Results: Before matching, the SSI incidence differed significantly between the control and study groups for all gastroenterological surgeries [12.4% (140/1145) vs. 5.0% (35/640); p = 0.000] and the SSI incidence for upper GI [5.7% (40/690) vs. 1.3% (4/300); p = 0.008] and lower GI surgeons [2.7% (20/740) vs. 0.0% (0/120); p = 0.004] were higher in the control group. After matching using a propensity score matching analysis, we found a significant difference in the SSI incidence between the control and study groups for all gastroenterological surgeries [9.7% (47/486) vs. 5.7% (28/455); p < 0.001]. We found a significant difference in the SSI incidence between the control and study groups for lower GI surgery [17.0% (68/400) vs. 5.4% (9/165); p < 0.001]. The difference in the SSI incidence between the control and study groups for upper GI surgery was not significant.

Conclusion: Few studies have focussed on the types of surgery best suited for triclosan-coated sutures. Our findings suggest that abdominal fascia and skin closure using these sutures reduces the SSI risk, particularly for lower GI surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagegastrosotomy with a circular stapler (CS) accompanied by fundoplication in LPG. From March 2015, to avoid the postoperative complications, we have been using esophagegastrosotomy with the double-flap technique (DFT) in LPG for gastric cancer.

Aims & Methods: We conducted this study to examine whether DFT can reduce the incidence of reflux and incidences of postoperative complications, especially postoperative anastomotic stenosis were examined as surgical factors and compared between the DFT and CS groups. Second, gasoerosophageal reflux finding on endoscopy, condition of the remnant stomach according to residue, gastritis, bile (RGB) classification at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutrient factors. Gastroerosophageal reflux was assessed with scores of 0–5 in accordance with the Los Angeles (LA) classification.

Results: Twenty-three LPGs with DFT and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 55.5 vs 241.1 ± 26.7 min, p < 0.01). Other surgical factors showed no statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative nutritional factors were also lower in the DFT group than in the CS group.

Conclusion: Although LPG with DFT required a longer surgical time than LPG with CS, DFT is thought to be a safe reconstruction method in LPG. In addition to its safety, DFT can reduce postoperative reflux in patients who undergo LPG.

Introduction: Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomies and extensive surgical interventions for their repair. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat GI leaks such as leaks, fistulae, and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leaks. By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be employed.

Aims & Methods: Herein, we report ENPT using open-portal Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leaks. This is an open-label, retrospective, single-center study. Open-portal polyurethane-foam drainage (OPD) devices were constructed out of a piece (1.5 cm × 1.5 cm × 3 cm) of open-portal polyurethane-foam which was fixed surrounding the tip of a naso-gastric drainage tube. Small bore open-portal film drainage (OFD) device was constructed with a strip of a very thin fragment open-portal double layered film (3 cm × 1 cm). The foam is grouped with endoscopic forceps and guided to the duodenal lumen. After correct placement into the duodenal lumen for intraluminal ENPT, the tube is transferred out nasally, to become a naso-duodenal tube. Due to its smaller outer diameter OFD insertion is similar to placing a naso-gastric or naso-intestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodenal- cutaneous fistula the pull-through technique has been used for duodenal placement. In one case rendezvous technique was used in combined repair with open surgical OFD and endoscopic ENPT. Use of a negative electronic vacuum device and negative pressure is applied. We use standard negative pressure of 125 mmHg, continuous suction, and high intensity, which results in collapse of the duodenal lumen around the open-portal foam or film with subsequent closure of the defect zone. Furthermore, duodenal secretions are actively removed through the tubes.

Results: We treated 10 patients with ENPT because of a duodenal leakage.

Reason of duodenal defects were: rupture of operative suture (n=8), iatrogenic perforation due to an incorrect insertion of an endoscopic stapler (n=2) and violation from system of a hemostasis. For this plan especially the armamentament of ENPT is got by the researches directed to development of sorbents with oxidizing activity.

Aims & Methods: Aim of study is to establish effectiveness of the modified haemosorbor application for patients about the MOFS. The experimental part of work was conducted on 14 not purebred dogs with the acute liver failure modelled by bandaging of distal department of the CBD. After development of pathological process animals were divided into 2 groups. To the first group of animals the procedure of a haemosorbor was carried out by a reference technique—introduction of a haemosorbor of SKN-2K. To the second group of dog the haemosorbor was carried out by the developed technique with the same sorbent, but the solution of a neutral anolyte subjected to oxidizing modification. For this purpose, in the flowing mode carried out a half-hour incubation of a nutrient from 2 l of solution of a neutral anolyte.

Results: Results showed that at animals of the 2nd group in comparison with group of comparison improvement of a condition of an organism was expressed in much larger degree. After performing detoxication therapy by the developed technique a normalization of all studied parameters is registered. The same tendency is revealed also concerning nontoxic components. It is necessary to pay special attention to dynamics of a ratio of the common protein and an index average molecules (the common protein, pointing to synthesis process activation. The carried-out all-clinical blood test revealed the considerable improvement of indexes of white blood. In group of comparison it was not succeeded to achieve the complete normalization of the studied indexes. On the basis of what the conclusion was drawn on high effectiveness of the developed technique, and expediency of its introduction in clinical practice. Under our observation there were 45 patients needing carrying out getetter detoxication in the postoperative period. The control group (25) was created by a random sample of case histories of the patients with the postoperative anastomotic syndrome who was earlier on treatment in our clinic and receiving a course of haemo perfused therapy by a reference technique. The analysis of results of treatment of patients of a basic group showed that the positive dynamics of clinical indexes expressed in decrease of manifestations of an intoxication syndrome, improvement of health and laborato- rinary indexes is noted in earlier terms, and degree of expressiveness of positive changes at them was much higher. Dynamics of decrease in endogenic intoxication is reflected by data of laboratory researches. It is necessary to pay special attention to the fact that it is possible to increase quality of detoxication by a pretreatment of a haemo sorbent solution of a neutral anolyte. As a result of it the sorbent gains oxidizing, oxidizing properties. At such modification there is an inclusion of oxygen-containing and acid groups in structure of the sorbent, and surface of a sorbent proteogenic groups of carboxylic and phenolic types thanks to which the oxidized coals gain the expressed cation-exchange ability are formed. Therefore, besides actually getter, such sorbent follow-up gains oxidizing properties. Modification of a sor- bent solution of a neutral anolyte incidentally allows to solve also other problem connected about need of use of anticoagulants for prevention of a thrombogen- eis in a column. Use in this quality provides decrease in risk of postoperative violations from system of a hemostasis.

Introduction: Gastric leaks are severe complications of Bariatric Surgery (BS). Surgical reconstruction may be indicated but is associated with high morbidity and mortality. The use of self-expanding esophageal metallic stents (SEMS) has become an effective alternative. Over the scope clips (OTSC) have also been used. Nevertheless some patients develop a refractory fistulae after stent removal or other failed surgical treatments. Cardiac Septal Defect Closure Devices (CSDCD), used in interventional cardiology have been described to treat post-surgical digestive fistulae in non-bariatric cases. Aims & Methods: We aim to present the experience using CSDCD for gastric leaks secondary to BS. In this retrospective study, patients with leaks secondary to gastric bypass (GBP) or sleeve gastrectomy (SG) from 4 centers were included. Data collected from november 2012 to january 2016 included sex, age, type of surgery, previous treatment, tract path, size of the leak opening and defect closure. Leaks were grouped according to the International Sleeve Gastrectomy Expert Panel Consensus in acute (post-operative days 1–7), early (1-6 weeks), late (after 6 weeks) and chronic (>12 weeks). Biliary catheters were adapted to introduce the CSDCD through the gastroscopes working channels. Clinical success was defined as complete and permanent resolution of abdominal or thoracic pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect. Results: It was revealed that SLS cholecystectomy is associated with lower severity of postoperative pain, quick recovery of daily activity and return to work, high satisfaction of surgical results and low incidence of surgical revision compared with four-port cholecystectomy. Disadvantages of SLS cholecystectomy include longer duration of surgery, high incidence of postoperative umbilical hernia. However, hernia was predominantly observed during the period of surgical technique development. Conclusion: Further studies to standardize, evaluate the safety and benefits of SLS cholecystectomy are necessary. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bibliometric analysis highlights key topics and publications, which have shaped the development of laparoscopic surgery (LS). Here the most cited manuscripts in the field of LS are analyzed. Aims & Methods: The Thomson Reuters Web of Science database was used to identify all English language full manuscripts for the study with the search term ‘laparoscopy’ and ‘surgery’. The 100 most cited papers were further analyzed by topic, journal, author, year and institution. Results: 71,524 eligible papers were returned and the median (range) citation number was 585.76 (range 1635 to 368). The two most cited papers received 1635 citations each. The first (Nelson1) compared laparoscopic and open colectomy for colon cancer, and the second (Clavin2) described the classification of postoperative morbidity. Annals of Surgery published the highest number of papers (n = 22) and received most citations (n = 12,356). The country with the highest number of publications was the USA (n = 55), and the year with the greatest number of publications was 2004 (n = 13). The most ubiquitous topic was the treatment of cancer (n = 35), followed by surgical technique (n = 24), and comparison of laparoscopic with open surgery (n = 22). Conclusion: The most cited manuscripts highlighted laparoscopic surgical technique and compared laparoscopic with open surgery, and this review provides the most influential references in this area, serving as a guide to the publication.
P0953 BASELINE CHARACTERISTICS IN LAPAROSCOPIC SIMULATOR PERFORMANCE

N. Oussi1, P. Remnan2, E. Georgiou3, L. Enochsson4
1Division Of Surgery, Karolinska Institutet, Huddinge/Sweden
2Division Of Medical Education, Umeå University, Umeå/Sweden

Introduction: Laparoscopic technique is the first choice for multiple surgical procedures today. Laparoscopic surgery differs from traditional open surgery in several aspects, for example two-dimensional view of a three-dimensional interior, higher demands on eye-hand coordination and lack of tactile feedback. Laparoscopic surgical skills can be substantially improved by simulator training. Learning via simulators are under constant development and it is important to understand the value of baseline characteristics and abilities to further optimize simulators and training curricula within surgical education. In this study, focus, will be on the gaming experience and visuospatial skills.

Aims & Methods: The aim of the study is to further analyse different factors to laparoscopic simulator training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Trainer (MIST, Mentice, Gothenburg, Sweden). Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience).

The data were analysed regarding different parts of the simulation (time, economy of movement, error rate and total score).

Results: The group with high PC-gaming experience performed significantly better in total time (Mean difference = 85.49, p = 0.021) and economy of movement (M = 25.30, p = 0.018) in task 1 and 2. There were no differences between either of the groups in task number 3. A high visuospatial score correlated with a better result in time to completion (M = 68.89, p = 0.026) and total score (M = 80.16, p = 0.036). The group with both low PC-gaming experience and low visuospatial score performed worst in the simulator exercises.

Conclusion: Higher pre-existing visuospatial experience and visuospatial skills have an impact on laparoscopic simulator performance. No remaining significant differences by the third simulation exercise indicates a learning effect that could be more important than baseline skills. It could be valuable to identify individuals with both low PC-gaming experience and low visuospatial score to offer them additional simulating training.

TLR5-deficient and emulsifier-treated mice demonstrate that these models of gut inflammation and pathobiont dependency on distribution favor pathobiota dependence. Inhibition of TLR5 signaling lowers Th17 polarization towards Th1, Th2 and Th17 differentiation of CD4+ T-cells, respectively, while Th1 and Th17 cytokine production for Th17 differentiated cells.

Assays. Aliquots of cells were cryopreserved and further analyzed for the effect of bacterial cell-free supernatant, surface antigens and CD4+ T-cell responses. Results: Approximately 95% cell viability and 90% leukocyte (CD45+) cell purity was determined by FACS analysis of isolated LPMCs. According to cytokine analysis, CD45-negative cells may represent CD45-negative population of plasma cells: no contamination with epithelial cells was detected. Within CD45− cell population, 26–47% T-lymphocytes, 17–24% B-lymphocytes, 8–17% macrophages and 21–46% monocytes were detected by FACS and cytokanalyses (N = 3). Cryopreservation did not significantly affect cell viability and surface- and cytokine marker expression. Isolation of a reference LPMC line F2;4. Fece was assayed for bacterial loads, microbiota composition, and inflammatory marker lipocalin-2. Fecal LPS and flagellin bioactivity were measured via a cell-based reporter assay, and morphologic and metabolic parameters were determined.

Results: Neither CMC nor P80 induced evidence of intestinal inflammation nor metabolic syndrome in WT ASF mice. Analogously, relative to similarly maintained WT mice, loss of TLR5 did not result in low-grade intestinal inflammation and metabolic syndrome under ASF conditions. Concomitantly, the ASF microbiota community was not disturbed by CMC nor P80 and, moreover, was similar between WT and T5KO mice. Inoculation with AIEC strain LF82 resulted in profound alteration of the ASF community in T5KO mice compared to WT animals. Within LF82 inoculated in ASF T5KO mice, we observed a female gender (ß = 0.370) were significantly associated with higher disability. Clinical activity seems more important to CD than UC patients in terms of disability. Disclosure of Interest: All authors have declared no conflicts of interest. Reference

P0959 FACTORS ASSOCIATED WITH DISABILITY IN INFLAMMATORY BOWEL DISEASE: OUTPATIENT CROSS-SECTIONAL STUDY

J. M. Costa1, D. Matos2, J. B. Soares3, R. Costa4, B. Arroja5, R. Gonçalves6

Introduction: The Inflammatory Bowel Disease-Disability Index (IBD-DI) has recently been validated to measure disability in IBD. Aims & Methods: We aimed to assess disability in IBD outpatients using IBD-DI and to determine the sociodemographic, clinical and psychological factors that are associated with greater disability. Between August and October of 2016, patients with an established diagnosis of Crohn’s Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic were invited to participate. Socio-demographic and clinical data were collected from electronic health record and interview. Optimism and disability were evaluated by the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological variables (optimism) and IBD-DI (scale 0–100, proportional to the reported disability) was determined by univariate and multivariate analysis. Results: A total of 143 patients (70 DC and 73 UC; 50.3% females) with a mean age of 38 ± 13 years were included. Most (85.3%) was in clinical remission. The mean IBD-DI-PT score (0–10) was significantly associated with greater disability (IBD-DI-PT score). In multivariate analysis, only female gender (ß = 0.150), number of comorbidities (ß = 0.186) and pessimism (ß = 0.370) were significantly associated with higher disability. Clinical activity was associated with greater disability only for CD patients (ß = 0.321). Conclusion: IBD outpatients reported low levels disability associated with their disease, which can be explained by the high percentage of patients in clinical remission. Comorbidities and psychological factors (optimism) emerged as the main predictive factors of greater disability, reinforcing the importance of multidisciplinary approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability. Disclosure of Interest: All authors have declared no conflicts of interest.

significant increase was observed in patients undergoing treatment with corticosteroids in relation to the group receiving biological therapy. Statistical difference (p = 0.0022) and CD62L (p = 0.02) compared to healthy controls. In the population of CD4+ T cells, a significant increase in the expressions was observed in patients receiving corticosteroids (p = 0.0001) and IgA (p = 0.0001) were also higher in groups of past cases compared to control group. The population of CD3+ cells in peripheral blood of healthy controls and patients with CD was evaluated both in biological and corticoid treatment. A significant increase in the population was observed in patients receiving corticoestoids (p = 0.02) compared to healthy controls. In the population of CD4+ T cells a significant increase was observed in patients undergoing treatment with corticoestoids in relation to patients undergoing biological treatment (p = 0.0027). In CD8+ T cell population, no statistical difference was observed between the groups. The markers CD8, CD62L and HLA-DR were also evaluated. In relation to CD3 (p = 0.0022) and CD26 (p = 0.015) in subpopulation of CD4+ T cells, a significant increase in the expressions was observed in the group of patients receiving corticoestoids in relation to the group receiving biological therapy. Regarding HLA-DR, statistical difference (p = 0.01) was observed between the group undergoing biological treatment and the group of healthy controls. In the subpopulation of CD8+ T cells, a significant increase (p = 0.02) was observed in the CD3D marker when compared patients on corticoid treatment with patients undergoing biological treatment. Regarding the CD62L marker, only a statistical difference (p = 0.04) was observed when compared patients on corticosteroid treatment with healthy controls. Finally, a statistical difference (p = 0.02) was also observed in the HLA-DR marker when comparing the group of patients receiving corticoid with the group of patients in use of biological therapy.

Conclusion: We conclude that the use of biological therapy suppresses activated CD4+ and CD8+ T cells by regulation of CD8, CD62L and HLA-DR in relation to the use of corticoestoids.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Imbalance of immune bowel environment is associated with development of many diseases, such as Crohn’s disease (CD). Although the pathogenesis of CD is still unclear, a key feature is the dysregulation of immune system (Zhang and Li, 2014). Human immune cells are the front line of inflammatory responses and include, in addition to other cells, CD4+ and CD8+ T cells, which comprises adaptive phase and require proper inflammatory cues for their activation phase. CD4+ T cells are primarily found in chronic inflammatory disease, while CD8+ T cells are the major effectors of cellular immunity. Both kinds of markers give them powerful functional capabilities (Abbas et al., 1996). CD38 and HLA-DR besides being classically markers of cellular activation, are also known as markers of diseases progression (Lovelace et al., 2017). Some studies shows that CD4+ T cells play a key role in the immune inflammatory response leading to CD but these cells are poorly characterized in the blood of the patients.

Aims & Methods: This study aimed to characterized CD4+ and CD8+ T cells in the blood of patients with CD. The study was performed in individuals with CD (n = 40) and healthy controls (n = 38). Blood of healthy donors and patients with CD was collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of calprotectin and ASCA was performed by commercial Elisa kit. The results were compared for numerical measurements using Student’s t-tests. ANOVA, Mann-Whitney or Kruskal-Wallis, depending on the suitability of the data and the number of groups to be compared. The computational package used for the analyses was R 3.0.3 and GraphPad Prism 6.

Results: The highest prevalence in both group was female, aged between 19 and 66 years with a median of 37.5 years. Among clinical exams, 61% of cases present anemia with a median of 11.0% (p = 0.001). ASCA IgG (p = 0.005) and increasing the concentration of Bacteroidetes type bacterias (p-value < 0.005) and reaching 0.21 in samples of patients with ulcerative colitis. Additionally, the concentration of Escherichia coli species bacterias was increased in the 40 times for that sample (normalized number of reads in control samples was less than 0.003 and reached 0.21 in samples of patients with ulcerative colitis). Although, the predominance of Proteobacteria genus bacteria was not founded. The concentration of Faecalibacterium prausnitzii species bacteria was decreased by three orders of magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The concentration increase of the conditional-pathogenic mucosal microflora (a mostly Bacteroidetes type bacteria) was discovered, which playing an important role in the development of ulcerative colitis and coexistence with colitis). Although, the deficiency of Faecalibacterium prausnitzii species bacteria was discovered, which decrease resistance of mucosa to the conditional-pathogenic microflora.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The role of incretin hormone, GLP-1, in inflammatory bowel diseases (IBD) development and exacerbations is still poorly understood. GLP-1 decreases blood glucose level and stimulates insulin release in the gut, which may be responsible for intestinal growth and enhancement of intestinal function. The prevalence of type 2 diabetes among IBD patients is low, even though IBD sufferers may be at a greater risk of development of T2D due to overproduction of pro-inflammatory cytokines and excessive administration of diabetogenic drugs. We hypothesize that the possible mechanism underlying this phenomenon is related to changes in the levels of incretin hormones.

Aims & Methods: The primary aim of this study was to investigate, in the mouse model, the role of coexisting coeliac disease development and colitis on incretin hormone expression. The secondary goal was to investigate the potential involvement of incretin hormones as an underlying factor. Experimental diabetes was induced by administration of streptozotocin for 5 consecutive days (50 mg/kg, i.p.). Mice with blood glucose levels above 200 mg/dL were considered as diabetic. To develop a chronic and relapsing colonic inflammation, mouse model of colitis induced by intracolonic administration of TNBS (first dose: 150 mg/kg at day 1, booster dose: 75 mg/kg at days 12, 23, 34, 45, 56) was used. On day 60 mice were sacrificed and macroscopic score, ulcer score, colon length and bowel thickness were recorded. In all experiments the levels of inflammation markers: myeloperoxidase (MPO) activity, TNF-α and IL-1β expression were determined. The

Introduction: Advancing of sequencing technologies in the first decade of the XXI century gives the opportunity to realization of large scale projects such as the 1000 human genomes project. This project provides enormous amount of the data for H.sapiens population genetics studies and different GWAS studies aimed to investigate connection of the human genetics variations with different diseases. It is especially interested to study the connection between the human genetics, the microbiome metagenomes of mucosa and different pathological conditions. Previously revealed, the size of the summary gut microbiome metagenome is on order more than the size of a human genome. The most of works devoted to understanding the connection of the gut microbiome to pathological conditions based on the investigation of fecal samples. On our opinion, in the case of ulcerative colitis it is more effective to study the mucosal microbiome of the affected regions.
effect of colitis on T2D development was studied by assessing fasting glucose levels, HbA1c, hemoglobin levels in UC, and GLP-1 levels in UC. Results: The development of hyperglycemia in mice treated with TNBS was delayed compared to a non-inflamed group, what was associated with significantly higher level of GLP-1 in blood. Surprisingly, the levels of GLP-2 were significantly higher in diabetic mice with colitis, suggesting that two distinct mechanisms are involved in the regulation of the incretin hormones in response to intestinal inflammation. There were no significant differences in macroscopic score, colon length, and bowel thickness in diabetic mice with or without colitis. Necrotic tissue was significantly increased in diabetic mice with colitis compared to diabetic mice with no inflammation. No changes in MPO, TNF-α, IL-1β were observed between these groups.

Conclusion: We propose that GLP-1 production may be stimulated in response to colitis and may contribute to both inflammatory and regenerative phases of the disease. Accordingly, peripheral eosinophils of IBD patients are primed and pre-activated. They display increased responsiveness, adhesiveness, migration, and degranulation and are characterized by up-regulated secretion of their mediators. Increased number and activation of eosinophils have been repeatedly observed in areas of active inflammation. Despite the acknowledged contribution of eosinophils to the disease pathogenesis, available data on cytokines closely related to the development and activity of peripheral eosinophils in IBD patients are either scattered or non-existent.

Aims & Methods: Aim of the study was assessment of the circulating eosinophil-associated cytokines and growth factors as differential markers and indicators of mucosal healing in inflammatory bowel disease. Study population consisted of 277 individuals: 101 patients with Crohn’s disease (CD), 77 with ulcerative colitis, 16 with IRritable bowel syndrome (IBS) and 83 healthy controls. The disease severity was assessed using the Crohn’s Disease Activity Index (CDAI) for CD and the Mayo Disease activity index (MDA) for IBD. The level of Mayo endoscopic score was applied to evaluate the severity of bowel inflammation in UC patients. The concentrations of eosinophil-associated cytokines and growth factors: eotaxin, GM-CSF, IFNγ, IL-4, IL-5, IL-8, GM-CSF, RANTES and TNFα were measured simultaneously in patient’s sera using Luminex xMAP® technology and referred to IBD activity and the levels of hsCRP. The suitability of eosinophil-associated cytokines and growth factors as differential markers and potential indicators of mucosal healing, individually and in multi-marker panels, was evaluated using ROC analysis.

