colon cleansing Sensitivity (≥6 mm); n = 272 Specificity (≥6 mm); n = 495

| Adequate cleansing | 153/195 = 78.5% (72.2%–83.7%) | 308/350 = 88.0% (84.2%–91.0%) |
|                   | 54/77 = 70.1% (59.1%–79.2%)  | 130/145 = 89.7% (83.5%–93.7%)  |

P-value 0.147

| Poor cleansing    | 3/9 = 33.3% (11.7%–64.9%) | 15/16 = 93.8% (69.7%–100%) |

Fair, good and excellent cleansing

| Sensitivity       | 204/263 = 77.6% (72.1%–82.2%) | 423/479 = 88.3% (85.1%–90.9%) |

P-value 0.007

| P-value           | 0.007 |

Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps is similar in inadequate (“poor” + “fair”) cases compared to adequate (“good” + “excellent”) cases (70.1%, 78.5% respectively; P-value = 0.147).

Introduction: A many variety of pharmaceuticals for the treatment of colon disease can be more effective and have less side effects if targeted for precise delivery in the colon. Over the years, many types of delivery vehicles have been developed with the aim of targeting the colon, such as PB based delivery technologies, time dependent drug release mechanisms, pressure based mechanisms, flora sensitive mechanisms and others. These technologies have performed with variable degrees of success due to the wide distribution of motility and other physiological variability between patients. We describe a novel capsule technology which incorporates a diffused gas sensor that allows for an accurate sensing of colon entrance; as well as a 3D real time positioning system that allows for an accurate, programmable, localized, and in colon drug delivery system.
Multivariate logistic regression revealed that after adjusting to polyph's size, cecal and rectal segments were associated with increased chance of CCE additive value to colonooscopy (cecum vs. ascending or transverse colon: Adj.OR = 3.2 [95%CI: 1.3–7.6] and Adj.OR = 4.5 [95%CI: 1.4–14.6] respectively; rectum vs. ascending or transverse colon: Adj.OR = 2.6 [1.1–5.8] and Adj.OR = 3.6 [95%CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonooscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonooscopy, especially lesions in the cecum and rectum.

Introduction: Only small series (<10 patients) have described endoscopic management of postoperative pancreatic fistulas (POPF). The purpose of this retrospective study was to describe the indications, technique and results of endoscopic treatment of POPF.

Aims & Methods: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified. Only patients whose ERCP was classified according to the definition of the International Study Group of Pancreatic Fistula Working Group. The indications, the techniques and results of endoscopic drainage and the patients’ outcomes were registered.

Results: Among 6473 ERCP performed during the inclusion period, 31 patients had POPF treated endoscopically (14 men, 7 women, mean age 55±12 years). Surgeries at the origin of the fistula were: distal pancreatectomy with spleen resection (n=19), spleen preserving distal pancreatectomy (n=3), central pancreatectomy (n=21), enucleation (n=4), partial pancreatectomy (n=1); left nephrectomy (n=2), for the following indications: IPMN (n=7), pancreatic adenocarcinoma (n=5), neuroendocrine tumors (n=4), inflammation (n=3), adenocarcinoma (n=6), metastasis (n=2), phaeochromocytoma (n=1), cystadenomatus (n=2), spleen artery aneurysm (n=1). The mean time between surgery and first ERCP (±SD, range) was 70 days (±145, [6-806]). POPF was grade B in 19 patients and grade C in 12 patients.

The indications for endoscopic drainage and the patients’ outcomes were registered.

Conclusions: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified. The present study was designed to determine feasibility and safety of stent placement using a thin delivery-system stent without dilation step during ERCP. Three of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with hard tip (7Fr hard tip) and 7Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with a 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10 pigs, EUS-BD (cholledochoduodenostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events were analyzed for two weeks after EUS-BD. The use of three types of stents was clinically related to adverse events.

Aims & Methods: The present study was designed to determine feasibility and safety of stent placement using a thin delivery-system stent without dilation step during ERCP. Three of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with hard tip (7Fr hard tip) and 7Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with a 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10 pigs, EUS-BD (cholledochoduodenostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events were analyzed for two weeks after EUS-BD. The use of three types of stents was clinically related to adverse events.

Results: Among the three types of stents, 7Fr soft tip had the least resistance in the phantom model. In the animal model, the median common bile duct diameter before puncture measured on EUS and the median procedure time was 7.6mm (4.05–9.5) and 29.3 minutes (16–47) respectively. In all pigs, EUS-BD using the three types of stents were technically successful. Distal stent placement was successful in 25% (1/4), 0% (0/2) and 100% (4/4) for the 7Fr hard tip, 7Fr hard tip and 7Fr soft tip respectively. Even in the cases requiring dilation, stent placement was successful immediately after dilation only with a thin catheter (3.5Fr). Neither 5Fr cholecystectomy nor balloon dilation was needed. There were no procedure-related complications occurring during and 2 week after EUS-BD. All stents remained in place without migration. At necropsy, fistulas were created between the bile duct and duodenum in all pigs and the growth of fibrous tissue was observed in the microscopic findings.
Conclusion: Among the three types of stents, the 7Fr soft tip was suitable for ERCP in the phantom and animal models. The bio-absorbable system stent may be technically feasible and safety for EUS-BD and possibly reduce adverse events.

Introduction: Post-endoscopic sphincterotomy bleeding is treated endoscopically with pharmacologic injection, electro surgical coagulation, balloon tamponade or clipping, but severe cases may require angiographic or surgical approach. An alternative long-acting tamponade treatment with fully-covered metal stents (FCMS) has been advocated.

Aims & Methods: We report here on the use of FCMS in post-sphincterotomy early and late bleeding. Patients referred for in- and out-patient ERCP were informed of the potential off-label treatment with FCMS of post-sphincterotomy bleeding, and of treatment approval by the local ethical committee. We treated post-sphincterotomy bleeding first with adrenaline and/or sclerosing agent injection. When this first line hemostasis failed, we placed short FCMS in the distal cholecodochus. Endoscopy was rescheduled after 1 month to remove the FCMS. During the early post-procedural period the patients were treated with blood transfusions if needed, and amiplaedet drugs as well as oral anticoagulants were avoided.

Results: 17 Patients (10M/7F), aged on an average 70 years (range 38–90) received 18 FCMS (10 mm x 40 mm, Boston Scientific) for failed hemostasis since USA was 100%. 4 patients had pain (symptomatic) and rest 9 were asymptomatic. 15/20 underwent interventional procedures before achieving satisfactory stricture resolution. In recent years, standard of practice of endoscopic retrograde cholangiopancreatography (EUS-BD) or double pigtail plastic stent. All these patients underwent MRCP after EUS guided drainage of PFC. Patients of acute or chronic pancreatitis with DPDS were included in the study. The FCMS spontaneously migrated in 3 of 18 cases, one had been removed for incomplete bleeding control and substituted after 3 days, and 13 were easily removed as per protocol. In two cases FCMS were removed and a plastic double pigtail stent was put in place, for persistent choledochal distal stenosis.

Conclusion: These cases represent a large collection of evidence showing that treating post-sphincterotomy early bleeding with FCMS is feasible, safe and effective. Late bleeding associated with needle-knife pre-cut was much harder to control and required endoscopic revision, intensive care unit support and re-stenting. Our results are consistent with and support previous research in the field.

Efficacy of Self-Expandable Metallic Stent Placement in the Management of Anastomotic Stricture after Orthotopic Liver Transplantation

S. Jiang, M. Parsi, R. Lopez, A. Bhatt, J. J. Vargo
Gastroenterology, Cleveland Clinic, Cleveland/United States of America/ OH

Contact E-mail Address: jangs@ccf.org

Introduction: Anastomotic bile duct stricture (ABS) remains as one of the most common complications after orthotopic liver transplantation (OLT). Current standard of practice of endoscopic retrograde cholangiopancreatography (ERCP) with insertion of multiple plastic stents (PS) often requires multiple procedures before achieving satisfactory stricture resolution. In recent years, studies utilizing covered self-expandable metallic stent (cSEMS) in refractory ABS management reported varying degree of success.

Aims & Methods: The aim of this study was to analyze efficacy of SEMS in resolution of anastomotic stricture in patients with orthotopic liver transplantation (OLT). In addition, we sought to identify factors influencing the likelihood of stricture resolution, the rate of adverse outcome(s) A retrospective cohort study was conducted using a registry of consecutive patients who underwent ERCP with biliary SEMS placement from January of 2010 to November of 2016 for the management of refractory ABS. Demographic variables including age, gender, and clinical variables including body mass index (BMI), number or prior ERCP with PS insertion, stent brand and dimensions and duration of SEMS insertion period were collected. The rates of stricture resolution, adverse outcomes including post ERCP pancreatitis, cholangitis and stent dysfunctions (occlusion, migration, shorting) were assessed. The study was approved by the Institutional Review Board of the Cleveland Clinic.

Results: There were 47 OLT patients who underwent ERCP-cSEMS insertion for refractory ABS during the study period. Of 47 patients, 37 patients (78.8%) achieved stricture resolution after single SEMS treatment. Longer duration of SEMS insertion was the only variable associated with increasing probability of stricture resolution as there was 20% increase in odds of stricture resolution for every additional week SEMS was in place. Among those who achieved initial stricture resolution, 27 patients (57%) had maintained bile duct patency throughout the follow up period. The most common adverse outcome was internal migration of cSEMS which occurred in 11 patients (23.4%). Post-ERCP pancreatitis was observed in 3 (6.4%) patients

Conclusion: The efficacy rate observed in resolving refractory ABS with cSEMS placement appears to be comparable to that of multiple ERCPs with PS placement method. Furthermore, durability of ABS resolution with cSEMS use further supports its potential long-term efficacy. Hence, cSEMS should be considered as a viable alternative to ERCP. The follow up period is associated with higher likelihood of ABS resolution. The high rate of internal migration observed with SEMS warrants further endeavor in stent design improvements.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We experienced six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 66 years; age range: 54–80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary surgery and sphencterotomy, and one patient underwent ERCP for biliary surgery. All patients were initially treated with fully covered self-expandable metallic stent (FCSEMS) and nasobiliary drainage. In our institution, from 2010 we have been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. These stents have the advantage of covering the laceration and allowing free flow of bile into the duodenum instead of into the retroperitoneal space. The aim of this study was to evaluate in our cohort of patients, the benefits of FCSEMS in type II perforations.

Aims & Methods: The aim of this study is to clarify the factors that reduce clinical success rate of stent placement. This study was conducted by a retrospective chart review at a single center. The endoscopy database and clinical records from the University of Tokyo Hospital, Tokyo, Japan, were reviewed retrospectively between May 2007 and February 2017. Patient’s symptoms, characteristics, clinical data were obtained from electronic medical record. The obstructions were diagnosed clinically and radiologically and were evaluated by the Colorectal Endoscopy Scoring System (CROSS). Technical success was defined as deployment of a stent across the entire length of the stricture on the first attempt. Clinical success was defined as resolution of symptoms and radiological relief of the obstruction within 24 hours, as confirmed by radiographic observations.

Results: A total of 172 patients (91 males, 81 females; mean age 66.9 years; range 21–93 years) with malignant large bowel obstruction (LBO) were included. The mean GOOSS before DS and after DS were 0.5 and 2.6 respectively (p < 0.001). The median time to restart soft solid meal after DS was 2.9 days. Biliary obstruction was seen in 13 patients and managed with endoscopic biliary stent. Adverse events occurred in 6 patients, including 1 with choanalithiasis, 1 with bleeding and 3 with stent occlusion. The reintervention technical and clinical success rates were 100% (5/5) and 80% (4/5), respectively. The median survival time after DS was 159 days. In neoadjuvant chemoradiotherapy patients, 4 patients were planned surgical for APC.

Conclusion: DS in patients with APC was effective and safe. The findings of this study suggest that DS is worth considering as the bridge to surgery in patients receiving neoadjuvant therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
Complete partial response of MMC for RES patients: 59.5%/40.5%, respectively.

Aims & Methods: The aim of this study was to evaluate the clinical efficacy of MMC injection therapy in patients who had refractory benign esophageal stenosis. Between October 2013 and February 2016, 46 consecutive patients with refractory benign esophageal stenosis who did not respond even after five or more endoscopic dilation therapy. The patients should be more than eighteen year old. Exclusion criteria: Malignant esophageal stenosis, Pregnant or breast feeding women, Deteriorated patients who could not tolerate endoscopic procedure. The method of MMC application -Via 23 gauge injection needle (Optimos injector, Taewoong Medical, Korea) -4 mL of saline-diluted MMC was prepared, with concentration of 0.5 mg/mL. -Injection of 0.5 mL MMC at eight points of the stenotic site immediately after bougination. Follow-up -Interview After 1 week and every four weeks after MMC injection upto 52 weeks. Endoscopy Four weeks after MMC injection and while the obstructive symptoms appeared. Primary end-point -The rate of clinical success. Secondary end-points The mean score of GOOSS before and after MMC injection therapy, Complication -Definition - Clinical success: Improvement of GOOSS score more than one point after MMC injection therapy, compared before MMC injection

Results: Ten patients with refractory benign esophageal stenosis were initially enrolled. Two patients were excluded due to death from hypovolemic shock due to persistent bleeding and esophagectomy as patient’s wish. Finally, Eight patients were analyzed. The rate of clinical success of MMC injection therapy in patients with refractory benign esophageal stenosis was 87.5%. Mean scores of GOOSS were significantly reduced after MMC injection therapy, from 2.5 to 0.29. In all patients, MMC injection therapy below two sessions was needed to improve the symptoms of enrolled patients. Major complications did not occur in any patients.

Conclusion: In our study, the mitomycin injection therapy was effective in patients who had refractable benign esophageal stenosis. The mitomycin injection therapy could be considered as an alternative for refractable benign esophageal stenosis. A large-scale prospective studies are required in future.