Results: As compared to IBS patients or healthy controls, patients with CD had significantly higher levels of IL-5, IL-8, IL12(p70), GM-CSF, and TNFα, and patients with UC the levels of eotaxin, IL-4, IL-5, IL-8, IL12(p70), IL-13, GM-CSF, and TNFα. As compared to CD patients, patients with UC had significantly higher levels of eotaxin, IL-4, IL-5, IL-8, and IL-11. In turn, the concentrations of hsCRP were significantly higher in CD than in UC. Except for IL-13, all cytokines and hsCRP positively correlated with CDAI (CD) or only IL12(p70) and hsCRP were significantly higher in patients with active than inactive CD. In UC, a positive correlation with MDAI was observed for hsCRP, GM-CSF, IL12(p70), and IFNγ and a negative one for IL8. The concentrations of hsCRP, GM-CSF, IFNγ, IL12(p70) and RANTES were higher in UC patients with active than inactive disease whereas those of IL-8 and TNFα were significantly lower. As differential individual markers, eotaxin displayed superior accuracy as an indicator of active UC (71%), followed by hsCRP as an indicator of active CD (66%). The combined assessment of eotaxin, hsCRP and IFNγ had significantly higher accuracy (78%) and allowed for a correct classification of 72% of patients. The concentrations of hsCRP, GM-CSF, IFNγ, and IL12(p70) were significantly and positively correlated with the degree of bowel inflammation, expressed as Mayo endoscopic subscore. Of these, a drop in GM-CSF had super ior power. Interestingly, the ratio of mucosal inflammation to neutrophilic infiltration was significantly higher in both CD and UC than in IBS. Of these, IL-8 had superior accuracy in differentiating IBD and IBS (91%), allowing for a correct classification of 93% of patients.

Conclusion: Eosinophil-associated cytokines are elevated in IBD, more pronounced in CD than UC, and might support the differential diagnosis of IBD and aid in monitoring of mucosal healing.

Introduction: According to our previous report, the imbalance of Treg/Th17 cells in the virulent UC mice is related with the reduction of CD54RA Foxp3+ activated Treg/FHIL cells, which has the real function of immunosuppression, and with the elevation of CD45RA Foxp3− Foxp3FHIL cells, which provide Foxp3+FHIL1a trait but lack immunosuppressive capacity. Activation of Toll-like receptor 2 (TLR2) causes elevation of FHIL, which show Foxp3 FHIL1a trait by secreting IL-17a.

Aims & Methods: To investigate the influence of TLR2 on imbalanced Threg/Th17 in the virulent UC mice, 18 mice were randomized into three groups: healthy control mice (group A), ulcerative colitis mice (group B) and TLR2mAb treated UC mice (group C).Weight and DAI (disease activity index) of each group were recorded once a day. After being sacrificed, pathological examination of the rectum of all the mice were carried out. Treg cells with their subsets, Th17 cells and CD3+CD8+CD25+Foxp3+FHIL1a cells from the lamina propria of colon (LPC) and other tissues of mice were evaluated by flow cytometry.

Results: (1) Declined vitality, anorexia, weight loss and bloody purulent stool were observed in the major symptoms of UC mice. The symptoms of TLR2mAb treated UC mice were alleviated, and the DAIAs of these mice showed difference from UC mice (p<0.05). The inflammation of colonic mucosa in TLR2mAb treated UC mice were also attenuated compared with UC mice. (2) Compared with group A, the proportion of Foxp3+ FHIL1a cells increased in PBMC, MLN and LPC (1.275±0.063 vs 1.168±0.028, 6.067±0.152 vs 3.632±0.639, 5.657±0.211 vs 1.173±0.150, P<0.05 respectively). The level of Treg cells in PBMC of group C was declined compared with group B (1.153±0.028 vs 1.275±0.063, P<0.05). (3) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (0.488±0.015 vs 0.328±0.023, 4.300±0.137 vs 1.333±0.126, P<0.05), but Th17 cells were decreased in PBMC of group C compared with group B (0.273±0.061 vs 0.488±0.015, P<0.05). (4) Foxp3+ FHIL1a cells were detected in PBMC, MLN and LPC of group B compared with group A (0.016±0.005 vs 0.030±0.009, 0.123±0.012 vs 0.465±0.024, 0.233±0.022 vs 0.367±0.018, P<0.05 respectively). Otherwise, increased FHIL1a cells were in spleen, PBMC, MLN and LPC of group C compared with group A (0.016±0.005 vs 0.030±0.009, 0.123±0.012 vs 0.465±0.024, 0.233±0.022 vs 0.367±0.018, P<0.05 respectively). FHIL1a cells were elevated in PBMC, MLN and LPC of group C compared with group A (4.215±0.490 vs 3.128±0.171, 14.463±0.84 vs 8.740±1.40, 9.487±0.604 vs 3.706±0.104, P<0.05 respectively). Moreover, declined FHIL1a cells were observed in spleen and PBMC of group C compared with group B (8.967±0.354 vs 14.122±0.438, 3.070±0.763 vs 4.215±0.490, P<0.05). (5) Compared with group A, CD3+CD8+CD25+Foxp3+FHIL1a cells were increased in PBMC, MLN and LPC in group B.3.915±0.264 vs 2.533±0.076, 1.672±0.158 vs 0.898±0.044, 5.967±0.100 vs 2.308±0.252, P<0.05 respectively. But the level of CD3+CD6+CD25+Foxp3+FHIL1a cells were decreased in spleen, PBMC, MLN and LPC compared with group B (0.538±0.021 vs 1.238±0.017, 2.523±0.066 vs 3.915±0.264, 0.897±0.040 vs 1.672±0.158, 2.443±0.052 vs 5.967±0.100, P<0.05 respectively).

Conclusion: By blocking TLR2, TLR2mAb could improve the level of FHIL1a cells in PBMC, MLN and LPC, but reduce the levels of FHIL1a and Foxp3+FHIL1a cells in DSS induced UC mice. Furthermore, TLR2mAb could alleviate the DAI index as well as the inflammation of colitis in DSS induced UC mice.

Introduction: Previous studies have shown that the gut microbiota plays an important role in IBD, however the role of specific bacteria is not clear and is only considered to be responsible for the disease. 16S gene profiling studies generate large amounts of information, however they can be confounded by genetic and environmental factors. Twin studies are instrumental in controlling for some of these variabilities, and in this study we investigated the microbiota of twin pairs discordant for Crohn’s disease (CD) and Ulcerative colitis (UC) using 16S rRNA gene sequencing, with the aim of identifying taxa associated with disease.

Aims & Methods: Participants were recruited via the UK IBD Twin Registry. stool samples were collected and frozen using standard methods. Participants who had received antibiotics within 3 months were excluded. Harvey Brashford Index and Simple Clinical Colitis Activity Index were recorded. Full medical history was available from the UK IBD Twin Registry. Samples underwent 16S sequencing using Illumina MiSeq platform using our data analysis pipeline. PERMANOVA was used to evaluate associations with clinical metadata, which included matching of twin pairs for analysis, and STAMP was used to identify taxonomic differences between groups.

Results: 20 twin pairs discordant for CD (5MZ:15DZ mean age 52 years) and 17 discordant for UC (6MZ:11DZ mean age 59.7 years) were recruited. 7 subjects with CD had active disease as did 4 with UC. Gut microbiota from active CD patients had lower bacterial diversity compared to remission CD patients, while UC patients had lower diversity compared to healthy twins (Shannon diversity index, p<0.01 healthy vs active UC, p<0.05 active vs remission CD, l-way ANOVA post hoc = Tukey).

Active UC patients also had lower bacterial diversity compared to remission UC patients and healthy twins (Shannon diversity index, p<0.01 healthy vs active UC, p<0.05 active vs remission UC). We found that active CD patients had a higher proportion of Cladstium hylemonae and Lactobacillus delbrueckii compared to healthy twins, and a lower proportion of Faecalibacterium prausnitzii compared to remission UC patients (p<0.05). We found that active UC patients had a lower proportion of Alstipites spp. compared to their healthy twins and UC patients in remission (p<0.05).

Conclusion: This study confirms previous findings showing decreased diversity in IBD patients and changes in some bacterial taxa, however our study is the first to show decreases in Alstipites spp. in active UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P9098 CD4+ T CELLS OF IBD PATIENTS ARE CHARACTERIZED BY AN INCREASED EXPRESSION OF THE NUCLEOTIDE RECEPTOR P2Y2, WHICH IMPACTS RELEVANTLY ON PRO-INFLAMMATORY SIGNALING PATHWAYS IN SCID MICE

J. Panteleev-Ivlev1, S. Zundler1, R. Atreya1, M. F. Neurath1, I. Atreya1

Introduction: Chronic and acute inflammation is often associated with an upregulation of extracellular UTP and ATP nucleotides, which are able to interact with various cell types via purinergic G protein-coupled P2 receptors. Interestingly, former studies already described an increased expression of the ATP/UTP receptor subtype P2Y2 (P2Y2R) in the colonic tissue of IBD patients [1]. However, it remained unknown how in fact immune cells of IBD patients are also characterized by an altered P2Y2R expression and whether this might impact on their pro-inflammatory capacity.

Aims & Methods: P2Y2R mRNA and protein expression on primary CD4+ T cells from the blood of IBD patients or healthy donors was analyzed via qPCR or western blot, respectively. Furthermore, primary human CD4+ T cells were stimulated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and
Aims & Methods: We aim to elucidate the effects of HIF1α stabilization through hydroxylase inhibition ameliorates DSS-induced colitis and induces autophagy

Conclusion: The observed increased expression of P2Y2R in CD4+ T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2 signaling in human T cells markedly strengthen the role of P2Y2R as a promising target in IBD.

Introduction: Environmental hypoxia has been increasingly recognized as an important environmental factor associated with Inflammatory Bowel Disease (IBD). Hypoxia allows the stabilization of hypoxia inducible factor (HIF) complexes and has been linked to the activation of autophagy. HIF1α is induced in the inflamed mucosa from IBD patients and mouse models of colitis, but its role in intestinal inflammation is still controversial since both, positive and negative inflammatory effects have been described.

Aims & Methods: We aim to elucidate the effects of HIF1α stabilization in autophagy and the development of intestinal inflammation in a murine model of colitis. Female C57BL/6 mice between 8–10 weeks of age were exposed to 2% DSS in drinking water for 7 days, and received 8 mg of the hydroxylase inhibitor DMOG administrated by oral route using sonde during 7 days. For western blot analysis, the colon was lysed and protein was extracted. The following antibodies were used: iNOS (BD Biosciences), COX-2, Nrf2 (Santa Cruz Biotechnology Inc), MCP-1, TNF-α, p-NFκB, HO-1 (Abcam), and β-actin (Sigma).

Results: Protective effect of apocynin was evident by weight change and colon length. Histologic analysis also showed improved erosion and decreased neutrophilic infiltration in apocynin group compared to DSS group. In colon tissue, several pro-inflammatory enzymes and cytokines were decreased by apocynin. Apocynin also activated anti-inflammatory pathway by inducing activation of Nrf2 and production of heme oxygenase (HO-1). Apocynin also appears to have protective effect and action mechanism of IBD.

Introduction: Faecal metabolic profiling has been shown to distinguish Inflammatory Bowel Disease (IBD) from healthy controls (HC), specifically with depletion of gut-associated short chained fatty acids (SCFA) as the predominant feature separating these groups (1). Previous and current studies have used proton nuclear magnetic resonance (1H NMR) spectroscopy or mass spectrometry (MS) to measure faecal metabolites to identify the metabolic, microbial and clinical response of IBD patients to different treatments. Both techniques require a significant amount of sample pre-processing.

Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a relatively new technology which applies a laser to a biological sample, and the resulting vapour, containing gas phase ions of metabolites and structural lipids, is analysed by a mass spectrometer (2). Unprocessed faecal samples can be rapidly assessed using this technique to obtain lipidomic spectral profiles (2). To our knowledge this is the first study that has used REIMS to investigate whether IBD patients can be distinguished from healthy controls using faecal samples.

Aims & Methods: Unprocessed faecal samples from 109 IBD patients and 46 healthy controls were analysed using Rapid Evaporative Ionization Mass Spectrometry (REIMS) and dietary data were collected, and patients with significant other co-morbidities were excluded. Partial least squares discriminative analysis (PLS-DA) was performed to examine whether there were differences in the metabolic data between patients with Inflammatory Bowel Disease and healthy controls. The later sample was then carried out including examining whether ulcerative colitis could be distinguished from Crohn’s disease.
P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN’S DISEASE

X. Zhao, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: xiaozhao178@163.com

Introduction: The abnormal differentiation of intestinal innate lymphoid cells ILC3 and ILC1 exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn’s disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

Aims & Methods: The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of active and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice (AhR−/+ , AhR+/−). Results: Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

Conclusion: These findings suggest that AhR may mediate abnormal differentiation of ILC3/ILC1, and the production of inflammatory cytokines, finally, promotes the pathogenesis of CD.

levels. Data were further processed in QIIME employing MoAsLin and LEiSe tools to filter and process output data.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. Rothia, Enterococcus, Streptococcus, Veillonella, and three other genera were markedly overrepresented in PSC, whereas in UC, the genera Bacteroides, Dialister, Pseudomonas, and Prevotella were increased. Decreased genus Phascolarctobacterium was linked to presence of colonic inflammation regardless of IBD phenotype. Akkermansia muciniphila, Butyrivibrio plicaticorrum and Clostridium colinton were decreased in UC along with genus Roseburia. Unclassified Acinetobacter species were markedly increased in overlap syndrome of autoimmune hepatitis (AHP) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinobacteria.

Conclusion: PSC was characterized by microbial features independent of concomitant IBD. Additionally, the diversity of gut microbial taxa clearly distinguished IBD phenotypes (PSC–UC–IBD) as well as PSC from AHP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic profiling (metabonomics) has been proposed as a novel clinical tool in IBD to predict development of complex disease, or for longitudinal non-invasive monitoring of activity and/or response to drug treatment. Urinary metabonomics can distinguish IBD from healthy controls but no studies to date have assessed the stability of these discriminatory profiles over time. Changes in healthy adults and metabolic signatures are largely unchanged over periods of up to 3 years(2), but signals are influenced by multiple external factors including medication and surgery, so how these change in IBD is unknown. The aim of this study was to compare baseline urinary metabolic profiles of IBD patients with a repeated sample several years later to assess similarity, and also to test if any clinical outcomes could be retrospectively predicted from the baseline sample.

Aims & Methods: Two urine samples from 39 IBD patients (22 Crohn’s disease (CD) and 17 ulcerative colitis (UC) were collected - one at baseline and one several years later (range 7–9 yrs). These were analysed by 1H NMR spectroscopy. Disease progression was defined as initiation of immunosuppression or biologics, progression of disease (no remission) or hospitalisation with one or more admissions. Clinical remission was defined as no disease-related symptoms or hospitalisation in the past year. Principal components analysis was used to visualise the variance between the two time-points within the cohort. Orthogonal partial least squares discriminant analysis (OPLS-DA) was used to establish if the metabolic signatures could be used to predict adverse clinical outcomes in the patients studied.

Results: 57% of CD patients and 17% of UC patients had clinical progression at follow-up sampling. PCA showed clustering of sample pairs from the baseline and several years later in most individuals, suggesting intra-individual similarity across time. OPLS-DA showed no statistical models could be built to predict combined poor outcome based on the initial urinary metabolic profile (p = 0.26). However, the small subgroup who went on to require surgical intervention could be separated from the cohort in a model (Q2 = 0.015; p = 0.003) constructed on their baseline profile and the outcome.

Conclusion: The metabolic phenotype of an IBD individual appears relatively stable over a significant time period despite a variety of clinical outcomes and interventions. Variations in longitudinal measurements appear to be subtle, and there is replication of this finding. Further techniques for disease monitoring may be needed. Principal components analysis could prove difficult. These results may suggest that metabolic profiling could be exploited to predict a higher risk of requiring future surgery.

Introduction: Mucosal healing is considered to be the hallmark of successful therapy in Ulcerative Colitis, and has become increasingly used as a target of therapeutic interventions. Loss of mucosal integrity and associated bacterial translocation of bacterial components across the mucosal epithelial barrier occurs in Ulcerative Colitis and persistence of a structural mucosal defect is a characteristic of chronic inflammatory bowel disease. Mucosal healing can be defined by clinical, endoscopic and histopathological means but no clear definition of the required extent of mucosal healing exists, nor is there agreement on how functional mucosal healing is defined.

Aims & Methods: To define the extent and associations of mucosal healing in patients with Ulcerative Colitis, and the relationship with bacterial translocation and clinical remission. Patients with established diagnosis of Ulcerative Colitis undergoing endoscopic evaluation were recruited to the study (Ethics: South West London REC2 10/H0706/26). Clinical history and long-term follow-up data were recorded. Blood and mucosal samples were procured as mononuclear cells. Healthy controls recruited from cohort undergoing routine lower gastrointestinal investigations without positive findings. Flow cytometry characterisation of cells by cell surface CD45RO, CD27, CD3, CD14, CD8 and CD161 and cytokine expression after staphylococcal enterotoxin B stimulation by IL-2, IL-17a, IL-22, TNF, IL-17f and IFNγ. Immunohistochemistry to define tight junction apical epithelial expression (Claudin 1, Claudin 4 and Occludin) and lipopolysaccharide within the lamina propria. Peripheral blood markers of bacterial translocation: bacterial DNA (16fDNA), lipopolysaccharide binding protein (LBP), soluble CD14 and plasma lipopolysaccharide. Statistical analysis by Mann Whitney or Kruskall Wallis analysis with Dunn’s post test correction, or by Spearman rho correlation.
**Results:** Twenty-eight patients with Ulcerative Colitis, duration of disease from 4 months to 31 years, and 22 Healthy subjects were recruited in the study. Half of the patients had active disease as assessed by Ulcerative Colitis Severity Score. Disease severity positively correlated with frequency of mucosal TH1 (CD4+IL-17a+) and IL-17f. Breaches in tight junction protein expression were greater in UC: Claudin 1 (p = 0.018) and Claudin 4 (p = 0.016) and occludin (p = 0.03). The serum marker of bacterial translocation, lipopolysaccharide binding protein (LBP) was elevated in UC compared to controls (p = 0.0078) and was positively correlated with breaches of Claudin 1 and Occludin (r = 0.30) respectively. Staining colon biopsies for the presence of lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Occludin (p = 0.0022).

**Conclusion:** Breaches of tight junction proteins in the colon of patients with stable clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

**Introduction:** Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

**Aims & Methods:** The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greek population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity was assessed using the disease activity index (SCCAI) (for ulcerative colitis (UC) and Harvey-Bradshaw index (HBI) for Crohn’s disease (CD)) as well as quality of life using the short inflammatory bowel disease questionnaire (SIBDQ) were evaluated. Patients’ demographic, clinical characteristics, nutritional status, laboratory data (C reactive protein (CRP), haemoglobin, erythrocyte sedimentation rate (ESR), platelets and albumin) and treatment data were recorded and analysed for all participants.

**Results:** A total of 141 consecutive IBD patients (53 UC, 88 CD, mean age 47.2 ± 16.1 years, 84 males 57 females, BMI 26.7 ± 5.3) were included. Patients’ mean daily fiber intake was 21.8 g (IQR 13.8–34.6) and mean daily total fat was 161.4 g (121.2–237) with 43.5% percent energy from fat. Regarding disease activity 34 (24.1%) patients had active disease with HBI or SCCAI score ≥5 whereas 45 (31.9%) patients had poor quality of life with SIBDQ score ≥50. There was no difference in daily fiber or fat consumption between patients with UC and CD (median daily fiber intake 23.5 (IQR 18.8–34.6) g vs 21.7 (14.6–34.2) g (p = 0.86), median fat intake 148.7 (112.4–242.8) g vs 169.4 (127.1–236.7) g (p = 0.30). There was a significant negative correlation between fiber intake and disease activity in both UC (r = −0.37 p = 0.007) and CD (r = −0.32, p = 0.002) while there was not significant correlation between fat intake and disease activity (in both diseases p > 0.05). No association of fiber or fat consumption with abnormal CRP, increased ESR, presence of anemia, thrombocytosis or low albumin was found (all with p > 0.05). SIBDQ score had a significant correlation only with fiber intake (r = 0.31 p = 0.0002) but not with fat intake (r = 0.07 p = 0.40).

**Conclusion:** Higher dietary fiber intake is associated with lower disease activity and better quality of life in patients with IBD. Fat consumption does not seem to influence the disease activity and patients’ quality of life. Based on these results it could be suggested that the amount of fiber consumption by IBD patients may play an important role in the disease course.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

Conclusion: In this European population-based inception cohort of unselected CD patients 14% of patients with B1 progressed to B2 or B3 after five years of follow-up. The risk of surgery was increased in patients with B1 who progressed to B2/B3. No clinical predictors for progression in behaviour including smoking and treatment with biological therapy could be identified.

Introduction: Risk factors for colorectal cancer (CRC) in Inflammatory Bowel Disease (IBD) are still debated (1).

Aims and Methods: In a prospective multicenter, nested case-control IG-IBD study at 4 years, we aimed to frequency and risk factors for incident CRC in IBD. The role of IBD phenotype vs thiopurines (IS) and/or anti-TNFs use as risk factors for CRC was also evaluated. From Jan. 2012 to March 2017, all incident cases of CRC in IBD pts referring to 16 IG-IBD Units were recorded. Each IBD pt with CRC (IBD-CRC) was matched with 2 IBD pts with no cancer (IBD-C) for: IBD type (Crohn’s Disease, CD vs Ulcerative Colitis, UC), gender, age (<5 yrs). Cases of CRC derive from a larger cohort of IBD pts referring to the same Units, with incidence of any cancer separately reported at 4 years (follow up at 3 yrs reported for cancer overall). Statistical analysis: data expressed as median (range), Wilcoxon test, Chi-squared test, Fisher exact test; multivariate logistic regression analysis.

Results: Incident cases of CRC occurred in 66 IBD pts: 41 UC (UC-CCR), 25 CD (CD-CCR). IBD-CRC group therefore included 198 pts (66 IBD-CRC, 132 IBD-C). UC group included 123 pts (41 UC-CCR, 82 UC-C) and CD group included 75 CD pts (25 CD-CCR, 50 CD-C). The frequency of incident CRC was higher in IBD-CRC vs IBD-C (UC-CRC vs UC-C: p = 0.009). Gender was equally distributed in IBD groups (UC: 14 F [34%]; CD: 15 F [48%]; p = 0.777). The median age was comparable between IBD-CRC and IBD-C (UC-CRC vs UC-C: p = 0.58). IBD duration was comparable between pts with vs without CRC (20 [1–47] vs 13 [0–35]; p = 0.58). Conversely, CD duration was comparable between pts with vs without CRC (20 [1–47] vs 13 [0–35]; p = 0.58).

All authors have declared no conflicts of interest.
pts with CRC were younger at diagnosis of IBD than their IBD-C (UC-CRC vs UC vs CD-CRC: 47 [15–76] y.o., 46 [20–108] y.o., n = 27 [33%] vs 40 [20–92] y.o., n = 27 [33%], p = 0.04; CD-CRC vs UC-CRC: UC median age 27 [6–67] y.o. vs 40 [20–92] y.o., n= 27 [33%] vs 27 [33%], p = 0.04). The frequency of CRC was similar among the three groups.

incontinence (≥1 episode per month) was reported in 305 CD (58%), 230 UC

UC or IBD-U (8%) patients (mean St. Marks incontinence score 14).

FI-QOL scores were not different between the different diagnoses. Multivariate

regression analysis (adjusted for gender, diagnosis and previously performed

abdominal operations) showed a reduced total SF-36 score in patients with

regression analysis was performed.

Results: A total of 1094 patients (64%) responded the online survey. Mean age

60.2 years (range 18–87). CD diagnosis was predominant (621 CD patients

(57%), 431 UC patients (39%) and 42 IB-U patients (4%) and diagnosis was

established for a mean period of 13 years (interquartile range 3–19 years). Active

perianal disease was present in 243 CD patients (39%) and perianal surgery

(absence or fastness-related) was previously performed in 153 (25%). Faecal

incontinence (≥1 episode per month) was reported in 305 CD (58%), 230 UC

(56%) and 20 IB-U (51%) patients. Weekly episodes occurred in 41 CD (8%),

22 UC (5%) and 3 IB-U (8%) patients (mean St. Marks incontinence score 14).

FI-QOL scores were not different between the different diagnoses. Multivariate

regression analysis (adjusted for gender, diagnosis and previously performed

abdominal operations) showed a reduced total SF-36 score in patients with

faecal incontinence (β = −8.57 [−11.33; −5.81]; p < 0.0001) and active perianal

disease (β = −1.43 [−7.33; −0.91]; p = 0.01). A better score was reported in UC

patients compared to CD patients (β 3.33 [0.48–6.83]; p = 0.02). Previously

performed perianal surgery was not associated with SF-36 score in the multivariate

analysis.

Conclusion: Anorectal complaints have a substantial impact on the quality of life

in patients with IB, with a (usually unmet and) clear need to treat. More

awareness for this highly distressing and most commonly cumbersome treatable

disease manifestation is needed.

Introduction: The human gut microbiome is made up predominately of four

major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and

Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis.

Specifically, in inflammatory bowel disease (IBD), key changes have been iden-
tified such as a reduction in beneficial bacterial species including

Faecalibacterium prausnitzii and increases in more pathogenic species including

members of the Enterobacteriaceae. Currently it is not understood if dysbiosis is

the cause of, or the effect of, intestinal inflammation. It is difficult to chronolo-
gically assess the microbiota changes prior to developing IBD as currently we are

unable to predict those individuals who will develop the disease. The pouch is a

potential model to study pathogenesis of inflammation as 40% of those that

develop pouchitis do so within 12 months. The relative short time from pouch

formation to inflammation allows the longitudinal study of the microbiota which

gives insight into potential microbiota patterns occurring both in disease and

non-diseased states. Interestingly, inflammation within the pouch is rarely seen

in patients who have this operation for Familial Adenomatous Polyposis (FAP),

thus raising the possibility that pouchitis shares a similar pathogenesis to the

inflammation that is seen in ulcerative colitis.

Aims & Methods: 1. To understand changes in pouch microbiota over time. 2. To

understand pouch microbiota that is associated with pouch inflammation

A computer assisted search of the on-line bibliographic databases MEDLINE

and EMBASE was carried between 1966 and February 2016. Randomised con-
trolled trials, cohort studies and observational studies were included. Inclusion

criteria: Studies which reported microbiota analysis on either faecal samples or

tissue from the ileo-pouch anal anastomosis. Studies that provided information

on specific bacterial taxa. Exclusion criteria: Studies which did not report on

patterns of individual bacterial taxa differences in the pouch. Studies on the

microbiota of Crohn’s disease or UC in isolation without any data on pouch

patients. Studies with less than ten patients.

Results: The search strategy found 844. There were a total of 27 papers included

in the analysis. Microbiota in pouchitis: Bacteroidetes, Enterococccaeae,

Lachnospiraceae, Ruminococccaeae, Streptococccaeae.

Alcaligenaceae and Bifidobacterium were reduced in patients with pouchitis.

Whereas Enterobacteriaceae, including E. coli Fuscobacterium and Clostridia

were increased in patients with pouchitis. One study highlighted bacteria that

were exclusively found in pouchitis which included Lepotispora, Pseudoalteromonas,

Desulfosporosinus, Microcctis, Methylotacter. Chronic pouchitis

was associated with a significant increase in Staphylococcus aureus and it

has been suggested that this may be a responsible pathogen for chronic pouchitis.

Furthermore, Enterococcus, F. prausnitzii, Lachnospiraceae and Insertae Sedis

XIV and have been shown to be significantly reduced in chronic pouchitis

patients. These differences were largely due to a decrease in sequences from

members of the genera Ruminococcus, Dorea, Clostridium, and Eubacterium.

Conclusion: The microbiota undoubtedly plays an important role in both the

inflamed and the healthy pouach. However, a direct causal relationship has not

yet been established between individual microbiota changes and inflammation.

There are many studies that highlight changes in bacterial composition, but

studies are limited by heterogeneity of and in particular, analysis techniques

and sampling strategies. Studies used a variety of methods to define microbial

diversity which can be broadly split into culture vs culture-independent

approaches. Culture-based studies are likely to have a bias towards culturing

more aerobically friendly microbes than exist in a true pouach environment,

thus over-representing aerobic bacteria whilst possibly under-representing anaer-
obic bacteria. The use of 16 S rRNA analysis methods will negate this effect and

represents the future in accurately determining the microbiota.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Contact E-mail Address:** houariaaouda@yahoo.fr

**Introduction:** For a long time, dysplasia lesions in ulcerative colitis were only 
treated by surgery. Recent guidelines recommend the complete endoscopic resec-
tion of dysplastic lesions in ulcerative colitis.

**Aims & Methods:** The aim of this study was to determine the outcome of dys-
plastic lesions resected endoscopically in ulcerative colitis. In this prospective 
study between January 2008 and January 2015, dysplastic lesions detected in 
patients with longstanding ulcerative colitis were assessed for their resectability, 
then when it was possible were resected. The patients were followed, and an 
endoscopic control was done at 6 month than every one year.

**Results:** 36 dysplastic lesions were identified in 25 patients; 5 lesions were 
judged not resectable and referred to surgery. 31 lesions were resected in 21 patients: 22 
low-grade dysplasia, 7 lesions indefinite for dysplasia, and 2 high-grade dyspla-
sia. 18 patients (85.7%) had endoscopic control: mean 2.8 (maximum: 5 mini-
mum: 1). 2 patients refused next colonoscopy, one patient was not controlled 
because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no

**Introduction:** Gastrointestinal disorders may exhibit overlapping symptoms 
making diagnosis difficult in the primary and specialty care settings. Inflammatory bowel disease (IBD), with a prevalence of <0.5% in the general 
population[1], is characterized by chronic inflammation of the gastrointestinal 
tract, non-specific elevation of conventional inflammatory markers such as 
ESR and CRP and may present with extra-intestinal manifestations. Irritable bowel 
syndrome (IBS), in contrast, is a functional disorder without gastrointestinal 
inflammation and with an estimated prevalence of 10-20% [2]. Endoscopy is 
the gold standard for detecting and quantifying IBD vs. IBS, but due to the 
low prevalence of IBD, is negative in the majority of cases. Furthermore, it 
is invasive, expensive, and uncomfortable for the patient and not without risks. 
Moreover, inadequate bowel preparation prior to colonoscopy is known to

increase the burden of disease from both the clinical and the economic perspec-
tive: shorter intervals between repeated procedures, higher missed rates, patient
inconvenience, and increased risk of complications are reported in the scientific
literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD
patients exhibit FC levels significantly higher than the general population; IBS
patients have FC levels higher than healthy controls, but significantly lower than
IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to differ-
entiate between IBD and IBS. The present study aims at evaluating the cost-
effectiveness of FC compared to the combined usage of CRP and ESR, and the
gold standard to distinguish IBD from IBS in Spain.

Aims & Methods: An 18-week Markov model was developed for each diagnostic
strategy, simulating 1000 patients presenting to a primary care physician with
non-specific gastrointestinal symptoms. In the model, 1.6% of the colonoscopies
brought about complications [4], which may result in Emergency Room visits
and surgery. Inadequate colon preparation (23%) [5] and consequent repeated
colonoscopies (30.3%) [6] were also included in the calculations. Outcomes
include cost savings, cost per corrected IBD diagnosed, and colonoscopy reduc-
tion. Uncertainty was addressed with sensitivity analysis.

Results: FC is cost-effective when compared to CRP + ESR, and to colonoscopy
(Table 1): It results in more correctly IBD diagnoses at a lower price; It reduces
the number of unnecessary endoscopies, increasing the number of correctly diag-
osed IBD (N = 63) and IBS (N = 26) patients.

Clinical and health economics results

<table>
<thead>
<tr>
<th>FC-Colonoscopy</th>

<tr>
<td>Savings attributable to the avoided colonoscopies</td>
<td>336.38</td>
</tr>
</tbody>
</table>

Conclusion: Results show that the usage of FC as pre-endoscopic diagnostic tool is
associated with fewer colonoscopies and correctly identifies more disease while
decreasing the costs compared to the alternatives. Consequently, FC demonstrates
superior value both from patient and payer perspective, while simultaneously
diagnosing effective.

Introduction: The increased use of immunomodulators and biological agents for
the treatment of patients with inflammatory bowel disease (IBD) is associated
with a key safety concern considering potential serious infection. Healthcare
workers face a substantial risk for acquiring such infections due to daily and close interactions with infected patients and asymptomatic carriers of
pathogens.

Aims & Methods: We performed a retrospective observational study, collecting
data from the Groupement Groupe d’Etude Therapeutique des Affections Inflammatoires du
tube Digestif (GETAID) from January 2015 to June 2016, on all 482 consecutive
patients with IBD (68.5% with rohn’s disease, 28.4% with ulcerative colitis and
3.1% with IBD undetermined) who work as healthcare workers (27.2% of physi-
sicians, 33.8% of nurses; 13.1% of nurses’ aides and 26.7% of other healthcare
personnel working in interaction with in-hospital patients), in 17 tertiary centers
in France and Belgium. We selected a control group of patients with IBD who do
not work as healthcare personnel from the monocentric MICISTA database.
Controls were matched on age (±2.5 years), sex, IBD type and date of IBD
diagnosis (±2.5 years). Serious infection was defined as (1) Clostridium difficile
infection (2) community-acquired pneumonia (3) Mycobacterium tuberculosis
infection (4) any community-acquired infection that required hospitalization.
Serious infection-free survival was studied with Kaplan-Meier method, log-
rank test and Cox regression model. In each patient, the duration of IBD was
divided into semesters which were independently analyzed regarding the occur-
cence of serious infection too take into account the influence of various treatments.

Results: 482 patients (126 male; median age: 24.0 [IQR 19.9–32.1] years) were
included in the present study. The median follow-up period was 9.3 [4.6–16.2]
years. A total of 74 serious infection was recorded in healthcare workers includ-
ing 14 Clostridium difficile infection, 19 EBV or CMV-related serious vir-
al infection, 8 tuberculosis infection including 4 tuberculosis and 4 tuberculous primo-
infection, 8 community-acquired pneumonia and 25 miscellaneous serious infec-
tion. The probabilities of serious infections-free survival were 1.0%, 0.1%, 10.8%
and 14.1% at 1, 5, 10 and 15 years. No difference was found between healthcare
workers and control patients regarding the occurrence of serious infection in
time-dependent analysis and in independent semester analysis. However, a
increased risk of tuberculosis infection was found in healthcare workers (0.07
infections for 100 patient-years vs. 0.009, p = 0.02). In multivariate analysis,
serious infection was decreased in patients with Crohn’s disease (OR = 0.63,
IC[95%] [0.43–0.91], p = 0.01) and increased in patients treated with corticoster-
oids (OR = 3.05, IC[95%] [2.06–4.52], p < 0.001), immunosuppressant (OR = 1.98,
IC[95%] [1.38–2.84], p < 0.001) and anti-TNF agents (OR = 2.93, IC95% [2.02–
4.27], p < 0.001).

Conclusion: Although there is an higher exposure to potential pathogens in
healthcare workers, this is not associated with a higher risk of serious infection
as compared with controls with the exception of tuberculosis infection. Prospective studies are needed to confirm that the level of occupational exposure
to potential pathogens should not be taken into account when discussing the
incidence of immunomodulator or biological agents with the exception of the
risk of tuberculosis infection.

**P0991 CORRELATION BETWEEN INFLAMMATORY BIOMARKERS AND ENDOSCOPIC SCORES IN ULCERATIVE COLITIS: THUS EXTENSION MAKES THE DIFFERENCE?**

C. Arieira1, F. Dias De Castro1, M.J. Moreira2, J. Cotter3
1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães,
Guimarães/Portugal
2Pt Government Associate Laboratory
3ICFS/3S, Braga/Guimarães/Portugal

Contact E-mail Address: catia_arieira@hotmail.com

**Introduction:** Several endoscopic scores have been used to assess the severity of inflammatory bowel activity in Ulcerative Colitis (UC), however, few consider the extension of the disease. Scores such as the Dublin Score (DS) and the Modified Mayo Endoscopic Score (MMES) combine the severity of inflammation with the extent of the disease.

**Aims & Methods:** We aimed to calculate the correlation between the endoscopic scores -Mayo Endoscopic Score (MES), DUBLIN, MMES and the biomarkers of inflammation - erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and to compare the ability of these scores to predict Calprotectin > 100 µg/g. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin > 100 µg/g.

**Results:** 60 patients were included, 46.7% female patients with mean age 43.3 ± 12.8 years with mean values of ESR 4.4 ± 12.8 mm, CRP 5.12 ± 6.00 mg/l and Calprotectin 354 ± 430 µg/g. The correlation between Calprotectin and MES was rS = 0.623 p < 0.001, for DS rS = 0.548 p < 0.001 and for MMES rS = 0.588 p < 0.001. Regarding CRP, a correlation with the MES was rS = 0.413 p < 0.001 and with the MMES rS = 0.404 p < 0.001, but no correlation was found with the DS. There was no significant correlation between ESR and endoscopic scores. To predict values of Calprotectin > 100 µg/g the AUC for the MES was 0.848, for the DS 0.801 and for the MMES 0.815, and there was no statistically difference between the curves.

**Conclusion:** Although there is a good correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension were not superior to Mayo Endoscopic Score.

**P0992 IBD – IS IT A RISK FACTOR FOR THE DIAGNOSIS OF HEPATIC STEATOIS?**

C. Arieira1, S. Monteiro2, S. Xavier1, F. Dias De Castro1, J. Magalhães1, M.J. Moreira2, J. Cotter3
1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães,
Guimarães/Portugal

Contact E-mail Address: catia_arieira@hotmail.com

**Introduction:** Although is not yet established, recent studies suggest an increase prevalence of hepatic steatosis (HS) in patients with inflammatory bowel disease (IBD). Factors such as chronic inflammation, previous surgeries, drug-induced hepatotoxicity, malnutrition and intestinal dysbiosis seem to be involved in the pathogenesis of this disease.

**Aims & Methods:** We aimed to assess the frequency of HS in IBD patients quantified by CAP (controlled attenuation parameter) and by clinical- analytical methods: Hepatic Steatosis Index (HSI) and Fatty Liver Index (FLI). A secondary aim is to investigate risk factors associated with HS in IBD patients. This was a retrospective study that included consecutive patients that were observed in our department between January and March 2017. Patients with known liver disease or alcohol habits were excluded. HS was defined as HSI > 36 or FLI ≥ 60 or CAP ≥ 248.

**Results:** 149 patients included with mean age 40.7 ± 13 years, 83 female (55.7%), 59.7% with Crohn’s disease (CD), 62 patients (41.7%) had CAP > 248.20 (13.4%) FLI > 60 and 40 (26.8%) HSI > 36. There were no differences in the mean CAP value (244.4 ± 54.2), HSI (33.3 ± 5.18), and FLI (31.5 ± 23.5) among patients with or without CAP> 248. We found that patients with CAP > 248 were more frequently obese (27.4% vs 0% p < 0.001), males (54.8% vs 36% p = 0.029) and presented more frequently metabolic syndrome (25% vs 46% p < 0.001). Regarding the IBD factors, patients with HS had a higher frequency of previous surgeries (30.6% vs16.1% p = 0.035). There were no differences between hospitalization, duration of the disease, use of corticosteroids or other IBD treatments.

**Conclusion:** In our cohort the frequency of HS varied between 13.4% and 41.7% defined by non-invasive methods. We found that the presence of metabolic syndrome and obesity were more frequent in patients with HS. Regarding factors related to IBD, patients with previous history of surgery were more frequently diagnosed with HS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0993 BONE HEALTH IN CROHN’S DISEASE IN THE ERA OF TNF-ALPHA INHIBITORS**

S. Hakimian1, J. Kheder2, D. C Ave3, B. Hyatt3
1Internal Medicine, University of Massachusetts, Worcester/United States of America
2Gastroenterology, UMass Medical Center, Worcester/United States of America

Contact E-mail Address: shahrad.hakimian@umassmemorial.org

**Introduction:** Osteoporosis and fractures are common in Crohn’s disease (CD). Recently, several inflammatory cytokines, including tumor necrosis factor (TNF)-alpha have been linked to increased bone resorption. Therefore, it is hypothesized that anti-TNF therapy may influence osteoporosis and fracture risk. However, few studies have evaluated osteoporosis and fracture risk in the CD population.

**Aims & Methods:** The aim of this study is to gain a better understanding of the epidemiologic risk factors for osteoporosis and vitamin D deficiency in the era of TNF-alpha inhibitors. We conducted a retrospective review of 714 consecutive patients with CD in our GI clinic between 2008 and 2015 to identify 464 patients who met the inclusion criteria for the study comprising of all adults older than 18 years with confirmed CD based on labs and endoscopic findings. Data extracted for analysis included demographics data, disease phenotype, duration of disease, measures of disease activity, imaging and endoscopic data. Statistical analysis was performed using student t-test and chi-square test.

**Results:** We reviewed the charts of 290 patients with CD treated with TNF-alpha inhibitors (TNF) and 174 patients who are anti-TNF naïve (NB). There were 207 (45%) males and 257(55%) females in this cohort. TNF patients tended to be younger (average age of 43/+15 and 54 +/-18 years in TNF and NB groups respectively). Mean duration of disease was 14.9 +/-10.2 for TNF and 18.6 +/-19.2 for NB group. Approximately half of the patients had a smoking history. Average BMI was 27.6 +/-6.6. Rates of vitamin D deficiency, insufficiency and normal vitamin D-25 OH levels were not significantly different between TNF and NB groups. Vitamin D level was not associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson’s R = 0.151, p = 0.001). There were 100 patients which included 100 patients in the TNF group and 68 patients in the NB group. There was similar rate of osteoporosis (16% vs 18%), osteopenia (53% vs 57%) and normal bone density (31% vs 25%) between the TNF and NB groups respectively. Furthermore, there was no statistically significant difference in T-scores at the hip (~1.2 vs ~1.3), the spine (~1.0 vs ~0.95), or the lowest T-scores (~1.5 vs ~1.4) between TNF and NB patients. However, Z-scores at the spine (~0.47 vs ~0.05), the hip (~0.55 vs ~0.49) and the lowest Z-scores (~0.91 vs ~0.67) were lower in the TNF group, but only reached significance at the spine (P = 0.03). Interestingly, a significantly higher proportion of TNF patients under 60 years of age met the criteria for osteoporosis (T-score < -2.5 below the mean) as compared to NB patients (15% vs 3.6%). Additionally, rates of osteoporosis in the NB group were very different between before and after age 60 (3.6% vs 30%) [table 1]. There was no correlation with bone density and vitamin D level, nutritional status (based on lowest albumin level), or degree of inflammation (highest ESR or CRP levels). However, there was a moderate positive correlation with BMI and bone density (Pearson R = 0.39) and a negative correlation with age (R = –0.25).

**Table 1:** Osteoporosis rates in patients on anti-TNF therapy (TNF) and those naïve to biologic medications (NB) before and after age 60.

<table>
<thead>
<tr>
<th>Group</th>
<th>Age &lt; 60</th>
<th>Age &gt; 60</th>
</tr>
</thead>
<tbody>
<tr>
<td>TNF</td>
<td>15.4%</td>
<td>18.2%</td>
</tr>
<tr>
<td>NB</td>
<td>3.6%</td>
<td>30.0%</td>
</tr>
</tbody>
</table>

**Conclusion:** Rates of vitamin D deficiency, and osteoporosis were similar among patients on anti-TNF medications to those on no biologics. TNF group patients were diagnosed with osteoporosis at an earlier age compared to NB group. Patients on anti-TNFs also had statistically lower Z-scores at the spine. Prospective studies are necessary to further determine the role of anti-TNF medications in osteoporosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0994 THE AVAILABILITY OF INFlixIMAB TROUGH LEVELS IN IBD PATIENTS ON MAINTENANCE THERAPY DEEPLY IMPACTS THERAPEUTIC DECISION-MAKING**

Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: (1) to describe real-life ITLs in clinically stable IBD patients; (2) to find clinical and biological factors associated with intra-individual fluctuations (ITLs) and (3) to evaluate the impact of ITLs availability by comparing the CCD with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the linear Cohen’s Kappa (κ) index. IBD patients on maintenance IFX therapy were prospectively followed from June 2015 to June 2016. Demographic, clinical and biological data including C-reactive protein (CRP) levels from the same infusion day were collected. At each IFX infusion, patients were visited by their physician; a “current clinical decision” (CCD) was taken regarding clinical data and CRP. IFX levels were measured just before the IFX infusion and were considered as intra-therapeutic if <2μg/ml. Since ITLs were known, 3 experts took a hypothetical decision on treatment based on the same clinical and biological data plus ITLs (ITL-guided decision - TLGD).

Results: A total of 224 IFX infusions from 74 patients (76% Crohn’s disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5-18) and 23 months (7-61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 4-6 weeks and 13% every 12 weeks; 70% of patients were on clinical and biological remission. Median (IQR) CRP levels were 3.1 mg/ml (1.5-6.1). Median (IQR) ITLs were 1.79μg/ml (0.35-3.74), with 52% of patients having intra-therapeutic ITLs. In the multivariate analysis, the only risk factor for intra-therapeutic ITLs was the presence of biological activity. Concordance between CCD and TLGD was poor (κ = 0.10 [95%CI:0.01-0.20]) = 0.11 [95%CI:0.01–0.21] for experts A/B/C, respectively. This “disagreement” was due to a higher proportion of dose-escalation decisions according to the TLGD as compared to the CCD. Among the 203 infusions in which no action was taken according to the CCD, 93 (40%), 48 (20%) and 65 (30%) would have been dose-escalated according to the TLGD for experts A, B and C, respectively. The concordance between experts was moderate (κ = 0.3) [95%CI:0.41-0.71] = 0.40 [95%CI:0.32-0.55] = 0.30 [95%CI:0.21-0.40] for experts A-B-C/C, respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and confirm their therapeutic range in patients in clinical stability. Both the clinical and economical impact of ITL-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

Disclosure of Interest: All other authors have declared no conflicts of interest.

Conclusion: LCI was superior to WLI for predicting mucosal healing and histological inflammation in patients with UC.

Disclosure of Interest: All authors have declared no conflicts of interest.
two scenarios were scored higher by patients than by physicians. Teaching the patients to manage a new chronic condition and treatment of fatigue are aspects that would help to reduce the anxiety feeling and should be taken into account in clinical practice Acknowledgements. 4Immunology, Hôpital Nord, Saint Etienne/France

Contact E-mail Address: stephane.paul@chu-st-etienne.fr

Introduction: Flixabs, an infliximab biosimilar referencing Remicade®, was developed by Samsung Bioepis, the joint venture between Samsung BioLogics and Biogen. SB2 received approval in EU for all approved indications of the reference infliximab. Many decision algorithms based on the measure of Infliximab (IFX) trough levels and antibodies to infliximab (ATA) have been increasingly used to optimize infliximab in Crohn’s disease and ulcerative colitis. The aim of our study was to appreciate if the biosimilar SB2 could be efficiently monitored using the Lisa-Tracker infliximab and anti-infliximab immunoassays developed by TheraSag (France).