Introduction: Anastomotic stenosis or dehiscence are serious complications of colorectal surgery. Colostomy or ileostomy and later redo anastomosis or Hartmann’s procedure are the mainstay of therapy, but edema and inflammation around the primary anastomosis or later adhesions can prevent or delay a further attempt at endoscopic management, and therefore alternative salvage repair methods may be required. Reabsorbable polydioxanone stents are a proposed method but with still debatable results in terms of correct placement, clinical success, early and late stenosis, stent migration, perforation, bleeding, fecal incontinence and local pain.

Aims & Methods: We report here on the use of reabsorbable polydioxanone stents (RPS) in colorectal anastomotic stenosis or dehiscence. We treated with RPS placement, endoscopic dilation and daily mesalazine enemas and/or suppositories. 5 complex cases since 2015. Endoscopy was repeated 1 month after and then every two months or earlier if needed. Endoscopic dilation and progressive apposition of partially overlapping stents were repeated until a stable lumen was observed. During follow-up the patients were treated with local mesalazine, stent migration, perforation, bleeding, fecal incontinence and local pain.

Introduction: The prevalence of post-ESD esophageal stricture is non-negligible, with a critical impact on the patients’ quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

Aims & Methods: This is an observational and analytical retrospective study. Sixty-eight consecutive patients (mean age: 65 ± 11, 76.5% men) who underwent endoscopic dilation because of post-ESD symptomatic esophageal strictures between 2006 and 2016 were included. They had Barrett’s esophagus (n = 46, 67.6%), epithoid carcino ma (n = 21, 30.9%) and other (n = 1). Patients with severe esophageal narrowing, esophagitis, radiationinduced esophageal strictures, esophageal diverticula, motor disorders were excluded. Clinical, morphological and technical features were collected and analysed to determine the factors associated with a positive outcome, defined as the absence of dysphagia during at least twelve months following last dilation. The need of surgery, gastrostomy or prosthesis was considered as a negative.

Results: Resected lesions (95.6% en-bloc) presented a median size of 52.5 mm (range: 22–110) and achieved ≥75% of the circumference in 50% of cases due to post-ESD fibrosis (p = 0.435). They were mostly located in inferior esophagus (70.6%, p = 0.231) and required two endoscopic sessions in 8 patients (11.8%). Oral and injected corticoids were used in 11 (16.2%) and 12 (17.6%) cases, with no effect in outcome (p = 0.181, 0.282). No specific factor could be associated to a better outcome (median follow-up: 23 months): early dilation (≤15days after ESD), number of dilations (p = 0.345), short (≤2cm) stenosis (p = 0.319), balloon diameter (p = 0.475) and Barrett’s vs. squamous cell carcinoma (p = 0.458). The overall positive outcome rate was 92.6% after a median of 3 (range: 1–27) dilations and 5 months of treatment (1 dilation/6weeks). A prosthesis was placed in 4 patients with clinical improvement in two of them. There were 3 complications (4.4%, all perforations).

Conclusion: Most of patients presenting with post-ESD strictures and dysphagia improve at long-term but they need a median of 3 sessions. No specific factor was associated to a better outcome. Disclosure of Interest: All authors have declared no conflicts of interest.
P0934 EFFECTIVENESS OF REPEATED DILATIONS IN THE MANAGEMENT OF ESOPHAGEAL BENIGN STRICATURES

A. Benezech, A. Deboutre, J. Gonzalez, M. Barthe
Service De Gastroentérologie, Assistance Publique - Hôpitaux de Marseille, CHU Nord, Marseille, France

Contact E-mail Address: alban.benezech@ap-hm.fr

Introduction: Refractory or recurrent esophageal benign strictures (REBS) are frequent, and defined as the impossibility to reach or maintain a diameter of 14 mm after 5 sessions of endoscopic dilation (ED). Because of a lack of guidelines, their management remains challenging, especially leading to surgical procedures.

Aims & Methods: The aim of this study was to define the efficacy of long-term and repeated ED in the management of REBS. This was a monocentric retrospective study involving patients managed in our tertiary center between January 2002 and April 2017 for REBS. All the endoscopic dilations were performed using Savary bougies or hydraulic balloons, depending on the operator's choice. Demographical and clinical data were recorded for each patient. The endoscopic management was detailed with the number of procedures, the endoscopic device used, the diameter of dilation, and potential concomitant treatment (as self-expanding metal stent, steroid injection or incision therapy). The primary endpoint was the efficacy of sustained and recurrent ED, defined as the absence of further dilation within 3 months of the last procedure or an interval between the 2 last ED greater than 3 months. A failure was considered in case of death, need for surgery, permanent enteral feeding tube or an interval between the last 2 procedures lower than 3 months. The secondary endpoints were to document the characteristics of dilation procedures and concomitant treatments, the decreasing of the number of dilations per trimester, and to elucidate potential predictive factors for success of ED.

Results: A total of 39 patients (23 men) with a mean age of 47.5 ± 20.7 years were included. The etiologies of strictures were anastomotic (46.1%), caustic (28.2%), peptic (10.3%) or other etiologies (radiation injuries, esophageal diverticulitis, severe viral esophagitis, 15.4%). A clinical success of repeated ED was achieved in 27 patients (69.2%). Twelve patients (30.8%) experienced failure, among them seven (17.9%) required frequent dilatations, two (5.1%) underwent surgery, two (5.1%) maintained an enteral feeding tube, and one patient (2.6%) died consecutively to inhalation pneumonia. A mean of 9.8 ± 4 ED sessions were performed per patient, with a mean treatment duration of 22.6 ± 20.1 months. Regarding concomitant treatments, 16 patients (41%) had at least one fully covered metallic stent placement, incisional therapy was performed in 11 patients (28.2%), and 3 patients (7.7%) received corticosteroid injections. The number of dilations per trimester gradually decreased over time. No significant predictive factor of success was found, such as etiology of stricture or the use of concomitant treatment, particularly. Nevertheless, an greater number of dilations during the first trimester could promote the success of the management (3.2 ± 2.2 dilations in the success group vs 2.2 ± 0.8 in failure group, p = 0.056).

Conclusion: Repeated and maintained endoscopic dilations are effective (70%) in the management of REBS, regardless of the etiology of stricture. A prolonged management up to 2 years, and the initial rhythm of endoscopic procedures may favor the final success. A systematic schedule for ED would improve the efficacy of this management.

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMSs) is a widely accepted procedure for treating malignant colonic obstruction. This procedure was covered by the National Health Insurance in Japan in January 2012, and the WallFlex colonic stent and Niti-S colonic stent can currently be used in Japan. In the previous study, we reported that the WallFlex colonic stent has more expanded force than the Niti-S colonic stent. On the other hand, the risk of stent-related perforation was lower when using the Niti-S stent due to its structure. Currently, we newly developed an SEMS (Niti-S structure, with 18-mm diameter with increased expanded force compared with the conventional type), which comprised the benefits of both WallFlex and Niti-S. In this study, we compared the efficacy and safety of the newly developed colonic stent with the conventional colonic stents.

Aims & Methods: This study aimed to compare the efficacy and safety of the newly developed colonic stent with the conventional colonic stents (the WallFlex colonic stent and the Niti-S colonic stent). Overall, 91 patients (96 lesions, male/female: 48/43, average age: 73.2 years) underwent endoscopic SEMS placement between November 2011 and March 2017 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), the Niti-S colonic stent in 51 patients (53 lesions: Group N), and the newly developed colonic stent in 5 patients (5 lesions: Group D). Stratified analysis of the clinical backgrounds, technical success rate, procedure time, clinical success rate, and complications was performed to compare Group W, Group N, and Group D.

Results: Endoscopic SEMS placement was attempted in 96 lesions as a bridge to surgery (BTS) in 52 lesions (54.2%) and as palliative therapy (PAL) in 44 lesions (46%). In Group W, SEMS was placed in 19 lesions (50%) as BTS and in 19 lesions (50%) as PAL; in Group N, SEMS was placed in 32 lesions (60%) as BTS and in 21 lesions (40%) as PAL; and in Group D, SEMS was placed in 1 lesion (20%) as BTS and in 4 lesions (80%) as PAL. The technical success rate was 100% in all groups. The overall clinical success rate was 93.7% (90/96): 89.5% (46/51) in Group W, 96.2% (51/53) in Group N, and 100% (5/5) in Group D. Complications within 7 days included abdominal pain (3/38, 8%), poor...
Conclusion: The technical and clinical success rates were extremely high in all groups. Primary and secondary peroperative perforation were also low. The mean length of the muscular layer incision was 14.3 ± 1.6 cm on the esophageal side and 2.8 ± 1.0 cm on the gastric side. The mean duration surgery was 191 ± 56.9 minutes. All patients recovered from the contralateral site of the previous myotomy. Moreover, POEM enables making a long myotomy that cannot be made in laparotomy. At our hospital, we have performed POEM on 12 cases that previously underwent the Heller-Dor operation. Herein, we report the outcome of the cases. Aims & Methods: We performed POEM on 210 cases between September 2011 and April 2017. Of those cases, 12 cases (5.7%) had previously undergone Heller-Dor operation. The preoperative and postoperative lymphocyte count was the only predictor of the preoperative and postoperative lymphocyte count. Similarly, in a model that also included the interval between the end of neoadjuvant therapy and the endogastric stapled esophagectomy, the number of surgical accesses (laparotomy, thoracotomy and cervicotomy) and the number of nodal metastasis, only the final dose of radiotherapy resulted to be an independent predictor of preoperative lymphocyte count. POEM: Patients with esophageal and esophago-gastric junction cancer present a significant post operative immunosuppression that lasts at least for the first postoperative week. The total amount of radiation received by the mediastinum is the only predictor of the preoperative and postoperative lymphocyte count.

CS group, 16 patients had unresectable disease (due to lack of remnant liver volume in the left liver, or to three hepatic veins and 9 initially had unsuitable disease (progressive primary disease or suspicion of other distant metastasis); therefore, upfront chemotherapy was selected.

**Results:** The frequency of adverse prognostic factors tended to be higher in the CS group than in the S group (p=0.037 and 0.047, respectively). There were no significant differences in clinical features and operative outcomes between the two groups (p=0.523 and 0.590, respectively). Patient with infected bile duct cancer (R1 resection) in the CS group died from post-operative septic shock (mortality rate 5.3%).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pancreatoduodenectomy (PD) is one of the operations associated with high rate of surgical site infection (SSI). The one of the reasons is that SSI is associated with the preoperative biliary infection caused by preoperative examinations or drainage of biliary tract. In our clinical trial [1], SSI after pancreateoduodenectomy could be decreased by using the perioperative selective antibiotics based on preoperative bile culture. The bacteria cultured from SSI were Enterobacteriaceae such as Enterococcus and Enterobacter species with high frequency.

**Aims & Methods:** Sixty-nine patients underwent PD at Hokkaido University Hospital (Japan) between April 2015 and March 2016, when prospective surgical site infection surveillance was performed. Thirty-eight patients were administered CMZ as perioperative prophylactic antibiotics from April 2015 to March 2016, and 31 were PIPC/TAZ + VCM from April 2016 to March 2017. CMZ was injected intravenously every three hours from the start of operation, and once after the operation. PIPC/TAZ was injected intravenously every three hours from the start of operation and three times on the next day of the operation. VCM was injected intravenously in the morning of operation (20 mg/kg) and just after the operation (15 mg/kg).

**Results:**

- There were no significant differences in clinical features and operative outcomes between the two groups. The patients with PIPC/TAZ + VCM received slightly shorter duration of postoperative antibiotics administration than the patients with CMZ (5.9 ± 8.5 vs. 13.0 ± 18.2 days; p = 0.048).
- Significantly lower incidence of SSI was revealed in patients with PIPC/TAZ + VCM (9/31(29.0%) vs. CMZ (12/38(31.6%); p = 0.004).
- The redneck syndrome as one of the side effects of VCM was observed in 5/31(16.1%) patients and the bacteria were identified as Enterococcus and Enterobacter species.

**Conclusion:** The broad-spectrum perioperative antibiotics covering Enterobacteriaceae such as Enterococcus and Enterobacter species could decrease the incidence of SSI and duration of postoperative antibiotics administration compared to CMZ. More strict indication to select the patients who should be administered VCM, because the occurrence of side effects of VCM was relatively high.

INFECTIONS AFTER GASTROENTEROLOGIC SURGERY: A INCIDENCE OF SUPERFICIAL INCISIONAL SURGICAL SITE INFECTIONS AFTER GASTROENTEROLOGIC SURGERY: A PROBABILITY SCORE MATCHING RETROSPECTIVE STUDY

Department Of Gastroenterological Surgery, Fukuoka University Faculty of Medicine, Fukuoka,Japan

Contact E-mail Address: kanefumi0519@yahoo.co.jp

Introduction: Surgical site infections (SSIs) after gastrointestinal surgery cause significant morbidity, prolong hospitalisation and increase health care costs. Thus, SSI prevention is critical. To prevent bacterial colonisation in suture mate-
rial, which disables local mechanisms of wound decontamination, triclosan-
coated sutures were developed. We retrospectively analysed the efficacy of tri-
closan-coated polydioxanone sutures in abdominal fascia and skin closure using a propensity score matching analysis. We further analysed the surgery types for which these sutures are best suited.

Aims & Methods: The study protocol followed the principles of the Declaration of Helsinki and received ethical approval from the Ethics Committee of the Fukuoka University (approval no. 12-7-96). At our department, we used conven-
tional abdominal closure methods during gastroenterological surgery before August 2012. Thus, we retrospectively collected surveillance data over a 1.5-year period for the control group. From September 2012, we began using triclosan-
coated sutures for closure. Here, we evaluated outcomes for the control group from September 2012 to September 2013. In total, we included 1768 patients (control group, n = 640; study group, n = 1128) who underwent gastrointestinal surgery. Baseline differences and selection bias were adjusted using propensity score matching.