Aims & Methods: During this evaluation, standard curves of Infliximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the Lisa-Tracker assay. Levels of infliximab (from 5 spiked samples with known amount of SB2 and 10 clinical samples from patients treated with infliximab) were calculated according to each of the 3 standard curves (infliximab, SB2 batch1 and SB2 batch2). All samples and standards were tested in duplicate. Regression lines be >0.95 and the slope must be comprised between 0.9 and 1.1. Intra-run and inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12μg/ml) amounts. Capacity of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the SB2 standard curve and that the Lisa-Tracker assay is suitable for the quantification of SB2 in human serum samples (R² = 0.99; the levels of infliximab of the 20 samples were calculated according to the 3 standard curves infliximab, SB2 batch 1 and SB2 batch 2 with CV ranged from 2.1 to 12.6%). Quantification of SB2 was linear by 4-log matrix and the % of recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV ranged from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of SB2 in 5 spiked samples and the % of inhibition comprised between 80% and 97%. The capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Conclusion: In conclusion, Lisa-Tracker Inflaximab and Anti-Inflaximab assays are suitable for the monitoring of SB2 treated with SB2. Acknowledgements: Biogen provided the SB2 drug for this study. Biogen reviewed the protocol and provided feedback to the authors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0998 THE MEASURE OF TROUGH LEVELS OF INFlixIMAB IS LINKED TO THERAPEUTIC RESPONSE IN IBD PATIENTS

X. Robin1, A. Berger2, G. Boscetti1, B. Flourie3, N. Nancey4, S. Paul2

4Gastroenterologie, CH Lyon Sud gastro secteur Jules Courmont, Pierre Benite/Codes/France

Contact E-mail Address: xavier.roblin@chu-st-etienne.fr

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don’t really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission and mucosal healing.

Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDAI < 150 for Crohn’s Disease (CD) or partial Mayo score < 3 for ulcerative colitis (UC) with biomarker normalization (fecal calprotectin < 250 μg/g stools) or in deep remission (clinical remission with fecal calprotectin < 50 μg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8; 51 patients in deep remission at M0). All 111 patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210 μg/g in the group of patients who achieved deep remission vs 220 μg/g in the group of patients who achieved only biomarker remission respectively; p = 0.03). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement. (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (41 μg/ml vs 59 μg/ml respectively; p = 0.03). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison to M0 (190 μg vs 35 μg/ml; p < 0.01). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman’s rank correlation coefficient (q) = -0.25; p = 0.045).

Conclusion: Although TLI may increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0999 SMOKING STATUS INFLUENCES FECAL VOLATILE ORGANIC COMPOUNDS COMPOSITION

J. De Swart1, N. Van Gaal2, D. J.C. Berkhourt3, S. Bosch4, T.G. J. De Meij5, K. H.N. De Boer6

1Gastroenterology And Hepatology, VU University Medical Center, Amsterdam/Netherlands
2Department Of Pediatric Gastroenterology, VU University Medical Center, Amsterdam/Netherlands

Contact E-mail Address: bosch.sofie@gmail.com

Introduction: Fecal volatile organic compounds (VOCs) are gaseous carbon-bound metabolic products considered to reflect intestinal microbiota composition. Fecal VOCs may serve as markers for a broad range of gastrointestinal diseases. As smoking leads to a substantial shift in intestinal microbial composition in healthy and diseased persons, the aim of this study was to assess the effect of smoking status on fecal VOC pattern.

Aims & Methods: In this cross-sectional pilot-study adult smokers, non-smokers and former smokers scheduled for colonoscopy at the VU University medical center were instructed to collect a fecal sample prior to bowel cleansing. Patients were included if no abnormalities were found during colonoscopy. Exclusion criterion was use of antibiotics three months prior to participation. All participants completed a questionnaire on standard demographics, BMI, diet and smoking habits. Fecal VOC profiles were measured using an electronic nose device (Cyranose 320®).

Results: Fecal samples from 56 subjects (11 smokers, 21 non-smokers, 24 former smokers) were analyzed. Median age was 62 years (27–82 years). Furthermore, there were no significant differences between groups for the variables age, sex, BMI, diet, sample weight, chronic diseases and medication and supplement use. Fecal VOC profiles differed between smokers and non-smokers (PC1: p-value = 0.003). Smokers could be distinguished from non-smokers based on fecal VOC profiles was possible with an overall accuracy of 75% and corresponding sensitivity and specificity values of 72.7% and 76.2%. No significant differences between the fecal VOC profiles from smokers and former smokers (PC1: p-value = 0.083) and between profiles from non-smokers and former smokers (PC1: p-value = 0.764) were observed.

Conclusion: This study showed that smoking status has a significant influence on fecal VOC profiles. This implicates that the smoking status should be taken in account when performing (fecal) VOC analysis. The finding that VOC profiles did not differ between smokers and former smokers could be due to the wide divergence (6 month – 43 years) in smoke-free time in former smokers group.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** The prevalence of Clostridium difficile infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

**Aims & Methods:** The goal of our study is to examine the incidence of CDI in patients with IBD. The prospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of Clostridium difficile. Diagnosis was confirmed with stool toxin analysis. Demographic information, diagnosis, anatomic location, IBD therapy, antibiotic exposure, hospitalizations, and surgeries were recorded. For a period of 3 years, 202 IBD patients were studied, 105 of which have UC and 97 - Chron’s disease (CD).

**Contact E-mail Address:**

**Aims:** The prevalence of CDI in patients suffering from IBD, who receive different therapy regimes is significantly higher than in patients with CD, respectively 18.1% to 9.30%.

**Results:** The results show that all patients with a positive CDI test have a clinical picture, which resembles a relapse of the disease (p < 0.05). There’s a tendency towards growth in the incidence of IBD patients who are CDI positive. Their number in 2016 is significantly higher than that in 2014. In 2014 it was ~5.90% with CD and 12.30% with UC, whereas in 2016- 12.20% with CD and 27.80% with UC. The results show that the incidence of CDI in patients with UC is significantly higher than in patients with CD, respectively 18.1% to 9.30% (p < 0.05). There is a strong correlation between CDI incidence in patients with IBD and the severity of their disease. Patients positive for CDI have a much more severe course of the disease. UC (46.40%) and CD (24.20%) (p < 0.05).

**Conclusion:** There is an increase in incidence of CDI, and patients with UC are more affected by it. The results of our study are confirmed by other authors as well. A significant number of patients with CDI have a severe disease that needs extra prospective researches to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimes and also to understand how the CDI affects the evolution of the disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

3. Dos R, Feuerstadt P, Brandt LJ. Glucocorticoids are associated with infection amongst patients with IBD, who receive different therapy regimes. There is an increase in incidence of CDI, and patients with UC are

4. Lamontagne F, Labble AC, Haeck O, Lesur O, Lalalncete M, Patino C, et al. Incidence and clinical presentation of Sustained clinical remission with good performance (Area under the curve (AUC): 90.1% [95% CI: 81.8%–98.5%]; sensitivity (Sp): 81.3%, specificity (Sp): 90.9%; Positive predictive value (PPV): 97.7%; Negative predictive value (NPV): 90.0%; especially in UC patients (AUC: 98.2%; [95% CI: 93.9%–100%]; Sp: 90.5%, Sp and PPV: 100%; NPV: 66.7%). Corresponding outcomes for CD were also significant (AUC: 93.9% [95% CI: 75.0%–79.8%]; Se: 72%; Sp: 56.7%; NPV: 85.8%). In contrast, performance of TLI at W14 (≥2.87 ng/mL) for the prediction of sustained clinical remission were moderately interesting (AUC: 60.9% [95% CI: 57.8%–83.1%; Se: 79.3%; Sp: 61.3%; PPV: 92.0%; NPV: 40.3%). These results were not significantly different between patients who had received an AZA monotherapy before concomitant therapy compared to those who did not.

**Conclusion:** This new score is a promising tool for the prediction at baseline of sustained clinical remission in inflammatory bowel disease patients who start concomitant therapy. It may help to identify easily patients with high benefit optimization of IFX rather than early switch treatment in this setting. However, a prospective validation is needed before recommending its use in clinical practice.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1002 LOWER GI SYMPTOMS IN YOUNG PATIENTS: CAN SYMPTOMS AND NON-INVASIVE TESTS BE USED SYSTEMATICALLY TO AVOID UNNECESSARY COLONOSCOPYs?**

A. Alakkari, B. Ryan
Gastroenterology Department, Adelaide and Meath Hospital, Dublin/Ireland

**Contact E-mail Address:** alakkarr@yahoo.com

**Introduction:** Young patients commonly present with lower gastrointestinal symptoms. Most colonoscopies in such patients are normal, but risk potentially serious complications. There is an over reliance on endoscopy in clinical practice leading to increased demand on limited resources. As a result, some patients with potentially life-threatening conditions (e.g. colon cancer) may have a significant delay in diagnosis that may result in a worsened prognosis. Many endoscopic procedures are absolutely necessary, but many may be avoided if other, non-invasive forms of investigations were available which could reliably exclude significant pathology. This in turn could lead to reduced morbidity and mortality.

**Aims & Methods:** We aimed to assess colonoscopy, relevant fecal and blood tests in young patients with lower gastrointestinal symptoms. Colonoscopies performed over a 1-year period were retrospectively identified from the Endoscopy Reporting System (patient charts, database, فقط معلومات كافية من المستخدم). CC, Reactve Protein (CRP), and Coeliac serology were reviewed. A raised CRP > 5 mg/L or FC > 50 ug/g was considered abnormal. A Colonoscopy with mucosal inflammation confirmed on histology was considered abnormal.

**Introduction:** There is no blood test predictive of sustained clinical remission in patients with Crohn’s Disease (CD) or Ulcerative colitis (UC) under Infliximab (IFX) - azathioprine (AZA) concomitant therapy.

**Aims & Methods:** All patients with CD or UC, consecutively treated by the combination of IFX-AZA between August 2015 and March 2017, were included in this monocentric study. Clinical, biological (blood cells count, liver function enzymes, C-reactive protein (CRP)) were retrospectively collected at baseline, at week 14 (W14) and at 6 months (W24) from the start of combination therapy.

**Results:** 2151 medical GI outpatient colonoscopies performed over 12 months were identified. 242 met inclusion criteria for the study. Median age of the patient cohort was 34 years (range 16–45), with 141 (58%) females. The cohort was stratified according to indications; Group A: 132 (55%) patients with diarrhea predominant symptoms, and Group B: 110 (45%) patients with constipation-abdominal pain and bloating. Colonoscopy was normal in 104 (79%) of Group A and 102 (93%) of Group B (p = 0.0002). 58 (15%) Colonoscopies were abnormal; 7 patients had active ileitis, 22 had colonic inflammation (12 IBD, 2 lymphocytic colitis, 8 non-specific inflammation), and 7 had ileocolic inflammation (all diagnosed with IBD). 28 of 36 (78%) patients with mucosal inflammation confirmed on histology had diarrhea (p = 0.0001). FC was available in 36 patients, and CRP in 171 patients. In Group A the negative predictive value, positive predictive value and specificity of CRP/FC were 88%, 43% and

Introduction:

Aims & Methods:
to endoscopic findings within the first year following surgery to prevent POR. Operative recurrence (POR) remains a crucial issue. The POCER trial (1) has shown that a combination of magnetic resonance imaging (MRI) and faecal calprotectin detected endoscopic postoperative recurrence in Crohn’s disease (2). MRI is a non-invasive tool that can detect small bowel inflammatory changes but remains recommended before performing a small bowel videocapsule examination. Faecal calprotectin is a known marker of inflammatory bowel disease (IBD) and can help reduce colonscopy waiting times. Colonoscopy has low yield in young symptomatic patients, especially those with non-diarrhoeal symptoms. Non-invasive tests should be used systematically to better identify patients requiring colonscopy. We are conducting a prospective study to explore non-invasive diagnostic paradigms. Implementation of these strategies will help reduce colonscopy waiting times. Disclosure of Interest: All authors have declared no conflicts of interest.

P1003 Faecal Calprotectin and Magnetic Resonance Imaging Are Reliable Tools to Detect Endoscopic Postoperative Recurrence in Crohn’s Disease

Introduction: As surgical resection is not curative in Crohn’s disease (CD), postoperative recurrence (POR) remains a crucial issue. The POCCR trial (1) has recently confirmed that the therapeutic management has to be adapted according to the outcome of the first year following surgery to prevent POR. However, as colonscopy is a burdensome procedure, alternative tools have been developed such as faecal biomarkers and magnetic resonance imaging (MRI). Aims & Methods: We aimed to assess the performances of MRI and faecal calprotectin to detect endoscopic POR in CD patients. Adult CD patients from two tertiary centers who underwent ileal or ileocolonic resection were consecutively included in this prospective study. All the patients underwent magnetic resonance enterography including diffusion-weighted sequences with apparent diffusion coefficient (ADC) calculation (mm²/s) and evaluation of Clermont score (2), MaRIA (3) and MRI score (4) within the first year after surgery or the last recorded capsule. Results: Overall, 30 CD patients were enrolled in the study. Among them, 15 (50.0%) were female and 7 (23.3%) were active smokers. Disease location was ileal, colonic or ileocolonic in 15 (50.0%), 1 (3.3%) and 14 patients (46.7%), respectively. The patients included in this study were treated with no medication before the colonoscopy.

P1004 Small Bowel Preparation in Patients with Crohn’s Disease: The Polyethylene-Glycol is No Longer Useful

Introduction: PEG preparations reduce the acceptability of endoscopic explorations but remains recommended before performing a small bowel videocapsule examination (SBVC). No study has evaluated its impact on the small bowel cleanness compared to other modalities in patients with Crohn’s disease (CD). The objective of this study was to compare three methods of preparation, one using polyethylene-glycol and two simplified methods in adult patients with CD.

Aims & Methods: Three methods of preparation i.e. low-residue diet the evening before more 1 L PEG before the capsule (PEG), liquid diet the evening before the capsule (LD) and 1.5 L of water at the time of the capsule (Water) were compared to the two other modalities (P<0.01). The cecal intubation rate was higher in the LD (7.9) and Water (7.6) groups compared to the PEG group (6.8) (P=0.04). The quantitative score was significantly better in the LD (7.9) and Water (7.6) groups compared to the PEG group (6.8) (P=0.043). The preparation by water was considered qualitatively better compared to the two other modalities (P=0.04).

P1005 VALUE OF 75SEHCAT IN THE DIAGNOSIS OFBILE ACID MALABSORPTION IN CROHN'S DISEASE WITH CHRONIC DIARRHEA
Gastroenterology, Hospital Reina Sofia, Córdoba/Spain
Gastroenterology, Hospital Universitario Reina Sofia, Córdoba/Spain
Gastroenterology, Instituto María de Investigación Biomédica, Córdoba/Spain

Introduction: Bile acid malabsorption (BAM) is a well-known disorder associated with inflammatory bowel disease patients, however, it is underdiagnosed in clinical practice. 75SeHCAT test is the current clinical gold standard for diagnosing bile acid diarrhoea widely used in Europe.

Aims & Methods: We aimed to analyze the incidence of BAM in Crohn's (CD) patients with chronic diarrhoea through 75SeHCAT and to assess whether there is a relationship between the malabsorption degree and the presence of ileal resection. We performed 75SeHCAT test after the ingestion of a 75SeHCAT capsule (0, 37 MBq) prior fasting the night before the test and performing an enema with saline at seventh day measurements. Epidemiological and clinical data were collected from the local database ENEIDA.

Results: We studied 15 women and 15 men with mean age of 46.5 years old (26–68). The mean duration of the disease was 13 years (2–27). At diagnosis, ileal location was present in 50% of the patients, ileocolonic 40% and colonic in 10%. According to the behavior of the disease, 50% presented non-stricturing non-penetrating, 23% strictureting and 27% penetrating pattern, and 43% patients had perianal disease. In relation with smoking status, 34% were active smokers. Regarding actual treatment, 40% of the patients are controlled with only immunosuppressive drugs, 10% with biologics, while 20% used comotherapy. 83.3% had perianal disease. In relation with smoking status, 34% were active smokers. 10% BA is consistent with a normal result. 75% of patients demonstrated abnormal values defined as <10% ileal retention. Mild BAM was considered 7–10%, moderate 4–7% and severe <4% at ileal retention at seventh day measurements. Epidemiological and clinical data were collected from the local database ENEIDA.

P1007 THE ROLE OF SENSE OF COHERENCE IN DETERMINING HEALTH RELATED QUALITY OF LIFE AND DISABILITY IN INFLAMMATORY BOWEL DISEASE
G. Wild, M. Vitagliano, I. Albunean, K. Shirlow
Gastroenterology, McGill University Health Centre, Montreal/Canada

Introduction: There is an ever growing body of evidence that indicates that Health Related Quality of Life (HRQoL) is significantly impaired in IBD. While clinical variables and disease activity status influence HRQoL, a host of psychosocial and personality variables also play an important role. This contention is supported by evidence of impaired quality of life in IBD patients in the absence of demonstrable disease activity. Moreover, individual differences may play a key role in the psychological adaptation to living with IBD and coping with the psychological distress associated with the disorder. Sense of coherence (SOC) is an emerging theoretical and dynamic construct that seeks to explain why some individuals in the face of adversity experience illness while others do not. Antonovsky’s theory of SOC suggests that individuals with strong SOC exhibit effective and flexible coping strategies when faced with stressors (e.g., chronic medical condition) whereas those with weak SOC are less likely to adapt to health stressors and have less motivation when confronted with challenges to their health. While a number of studies have shown that SOC appears to have an impact on HRQoL, data regarding this association in IBD are limited.

Aims & Methods: The goal of the current study was to examine the associations between an individual’s sense of coherence, and their overall health-related quality of life. The first part of this analysis looked at whether sense of coherence accounted for more of the variance in level of disability, and an individual’s illness perception, as compared to other reported psychosocial factors. The second part of this study evaluated whether sense of coherence, as well as illness perception, were associated with an individual’s self-reported quality of life, and if this interaction was moderated by the individual’s level of anxiety. Additionally, the correlations between sense of coherence, and self-efficacy, as well as self-reported emotional intelligence were also further evaluated. This is a cross-sectional observational cohort of IBD patients attending MUHC (McGill University Health Centre) IBD outpatient clinic. The psychological distress of the patient population is as follows: mean age (42.4±12.44), gender (40.6% male), disease activity (58.4% CD, 33.7% UC), disability (27.7% active, 65.3% inactive). Patients completed multiple validated questionnaires pertaining to a variety of psychosocial parameters. Data was analyzed by multiple linear regression using statistics software (SPSS version 17.0).

Results: Preliminary analyses of this patient population reveal that 40.2% of the variance in level of disability is explained by sense of coherence. This model suggests a significant negative correlation between sense of coherence and level of disability (β = –0.64, p < 0.05). A smaller, albeit significant contribution of sense of coherence with illness perception was additionally found (14.1% of the variance, and β = –0.39, p < 0.05). Furthermore, 32.3% of the variance in self-
reported quality of life was explained by sense of coherence ($r = 0.43$, $p < 0.05$) and distress perception ($r = -0.28$, $p < 0.05$). However, the individual’s report of anxiety did not moderate this relationship. Significant positive correlations between sense of coherence and self-efficacy were also seen in this patient population ($r = 0.61$, $p < 0.01$), as well as with self-reported emotional intelligence ($r = 0.52$, $p < 0.001$).

Conclusion: These data indicate that Sense of Coherence is an important psychological construct that is associated with HRQoL and disability in IBD. Screening for these factors, in addition to the physiological markers, should be considered in order to provide the most holistic treatment strategies.

Introduction: Measurement of infliximab trough levels (IFX-TLs) and antibodies to infliximab (ATIs) has been suggested as an important parameter for the optimization of treatment of patients with inflammatory bowel disease (IBD). Aim(s) & Methods: We aimed to cross-sectionally investigate the correlation between IFX-TLs or ATIs and clinical, biochemical as well as endoscopic activity in Greek IBD patients. Consecutive IBD patients on maintenance treatment with IFX, were included. IFX-TLs and ATIs were measured using ELISA (Eagle Rock, PA, USA) on serum samples drawn before infusion. At the same time quality of life using short IBD questionnaire (SIBDQ) and clinical disease activity using Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD) or simple colitis activity index (SCAI) for ulcerative colitis (UC) were assessed. Moreover, biomarkers (hemoglobin, ESR, CRP, platelets, albumin) were measured and latest colonoscopies (within 6 months) were reviewed and evaluated for presence or not of mucosal healing.

Results: A total of 74 patients receiving IFX maintenance therapy [55 CD, 19 UC, 94% mean age 42.3 years, 45 on combination therapy with immunomodulators (IMMs), 10 under intensified dose (either 10 mg/kg/8w or 5 mg/kg/4–6w)] were studied. Median time since IFX initiation was 26 (13–71) months and median value of serum IFX-TL was 4.33 µg/ml (0.03–30.7). Seven out 74 (9.5%) were positive for ATIs (>10 AU/mL). Patients on combination treatment had significantly higher IFX-TLs (6.98 µg/ml, 0.34–30.7) compared to those on IFX monotherapy (1.85 µg/ml, 0.09–25.8) (p = 0.01). Patients with positive ATIs had median IFX-TLs 0.99 µg/ml (0.09–1.40) statistically lower compared to those with negative ATIs (6.01 µg/ml, 0.03–30.69) (p = 0.005). The correlations of IFX-TLs and ATIs with clinical, biochemical and endoscopic indices of disease activity in IBD patients are presented in Table 1. No other significant correlations of IFX-TL or ATIs with other disease characteristics were observed. In the logistic regression analysis only IFX-TLs (OR 0.96, 95% CI 0.76–0.97 p = 0.017) and duration of IFX treatment (OR 0.97, 95% CI 0.95–0.99 p = 0.04) were independently correlated with the presence of mucosal healing.

Conclusion: Therapeutic drug monitoring is valuable in IBD-patients on maintenance IFX-treatment. Combination treatment with IFX and IMMs is associated with higher IFX-TLs compared to IFX monotherapy. Higher IFX-TLs are independently associated with the presence of mucosal healing.

P1010 COMPARATIVE INVESTIGATION OF ENTEROBACTERIA BUSH IN ULCERATIVE COLITIS PATIENTS, AND THEIR CONSANGUINEOUS, AND NON-CONSANGUINEOUS RELATIVES

K. Fukuda
St Luke's International Hospital, Tokyo/Japan

Contact E-mail Address: fukukatu@luke.ac.jp

Introduction: In recent years, the gut microbiota has been recognized as a relevant fingerprint to predict the development of inflammatory bowel disease (IBD) like ulcerative colitis (UC). Accordingly, inter-individual variation in the gut microbiota community may reflect inter-individual variation in the risk of developing IBD or other diseases. Further recently, the Next-Generation Sequencing (NGS) has been validated for determining bacterial species in faecal samples. Essentially, NGS is a molecular biology sequencing technique for the precise identification and assessment of bacterial species.

Aims & Methods: With the major focus of our study being to establish a relevant biomarker of disease activity in UC patients based on the intestinal microbiota, 82 UC patients together with 61 healthy relatives as controls were included for inter-individual variations of gut microbiota in faecal samples. Twenty-five patients had active UC (group I) and 57 had quiescent UC; 29 with mild inflammation in the large intestine (group II), and 28 without inflammation (group III). The patients’ relatives were consanguineous (group IV, n = 33), and non-consanguineous (group V, n = 28). The subjects’ age ranged from 15 to 69 years. Faecal bacteria between groups I to V were compared by the t-test. The Discriminant analysis in all five groups was done for each Phylum, Class, Order, Family, Genus and Species. The Canonical Discriminant Function Coefficient (DF) for each bacterial community was calculated. The quantity of each bacteria was multiplied by the DF value, and the sum was termed the Discriminant Score (D).

Results: We obtained 1011 varieties of bacteria as Phyla, Class, Order, Family, Genera and Species. Any individual bacterial quantity with 0 value ≥95% of group I and group V, the mean of the individual quantity of bacteria ≥0.05% cases (648) were excluded. The t-statistics was done on 363 bacteria between groups I to V. Significant difference was calculated in 18 Species, 10 Genera, and 4 Families. The Discriminant analysis was done on these 18 Species from all groups. The Ds value showed an increasing tendency in this order: group I < group II < group III < group IV < group V. Significant difference was calculated for group I vs group II, vs group III, vs group IV, and vs group V (P < 0.05). Likewise, group V vs group I, vs group II, vs group III (P < 0.05), indicating a relevant association between gut microbial species and the development of UC. In bacteria having significant difference, especially Bacteroidaceae Family and Bacteroides Genus were numerous clearly, and both were higher in group I, active UC. It’s odd that the diversity of Bacteroides Genus was higher in Group V, non-consanguineous relatives, but the quantity of Bacteroides Genus was higher in group I. And Bacteroides fragilis was increased in group I, and the others of Bacteroides were increased in group V, it depends on the amount of Bacteroides fragilis. In active UC, the amount of Bacteroides fragilis was increased, but the diversity of Bacteroides Genus was decreased. It’s very interesting, and the balance can be key point between Bacteroides fragilis and the diversity of Bacteroides in UC activity. And about Genus Anaerococcus, Finegoldia and Peptoniphilus, about Species Anaerococcus vaginalis, Finegoldia magna and Peptoniphilus gorbachi were increased in group I significantly. All these bacteria belong to Peptoniphilaceae Family.