Results: Before matching, the SSI incidence differed significantly between the control and study groups for all gastroenterological surgeries [12.4% (140/1128) vs. 5.5% (64/114), p < 0.001], the SSI incidence for emergency surgery and 5.1% (1/136) vs. 1.0% (1/103) (p = 0.045) for hepato-biliary-pancreatic surgery, 18.2% (40/220) vs. 7.8% (5/64) (p = 0.030) for emergency surgery and 5.1% (7/136) vs. 1.0% (1/103) (p = 0.074) for others. Of 1768 cases, 483 pairs were matched using propensity score matching. No parameter used for the propensity score differed between the groups. After matching, we found a significant difference in the SSI incidence between the control and study groups for all gastroenterological surgeries [9.7% (47/436) vs. 5.7% (28/455); p < 0.001]. We found a significant difference in the SSI inci-
dence between the control and study groups for lower GI [17.0% (68/398) vs. 10.3% (41/390), p = 0.008] and hepato-biliary-pancreatic [16.4% (41/256) vs. 4.3% (6/136), p = 0.049] surgeries. No significant difference was found between the groups for upper GI surgery, emergency surgery and others. Multivariable logistic regression analysis showed that triclosan-coated suture use for lower GI surgery was the independent factor affecting the SSI incidence (p = 0.017). The sutures demonstrated a significant efficacy in lower GI surgery.

Conclusion: Few studies have focussed on the types of surgery best suited for triclosan-coated sutures. Our findings suggest that abdominal fascia and skin closure using these sutures reduces the SSI risk, particularly after lower GI surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagogastrectomy with a circular stapler (CS) accompanied by fundoplication in LPGs. From March 2015, to avoid the postoperative complications, we have been using esophagogastrectomy with the double-flap technique (DFT) in LPG for gastric cancer.

Aims & Methods: We conducted this study to examine whether DFT can reduce the incidence of reflux and influence postoperative complications. Postoperative hospital stay, incidence of anastomotic stenosis was examined as surgical factors and compared between the DFT and CS groups. Second, gastroesophageal reflux finding on endoscopy, condition of the remnant stomach according to residue, gastritis, bile (RGB) classification at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutrient factors. Gastroesophageal reflux was assessed with scores of 0-5 in accordance with the Los Angeles (LA) classification.

Results: Twenty-three LPGs with DFT and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 35.5 vs 241.1 ± 26.7 min, p < 0.01). Other surgical factors did not show any statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative nutrition analysis showed no significant difference between the two groups.

Conclusion: Although LPG with DFT required a longer surgical time than LPG with CS, DFT is thought to be a safe reconstruction method in LPG. In addition to its safety, DFT can reduce postoperative reflux in patients who undergo LPG.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0949 INFLUENCE OF THE HYBRID METHOD OF DETOXICATION ON BLOOD CLARIFICATION EFFECTIVENESS AT PATIENTS WITH THE MULTIORGAN FAILURE SYNDROME

K. G. Khalikulov, B. A. Saidkhanov, D. B. Saidkhanova

Extraorporal Detoxication, National Center of Surgery named after acad. V.Vakhlod, Tashkent City/Uzbekistan

Contact E-mail Address: drghh@hotmail.com

Introduction: The main releaser for development of multiorgan failure syndrome (MOFS) are mediators of the inborn and the acquired immune system, which often occur after surgical complications and more than in 70% of cases leads to lethal outcomes. Increase of an endotoxemia leads to development of the expressed pathological processes and to a fast decomposition of bodies of mammals. Increase of the reactivity of the developed MOFS is expressed pathological processes and to a fast decomposition of bodies of mammals. Increase of detoxication ability of sorbents can happen due to change of chemical composition, or due to collimating of padding properties to them by their modification by various agents by means of an immobilization on their surface of active elements. The aim of this plan especially important role is got by the researches directed to development of sorbents with oxidizing activity.

Aims & Methods: Aim of study is to estimate effectiveness of the modified haemosorbert application for patients about the MOFS. The experimental part of work was conducted on 14 not purebred dogs with the acute liver failure modelled by bandaging of distal department of the CBD. After development of pathological process animals were divided into 2 groups. To the first group of animals the procedure of a haemorsorption was carried out by a reference technique, that is the use of a haemosorbing agent SKN-2K. To the second group the haemorsorption was carried out by the developed technique with the same sorbent, but the solution of a neutral anolyte subjected to oxidizing modification. For this purpose, the flowing mode carried out a half-hour incubation of a solution from 2 l of solution of a neutral anolyte.

Results: Results showed that at animals of the 2nd group in comparison with group of comparison improvement of a condition of an organism was expressed in a much larger degree. After performing detoxication therapy by the developed technique a normalization of all studied parameters is registered. The same tendency is revealed also concerning nonoxical elements. It is necessary to pay special attention to dynamics of a ratio of the common protein and an index average molecules the common protein, pointing to synthesis process activation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomy and extensive surgical interventions for their repair. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat GI leaks such as leaks, fistulae and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leaksages. By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be repaired. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat duodenal leakages. Advantage of OFD is the small diameter which allows easy endoscopic placement through small openings and naso-jejunal insertion. ENPT + OFD is a new method of treating duodenal leaks.

Aims & Methods: Herein, we report ENPT using open-pore Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leakages. This is an open-label, retrospective, single-center study. Open-pore polyurethane-foam drainage (OFD) devices were constructed out of a piece (1.5 cm x 3 cm) of open-pore polyurethane-foam which was fixed surrounding the tip of a naso-duodenal drainage tube. Small bore open-pore film drainage (OFD) device was constructed with a strip of a very thin fragment open-pore double layered film (1.5 cm × 3 cm) which was fixed surrounding the naso-duodenal drainage tube. The open-end film consists of two permeable membranes with a small interspace. Fluids are drained along the interspace and through the membranes. Diameter of small-bore OFD is 4–6 mm, depending on the diameter of the drainage tube. OFD is inserted transgastrically. The foam is grouped with endoscopic forces and guided to the duodenal lumen. After correct placement into the duodenal lumen for intraluminal ENPT, the tube is transferred out nasally, to become a naso-duodenal tube. Due to its smaller outer diameter OFD insertion is similar to placing a naso-gastric or naso-intestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodenal- cutaneous fistula the pull-through technique has been used for duodenal placement. In one case rendezvous technique was used in combination with operative OFD. OPD and ENPT is an ex vivo electronic vacuum device and negative pressure is applied. We use standard negative pressure of 125 mmHg, continuous suction, and high intensity, which results in collapse of the duodenal lumen around the open-pore foam or film with subsequent closure of the leak suture.

Results: We treated 10 patients with ENPT because of a duodenal leakage. Reason of duodenal defects were: rupture of operative suture (n = 8), iatrogenic perforation due to naso-duodenal leak. Nine patients were treated with intraluminal and one patient with intracavitary variant of ENPT. In 7 patients we used the OPD device, in one patient OFD, and in two patients OPD and OFD. All leakages (100%) were successfully closed after 7–18 days. Postoperative complications were minor such as local pain, which was managed by analgesics only. Our complication rate was similar to other reports in the literature [1].

Conclusion: ENPT using small diameter tube with open-pore film was effective to treat duodenal leakages. Advantage of OFD is the small diameter which allows easy endoscopic placement through small openings and naso-jejunally. ENPT + OFD is a new method of treating duodenal leaks.

Introduction: Gastro leaks are severe complications of Bariatric Surgery (BS). Surgical re-intervention may be indicated but is associated with high morbidity and mortality. The use of self-expanding esophageal metallic stents (SEMS) has become an effective alternative. Over the scope clips (OTSC) have also been used. Nevertheless some patients develop a refractory fistulae after stent removal or other failed endoscopic treatments. Cardiac Septal Defect Closure Device (CSDCD), used in interventional cardiology have been described to treat post-surgical digestive fistulae in non-bariatric cases.

Methods: We aim to present the experience using CSDCD for gastric leaks following laparoscopic gastric bypass (GBP) or sleeve gastrectomy (SG). A total of 34 patients were included and treated from April 2010 to June 2015. Patients with leak secondary to GBP underwent early intervention. Patients with leak secondary to SG underwent early intervention or laparoscopically assisted and open colectomy for colon cancer. However, hernia was predominantly observed during the period of surgical technique development.

Conclusion: Further studies to standardize, evaluate the safety and benefits of CSDCD is needed.

P0951 COMPARATIVE EVALUATION OF LAPAROSCOPIC SINGLE-PORT (SILS) CHOLECYSTECTOMY AND LAPAROSCOPIC FOUR-PORT CHOLECYSTECTOMY
A. Alekberzade, N. Krelyov, E. Lipitinsky
Surgery, Sechenov First Moscow State Medical University, Ministry of Health of the Russian Federation, Moscow/Russian Federation

Contact E-mail Address: a.alekberzade@gmail.com

Introduction: Laparoscopic cholecystectomy is the gold-standard for the treatment of gallbladder disease. Single-incision laparoscopic (SILS) cholecystectomy was introduced with the aim of reducing the invasiveness of classic laparoscopic surgery. Despite satisfactory cosmetic results of SILS cholecystectomy and its repute of a painless procedure, there are few published studies comparing early and long-term postoperative period of laparoscopic SILS cholecystectomy versus laparoscopic four-port cholecystectomy.

Aims & Methods: The aim of this study is the comparative evaluation of SILS cholecystectomy and laparoscopic four-port cholecystectomy. Early and long-term postoperative period has been analyzed in 240 patients who underwent laparoscopic cholecystectomy including 120 cases of single-port technique and 120 cases of four-port technique. Both groups were compared in surgical time, pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect.

Results: It was revealed that SILS cholecystectomy is associated with lower severity of postoperative pain, quick recovery of daily activity and return to work, high satisfaction of surgical results and their aesthetic effect.

Conclusion: Further studies to standardize, evaluate the safety and benefits of SILS cholecystectomy are necessary.

Introduction: Bibliometric analysis highlights key topics and publications, which have shaped the development of laparoscopic surgery (LS). Here the 100 most cited manuscripts in the field of LS are analyzed.

Aims & Methods: The Thomson Reuters Web of Science database was used to identify all English language full manuscripts for the study with the search term “laparoscopy” and “surgery”. The 100 most cited papers were further analyzed by topic, journal, author, year and institution.

Results: 71,524 eligible papers were returned and the median (range) citation number was 585.76 (range 1635 to 368). The two most cited papers received 1635 citations each. The first (Nelson1) compared laparoscopic and open colectomy for malignancy, and the second (Clavien2) described the classification of postoperative morbidity. Annals of Surgery published the highest number of papers (n=22) and received most citations (n=12,356). The country with the highest number of publications was the USA (n=55), and the year with the greatest number of publications was 2004 (n=13). The most ubiquitous topic was the treatment of cancer (n=35), followed by surgical technique (n=24), and comparison of laparoscopic with open surgery (n=22).

Conclusion: The most cited manuscripts highlighted laparoscopic surgical technique and compared laparoscopic with open surgery, and this review provides the most influential references in this arena, serving as a guide to an ecitable paper.

Aims & Methods: The aim of this study was to further analyse different factors to laparoscopic simulator training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Trainer (MIST, Mentice, Gothenburg, Sweden). Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience). The data were analysed regarding different part of the simulation (time, economy of movement, error and total score).

Results: The group with high PC-gaming experience performed significantly better in total time (M = 25.30, p = 0.018) and economy of movement (M = 68.89, p = 0.006) and total score (M = 80.16, p = 0.036). The group with low PC-gaming experience and low visuospatial score performed worst in the simulator exercises. Concerning the learning experience and visuospatial abilities might have an impact on laparoscopic simulator performance. No remaining significant differences by the third simulation exercise indicates a learning effect that could be more important than baseline skills. It could be valuable to identify individuals with both low PC-gaming experience and low visuospatial score to offer them additional simulator training.

Aims & Methods: We collected all patients hospitalized for peritoneal tuberculosis from 2004 to 2015 at the Department of Surgical and Perioperative Sciences, Umeå University, Sweden. The aim of this retrospective study was to study the epidemiological, clinical, pathological, diagnostic, therapeutic and specific features of peritoneal tuberculosis in its various presentations.

Results: The total number of patients was 49. It was 15 men (31.0%) and 34 women (69.0%). The sex ratio was 0.3. The mean age at diagnosis was 40 years (15–79 years). No personal history of tuberculosis has been found in our series. A personal history of tuberculosis was found in 3 patients (4.6%). The general signs of tuberculin impregnation were found frequently (91%). The digestive functional stasis that brought the patients to consult are: abdominal pain (87.7%), abdominal distension (85.7%), diarrhea (16.9%) and sub oclusive symptoms (4.6%). An abdominal mass was observed in only 4 patients (6.1%). Hepatomegaly and splenomegaly were noted in 2 cases for each. The intradural reaction was positive in only 24% of patients. The research of BK in the ascites fluid was systematically performed in all patients but returned negative in all cases. The quanteron-TB Gold was performed in 3 patients only and returned positive. The mean level of CA 125 was 253.8 ml/ml. Confirmation of diagnosis was determined on the histological analysis of peritoneal biopsy, peritoneal washings and mesenteric nodes. The main operative findings (in patients with coeloscopy or exploratory laparotomy) were: Whith variculans granulations (98%), adhesions (43.1%) and agglutinated loops (1.5%). The presence of tuberculosis granuloma was observed in 52 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Peritoneal tuberculosis raises diagnostic problems in the first place, because of its polymorphic and non-evocative clinical expression. Hence the value of carrying out radiological, endoscopic and histo-bacteriological investigations to confirm the diagnosis before the evolution towards serious or even fatal forms.

TLR5-deficient and emulsifier-treated mice demonstrate that these models of gut inflammation and gut microbiota dependency on disturbance of epithelial tightness in microbiota dependency of inflammation reflects an inability to manage pathobiont bacteria, such as Adherent-Invasive *E. coli* (AIEC).

**Aims & Methods:** Our goal was to examine extent to which microbiota mismanagement and associated inflammation in TLR5-deficient and emulsifier-treated mice would manifest in a limited pathobiont-free microbiota. WT and TLR5-deficient mice were maintained in gnotobiotic isolators containing altered Schaedler flora (ASF), a community of eight bacterial species. Mice were treated with either CMC or P80, or inoculated with AIEC LF82 [4]. Feaces were assayed for bacterial loads, microbiota composition, and inflammation marker lipocalin-2. Fecal LPS and flagellin bioactivity were measured via a cell-based reporter assay, and morphologic and metabolic parameters were determined.