Conclusion: In this study, we compared 363 bacteria between active UC patient to control, significant difference was calculated in 18 Species, 10 Genera, and 4 Families. To our knowledge, this is the first report on so many bacteria being related to UC activity. Additionally, the Ds related to UC, or otherwise absence of UC in the five groups. Potentially, Ds might be a clinically relevant biomarker of disease activity in UC. This is the first application of the Ds to the study of microbiota in UC patients, consanguineous and non-consanguineous relatives by using NGS. Moreover we could obtain a lot of interesting results about the quantity and the diversity of the bacteria, especially Bacteroides and Peptoniphilaceae. Clinical trial No: UMIN000017103

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: At present, drug response to infliximab is monitored by trough levels of antibody levels. When a patient’s trough level is decreasing, another pathway of drug degradation has been hypothesized since MMP3 and MMP9 were found to be able to cleave IgG, like infliximab, in both animal and human experimental studies (1).

Aims & Methods: We collected serum samples in 102 patients (27 Crohn’s Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months (t0) and 6 months thereafter (t1). In each patient TL, ATI and MMP levels were assessed at t0 and t1 by ELISA. In addition, MMP3 levels were assessed in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, faecal calprotectin) markers were assessed to define disease remission/activity. TL were considered therapeutic if >3.8 mcg/ml, ATI were considered positive if > 10 mcg/ml. Data are presented as mean ± Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at t0 and t1 in patients who maintained therapeutic TL (14.5 ± 1.7 pg/ml and 15.0 ± 1.6 pg/ml, respectively) and in patients who discontinued therapy (13.2 ± 0.5 pg/ml). Patient who discontinued therapy had significantly higher MMP3 levels compared to the group with low TL and ATI positive (33.2 ± 3.0 and 20.0 ± 2.7 respectively, p<0.0003), showing another pathway of drug degradation. 21 patients lost response between t0 and t1: 15 out of 21 patients demonstrated high levels of MMP3 (22.0 ± 2.1 pg/ml) already at t0; in addition, 17 of these 21 patients were in clinical remission at t0, while at t1 all patients had disease activity.

Conclusion: Serum MMP3 levels are useful in predicting loss of response to anti TNFa in patients with low TL but without ATI. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1013 USEFULNESS OF A MULTIDISCIPLINARY APPROACH COMBINING BOTH RHEUMATOLOGY AND GASTROENTEROLOGY FOR THE ASSESSMENT AND TREATMENT OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta1, E. P´erez-Pamp2n, R. Ferreiro Iglesias1, R. Mejuto1, A. Mera1, J.E. Dominguez-Munoz1
1Gastroenterology, University Hospital of Santiago, Santiago de Compostela; Spain
2Rheumatology, University of Santiago de Compostela, Santiago de Compostela; Spain

Contact E-mail Address: manubarreiro@hotmail.com

Introduction: More than one third of inflammatory bowel disease patients (IBD) present periodic manifestations, with a more common, clearly the more incapacitating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Aims & Methods: The aim of the study was to evaluate the impact of a multidisciplinary approach carried out by both a rheumatologist and a gastroenterologist in the management of these patients. Therapeutic changes after the consultation were also evaluated. From April 2014 to April 2015, all IBD patients reporting articular pain to the IBD-dedicated gastroenterologist were referred to an experienced rheumatologist. The day of the consultation a multidisciplinary committee with a rheumatologist and a gastroenterologist assessed the patient’s status. In 41% (51.5% presented axial arthropathies) of patients, more common, clearly the more incapacitating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Conclusion: A multidisciplinary consultation combining inflammatory bowel disease and rheumatology allows both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD patients, though it is important that it is detected it should not be confused with the other rheumatological conditions.

Introduction: Adalimumab (ADA) is a anti-TNFα drug approved for patients with refractory luminal Crohn’s disease (CD). Recently, mucosal healing (MH) emerged as a major therapeutic goal in inflammatory bowel disease. Few data are available on ADA trough levels (TL), anti-ADA antibodies (AA) during long term follow-up of CD patients, and their potential association with MH and disease outcome.

Aims & Methods: The aim of our prospective study was to evaluate a possible association between achievement of MH, ADA TL, and AAA in CD patients. Moreover, we assessed the value of a possible association between clinical outcome and MH. We prospectively enrolled moderate to severe CD patients who were primary responders to ADA treatment. Blood samples were withdrawn at standardized time points during treatment (0-, 2-, 6-week and every 8 weeks thereafter), before ADA administration. ADA TL were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed by means of Harvey-Bradshaw Index (HBI, remission defined by HBI < 5). As to endoscopic activity, we defined MH in case

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
of a value of Crohn’s Disease Endoscopic Index of Severity below 8, so far we included patients with an active disease and a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least after 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males, median age 43 years, range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher ($P = 0.0002$) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 0–9 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, specificity 100%, sensitivity 81.8%, PPV 84.6%, VPN 100%). Moreover, achievement of MH was associated with absence of AAA ($P = 0.012$). Lastly, HBI was significantly lower ($P = 0.0002$) in patients with MH (4, range 3–8) than in patients without (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between higher ADA-therapy and disease activity development. In this study, in particular, a threshold of 6.43 mcg/mL has been identified as the best cut-off to obtain endoscopic remis-
sion or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease clinical activity. Thus, we draw the support of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

P1016 ULTRASONOGRAPHIC RESPONSE TO ANTI-TNF IS ASSOCIATED WITH BETTER OUTCOMES IN CROHN’S DISEASE

E. Calabrese1, F. Zorzi1, E. Lohi1, S. Onali1, M. C. Fantini1, L. Biancone1, C. Gervasi1, G. Cassano1
1Gastroenterology, Department Of Systems Medicine, University of Rome Tor Vergata, Rome/Italy

Contact E-mail Address: emma.calabrese@uniroma2.it

Introduction: Crohn’s disease (CD) management targets mucosal healing on ileocolitis as a treatment goal.

Aims & Methods: We hypothesized that ultrasonographic response to anti-TNFs is associated with better long-term outcomes. Patients with CD treated with anti-TNFs who had serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. Disease site (based on bowel wall thickness), extent of lesions, and presence of complications (stenosis, prestenotic dilation, abscess, or fistulas) were evaluated using SICUS. Inclusion required pre-therapy SICUS with follow-up SICUS after 12 months, or 2 SICUS ≥ 12 months apart while on maintenance therapy. At second SICUS, complete or improved responders had no new lesions, and partial responders had fewer new lesions, and partial responders had other scenarios. CD-related outcomes of corticosteroid need, hospitalization, and surgery were assessed at one year from the second SICUS.

Results: Seventy-nine CD patients treated with anti-TNFs (37% with Infliximab, 63% with Adalimumab) were identified. Most patients had ileal disease (67%) and strictureting phenotype (52%). Based on SICUS, thirty-six patients (46%) were complete sonographic responders, 30 partial (38%), and 15 non-responders (16%). Complete and partial responders at SICUS had a reduced risk for surgery in comparison with non responders ($p = 0.003$ (OR:3.46, CI:1.7–7.0), $p = 0.003$ (OR 12, CI:0.6–2.40)). Complete responders at SICUS had a reduced number of hospitalizations in comparison with non responders ($p = 0.04$ (OR 4.2, CI:1–18)), and complete or partial responders at SICUS had a reduced risk for need for rescue corticosteroids in comparison with non responders ($p = 0.005$ (OR:7.8, CI:1.9–32.4), $p = 0.002$ (OR 5.2, CI:1.7–15.3)).

Conclusion: Ultrasonographic response to medical therapy is associated with significant reductions in long-term risk of surgery, hospitalizations and steroid usage among CD patients. These findings suggest the significance of response assessed by ultrasonography as a treatment target.

Introduction: Inflammatory bowel disease (IBD) is characterized by recurrent flare of disease activity, which may lead to hospitalisations, surgery, and eventually disease progression. The exact role of psychosocial factors as triggers remains controversial and current literature focuses on the global presence of psychosocial symptoms preceding a flare instead of distinguishing pre-existing and novel symptoms. In this prospective study, we aim to explore the impact of newly developed symptoms of anxiety, depression, fatigue, psychological stress, and life events on IBD flares.

Aims & Methods: IBD patients were recruited from the MyIBDCoach study cohort (de Jong et al., Lancet 2017, in Press). MyIBDCoach is a telemedicine tool to monitor IBD patients at home. During the 12-month study period, participants reported on disease activity and psychosocial parameters (including psychological stress, anxiety, depression, fatigue, and life events) through MyIBDCoach every 1–3 months. Flares were defined as clinical disease activity in combination with one of the following: faecal calprotectin > 250 µg/g, disease activity on endoscopy or other imaging techniques, or dose escalation or initiation of a new drug to induce remission. For all psychosocial parameters, a binary variable was created to indicate whether symptoms were newly developed or pre-existing with reference to the previous measurement, thereby correcting for variability. A generalized estimating equation model was used to separately determine which psychosocial parameters were associated with flares in the three preceding months, correcting for immortal time bias after a flare and adjusting for gender, disease phenotype, smoking status and disease duration.

Results: In total, 2748 measurements from 381 IBD patients were included. Fifty-four (14%) and 16 (4.2%) flared after clinical remission was achieved. Newly developed psychological stress was associated with a flare in the following three months (odds ratio [OR] = 3.01; 95% CI = 1.48, 6.12). Newly reported symptoms of depression (OR = 1.29; 95% CI = 0.53, 3.14), anxiety (OR = 1.06; 95% CI = 0.46, 2.48), fatigue (OR = 0.76; 95% CI = 0.0, 4.15), or the occurrence of a life event (OR = 2.07; 95% CI = 0.94, 4.55) were not significantly associated, although the latter did occur more frequently before flares.

Conclusion: Newly developed psychological stress is associated with disease flares in IBD patients. Therefore, continuous monitoring combined with the use of interventions such as mindfulness and coaching might be interesting to prevent flares and eventually improve disease course.

Introduction: Strain elastography has become a new emerging technique in ultrasound diagnostics of gastrointestinal pathology. Currently there is few published data on the use of elastography for making the diagnosis and following the course of inflammatory bowel diseases.

Aims & Methods: Objective. To assess the accuracy of strain elastography concerning stricture detection in Crohn’s disease (CD).

Methods. Patients and Methods. 24 patients (43% females) were included into the study, 1 of them having a colonic stricture, 1 patient having a stricture of ileo-transverse anastomosis and 22 patients having a stricture in the small intestine. Surgical treatment was carried out in 22 patients, in each case histopathological examination of surgery specimens was conducted. We performed transcutaneous ultrasonic examination of the bowel using 7.5 MHz linear and 3.5 MHz convex probes with power Doppler mode and colonoception in all 24 patients. Strain elastography was used during each US-examination to differentiate inflammatory and fibrotic structures.

Results: Ultrasonic examination invariably showed local narrowing of the intestinal lumen in stricture sites. Inflammatory stricture length was 29 mm (21.1–55.5), (median (2.5th - 97.5th percentile)) with intestinal wall thickening of 6 mm (4.23–9.00) and the presence of ulcers. The lesion length in fibrotic structures was 30 mm (20–60), wall thickness – 6 mm (4.18–8.27), ulcers were visualized either. In 22.7% of cases we observed the signs of partial bowel obstruction. Strain ratio (SR) values for inflammatory structures were 1.53 (0.43–3.17), for fibrotic structures – 4.19 (1.57–6.42), the difference being statistically significant (Mann-Whitney test, p < 0.05). According to morphologic studies inflammatory structures were characterized by transmural inflammatory infiltration. In fibrotic structures we found fibrosis in submucosal layer with loci of muscularis propria involvement. No significant differences were found between ultrasonic and morphologic data, p > 0.05.
Disclosure of Interest: All authors have declared no conflicts of interest.

References

Conclusion: The proposed ultrasonic and elastographic signs of stricturizing CD facilitate preoperative detection and differential diagnosis of fibrotic and inflammatory strictures, helping to choose appropriate surgical treatment.

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability has been developed to address the spectrum of many other chronic diseases. Thus, specific tools have been used to assess the impact of disease and its treatment options on relevant end-points such as health-related quality of life (HRQL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations of functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics and HRQoL in a cohort of Sicilian patients with ulcerative colitis (UC) and Crohn’s disease (CD) follow up in a referral center.

Aims & Methods: IBD-DI and IBD-QI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activities and participation, body structures and environmental factors. IBD-DI consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional. Scores range from 1 (poorest QoL) to 7 (best QoL) with higher scores indicating better QoL. Disease activity was assessed by partial Mayo score for UC and by Harvey-Brandshaw Index for CD. The mean differences of DI score in relation to dichotomic clinical variables were performed by Student’s t-test. By linear regression analysis we assessed also the relationship between DI and IBD-Q. Differences between were regarded as statistically significant if p value was < 0.05.

Results: Data from UC and CD patients were analysed separately. 100 UC patients (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients had severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (72%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 28 patients (28%). The mean IBD-DI score was 23.15 ± 17.492; 62% of patients had low DI ≤ 25 (62/100) while 7% had high DI > 50. No correlations were found between IBD-DI and gender, disease duration, disease extension (Montreal Classification) and immunosuppressive therapy. IBD-DI was related to classical disease activity (p = 0.001) and extraintestinal manifestations (p = 0.005). By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² = 0.573, p < 0.001). Interestingly, 5% (n = 5) of patients with inactive or mild disease had severe disability (≥ 50) and 5% (n = 5) with active disease (≥ 50). CD patients (59%, males, median age 41 years) were enrolled; 22% were smokers. 94% had mild disease, 17 (6%) had severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 22 patients (40%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 32 patients (60%). The mean IBD-DI score was 20.17 ± 16.24; 72% of patients had low DI ≤ 25 (39/54) while only 2 patients had high DI > 50. No correlations were found between IBD-DI and disease characteristic (gender, disease duration, disease extension, extraintestinal manifestations) and linear regression analysis. IBD-DI was significantly associated with IBD-Q (R² = 0.604; p < 0.001).

Conclusion: Our preliminary results show that the IBD-DI is significantly related to HR-QoL both in UC and CD. In UC IBD-DI is also related to disease activity and presence of extraintestinal manifestations. However, most of our patients were in clinical remission. A larger sample with different grades of disease activity could provide a more accurate evaluation of the reliability of this tool in measuring functional status and disability in IBD. IBD-DI could become a major end-point in RCTs targeting the course of IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Aims & Methods: We conducted a prospective observational study at our tertiary care centre with the aim of assessing and correlating UC disease activity by clinical criteria, endoscopy, histology, serum and fecal biomarkers and PET-CT. 60 eligible patients of UC were enrolled into 3 groups (26 remission, 24 moderate and 10 severe activity) as per Mayo score and 18F FDG PET-CT was performed within 72 hours of endoscopy. ESR, CRP and fecal calprotectin levels were determined for all patients.

Results: Of 60 enrolled patients, 10% had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score (k = 0.465, p < 0.001), endoscopic sub-score (k = 0.526, p < 0.001), histological score (k = 0.496, p < 0.001), and fecal calprotectin levels (k = 0.279, p < 0.031). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation (k = 0.582, p < 0.001) with each other. We found that CRP at a cut-off level of 5 mg/L had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off level < 143 μg/g had a sensitivity of 82.35% and specificity of 88.46% to predict remission. Besides, PET-CT identified sacroiliitis in 1, mesenteric lymphadenopathy in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

P1023 THE IMPACT OF AN INFLAMMATORY BOWEL DISEASE EDUCATION CLINIC ON PATIENT OUTCOMES AND RESOURCE UTILISATION

W. On, B. Collins, H. Stanley, A. Westhoff, S. Tynan, D. Mcclements, V. Theis, J. Melindon, R. Chandy, A. Bassi

Gastroenterology, St Helens & Knowsley Teaching Hospitals NHS Trust, Liverpool/United Kingdom

Contact E-mail Address: weiheng.on@gmail.com

Introduction: Patient education and awareness in those who have inflammatory bowel disease (IBD) and is regarded by the United Kingdom (UK) IBD standards group as a key standard in the provision of care towards patients with IBD. Our district general hospital implemented an IBD education clinic in 2015 with the aim to provide a quarterly peer review by a multidisciplinary panel of doctors, specialists, nurses, pharmacists and dietitians. Patients who have been newly diagnosed with IBD are invited to attend this clinic. Clinic attendees are given an overview of their disease, treatment modalities, options of non-medical support (e.g: psychology) and are made aware of our telephone helpline open access service. To date, there has been no published data on the impact of an IBD education clinic on resource use or patient outcomes.

Aims & Methods: We aimed to evaluate the impact of the education clinic on resource use in patients who attended the clinic compared to patients who did not. A retrospective analysis was done of patients who were diagnosed with IBD between January 2013 and May 2015. 40 patients were identified and divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA).

Resource use was determined at 12 months from diagnosis in the NA group and 12 months from attendance in the CA group. The median time from diagnosis to clinic attendance in the CA group was 7 months. Data was obtained from our hospital’s electronic database system. Statistical analysis was carried out with the student’s t-test.

Results: The median age was 37 in the CA group and 33 in the NA group. In the CA group, 10 patients had ulcerative colitis (UC), 9 patients had Crohn’s Disease (CD) and 1 patient had unclassified IBD. In the NA group, 13 patients had UC and 7 patients had CD. The median of resource use and patient outcomes over a 12 month period (from diagnosis in the NA group and from clinic attendance in the CA group) is detailed in the table below.

Conclusion: In our cohort of patients, patients who attended the IBD education clinic were more likely to utilise our open access IBD telephone helpline service. There was a trend towards increased frequency of outpatient clinic appointments and blood tests in patients who did not attend the IBD education clinic although this was not statistically significant. There were no differences in the rates of hospital admissions or steroid courses in either group. The limitations of our data include the small sample size and short follow-up period.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1024 EMERGING ROLE OF IL-33/ST2 LEVELS IN PREDICTING PROLONGED RESPONSE TO ANTI-TNF THERAPY IN ULCERATIVE COLITIS

L.R. Lopetuso1, V. Petito1, C. Graziani2, T. T. Pizzaro2, F. Scaldaferri1, A. Gasbarrini1

1UOC Internal Medicine and Gastroenterology, Gastroenterology Area, Fondazione Policlinico A. Gemelli, Catholic University of Sacred Heart, Rome/Italy
2Pathology, Case Western Reserve University, Cleveland/United States of America/OH

Contact E-mail Address: lopetosoloric@libero.it

Introduction: Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be the mainstay of treatment for moderate-to-severe mucosal healing patients with moderate-to-severe Ulcerative Colitis (UC). The role of IL-33 and its receptor, ST2, in intestinal inflammation is incompletely understood, with both pro-inflammatory and regulatory properties described. Recent evidence has shown that anti-TNF is able to modulate IL-33 expression in inflammatory conditions. The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic MAYO score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). 24 UC patients (MAYO score at T0 ≥ 2) were enrolled. At each time point, serum samples were collected and ELISA performed to assess IL-33/ ST2 protein levels. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.

Results: IL-33 mRNA levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. non-responders at T0, with no differences between groups found at T2. Among responders, ST2 levels were dramatically reduced at T2 vs. T0. No significant differences were found in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared with other groups. IHC confirmed these observations. In particular, IL-33 and ST2 staining was more intense within the inflamed and ulcerated mucosa of responders compared to non-responders at T0. After 6 weeks, ST2 staining was even more evident in responders, notably localized to the healed mucosa and in close proximity to areas of re-epithelialization. No little to no staining for both IL-33 and ST2 was present in healthy controls.

Conclusion: Our results suggest a possible role for IL-33/ST2 in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF therapy. Further studies are underway to determine mechanisms of action that support these findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1026 CORRELATION BETWEEN CLINICAL, ENDOSCOPIC AND HISTOLOGICAL ACTIVITY IN INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE STUDY

B. Nori1, A. Rufia1, S. Romeo1, E. Grasso1, F. Zorzi1, G. Palmieri1, L. Biancone1

1Medicina Dei Sistemi, Universita degli studi di Roma Tor Vergata, Roma/Italy
2Anatomia Patologica, Universita degli studi di Roma Tor Vergata, Roma/Italy

Contact E-mail Address: benedettonegiri@gmail.com

Introduction: Several histological scores of activity have been developed in Inflammatory Bowel Disease (IBD). However, their usefulness in clinical practice and the correlation between clinical, endoscopic and histological scores is undefined.

Aims & Methods: To assess, in a prospective study, the correlation between clinical, endoscopic and histological activity scores in a cohort of IBD patients (pts) undergoing colonoscopy. Secondary end-point was to assess the role of histological scores in clinical practice. From Feb. to Dec. 2016, IBD pts undergoing colonoscopy according to clinical indication were enrolled. Inclusion criteria: 1. Diagnosis of IBD; 2. Age >18 and <80 yrs; 3. Regular follow up; 4. Indication for colonoscopy (i.e., clinical suspicion of activity or comorbidities). During colonoscopy, biopsies were taken ≥2 were biopsies were taken ≥1 macroscopically involved area and, possibly, from ≥1 uninvolved area. Clinical activity was assessed by the Mayo score (activity ≥3) for Ulcerative Colitis (UC) and the CDAI (activity ≥150) for Crohn’s Disease (CD) pts. All colonoscopies were performed by one IBD-dedicated gastroenterologist. Endoscopic activity was assessed in UC pts by the Mayo score (activity ≥2), and in CD by the Rutgeerts’ score (recurrence ≥2 or the SES-CD (activity ≥5), according to previous surgery. Histological activity was assessed by one pathologist using the Global Histologic Activity Score (GHAS) for CD (5) or the Geboes simplified score for UC (activity ≥1.6). Each of the 3 investigators was blind regarding the other results. Statistical analysis. Data expressed as median [range]. correlations assessed by the Spearman correlation test.

Results: IBD group included 107 pts. 67 [62.6%] UC (M 36 [53.7%], age 50 [24–80], UC duration 14 yrs [1–48]), 40 [37.4%] CD (M 24 [60%], age 46 [19–75], CD duration 14 yrs [1–36]). UC extent included: pancolitis in 34 (31%), left sided in 17 (20%), proximal in 16 (24%) pts. CD involved based on clinical (Harvey-Bradshaw score), biological and endoscopic or imaging techniques; partial or no response, as well as intensification decided by investigators were considered as non-remission patients. U-Mann Whitney test was used to assess association between IFX-TL and remission. ROC curves were included to obtain cut-off points for clinical use.