**Results:** Neither CMC nor P80 induced evidence of intestinal inflammation nor metabolic syndrome in WT ASF mice. Analogously, relative to similarly maintained WT mice, loss of TLR5 did not result in low-grade intestinal inflammation or metabolic syndrome under ASF conditions. Concomitantly, the ASF microbiota community was not disturbed by CMC nor P80 and, moreover, was similar between WT and TSKO mice. Inoculation with AIEC strain LF82 resulted in profound alteration of the ASF community in TSKO mice compared to WT mice with TLR5 exon 6 deletion in ASF TSKO mice, as evidenced by elevated levels of bioactive LPS and flagellin, and was associated with modest level of low-grade inflammation and increased adiposity. Therefore, in a limited-complexity pathobiont-free microbiota, loss of the flagellin receptor TLR5 or emulsifier consumption does not impact microbiota composition nor its ability to promote inflammation. Addition of AIEC to this ecosystem perturbs microbiota composition, increases levels of lipopolysaccharide (LPS) and flagellin, but modestly promotes gut inflammation and adiposity, suggesting that the phenotype previously observed require disruption of the coman microbiota.

**P0958 ISOLATION AND CHARACTERIZATION OF LAMINA PROPRIA MONONUCLEAR CELLS FROM HUMAN COLONIC MUCOSA**

S. Musladin 1, I. Zlatar 2, L. Pribolsan 1, K. Ilie 3, P. Nikolic 1, M. Antolic 3, S. Cuzic 1, G. Aralica 3, L. Patrlj 3, R. Klicek 3, M. Bosnar 1, V. Erakovic Haber 1

**Contact E-mail Address:** sanja.musladin@glpg.com

**Introduction:** Lamina propria mononuclear cells (LPMCs) are immune system’s first line of defense in the intestine characterized by the ability of differentiating invading pathogens from beneficial intestinal flora and swiftly removing them. Disrupted regulation of LPMCs is implicated in pathology of a group of disorders, namely inflammatory bowel disease (IBD). Two major types of IBD are ulcerative colitis, limited to the colon and Chron’s disease affecting any segment of the gastrointestinal tract. Chron’s disease and ulcerative colitis were shown to be mediated by Th1-polarized helper (CD4+ T-cell) and Th2-activated CD4+ T-cell, respectively, while Th17-polarized cells are involved in pathogenesis of both diseases [1]. Therefore, research into biology and regulation of LPMCs is of essential importance for development of treatments for IBD symptoms.

**Aims & Methods:** The aim of this study was development of a robust method for isolation and characterization of LPMCs from human colonic mucosa, compatible with further *ex vivo* cell culturing and research. Mucosal tissue samples contained the tissue not affected by tumor, removed during tumor surgery of patients with colorectal carcinomas, and surrounding resected tissue. The tissue may be considered as healthy in terms of IBD. We have employed an isolation method consisting of disruption of epithelial cells by incubation of mucosa in a DTT and EDTA containing solution, followed by enzymatic and mechanical digestion of tissue and purification of mononuclear cells by density gradient centrifugation. Isolated cells were characterized by flow cytometry (FACS) detection of cell-type specific surface antigens and cytokological analysis. To examine the plasticity of isolated cells in terms of polarization towards IBD-associated phenotypes, the cells were seeded at conditions mediating Th1, Th2 and Th17 differentiation of CD4+ T-cells and analyzed for activation of differentiation-specific gene expression and cytokine production by qPCR and ELISA assays. Aliquots of cells were cryopreserved and further analyzed for the effect of cryopreservation on cell viability, distribution of cell-type specific surface antigens and CD4+ T-cell responses.

**Results:** Approximately 95% cell viability and 90% leukocyte (CD45+) cell purity was determined by FACS analysis of isolated LPMCs. According to cytokological analysis, CD45-negative cells may represent CD45-negative population of plasma cells; no contamination with epithelial cells was detected. Within CD45+ cell population, 26-47% T-lymphocytes, 17-24% B-lymphocytes, 8-17% macrophages and 21-46% monocytes were detected by FACS and cytokological analyses (N=3). Cytorepression did not significantly affect cell viability and surface marker distribution. Isolated cells successfully polarized towards Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by IFNY gene expression and cytokine production for Th1, IL13 gene expression and IL5 cytokine production for Th2 and IL17 cytokine production for Th17 differentiated cells. Differentiation was confirmed in cryopreserved cells, with lower level of phenotype-specific cytokine production.

**Conclusion:** Method for LPMC isolation from human colonic mucosa tissue samples was successfully established with approximately 95% viability of isolated cells and 90% detectability of epithelial cell contamination. Within CD45+ cells, 26-47% of T-lymphocytes, 17-24% B-lymphocytes, 8-17% macrophages and 21-46% of monocytes were detected. Isolated cells were successfully polarized towards IBD-associated Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by activation of phenotype-specific gene expression and cytokine production. Cytorepression of isolated LPMCs did not significantly affect cell viability, distribution of cell-type specific surface antigens or polarization towards Th1, Th2 and Th17 CD4+ T-cell phenotypes.

**P0959 FACTORS ASSOCIATED WITH DISABILITY IN INFLAMMATORY BOWEL DISEASE: OUTPATIENT CROSS-SECTIONAL STUDY**

J. M. Costa 1, D. Matos 2, J. B. Soares 1, R. Costa 1, B. Arroja 1, R. Gonçalves 1
1Gastroenterology, Hospital de Braga, Braga/Portugal
2School Of Health Sciences, University of Minho, Braga/Portugal

**Contact E-mail Address:** julianamcosta78@gmail.com

**Introduction:** The Inflammatory Bowel Disease-Disability Index (IBD-DI) has recently been validated to measure disability in IBD [2].

**Aims & Methods:** We aimed to assess disability in IBD outpatients using IBD-DI and to determine the sociodemographic, clinical and psychological factors that are associated with greater disability. Between August and October of 2016, patients with an established diagnosis of Crohn’s Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic were invited to participate. Socio-demographic and clinical data were collected from electronic health record and interview. Optimism and disability were evaluated using, personally or by phone, the validated Portuguese versions of the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological variables (optimism) and IBD-DI (scale 0-100, proportional to the reported disability) was determined by univariate and multivariate analysis.