Results: 32 CD patients were screened, but finally 29 analysed, because 3 patients had IFX discontinued at week 14. Baseline characteristics included: 16 female: 52.5%, 31% smokers, 75.8% had inflammatory bowel disease patients, 44.8% inflammatory bowel activity, with 6.9% previous abdominal surgery and 86.2% on concomitant immunosuppressant, 34.8% non-naïve to biological therapy. On week 22, 44.8% patients were in remission; on week 54, 80.4% were in remission.
active in 5% (12%), in remission in 35% (88%) pts. Endoscopic activity: CD: Colonoscopy was incomplete in 2/20 pts. In the 24 pts with no previous surgery, SES-CD was: 0 (n = 4), 1 (n = 4), 2 (n = 3); 6 (n = 6); 8 (n = 7); 9 (n = 2); 10 (n = 1); 11 (n = 1); 12 (n = 1); 13 (n = 1); 14 (n = 1); 17 (n = 1); 19 (n = 1) pts (median 4 [0–19]; activity: 20/24 [80%]; remission: 4/24 [20%]). In the 16 pts with previous surgery, Rutgeerts’ score was: 0 (n = 3); 1 (n = 1); 2 (n = 6); 3 (n = 2) 4 (n = 4; recurrence: 12/16 [75%]). Histologic activity: CD: The GHAS was: 0 (n = 5); 1 (n = 1); 2 (n = 1); 3 (n = 4); 4 (n = 2); 5 (n = 1); 6 (n = 1) pts without previous surgery, and 0 (n = 3); 1 (n = 9); 2 (n = 1); 10 (n = 1) pts in previous surgery. In CD, the histologic score showed a slightly significant correlation with SES-CD (r = 0.41 ± 0.046) and no correlation with the Rutgeerts’ score (r = 0.31 ± 0.247).

Conclusion: In a prospective study, a significant correlation was observed between clinical, endoscopic and histological activity in UC. Histological activity may be observed in UC patients in endoscopic remission, thus suggesting that this finding may represent a predictive marker of clinical relapse.

Conclusion: Upon analysis of 57,861 infliximab and adalimumab patient samples from 2012−2016, 43% exhibited anti-drug antibodies. We found that low-titer antibodies do not appear to impact drug levels. Our findings are consistent with American Gastroenterological Association Critical Care Pathways for Crohn’s Disease, Ulcerative Colitis, and Crohn’s Disease where high antibody scenarios are managed very differently (increase drug/consider immunomodulator vs. switch drug within class). High resolution antibody assays may be helpful in dosing TNF inhibitors and in other treatment and management decisions.

**P1029 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN’S DISEASE**

C. Monast1, K. Li1, E. Myslik2, C. Brodmerkel2, J. Friedman3, F. Baribaud2
1 Janssen Research & Development, LLC, Spring House/United States of America/PA
2 Clarivate Analytics, Boston/United States of America/MA

**Contact E-mail Address:** emonast1@ITS.JNJ.com

**Introduction:** Biomarkers of inflammatory bowel disease activity have been researched for decades but objective markers of disease severity that support clinical decision-making are still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inflammation are best identified at the site of disease with a tissue-level assessment of disease activity.

**Aims & Methods:** Biopsy samples were obtained from participants in the UNITI trials of ustekinumab in moderate-to-severe Crohn’s disease. The UNITI induction trials included two cohorts, patients who failed ≥1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic flexure, and ileum. One biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (defined within the UNITI-1 and UNITI-2 cohorts).

**Results:** In UNITI-1, a single multivariate model comprising 16 genes was identified that predicted histological activities in rectum or splenic flexure biopsies. This model was characterized by $R^2 = 0.78$ for the training set, and $R^2 = 0.59$, 0.54, and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by $R^2 = 0.5$ for the training set and $R^2 = 0.45$ in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (I-TAC). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

**Conclusion:** Our analysis supports the ability of biopsy transcriptionomics combined with machine learning approaches to capture disease-relevant variability in Crohn’s disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identified specific genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring. Finally, the specific genes identified by our analysis provide insight into the molecular processes driving histological disease activity in Crohn’s disease.

**Introduction:** Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics’ relative efficacies.

**Aims & Methods:** A systematic literature review identified randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI < 150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn's disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work proposing a solution to this issue.

Aims & Methods: In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihood of response or remission than ADA given weekly (OR [CrI]: 1.36 [0.72; 2.58]) or every other week (85%, OR [CrI]: 1.41 [0.74; 2.68]).

Conclusion: This approach deals with methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihoods of response or remission than ADA given weekly (75%, OR [CrI]: 1.33 [0.83; 2.10]) or every other week (82%, OR [CrI]: 1.40 [0.74; 2.68]).

P1032 EFFICACY AND TOLERABILITY OF INITIATING, OR SWITCHING TO, INFILXIMAB BIOSIMILAR CT-P13 IN INFLAMMATORY BOWEL DISEASE (IBD): A LARGE SINGLE-CENTRE EXPERIENCE

R.P. Ratnakumar, N. To, D. Gracie, C. Seifinger, T. Clark, N. Carey, G. Dowson, K. Leigh, B. Bournier, A.C. Ford, P. J. Hamlin

Contact E-mail Address: raguprakash.ratnakumar@nhs.net

Introduction: Anti-TNF therapies have revolutionised the management of IBD. Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits with switches to CT-P13 with annual savings of £5400/patient (70 kg patient receiving 5 mg/kg w eakly). We present our experience of switching patients from the originator IFX to CT-P13 for new and existing patients.

Aims & Methods: Recorded baseline characteristics included indication, age, sex, disease duration, treatment duration, concomitant immunomodulators, baseline CRP and HBI/Mayo scores. Response to IFX induction was assessed retrospectively using symptoms and CRP. Treatment response and remission rates, primary and secondary loss of response, and adverse events in patients who initiated IFX in the 12 months pre-Feb 2016 were compared with those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was measured by the proportion of patients who continued with the original IFX.

Results: 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn's Disease (CD), 13 fistulising CD, 13 Ulcerative Colitis (UC)), 1 IBD-Undifferentiated (IBD-U) compared with 69 patients who commenced CT-P13 in the subsequent 12 months (23 CD, 9 fistulising CD, 35 UC, 3 BDU). Baseline characteristics did not differ, with a greater proportion of UC patients in the CT-P13 cohort (51% v 24.5% (p = 0.003)). This group had a higher mean CRP (20.2 v10.6 (p = 0.008)) although a lower median Mayo score (5 v 11 (p = 0.007)). There was no difference in response (12(23%) v 15 (21.74%) (p = 0.905)), remission (14(26%) v 29(42%) (p = 0.074)), primary non-response (8(15%) v 45.8% (p = 0.087)), secondary loss of response (12(23%) v 15(21.74%) (p = 0.905)), or adverse events (61(11%) v 68.7% (p = 0.629)) in those who initiated originator IFX compared with CT-P13.

Conclusion: Although the infliximab (IFX) biosimilar CT-P13 is an attractive alternative, further research is needed, particularly comparing with other biologics.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1033 SAFETY AND EFFICACY OF HELICOBACTER PYLORI ERADICATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

1Department Of Gastroenterology And Hepatology, Osaka University Graduate School of Medicine, Suita/Japan
2Department Of Gastroenterology And Hepatology, Tokyo Medical and Dental University, Tokyo/Japan
3Division Of Gastroenterology, Shiga University of medical science, Shiga/Japan
4Center For Advanced Ibd Research And Treatment, Kiskatsu University Kiskatsu Institute Hospital, Tokyo/Japan
5IBD Center, Sapporo Kosei General Hospital, Sapporo/Japan

Introduction: Helicobacter pylori (H. pylori) infection is a global health problem, which affects up to 50% of the world's population. Evidence suggests that H. pylori infection is associated with an increased risk of developing inflammatory bowel disease (IBD). The eradication of H. pylori in IBD patients can improve symptoms and reduce disease activity.

Aims & Methods: In patients with IBD who have documented H. pylori infection, the safety and efficacy of a standard triple therapy regimen were evaluated.

Results: A total of 50 patients with IBD and H. pylori infection were enrolled in the study. The overall eradication rate was 82% (41/50). No serious adverse events were reported.

Conclusion: The eradication of H. pylori in IBD patients is safe and effective. Further studies are needed to determine the long-term impact of H. pylori eradication on IBD outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Low prevalence of Helicobacter pylori (HP) infection has been reported in inflammatory bowel disease (IBD), however, it is unclear whether the eradication therapy for HP can exacerbate disease activity of IBD. We then aimed to clarify the safety and efficacy of HP eradication in patients with IBD.

Aims & Methods: This was a multicenter, retrospective cohort study in 26 institutions. Patients who eradicated HP by proton pump inhibitor and amoxicillin-based triple therapy after the diagnosis of IBD (ulcerative colitis (UC) or Crohn's disease (CD)) from March 2005 to July 2015 were enrolled. Two IBD patients without HP were excluded. The gender, age at diagnosis, severity, and observation period were matched with each HP-eradicated patient were enrolled in the same institution. Disease activity of IBD at baseline, 2 and 6 months after observation (eradication) was investigated. Eradication of IBD was defined as increase/addition of IBD drug, IBD-associated hospitalization or surgery; and physicians' assessment was also analyzed. Factors associated with exacerbation of IBD were assessed by univariate and multivariate logistic regression analysis.

Results: A total of 429 IBD (378 UC and 51 CD) patients, including 144 patients who eradicated HP (eradication group) and 285 control patients (non-eradication group), were enrolled. IBD exacerbation rates in 2 and 6 months of observation were 16.2% (16/102) and 11.8% (17/144) in eradication group, which showed no significant differences compared with those of 4.9% (14/285) and 7.7% (22/285) in non-eradication group. Physicians' assessment showed similar results in terms of disease exacerbation, but in 2 months of observation no patient was improved in eradication group whereas 3.2% (9/285) of patients was improved in non-eradication group (P = 0.019). Multivariate analysis revealed that the independent factor of IBD exacerbation after HP eradication was active disease at baseline (OR 5.3 (95%CI: 1.5–16.9), P = 0.001). HP was eradicated in 82.9% (102/123) of patients using clarithromycin as first-line treatment and 90.4% (19/21) using metronidazole as second-line, both of which were comparable with previous reports in non-IBD patients.

Conclusion: HP eradication therapy does not exacerbate disease activity of IBD without affecting its activity but may improve disease activity, suggesting that careful observation is necessary after eradication, especially for patients with active disease.

Introduction: According to infliximab (IFX) license in inflammatory bowel diseases (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duration of hospital stay and consequently costs. A pharmacokinetic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight pre-determined standard doses with a maximum theoretical deviation of $\pm 5\%$, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay (median hospital stay) in patients treated by IFX DB as compared to those treated by IFX WBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose below 250 and 800 mg were included in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reattributions and wasted infusions in the DBW and SB2 groups.

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238±21 min in the DB group and 308±32 min in the DB group, respectively (p<0.001). DB was associated with a mean reduction of length of stay of 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16m vs. 84 min with WBD (p<0.001). During the study, none of the 44 (0%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group (p=0.55). Two out these three infusions could be reattributed to other patients, saving 280€.

Conclusion: When used routinely in IBD, IFX DB is associated with a shorter length of hospital stay as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may improve functioning of daily hospitalisation units.

Introduction: Patients with gastrointestinal diseases such as inflammatory bowel disease (IBD) often suffer from iron deficiency anemia (IDA) and have a high annual iron need. Intravenous administration of high-dose iron is the most efficient approach to replenish iron stores. The present analysis evaluates safety and efficacy of high doses of iron isomaltoside in patients with gastrointestinal diseases.

Aims & Methods: This is a pooled analysis of 3 trials of iron isomaltoside performed in patients with gastrointestinal diseases and IDA [1–3]. Outcome measures were adverse drug reactions (ADR) and haemoglobin (Hb) measurements.

Results: 357 patients (108 men, 249 women) were included in the analysis of which 255 were diagnosed with IBD and 102 with other gastrointestinal diseases, incl. bariatric surgery, gastrointestinal bleeding etc. A cumulative dose of ≤1000 mg and >1000 mg iron isomaltoside was administered in 199 and 158 patients, respectively. ADRs were observed in 13.6% (36 events in 27 patients) and 12.0% (30 events in 19 patients) of the patients dosed with ≤1000 mg and >1000 mg iron isomaltoside, respectively (p = 0.8). Similar frequencies were observed in the IBD subgroup (14.3% versus 12.1%, p = 0.8). 0.5% of the patients experienced a serious ADR (2 events in 2 patients; grand mal convulsion and syncope). ADRs with a patient frequency >1% are shown in the table below:

No ADRs of hypophosphatemia were reported. In patients dosed with ≤1000 mg iron isomaltoside, Hb increased with a mean of 1.72 (95% confidence interval (CI): 0.13) g/dL to week 8. In patients dosed with >1000 mg iron isomaltoside, Hb increased with a mean of 2.00 (0.12) g/dL to week 4, and 2.32 (0.13) g/dL to week 8. In patients dosed with >1000 mg iron isomaltoside (p = 0.04). In the IBD subgroup, a similar dose-dependent statistically increase in Hb was observed at week 3 and onwards (p < 0.02).

Conclusion: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas Hb increased more after 3 weeks with doses >1000 mg. Thus, high doses (≥1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal side effects.

Introduction: Golimumab is an Anti TNF alpha antibody approved for the treatment of Ulcerative Colitis (UC) patients. Its efficacy and safety were studied in randomized, double blind trials1, 2, but its effectiveness and safety in daily clinical practice are still little known3.

Aims & Methods: The aim of this study was to assess the effectiveness and safety of Golimumab in daily clinical practice. All UC patients from 21 centers of south of Italy, treated with Golimumab, were consecutively enrolled starting from June 2015. Demographic information’s (age, gender, smoking status) and clinical data (extension and duration of UC, previous therapies, comorbidities) were collected. Clinical, laboratory and endoscopic data during the treatment with Golimumab were collected every three months.

Results: A total of 190 patients (120 males) were enrolled. The mean age at diagnosis and mean duration of disease were respectively 38.8±14.6 years, and 9.1± 7.0 years. Only 21 patients were active smokers (11%). About the extension, 111 were pancolitis (58%), 72 had distal colitis (38%) and 7 a proctitis (4%). At enrollment, the median Partial Mayo Score (PMS), Total Mayo Score (TMS) and Endoscopic Mayo Score (EMS), were respectively 6 (IQR 4–7), 9 (IQR 7–10), and 2 (IQR 2–3). The median values of ESR, C Reactive Protein and faecal calprotectin were respectively 25 mm/14 hour (IQR 15–38), 3 mg/dl (IQR 1–9), and 250 mg/kg (IQR 174–300). One hundred twenty five patients (66%) were naïve to anti TNF alpha, while 65 have been treated with Infliximab (n = 42), Adalimumab (n = 5) or both (n = 19). The indications for Golimumab were: 121 were primary UC (66%), steroid-dependence in 130 (68%), extra-intestinal manifestations in 6 (3%), and Anti TNF alpha failure in 17 (9%). Twenty two patients (12%) were treated with concomitant Golimumab and immunosuppressants. A total of 142 patients have been completed at least 3 months of therapy. Of these patients, a significant reduction of mean PMS (n = 142; p < 0.001), TMS (n = 45; p < 0.001), EMS (n = 45; p < 0.001), ESR (n = 125; p < 0.001), and CRP (n = 134; p < 0.001) were observed after 3 months. The rate of responders (reduction of ≥2 points of PMS) was 66%, while the rate of clinical remission (PMS < 2) was 39%, and the rate of mucosal healing (EMS ≤ 1) was 53%. Among the 85 responder patients, 67 (79%) have also completely discontinued the steroids. At univariate analysis for predictive factors of response (gender, duration of disease, smoking status, previous Anti TNF therapy)
TNF, combo therapy, PMS, EMS, TMS, ESR, CRP, calprotectin, and indication to the need of anti TNF (p<0.001), Table 2. CRP (p=0.001), PMS (p=0.001), TMS (p=0.001) and EMS (p=0.006) were associated with better response. About the indication, steroid-resistance was associated to the best response (p=0.002), while Anti TNF resistance with the worst response (p=0.002). At multivariate analysis only TMS (OR 1.5; CI 1.2-1.8) and Naive to Anti TNF alpha (p=0.015, OR 3.0; CI 1.2–7.5) were confirmed associated to better response. To date, only 33 patients have discontinued Golimumab (17%). A total of 15 adverse events (3 serious) were reported. Ten non-responder patients underwent to colectomy (7 of them were refractory to other anti TNF alpha).

Conclusion: Golimumab was effective and safe in induction of response in UC patients in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1040 OUTCOMES OF PATIENTS IN REMISSION WITH INFLAMMATORY BOWEL DISEASE WITH UNDETECTABLE INFliximAB TROUGH LEVELS AND POSITIVE ANTIBODIES TO INFliximAB

G.S.Z. Tun1, R. W. Downey1, K. Robinson1, A. Wright1, L. Marshall1, M. F. Hale1, A. J. Lobo1
1Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Introduction: The formation of antibodies to infliximab (ATI) is associated with decreased drug clearance. Patients with undetectable infliximab (IFX) levels and positive ATI may indicate a group who may no longer be benefiting from the drug. However, the optimal treatment decision when the patient is clinically well remains unclear.

Aims & Methods: The aim was to assess the course of disease in patients in remission, with undetectable IFX levels and positive antibodies. IFX trough levels and ATI were measured in all patients attending for IFX infusions from May 2016 to April 2017 at a large single referral centre. Results were retrospectively reviewed in March 2017 to identify patients with undetectable (<0.8 mg/L) IFX trough levels and positive ATI (>10 mg/L). A local guideline suggested that in well patients in all cohorts of patients, patients should be switched to an alternative biologic if duration of IFX treatment was <12 months, or if the duration of therapy was ≥12 months to consider withdrawal of IFX or to assess disease activity - with withdrawal of IFX in inactive disease or a switch to an alternative biologic for active disease. Trough levels for IFX and ATI were measured using direct capture immunosorbent assays (Biohit, UK). Relapse was defined as worsening of symptoms attributable to the inflammatory bowel disease, requiring an alteration in treatment. Kaplan-Meier with Tarone-Ware test was used to analyse survival curves for each group used to analyse the impact of the different treatment decision on the rate of relapse.

Results: 47/223 patients had undetectable IFX drug levels with positive ATI. Follow-up data was available in 45 patients. 17 patients were assessed as having active disease (2 primary, 15 secondary loss of response). Of the 28 in remission, 5 had all their symptoms and signs cleared within the 0.8 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab EU and infliximab US following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups.

Conclusion: A total of 148 subjects received study treatment (ABP 710: n=49; infliximab EU: n=49; infliximab US: n=50). After a single dose, the adjusted least square (LS) GM of AUC0-7 and Cmax were as follows: ABP 710, 33559 µg·mL⁻¹·h; infliximab EU, 33706 µg·mL⁻¹·h; infliximab US, 37523 µg·mL⁻¹·h; 127 µg·mL⁻¹; AUC0-28 of adjusted LS GM (90% CI) for AUC0-7 and Cmax between ABP 710 and infliximab EU were 0.996 (0.9042, 1.0963) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9848) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of AUC0-7 and Cmax between infliximab US and infliximab EU were 1.113 (1.0115, 1.2252) and 1.05 (0.9906, 1.1338). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab, as well as between infliximab EU and infliximab US. There were 14 deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study; 1 subject in the infliximab EU group developed polymyositis that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.8%; infliximab US: 86.0%); the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of study (Day 57), 51% of subjects on ABP 710, 27% of those on infliximab EU, and 32% on infliximab US were positive for binding ADAs; 13% on ABP 710, 19% in infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

Conclusion: Results of this study demonstrate PK similarity between ABP 710 and infliximab sourced from the EU and the US, as well as between infliximab EU and infliximab US following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups.

P1041 PHARMACOKINETIC SIMILARITY OF ABP 710 TO INFliximAB: RESULTS FROM A SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS

V. Chow, N. Zhang, P. Kaur, A. Kaliyaperumal, E. Krishnan
Amgen, Thousand Oaks/United States of America/CA

Contact Email Address: vchow@amgen.com

Introduction: ABP 710 is being developed as a biosimilar to infliximab, an anti-tumour necrosis factor monoclonal antibody. Analytical and functional comparability of ABP 710 and infliximab has been demonstrated. This report describes the results of a Phase 1 pharmacokinetic (PK) equivalence study comparing ABP 710 with infliximab

Aims & Methods: This was a single-blind, single-dose, 3-arm, parallel-group study in healthy adults, 18–45 years of age and with a body mass index of 18 to 30 kg/m². Subjects were randomised to receive a 5 mg/kg iv intravenous (IV) infusion of ABP 710 or infliximab sourced from the EU and the US after pre-treatment with an antimicrobial and acetaminophen 30 minutes prior to start of infusion. The primary objective was demonstration of PK similarity of ABP 710 with infliximab EU and with infliximab US based on area under the serum concentration-time curve from time 0 to infinity (AUC0–∞) as the primary endpoint.

V. Chow: I am a full time employee and stockholder of Amgen Inc N. Zhang: I am a full time employee and stockholder of Amgen Inc P. Kaur: I am a full time employee and stockholder of Amgen Inc A. Introduction: Complex perianal fistulas (CPF) are common among Crohn’s disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

Aims & Methods: To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000
VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHN’S DISEASE PATIENTS

Introduction: Vitamin D deficiency is common in patients with Crohn’s disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation has many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D (adjusted HR: 1.76; 95% CI: 0.84–3.67; p = 0.13).

Results: The study cohort consisted of 95 patients with a median age of 37 (IQR 27–48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10–36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 73% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04–3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84–3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SWIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

Abstract: P1042

Treatment | relapse/recurrence
---|---
Anti-TNF-α agents | 27 | 1 | 66
Infliximab | 3 | 6–52 | 41 | 1 | 52
Adalimumab | 4 | 9–38 | 0 | 1 | 9
Surgical interventions | 10 | 5–40 | 13–20 | 3 | 5–10
Combined medical and surgical management | 15 | 9–212 | 0–41 | 7 | 9–71
Standard of care | 4 | 15–250 | 23–66 | 3 | 79–250

44 studies reported treatment outcomes for CPF in CD patients. Most studies identified were small and/or non-comparative, and study methodologies, populations, endpoint definitions, and duration of follow-up varied. For studies with mixed populations, only results for patients with CD and CPF were considered. Defined as lack of or inadequate response to therapy (i.e. lack of complete response). Defined as standard of care used at each centre excluding anti-TNFs and surgery in 2 studies and as standard medical care at each centre including anti-TNF and surgery in 2 studies.
Adalimumab produces rapid improvement of quality of life since day 4. A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (13.3%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included in the statistical analysis (M/F 53/52, median age 43 years, CD/UC 42/40). Forty, 52 patients started IFX and ADA, respectively. QoL was significantly higher in CD than UC at baseline (median S-IBDQ 49 vs 59; p = 0.0001). In CD patients, anti-TNFα determined significant reduction of HBI (median 3 vs 1; p < 0.01), CRP (median 5 vs 2.9 mg/L; p < 0.004), fecal calprotectin (median 429 vs 119 μg/g; p = 0.001) but not haemoglobin (median 13.6 vs 13.2 g/dL; p = 0.25). QoL significantly improved (median S-IBDQ 49 vs 59; p < 0.001), both in IFX and ADA groups (IFX: p < 0.001; ADA: p = 0.02). In UC patients, anti-TNFα therapy improved disease activity (median MTWSI 7 vs 4; p = 0.013), haemoglobin levels (median 11.6 vs 13.2 g/dL; p = 0.006), fecal calprotectin (median 1660 vs 108 μg/g; p < 0.004), but not CRP (median 5 vs 2.9 mg/L; p = 0.08). QoL improved at 12 months (median S-IBDQ 32 vs 56; p = 0.001) both in patients treated with IFX (p = 0.003) and ADA (p = 0.005). No adverse events were reported during the study period.

Conclusion: Anti-TNFα therapy is safe and improves disease activity and quality of life of UC and CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1048 ENDOSCOPIC AND HISTOLOGIC FINDINGS CORRELATE WITH FREE INFLIXIMAB FOUND IN UNINFLAMED TISSUE IN IBD PATIENTS

H. Bar-Youseph, A. Blatt, S. Pressman, S. Gerassy, B. Ungar, S. Ben-Horin, Y. Chowers

1Gastroenterology, Rambam Health Care Campus, Haifa/Israel
2Gastroenterology, Chaim Sheba Medical Center Ramat Gan Israel, Ramat Gan/Israel

Contact E-mail Address: haggaiby@gmail.com

Introduction: Anti-TNFα agents are widely used in the treatment of inflammatory bowel diseases (IBD). Despite the fact that the intestine is the main therapeutic route of action of these agents, very limited data are available regarding the presence of anti-TNFα agents in non-inflamed tissue. The objective of this study was to evaluate the presence of anti-TNFα agents in uninflamed tissue within the colon of IBD patients.

Methods: A total of 6 adult IBD patients (4 UC and 2 CD) were included in this study. Endoscopic biopsies specimens were obtained from uninflamed mucosa adjacent to active disease. The biopsy specimens were snap frozen in liquid nitrogen and stored at -80°C. Free anti-TNFα was measured in the biopsy specimens using a commercially available ELISA assay. Histologic scores (HS) were assessed in the same biopsies using an immunohistochemistry method for TNFα.

Results: Free anti-TNFα was detected in uninflamed tissue in all the patients. The median HS was 0 (range 0-2). No correlation was found between free anti-TNFα and HS.

Conclusion: Free anti-TNFα is present in uninflamed tissue in IBD patients. The presence of free anti-TNFα in uninflamed tissue does not correlate with the histologic activity of the disease.

Disclosure of Interest: None declared.

Contact E-mail Address: haggaiby@gmail.com
target, little or no information is available regarding the ratios of free and TNF-bound infliximab in intestinal tissue.

Aims & Methods: We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of infliximab treated patients and TNF-bound and unbound infliximab were detected using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), serum TNF-bound infliximab levels, patient’s pharmacotherapy, clinical response based on physician global assessment (PGA) and endoscopic appearance (severity determined according to mayo scor- ing in ulcerative colitis and endoscopist’s assessment of ulceration severity, extent of disease and affected area in Crohn’s disease) and pathological results (severity determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman’s rank correlation test.

Results: Twenty four biopsies from 13 patients (11 Crohn’s disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not inflamed tissue levels, was correlated with SDL (R = 0.8499, p = 0.0077, FDR = 0.0185) and were negatively correlated with the endoscopic appearance (R = -0.7214, p = 0.0185) and pathological severity (R = -0.7095, p = 0.0059). TNF-bound infliximab was measured in both inflamed and non-inflamed speci- mens and did not correlate with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF- bound infliximab was measured in the serum.

Conclusion: These findings show that pharmacokinetic-pharmacodynamics inter- action, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies assessing changes during the process of mucosal healing may allow their use as surrogate markers for this process.

in just one of these 14 patients (1.4%) (p < 0.001). Median (IQR) TL were significantly higher in the ADA negative group compared to the ADA positive group [9.21 (7.00–12.99) vs. 3.45 (1.72–5.44) μg/mL, p < 0.001]. A significant correlation between TL and ADA levels could be found (Spearman's ρ = 0.562, p < 0.001). Although the presence of these ADA was not significantly associated with clinical remission at week 12, a clear tendency was observed (p = 0.136). During median (IQR) follow-up of 1.46 (0.32–3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation.

Importantly, escalation-free-survival significantly differed between ADA positive and negative patients (p < 0.001). Univariate analysis could not identify any more factors (weight, BMI, gender, disease behaviour, disease location, CRP, serum albumin, PRO2, concomitant therapy, smoking) associated with ADA presence at week 12. Interestingly, 50% of the ADA positive patients had TL above 4 μg/mL and would not have been dose optimized proactively according to current practice. Though, 3 out of these 7 patients needed dose-escalation afterwards which could have been expected based on the ADA positivity.

Conclusion: A drug-resistant assay can identify ADA to ADM before all drug has been neutralised and TL become undetectable. As these ADA at week 12 are significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 μg/mL, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

Results: Overall, data from 59 patients were analyzed. Of these, 27 (46%) were BN and 32 (54%) BE. Baseline patient’s characteristics and main study results are shown in Table 1. BN and BE patients were comparable in terms of comorbidity profile, age at diagnosis, disease duration, pattern of previous and concurrent conventional therapies, as well as of disease extension and severity. Overall, surgical intervention after GOL therapy was performed in 13 (22%) cases: 3 (11%) belonging to the BN and 10 (31%) and BE group, respectively (p = 0.2). In 10 (17%) patients AE’s were recorded, most of which were genitourinary or herpes simplex infections. Of note, two cases of basal cell carcinoma were registered. The rate of AEs did not significantly differ among the BN and BE groups (p = 0.2). In 5 (90%) patients AE’s were responsible for the discontinuation during the observational period. 4 of 4 (94%) patients who continued therapy, median IQR duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response to GOL. Clinical response was more similar in the BN and BE cohorts (p = 0.8). 28 (52%) patients were non-responders, without a statistically significant difference between the two groups (p = 0.8). At March 2017, 17 (31%) patients maintained clinical response, whereas 39 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Conclusion: In our cohort, clinical response at 3 months follow-up was obtained in almost half of patients while at the last follow-up in one third. BN and BE patients had similar results in terms of clinical response, even though we were unable to be a better early response in BN patients. Even if not statistically significant, surgery was required most frequently in the BE group. Rate of AE’s was acceptable and similar in both BN and BE patients. Although our findings need to be confirmed in larger studies, GOL appears to be safe and to achieve an acceptable disease control in both the biologic naïve and experienced setting.

P1054 ETROLIZUMAB TREATMENT IMPROVES HISTOLOGICAL ACTIVITY AS ASSESSED BY BOTH THE ROBARTS HISTOPATHOLOGY AND NANCY HISTOLOGICAL INDICES
1Nancy Univ Hospital, Lorraine Univ, Lorraine/France

Introduction: Etrolizumab, an anti-β7 monomolecular antibody targeting α4β7 and αEβ7 integrins, showed efficacy and safety versus placebo (PBO) during 10 weeks (wk) of induction in patients with moderate-to-severe ulcerative colitis in the Phase 2 EUCALYPTUS trial (Vermeire S. Lancet. 2014;384:309–18). Since a reduction in histologic inflammation has been linked with improved long-term clinical outcome (Yamaoka R. Gastroenterology 2016;150:408–14), it appears to be safe and to achieve an acceptable disease control in both the biologic naïve and experienced setting. Using both histologic and endoscopic assessments for efficacy evaluation, the effect of etrolizumab on histologic inflammation was evaluated in mucosal biopsies from EUCALYPTUS patients using the Roberts histopathology index (RHI; Mosh MH. Gut. 2017;66:50-8) and Nancy histological index (NHI; Marchal-Bressenot A. Gut. 2017;66:43–9).

Aims & Methods: 124 patients were randomly assigned (1:1:1) to receive subcutaneous etrolizumab (100 mg at wk 0, 4, and 8, with PBO at wk 2, or 420 mg loading dose at wk 0, followed by 300 mg at wk 2, 4, and 8) or PBO. Biopsies were taken using flexible sigmoidoscopy/full colonoscopy from the most inflamed colonic area within 10–40 cm from the anal verge at baseline (BL) and at wk 10. 62 patients provided consent for long-term sample storage for research; batch HE-stained slides were scored by a single pathologist using the Geboes scale (later converted to RHI) and NHI. At wk 10, mean changes in RHI and NHI scores for pooled etrolizumab or PBO were calculated. Subanalyses explored histologic response (reductions of ≥ 6 or 10 points or ≤ 50% improvement from BL RHI and ≥ 1 or ≥ 2 points from BL NHI remission (no neutrophils, RHI ≤ 4 and NHI = 0, ≤ 1 or 2) and correlation with endoscopic improvement.

Results: Analysis included 56 patients with BL data and BL NHI > 1. At wk 10, RHI and NHI scores decreased by a greater extent with etrolizumab compared with PBO, regardless of anti-tumor necrosis factor α (aTNF) experience (RHI: -8.4 vs –1.6; P = 0.032 and NHI: -1.2 vs –0.2; P = 0.011 for all comers). A greater proportion of etrolizumab-treated patients achieved categorical histologic improvement and remission with an endoscopic remission (HDI = 1) at wk 10 (n = 6), 100% experienced histologic response as assessed by RHI (5/5 with NHI non-missing at wk 10), and 83% (5/6) by NHI. Mean (SD) RHI changes were −19.2 (10.0) in patients with an ES ≤ 1 at wk 10 versus −4.4 (10.1) in patients with an ES > 1. Mean (SD) NHI changes were −2.5 (1.5) in patients with an ES ≤ 1 at wk 10 versus −0.6 (1.3) in patients with an ES > 1. Spearman’s
correlation coefficients between RHI and NHI were 0.82 at BL and 0.91 at wk 10, while both histologic scores were similarly correlated with ES (0.25–0.28 at BL and 0.38–0.40 at wk 10).

1*Must have achieved ≥1 point improvement
NHI 0 = no histologically significant disease
NHI 1 = chronic inflammatory infiltrate with no acute inflammatory infiltrate
NHI 2 = mildly active disease

Conclusion: Histologic activity assessment using RHI or NHI demonstrates improvement after wk 10 with etrolizumab treatment and was greater in aTNF-naive patients. Importantly, RHI or NHI reductions were associated with improved ES at wk 10.

Introduction: GO-COLITIS (NCT02092285; 2013-004533-56) is a phase 4, multi-centre, open-label, single-臂 trial in the UK assessing efficacy of golimumab (MedImmune) in induction and maintenance of clinical response in patients with moderate to severe ulcerative colitis (UC) resistant to conventional treatment. Results of the maintenance phase are presented here.

Aims & Methods: Anti-TNF-naive adults with UC ≥ 3 months who responded to induction therapy with subcutaneous golimumab at BL week 6, according to partial Mayo score (PMS, continued) to receive a maintenance dose of 50 mg or 100 mg GLM (dependent on the patient’s weight) every 4 weeks as per the Summary of Product Characteristics for a total of 54 weeks. Measurements were taken at week 6, week 36 and week 54. The primary endpoint was the proportion of patients meeting PMS response criteria at week 54 (defined as decrease in PMS ≥ 2 points and ≥30% from baseline, plus a decrease in rectal bleeding subscore of ≥1 point or absolute rectal bleeding score ≤ 1). Secondary endpoints included proportion of patients meeting PMS remission criteria at week 54 (defined as PMS <2 and no individual Mayo subscore >1), change from baseline in IBDQ and EQ-5D at each visit and normalization of CRP.

Results: Overall, 205 patients enrolled in GO-COLITIS and received at least one dose of GLM. Of these, 140 patients responded in the induction phase and received GLM in the maintenance phase. Clinical response was maintained through week 54 in 52/140 patients (37.1%; 95% CI, 29.1% to 45.7%) and 42/140 patients were in remission at week 54 (30.0%; 95% CI, 22.6% to 38.3%). Improvements in PMS subscores from baseline to week 54 were noted in stool frequency (mean change, −1.9; SD, 1.1 [n = 59]), rectal bleeding (mean change, −1.5; SD, 0.8 [n = 59]), and physician’s global assessment (mean change, −1.8; SD, 0.8 [n = 59]). Normal CRP levels at week 54 were seen in 30/59 patients (50.8%, 84.7%; 72.5%, 95% CI, 73.0% (to 92.8%). IBDQ and EQ-5D results are summarised in the Table. Serious adverse events (SAEs) occurred in 49/205 patients (23.9%), with 3 SAEs considered treatment-related.

Table: Mean (SD) Change from baseline to week 54 in IBDQ and EQ-5D.

</tbody>
</table>

Conclusion: In the maintenance treatment with GLM phase of GO-COLITIS, 37.1% and 30.0% of patients with moderate to severe UC in the UK demonstrated clinical response and remission at week 54, respectively. Improvements in patient-reported quality of life measures (IBDQ, EQ-5D) were seen; the degree of improvement in IBDQ total score exceeded the IBDQ increase cutoff (i.e. >20 for patient-defined remission previously identified as representative of a patient-defined improvement in an assessment of UC clinical endpoints.

Aims & Methods: The current pharmacological options achieve clinical remission (response rate, 84.7%; 95% CI, 73.0% (to 92.8%). IBDQ and EQ-5D results were consistent with previous observations.

Roche stock-holder S. R. Reddy: Employee of PHAR, LLC, paid by Genentech/Roche to conduct this research A.N. Ananthakrishnan: Consultant/Advisor for Abbvie, Janssen, and Merck Contact E-mail Address: thomas.knittel@indexpharma.com Introduction: Topical therapies for ulcerative colitis have shown evidence of good efficacy and can induce better responses and earlier improvement in distal ulcerative colitis (UC) when compared with oral therapies. Despite this attractive targeted approach of delivering medications topically to the left colon a certain resistance to the use of topical therapy seems to exist. Aims & Methods: The goal of this market research was to assess the familiarity with and perceptions of patients towards topical products. A qualitative market research study was performed in the USA and 3 European countries (Germany, UK and Italy). The primary patient recruitment sources were online web portals, e-mail campaigns and social networking sites. Informal feedback gathered from output of patient activists to identify the right sources was also used. In order to select patients with UC who had a shorter length of disease and/or a longer disease history current or past steroid medication was mandatory as a qualification for inclusion in the market research. A structured questionnaire covering 14 items was pre-tested and modified in phone interviews, which was then subsequently used in telephone interviews or as a web based interactive survey, both in local language. A total of 148 patient responses were obtained via 10 phone interviews and 138 web-survey, 60 patients came from the US, 27, 25 and 36 from Germany, UK and Italy, respectively. Results: In this survey cohort patients had been diagnosed with UC for >5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1–2 flare-ups each year, and less than a third of patients had them only rarely. ASA and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with oral products at some point during their treatment course. The majority stated that slightly lower number in the US (83%) compared to the EU countries (Range 89–92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painfull administration. Discussion: Despite a certain resistance to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resistance to use topical products in UC, less than 50% of the patients were actually concerned about the use of topical therapy in this study, thereby calling for better physician-patient communication.

influence the degree of SM a patient is willing to apply, such as: disease duration, active disease with ulcerative colitis, self-efficacy, patient's age, and level of trust between patient's and their IBD team. Caregivers were asked per item whether they thought this factor would be of influence and to name the three most important factors.

Results: 38 nurses (mean age 42 years) and 32 physicians (mean age 44 years) responded to the survey. The three most appealing options for nurses regarding SM were: availability of a SM web-app, Skype/Face-time consultation with nurse/physician, and an at-home faecal-calprotectin test. Physicians preferred the same type of SM web-app, an at-home faecal-calprotectin test, and making patients in charge of their patient records. When comparing the value of each of the 12 possible choices in which patients could apply SM, only one option was valued differently between nurses and physicians, 56% of physicians favoured patients being in charge of their records compared to 18% of nurses (p < 0.001). Physicians thought that the 3 most important factors influencing SM in patients were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor. Furthermore, nurses suggested that self-efficacy and disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patient's age was an important factor in patient's SM, compared to 34% of physicians (p < 0.001).

Conclusion: Our study indicates that, in contrast to disease characteristics, influence SM with self-efficacy being the most important. This study calls for further research on what patients and caregivers, want and need from SM, as SM is a team sport.

P1062 DISTINCT PATTERNS OF SHORT-CHAIN FATTY ACIDS IN PATIENTS WITH ULCERATIVE COLITIS EXPERIENCING A FLARE DURING TREATMENT WITH MESALAMINE OR A HERBAL PREPARATION

Contact E-mail Address: j.langhorst@kliniken-essen-mitte.de

Introduction: The combination of myrrh, chamomile flowers, and coffee charcoal has shown first evidence for potential efficacy in maintaining remission in ulcerative colitis. The SCFA are end products of the microbial fermentation of dietary fibers in the gut. They are involved in the regulation of the gut immune system, promote mineral absorption, lipid metabolism, mucin production and expression of antimicrobial peptides. UC patients often show reduced occurrence of SCFA especially in the proximal colon. This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Aims & Methods: The purpose of the present study was to evaluate the influence of mesalazine and of the herbal preparation on SCFA in ulcerative colitis. Analyses were performed as sub-study of a randomized double-blind, double-dummy, controlled clinical trial that has been published previously. Patients were treated with the herbal preparation consisted of 100 mg myrrh, 70 mg chamomile extract and 50 mg coffee charcoal (Myrrhital-Intest®, Repha GmbH, Hamburg, Germany). This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Results: A total of n=189 patients were included in the study. N=43 pts developed a clinical flare (descriptive statistics are shown in table 1). Patients who were treated with the SCFA showed a significant decline of the SCFA (M baseline = 66.12; SD = 39.59; M flare = 29.83; SD = 15.05; 95% BCI [18.86–58.60]) in the event of a flare. In contrast, patients who were treated with the herbal preparation showed no significant decline of the SCFA (M baseline = 64.80; SD = 53.74; M flare = 48.09; SD = 35.90; 95% BCI [-7.02–29.54]).

Conclusion: Findings show that the herbal preparation might induce different effects on the SCFA of patients with UC compared to mesalazine and therefore might exhibit different modes of action in treating UC. Since a decline of SCFA might lead to unfavorable health impairments like higher cancer risk, treatment options like the herbal preparation might yield additional beneficial effects in the treatment of UC. A combination of the two treatment modalities might be useful and should be investigated in further studies.

P1063 GRANULOCYTE-MONOCYTE APHERESIS (GMA) IN DIFFICULT-TO-TREAT INFLAMMATORY BOWEL DISEASE (IBD): A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Caroli, F. Lamboglia, I. Francenhet, C. Pozzan, D. Checchin, F. Bortoluzzi, R. Cappuccio, A. Vitalba

OUC di Gastroenterologia, Ospedale dell’Angelo, Mestre; Ospedale SS Giovanni e Paolo, Venezia, Mestre-Venezia/Italy

Contact E-mail Address: alessandro.caroli@uls12.ve.it

Introduction: Selective GMA using Adacolumn® device is a non-pharmacological therapeutic option for patients affected by IBD, but its precise role among the various treatments available and its true effectiveness are still debated. In particular, steroid-dependent patients, refractory or intolerant to immunosuppressant and biologics, represent a sub-group of patients with limited options of treatment. Recently, a multicentric open-label trial [the ART trial 1] showed, for the first time, a clinical benefit of GMA in these problematic patients.

Aims & Methods: The aim of this study was to further evaluate, in our real-life clinical experience, the efficacy and safety of GMA in these difficult-to-treat patients. We retrospectively reviewed the clinical data of patients treated with GMA-Adacolumn® in our center between 1/1/2008 and 31/12/2014. Only steroid-dependent and/or AZA/IFX/ADA-resistant or intolerant cases were considered. GMA was performed once a week for a minimum of five consecutive weeks. Occasionally, one or two additional sessions were performed. A clinical response was defined as a ≥ 3 points improvement in the clinical activity index (CAI) for ulcerative colitis (UC) and a ≥ 100 points reduction of the Crohn disease activity index (CDAI) for Crohn disease (CD) after 12 weeks from the beginning of the treatment.

Results: The study population included a total of 30 patients (17 males, 13 females, mean age 49 years, range 21–73) affected by UC (20 patients) and CD (10 patients). Eight patients (5 UC, 3 CD) were excluded from the final analysis for incomplete data. In the remaining 22 patients, a clinical response was observed in 15 (68%). The response was better in UC (11/15 [73%]) than in CD (4/7 [57%]). A steroid-sparing effect was observed in all responsive patients. GMA was generally well tolerated, as only 4 patients (13%) reported mild adverse events (headache in two, hypotension in one, vascular procedure complication in one) and no patients discontinued the apheresis due to the adverse events.

Conclusion: In our real-life single-center experience, focused to a selected group of difficult-to-treat patients affected by IBD, GMA with Adacolumn® seems to be, in a short-time evaluation, a useful and safe option of treatment, supporting the recent data from the ART trial. Prospective randomized trials in larger series of patients and with more extended follow-up are needed to confirm these results.

challenged human macrophages (THP-1) was investigated respectively using an IL8; CXCL10; CXCL13 release from cytokine-(10 ng/mL TNF IL1)

Aims & Methods: The present study aims to investigate the influence of the single and combined herbal extracts with regard to its anti-inflammatory and immune-modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isotonic pressure measurement in isolated rat small intestinal preparations. Furthermore, chemokine (IL8; CXCL10; CXCL13) release from LPS-stimulated human macrophages (THP-1). The IL8 was investigated respectively using an ELISA test system. Budesonide served as positive control. To characterize the combined effect, concentration-response relations of single components and the herbal combination were compared and IC50 values derived. Interpretation of the data was based on a dose reduction index (DRI = IC50(single)/IC50(combined)). which estimates the extent to which the dose of one or more components in the combination can be reduced to achieve effect levels that are comparable with those achieved with single component.

Results: Myrrh and chamomile flower extract exerted spasmolytic effects by inhibiting acetylcholine-induced contractions in rat small intestinal preparations (IC50: myrrh = 144 μg/mL; chamomile flower = 383 μg/mL). In combination, the chamomile flower and myrrh interacted additively (IC50: myrrh = 5 μg/mL; chamomile flower = 22 μg/mL; coffee charcoal = 29 μg/mL) achieving with single component. Synergistic effects exerted by the herbal combination in inhibiting CXCL13 release significantly reduced IC50 values (IC50: myrrh = 106 μg/mL; chamomile flower = 41 μg/mL; coffee charcoal = 364 μg/mL; coffee charcoal = 447 μg/mL) with comparably high IC50 values. However, application of the herbal combination, significantly reduced the IC50 of the plant extracts (myrrh = 25 μg/mL; DRI = 1.7; chamomile flower=IC50 = 124 μg/mL; DRI = 2.9; coffee charcoal=IC50 = 124 μg/mL; DRI = 3.6). IL8 release from cyto-kine-challenged Caco2 cells was inhibited after myrrh (IC50 = 3 μg/mL; 28% max inhib.) and coffee charcoal (IC50 = 218 μg/mL; 75% max inhib.) but increased after chamomile flower treatment (IC50 = 39 μg/mL; 29% max stim.). Treatment with all three plant extracts resulted in a moderate IL8 inhibition with an inverted U-shape concentration-response curve (IC50: myrrh = 56 μg/mL; coffee charcoal = 281 μg/mL; 77% max inhib.).

Conclusion: The herbal components myrrh, chamomile flower and coffee charcoal influenced chemokine signalling of stimulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower additionally exerted anti-inflammatory effects. Synergistic and additive effects between the plant extracts justify the inclusion of the composition of the traditional herbal medicinal product (Myrrhinil-Intest®) and its application for the treatment of inflammatory intestinal disorders.

P1066 IMMUNOSUPPRESSIVE CO-TREATMENT WITH INFliximab and ADALIMUMAB IS NOT SUPERIOR TO ANTI-TNF MONOTHERAPY TO PREVENT TREATMENT FAILURE AND TREATMENT DISCONTINUATION IN ULCERATIVE COLITIS S. Vieujean1, E. Louis2, C. Reenaers3
1Gastroenterology, CHU Liege, Liege, Belgium
2University Hospital CHU of Liege, Liege, Belgium
Contact E-mail Address: catherine.reenaers@chu.ucl.ac.be

Introduction: In Crohn’s disease there is clear benefit from combination therapy with infliximab (IFX) and immunosuppressive drugs (IS), while the benefit seems more limited for adalimumab (ADA). Although some studies suggest a benefit of combination therapy with IFX in ulcerative colitis (UC) few data are available in UC.

Aims & Methods: Our aim was to compare real life efficacy of anti-TNF mono-therapy (IFX and ADA) and anti-TNF + IS for UC maintenance. This was a retrospective study of patients with UC treated with IFX or ADA in 2 Belgian academic and regional Hospitals. Patients included in the study were 723 UC patients divided into 3 groups: IFX, ADA, and IFX + IS. Concomitant IS was considered as monotherapy if the patient relapsed and was treated with IFX or ADA for at least 3 months. Failure was defined as persistence of symptoms during double drug treatment or early relapse of some of them.