**Results:** A total of 143 patients (70 DC and 73 UC; 59.3% females) with a mean age of 38 ±13 years were included. Most (85.3%) was in clinical remission. The mean global IBD-DI-PT score was 7.9 ± 10.7, with a significant difference between DC and UC (p = 0.044). In univariate analysis, female gender, high level education, number of days off from work, articular manifestations, number of comorbidities, use of psychotropic drugs and pessimism (low LOT-R score) were significantly associated with higher disability (IBD-DI-PT score). In multivariate analysis, only female gender (β = 0.150), number of comorbidities (β = 0.186) and pessimism (β = 0.370) were significantly associated with higher disability. Clinical activity was associated with higher disability only for CD patients (β = 0.321). Inhibitory cytokines and T-cell receptor expression were not associated with disability in IBD patients. Clinical activity seems more important to CD than UC patients in terms of disability.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

A significant increase was observed in patients undergoing treatment with corticosteroids (p-value less than 0.0008) and IgA (p-value less than 0.0001) were also higher in groups when compared to control group. The population of CD4+ cells in peripheral blood of healthy controls and patients with CD was evaluated both in biological and corticoid treatment. A significant increase in the population was observed in patients receiving corticosteroids (p-value less than 0.001) compared to healthy controls. In the population of CD4+ a significant increase was observed in patients undergoing treatment with corticosteroids in relation to patients undergoing biological treatment (p-value less than 0.0007). In CD8+ population, no statistical difference was observed between the groups. The markers CD3, CD62L and HLA-DR were also evaluated. In relation to CD38 (p-value less than 0.0022) and CD62L (p-value less than 0.0015) in subpopulation of CD4+ T-cells, a significant increase in the expression was observed in the group of patients receiving corticosteroids in relation to the group receiving biological therapy. Regarding HLA-DR, statistical difference (p-value less than 0.001) was observed between the group undergoing biological treatment and the group of healthy controls. In the subpopulation of CD8+ T-cells, a significant increase (p-value less than 0.02) was observed in the CD62L marker when compared to the group of healthy controls receiving corticoid treatment with patients in use of biological therapy.

Conclusion: We conclude that the use of biological therapy suppresses activated T cells by regulation of CD38, CD62L and HLADR expression were determined. The use of biological therapy was associated with decreased expression of CD38, CD62L and HLA-DR.

Introduction: Advancing of sequencing technologies in the first decade of the XXI century gives the opportunity to realization of large scale projects such as the 1000 human genomes project. This project provides enormous amount of the data for human population studies and different GWAS studies aimed to investigate connection of the human genetics variations with different diseases. It is especially interesting to study the connection between the human genetics, the microbiome metagenomes of mucosa and different pathological conditions. Previously revealed, the size of the summary gut microbiome metagenome is on order more than the size of a human genome. The most of works devoted to studying of the connection of the gut microbiome changes with different pathological conditions based on the investigation of fecal samples. On our opinion, in the case of ulcerative colitis it is more effective to study the mucosal microbiome of the affected regions.

Aims & Methods: The aim of our work was to study the composition of mucosal microbiomes in the colon mucosa biopsies from patients with ulcerative colitis by using the target high throughput sequencing of bacterial 16S rRNA genes. Biopsies from four caucasoid race patients with left-sided ulcerative colitis in the abating activation. Ceymo endoscopic index - 3, Rachnevech clinical index - 4 and two patients from control group with irritable bowel syndrome were collected. The DNA was extracted from mucosal biopsies and 16S rRNA genes from it's were target sequenced by using Illumina MiSeq sequencer. Sequencing reads were quality checked by the FastQC software and trimmed by using the trimmomatic software. To characterize the composition of the microbiota, trimmed reads were analyzed by the QIIME software. The obtained results were compared with the earlier published data: SRA Project - ERP001780 (96 samples from patients of control group), 44 samples from patients with ulcerative colitis)[1] and SRA Project - SRP065002 (703 samples from patients with ulcerative colitis).

Results: More than 124 bacterial genera were found in biopsies of four patients with ulcerative colitis. The analyzed samples of patients with ulcerative colitis were split in two groups by using the PCoA analysis. The first group was characterized by decreasing the concentration of the Firmicutes type bacteria (p-value less than 0.005) and increasing the concentration of Bacteroidetes type bacterias (p-value less than 0.005). For the second group, it was founded decreasing of the concentration of the Actinobacteria type bacterias (p-value less than 0.05), 70-fold excess of Bacteroides vulgatus species bacterias concentration was revealed for one sample of the first group (normalized number of reads in control samples was less than 0.0003 and reached 0.21 in samples of patients with ulcerative colitis). Additionally, the concentration of Escherichia coli species bacterias was increased in the 40 times for that sample (normalized number of reads in control samples was 0.0003 in samples of patients with ulcerative colitis). Although, the predominance of Proteobacteria genus bacterium was not founded. The concentration of Faecalibacterium prausnitzii species bacterias was decreased by three orders of magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The concentration increase of the conditional-pathogenic mucosal microflora (a mostly Bacteroidetes type bacteria) was discovered, which playing important role in the development of ulcerative colitis. Also, the deficiency of Faecalibacterium prausnitzii species bacterias was discovered, which decrease resistance of mucosa to the conditional-pathogenic microflora.

Aims & Methods: The primary aim of this study was to investigate, in the mouse model with colitis coexisting with diabetes development, the gut microbiome composition and function which may be responsible for intestinal growth and enhancement of intestinal function. The prevalence of type 2 diabetes among IBID patients is low, even though IBID sufferers may be at a greater risk of development of T2D due to overproduction of pro-inflammatory cytokines and excessive administration of diabetogenic drugs. We hypothesize that the possible mechanism underlying this phenomenon is related to changes in the levels of incretin hormones.

Introduction: The role of incretin hormone, GLP-1, in inflammatory bowel diseases (IBD) development and exacerbations is still poorly understood. GLP-1 decreases blood glucose level and is co-secreted by intestinal L cells with secretin which may be responsible for intestinal growth and enhancement of intestinal function. The prevalence of type 2 diabetes among IBID patients is low, even though IBID sufferers may be at a greater risk of development of T2D due to overproduction of pro-inflammatory cytokines and excessive administration of diabetogenic drugs. effect of colitis on T2D development was studied by assessing fasting glucose levels, as well as retinol binding hormone levels, in UC and GLP-2 treated mice.

Results: Hyperglycemia in mice treated with TNBS was delayed compared to a non-inflamed group, which was associated with significantly higher levels of GLP-1 in blood. Surprisingly, the levels of GLP-2 were significantly reduced in diabetic mice with colitis, suggesting that this distinct mechanism is involved in the regulation of the incretin hormones in response to intestinal inflammation. There were no significant differences in macroscopic score, colon length, and bowel thickness in diabetic mice with or without colitis. Notably, the concentration of GLP-2 was significantly increased in diabetic mice with colitis compared to diabetic mice with no inflammation. No changes in MPO, TNF-α, IL-1β were observed between these groups.

Conclusion: We propose that GLP-1 production may be stimulated in response to colitis, thus protecting against diabetes. In contrast, diabetic mice with colitis were protected against diabetes. This observation is the first to reveal possible connections between T2D and IBD and may lead to better understanding of the pathophysiology of these two diseases. Furthermore, our data suggest that the incretin hormones may become a potential new target in treatment of IBD.

Introduction: Interleukin(IL)10 is an important anti-inflammatory cytokine for the maintenance of gut homeostasis. Defects in the IL10 signaling pathway in macrophages leads to deregulation of regulatory (M2) type macrophages and subsequent inflammatory bowel disease (IBD). IBD patients are frequently successfully treated with anti-TNFα antibody therapy, although not all patients are responsive.