Results: 478 patients in 60 patients with IFX and 175 semesters in 33 patients with ADA were included. The mean IFX and ADA treatment duration were respectively 49 (±23) months and 38 (±19) months. Within patients treated with IFX, 32/60 patients received IFX + IS during the first semester. IFX was administrated as monotherapy in 361/478 semesters (76%). Respectively 218/478 (46%) and 78/478 semesters (16%) with IFX required dose escalation and corticosteroids course. IFX + IS was associated with more semesters with failure (5% vs 3%, p = 0.02) and numerically more semesters with dose reduction (64% vs 28%, p = 0.06). There was no difference in corticosteroids use (p = 0.63). IS during the first semester was not associated with lower risk of IFX failure (p = 0.41) nor with a longer survival without IFX withdrawal (p = 0.20). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.18). Within patients treated with ADA, 19/33 patients received IS during the first semester. ADA was administered as monotherapy in 93/175 semesters (55%). Respectively 54/175 (48%) and 42/175 (24%) semesters with IS during the first semester was associated with lower risk of ADA failure (p = 0.01) and with a longer survival without ADA withdrawal (p = 0.78). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.20).

Conclusion: In this real-life experience, combination therapy of IFX or ADA with IS during the first semester or prolonged after the first semester was not associated with less dose escalations, steroid courses or treatment failures.

Introduction: Intestinal permeability may lead to bowel damage and clinical manifestations. Thus, environmental factors and, in particular, food intake may play a pivotal role in IBD pathogenesis.

Aims & Methods: The aim of this prospective study was to evaluate the effects of a 6-week low fermentable Oligosaccharides, disaccharides, monosaccharides and polyols (FODMAP) diet on disease activity and quality of life in patients with IBD. At first visit (T0), patients were clinically evaluated by a gastroenterologist and a nutritionist, filled a questionnaire on quality of life (the IBD-Q) and underwent blood tests as well as fecal calprotectin assessment. Disease activity was defined using the Mayo score and the Harvey Bradshaw Index (HBI) for UC and CD, respectively. After the baseline visit, patients were randomized into two groups: A) patients underwent a low FODMAP diet; B) patients underwent a diet with normal FODMAP amount. A food diary was used to assess patients’ adherence to the different diets. After six weeks (T1), patients had a second visit to assess disease activity, complete the IBD-Q, and repeat blood tests as well as fecal calprotectin assessment.

Results: In this prospective, interventional, cohort study, we enrolled 55 consecutive IBD patients who agreed to participate from an initial cohort of 127 IBD patients. Twenty-six patients were randomised to a low FODMAP diet (group A), while 29 patients to a standard FODMAP diet (group B). Among CD patients (n=35, 63.6%), median HBI values significantly decreased during the study, in the whole population and in group A, whereas no change was recorded in group B (respectively, P=0.02; F=0.02; P=0.3). Among UC patients (n=28, 36.4%), median Mayo scores did not significantly decrease during the study, both considering the whole population and the two groups (P=0.3, P=0.3, and P=0.8, respectively). Moreover, despite no statistically significant difference in quality of life in both groups at T0, in group A quality of life improved after the diet compared to group B (respectively, P=0.06, P=0.05 and P=1).

Conclusion: We demonstrated that a low FODMAP diet, for a limited period of 6 weeks, is able to improve both disease activity, at least for CD, and quality of life in IBD patients. Further, larger multicentre studies are needed to confirm these preliminary data.

Disclosure of Interest: All authors have declared no conflicts of interest.

From January 2015 to May 2016, twelve CD patients were treated with ustekinumab, all because of failure of several lines of therapies including anti-TNF antibodies. All but one patient were followed at least one year. An initial response was achieved in 9 (75%) patients, and remission in 5 (42%). At one year, the nine responders were still receiving ustekinumab with clinical benefit and without steroids need. Seven of them (58%) were on clinical remission. One patient experienced a sustained response to infliximab in patients with Crohn's disease.

PI073 RELATIONSHIP BETWEEN CLINICAL COURSE OF ULCERATIVE COLITIS (UC) DURING PREGNANCY AND OUTCOMES OF PREGNANCY: A RETROSPECTIVE EVALUATION STUDY
A. Ito, O. Teppeli, T. Katutishi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo/Japan
Contact E-mail Address: itoayumi@iee.twmu.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic, intractable disease with a long clinical course. UC has a marked influence on the lifestyle of patients, and its effects on pregnancy and childbirth can especially become a problem for women in their child-bearing years. Various studies have suggested that it is desirable for pregnant women with UC to give birth while remaining in a state of remission.

Aims & Methods: The present study evaluated pregnant women with UC attending our hospital who became pregnant during remission, in order to examine the factors that contributed to recurrence of UC during pregnancy. We investigated 40 pregnant patients in remission (44 cases) attending our hospital during January 2008 and July 2016 who had remained in remission for one year prior to pregnancy. After becoming pregnant while in remission, patients who stayed in remission until delivery were classified into the ongoing remission group (35 cases) and patients with recurrence during pregnancy were classified into the recurrence group (9 cases). Remission was defined as a Lichtiger clinical activity index (CAI) of less than 4. Relapse was defined as a CAI ≥ 5 with the need for initiation or dose escalation of steroids or administration of biological agents during pregnancy. Items examined: Clinical characteristics (age at onset, disease duration, age of becoming pregnant, disease type, and treatment), the CAI in the first, second, and third trimesters, and whether or not patients continued treatment during pregnancy were examined and compared between the two groups.

Results: There were significant differences between the two groups with respect to the age of becoming pregnant (32.9 ± 4.4 years in the ongoing remission group vs. 28.3 ± 7.0 years in the recurrence group), the CAI in the second trimester (2.9 ± 4.6 vs. 3.5 ± 1.6), the CAI in the third trimester (2.9 ± 0.7 vs. 5.4 ± 2.0), and whether oral treatment was continued (continuation of treatment [yes:no]; 30:5 in the ongoing remission group vs. 5:4 in the recurrence group). Regarding the discontinuation of oral treatment, two patients in the ongoing remission group and one patient in the recurrence group discontinued it on their own judgment, while two patients in the recurrence group discontinued it due to hyperemia. Discussion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemia. With regard to the effects of medications on the fetus, medical staff should provide an explanation about the safety of treatment and should be aware that patients may have various concerns about drug therapy. If patients have difficulty continuing oral treatment due to severe hyperemia, administration of long-term treatment should be considered.

Conclusion: During pregnancy, it is important to continue treatment for UC so that patients can give birth while remaining in remission. Accordingly, intervention by medical staff is particularly necessary in order to provide pregnant women with information and explanations regarding treatment.

Introduction: In patients with active ulcerative colitis (UC), myeloid lineage leukocytes are known to be elevated with activation behaviour, including the CD14+ CD16+ DR++ monocyte phenotype, which is a major source of tumour necrosis factor-α. Therefore, selective depletion of myeloid leukocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adsorban is expected to promote remission, or enhance drug efficacy. Potentially, GMA should be a relevant treatment option in patients in whom drug therapy has limitations.

Aims & Methods: Our major objective was to apply GMA as remission induction therapy in paediatrics and adolescents, as when first-line 5-aminosalicylates had failed. Thirty consecutive patients with active ulcerative colitis (UC), aged 11–19 years, body weight 33–55.5 kg were selected. Of the 30 patients, 27 received GMA with an Adsorban, at 2 sessions in the first week, then weekly, up to 11 sessions. Patients who achieved ≥50 decrease in the clinical activity index (CAI) after 5
GMA sessions continued with GMA while non-responders received GMA in combination with a low dose prednisolone. 0.5 to 1.0 mg/kg bodyweight. At entry and week 12, patients were clinically and endoscopically evaluated with each patient serving as her or his own control.

**Results:** At entry, all 30 patients were corticosteroid naïve and none had deep colectomy or any extensive loss of the mucosal tissue at the affected sites (GMA non-responders features). Ten patients achieved stable remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received prednisolone together with GMA, while 12 patients responded well to GMA, and achieved stable remission, but 2 patients withdrew to receive high dose prednisolone (up to 2 mg/kg bodyweight). At entry, the average CAI was 14 ± 0.4. Prednisolone was tapered to 0 mg within 3 months in those who received. Therefore, at week 12, all 30 patients were in remission, majority with mucosal healing.

**Conclusion:** In this treatment design, GMA in young corticosteroid naïve patients with active UC refractory to the first-line 5 -aminosalicylates was associated with clinical remission and mucosal healing, while in non-responders to GMA mono-therapy, addition of a low dose prednisolone may mask the efficacy of GMA and tapering of the prednisolone dose was not associated with relapse. Therefore, the majority of young steroid naïve UC patients who fail to respond to first-line 5-aminosalicylates should respond well to GMA and avoid pharmacologicals. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

**Conclusion:** In our cohort 35% of children presenting with AILD were subsequently diagnosed with IBD. Possible risk factors for development of IBD in AILD were low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IBD in the context of AILD. As current immunosuppression may mask mild symptoms and signs of IBD a lower threshold for endoscopy should be considered in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Results: Twenty-one patients with chronic refractory angiodyplasia bleeding were recruited in this study, included 10 women, aged between 40–85; 11 cases of massive age between 31–70. One patient with colic vascular malformation died of massive hemorrhage due to self withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1) Eight patients come across constipation, sleepiness and dry mouth. There were no skin rashes, peripheral neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2). The red blood cell after treatment (3.38 ± 0.60 × 10^12/L); hemoglobin after treatment (94.7 ± 13.15 g/L) compared with before treatment (83.2 ± 17.6 g/L); HCT after treatment (32.0 ± 0.05) compared with before treatment (0.29 ± 0.08); the difference was statistically significant (P < 0.05). (3). The ALT after treatment (32.9 ± 18.51 U/L) compared with before treatment (30.6 ± 12.8 U/L); AST after treatment (28.1 ± 8.56 U/L) compared with before (28.0 ± 12.4 U/L); γ-GT after treatment (34.4 ± 8.4 U/L) compared with before (35.6 ± 12.7 U/L); AKP after treatment (85.5 ± 19.8 U/L) compared with before (83.0 ± 20.8 U/L); ALB after treatment (36.2 ± 3.1 g/L) compared with before (36.3 ± 4.3 g/L); there was no statistically significant difference (P > 0.05). (4). Prothrombin time (PT) after treatment (12.1 ± 1.3 s) compared with before (11.8 ± 1.4 s); APTT after treatment (30.2 ± 3.7 s), compared with before (31.0 ± 6.2 s); the difference was not statistically significant (P > 0.05). (5). 6 cases of colonic capillary malformation review colonoscopy, and the vascular malformation improved significantly after treatment. Conclusion: Thalidomide, with its antiangiogenic mechanism of action, seems to be a promising drug in bleeding angiodyplasia as a treatment option for patients unable to benefit from other available modalities of treatment. The study drug was well tolerated.

Introduction: Colon diverticular bleeding is the most common cause of lower gastrointestinal bleeding. We have reported the preliminary safety results of endoscopic detachable snare ligation (EDSL), a new method for diverticular hemorrhage1. The bleeding diverticulum was ligated with a detachable snare. Unlike the endoscopic band ligation, removal of the scope to attach a ligation device and reinserter for treatment are not needed in this method. We performed a clinical trial to evaluate the efficacy and safety of EDSL.

Aims & Methods: This multicenter single arm phase II study was conducted in 12 Japanese hospitals. Patients suspected of diverticular bleeding were enrolled from June 2015 to March 2017. Patients with serious heart, renal, or liver failure, sepsis, disseminated intravascular coagulation, and high-dose steroid use (prednisolone dosage > 10 mg/day) were excluded. The primary endpoint was the early (within 1 month) rebleeding rate in patients who were treated with EDSL. The secondary endpoints were overall early rebleeding rate in patients who had colon diverticular bleeding treated with EDSL; prior to fundus appearance of EDSL; success rate of EDSL total procedure time, EDSL procedure time, identification rate of bleeding diverticula, and adverse events. This study was approved by the ethics committee of each participating hospital and conformed to the Helsinki Declaration and the Japanese Clinical Research Guidelines.

Results: Of 123 patients with diverticular hemorrhage, 101 were treated with EDSL and the early rebleeding rate was 5% (5/101). The rebleeding rate in ITT population was 9% (11/123). Success rate of EDSL was 78% (96/123). EDSL was an effective, safe, and convenient treatment method for colonic diverticular hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1080 RISK FACTORS FOR EARLY AND LATE RE-BLEEDING IN PATIENTS WITH COLONIC DIVERTICULAR BLEEDING
Gastroenterology And Hepatology, St. Marianna Medical University, Kawasaki/ Japan

Contact E-mail Address: y2satou@marianna-u.ac.jp

Introduction: Incidence of colonic diverticular bleeding has increased in recent years. Colonic diverticular bleeding is problematic because of the following reasons: the low detection rate of the bleeding source by endoscopy and frequent re-bleeding. At our hospital, we have a policy of performing emergency lower gastrointestinal endoscopy for all patients with colonic diverticular bleeding within 24 h of their admission. We have reported that the following factors could contribute to the successful identification of the bleeding source: extraction revealed by abdominal contrast computed tomography (CT), and mounting of a hood to the tip of an endoscope during lower gastrointestinal endoscopy. However, risk factors for re-bleeding in patients with colonic diverticular bleeding were still unknown.

Aims & Methods: In this study, we examined the risk factors for early and late re-bleeding in patients with colonic diverticular bleeding. From January 2004 to April 2016, we admitted 432 patients (285men and 147 women, mean age: 71 ± 12 years) to our hospital for treatment following a diagnosis of colonic diverticular bleeding based on abdominal CT and endoscopy findings. Early and late re-bleeding was defined as macroscopically bloody stools as a result of colonic diverticular bleeding during hospitalization and after discharge, respectively. Risk factors for early and late re-bleeding were retrospectively examined using univariate and multivariate analysis.

Results: Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years). The mean duration until re-bleeding was 3.9 ± 2.4 days, and the average, early re-bleeding recurred 1.7 ± 1.2 times. On average, lower gastrointestinal endoscopy was performed 2.7 ± 1.2 times and endoscopic hemos- static treatment was performed 1.0 ± 1.0 times. In the univariate analysis, significant differences were seen in males (P = 0.005), in the use of oral antplatelet agents (P = 0.012), and in patients not undergoing endoscopic hemostasis (P = 0.004). In the multivariate analysis, male gender (P = 0.006; odds ratio 2.06, 95%CI 1.23–3.44), the use of oral antplatelet agents (P = 0.008; odds ratio 1.85, 95%CI 1.17–2.93), and patients not undergoing endoscopic hemostasis (P = 0.005; odds ratio 1.5, 95%CI 1.31–1.81) were independent risk factors for early re-bleeding. Late re-bleeding was seen in 72 of 345 patients who were able to follow up (21%; 46 men and 26 women, mean age: 73 ± 12 years). The mean duration until late re-bleeding was 41 ± 40 months, and on average, late re-bleed- ing recurred 1.5 ± 1.2 times. Only the use of oral antplatelet agents (P = 0.05; odds ratio 1.72, 95%CI 0.98–2.98) was identified as an independent risk factor for late re-bleeding in the univariate and multivariate analysis.

Conclusion: Not undergoing endoscopic hemostasis and male gender were identified as risk factors for early re-bleeding, indicating the importance of choosing measures and hemostatic treatments to improve the detection rate of bleeding sources during endoscopy. The use of oral antplatelet agents was a risk factor for both early and late re-bleeding, suggesting the need for patient management through multi-departmental cooperation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Aim & Methods: Retrospective study. Emergency consecutive admissions for ALGIB were reviewed. Severe ALGIB was defined as transfusion of ≥ 2 units of packed red blood cells (PRBC) and/or hematocrit decrease of ≥ 20% within the first 24 h and/or recurrent bleeding after 24 h of stability. NOBLADS score was calculated and its discriminative capacity for severe ALGIB as well as for other outcomes was assessed.

Results: Included 118 patients with a mean age of 73.4 ± 14.4 years and 52.5% males. Most frequent etiologies for ALGIB were diverticular bleeding (23.7%) and post-polypectomy (21.2%). ALGIB was severe in 38.1% of patients. NOBLADS score showed a weak discriminative capacity to determine severe ALGIB (AUC = 0.68, p < 0.01). However, when comparing patients with NOBLADS ≤ 4 and > 4, patients with higher scores were significantly older (69.2 ± 15.7 years vs 78.6 ± 10.0 years, p < 0.01), had lower hemoglobin levels as admission (10.2 ± 2.5 vs 11.1 ± 2.9 g/dL, p < 0.01), were transfused with more units of PRBCs during the first 24 h and during hospital in-stay (0.4 ± 0.9 vs 1.1 ± 1.3, p < 0.01 and 1.0 ± 2.2 vs 3.0 ± 3.3, p < 0.01, respectively) and were more frequently admitted to intermediate care units (35.2% vs 59.6%, p < 0.01). No differences were found between the two groups regarding in-stay length, bleeding rate, need for surgery or death.

Conclusion: NOBLADS score showed a weak discriminative capacity to determine severe ALGIB however, patients with NOBLADS ≤ 4 had greater PRBCs transfusion need and were more frequently admitted to intermediate care units. New or improved scores that can predict severe ALGIB are needed to determine more precisely appropriate care and to allow for a standardized approach.

Conclusion: In 20–80 μg/Hgb/stool there were CRCs with smaller size, no invasion, in the proximal colon, Dukes A except for intra-mucosal CRCs and so on. When the cut off value is raised over 80 μg/Hgb/stool, the detection of early stage CRCs and proximal CRCs may be lost. There were many advanced CRCs with concentration over 200 μg/Hgb/stool. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCs can be discovered more likely in the proximal colon? It may be related to the fact that the number of detectable CRCs in the distal colon are more than in the distal colon. We will go on researching mechanism about this.

P1084 COLONOSCOPY SURVEILLANCE DETECTS A HIGH PREVALENCE OF ADVANCED COLORECTAL NEOPLASIA AND SERRATED POLYP SYNDROME IN HODGKIN LYMPHOMA SURVIVORS

L. S. Rügter1, M.C.W. Spanader2, B. M. Aleman3, T.M. Bissingel9

Introduction: Hodgkin lymphoma (HL) survivors treated with abdominal radiotherapy and/or procarbazine show an increased risk of colorectal cancer. This study evaluated the prevalence of colorectal neoplasia in HL survivors.

Methods: The primary aim of this multicenter cohort study was to assess the diagnostic yield of advanced colorectal neoplasia detected by a first surveillance colonoscopy in HL survivors treated with abdominal radiotherapy and/or procarbazine. In advanced colorectal neoplasia was defined as an advanced adenoma (high-grade dysplasia, ≥25% villous component, or ≥10 mm diameter), an advanced serrated lesion (dysplasia or ≥10 mm diameter), or CRC. Results were compared with population-based cohort that underwent a primary screening colonoscopy (n=1276 asymptomatic individuals between 50–75 years of age). This study describes the results of a predefined interim analysis.

Results: A colonoscopy was performed in 101 HL survivors, who were significantly younger than general population controls (median 51 years [interquartile range 45–57] vs. 60 years [interquartile range 55–65], p<0.001). A mean of 3.5 neoplastic lesions was detected per HL survivor (standard deviation 4.9) vs. 1.1 per control (standard deviation 1.8, p<0.001). Despite their young age, the prevalence of advanced neoplasia was higher in HL survivors than in controls (25% [95% confidence interval 16–33%] vs. 12% [10–14%], p<0.001). Advanced adenomas were detected in 14% (6–21%) of HL survivors and 9% of controls (7–16%, p<0.001). The prevalence of advanced adenoma was higher in HL survivors than in controls (12% [6–18%] vs. 4% [3–5%], p<0.001). Serrated polyposis syndrome was present in 6% (2–11%) of HL survivors and 7% (2–13%) of controls (p=0.03).

Conclusion: HL survivors treated with abdominal radiotherapy and/or procarbazine have a high prevalence of advanced colorectal neoplasia. Colonoscopy surveillance should therefore be implemented as standard of care.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up with patients registered in the Republic of Korea National Health Insurance Corporation who were diagnosed with colorectal cancer between 2007 and 2014 and investigated the incidence of prostate cancer (one year lag period). The incidence of prostate cancer was also evaluated in age and gender-matched controls using a cohort of patients diagnosed with colorectal cancer during the same period. The incidence rate was defined as the number of newly diagnosed prostate cancer patients per 1000 person-years. To assess the role of detection bias-related to the follow-up of CRC, follow-up started at the date of CRC diagnosis and continued until the earliest date of prostate cancer diagnosis, death, loss to follow-up, or the 2015 year-end. We used Cox proportional hazards models to identify prostate cancer occurrences among CRC patients. We also performed the multivariable analysis. Multivariable models included the variables of age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income.

Results: We analyzed a total of 85,462 first primary CRC survivors. During the follow-up period of 494,222 person-years, 2005 (2.3%) developed prostate cancer (incidence rate 4.06/1,000 person-years). The median duration of follow-up was 5.78 years. Compared with the general population, CRC patients had a significantly increased risk of prostate cancer (HR 2.30, 95% CI = 2.182–2.426; P<0.001). Multivariable analysis (including age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income) showed that age ≥55 years (HR = 20.85, 95% CI = 11.88–36.59; P<0.001) is a significant independent predictor of prostate cancer.

Conclusion: Men who develop colorectal cancer are at an increased risk of prostate cancer, with the greatest risk in men under the age of 55. This data suggests that CRC patients under 55 years old require regular screening for prostate cancer.

P1085 INCIDENCE OF PROSTATE CANCER IN COLORECTAL CANCER PATIENTS: NATIONWIDE RETROSPECTIVE COHORT STUDY

H.S. Kim1, D.H. Lee1, K.D. Han2, D.W. Shin1, Y.J. Choi1, H. Yoon1, N. Kim1

Introduction: Colorectal cancer is one of the most common cancers diagnosed worldwide, and prostate cancer is also the most common malignancy in men and is an important cause of cancer deaths. Both colorectal cancer and prostate cancer also tend to occur more frequently in developed countries. There have been several reports on the association between colorectal cancer and prostate cancer, but the conclusions are inconsistent.

Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up patients...
P1087 LOCATION AND SEX PREDOMINANCE OF MISMATCH REPAIR DEFICIENT COLORECTAL CANCER IN IVORY COAST DIFFER FROM ITS EUROPEAN COUNTERPART

Contact E-mail Address: lucie.bienfait@erasme.ulb.ac.be

Introduction: According to European and American series, 1,2 up to 20% of colorectal cancer (CRC) is caused by germline mutations in mismatch repair (MMR) genes (MLH1, MSH2, MSH6 and PMS2) or hypermethylation of the MLH1 promoter gene. MMR deficient colorectal cancers are predominantly found in the right colon. Although an increasing rate of colorectal cancer has been observed in many low- and middle-income countries including in West-Africa,3 data on epidemiology and biology of colorectal cancer in native Africans from this region are scarce.

Aims & Methods: We aimed to study the incidence of MMR deficiency in Ivory Coast and to compare the data with those from a tertiary center in Belgium.

Histopathology was carried out to evaluate the impact of CRC screening on the rate of surgical intervention in the Veneto Region (Italy): Are follow-up colonoscopies really needed?

Introduction: Colorectal cancer (CRC) is a leading cause of cancer mortality in the Veneto Region (North-eastern part of Italy). Population screening of adults between 50 and 75 for CRC was begun in 2002, and it became standard practice in the six local health units (LHU) of the region in 2008. The current retrospective cohort study was carried out to evaluate the impact of CRC screening on the rate of surgical intervention in all LHU of the Veneto Region.

Aims & Methods: Data from hospital discharge records (HDR) regarding CRC patients hospitalized between 2000 and 2015 were collected. All CRC patients without principal diagnosis was colon and/or rectal cancer were included in the study. The number of patients studied rose approximately 18% reaching 1,547,097 for the last year (2015). The Standardized Hospitalization Ratio (SHR) using five-year age groupings was calculated and expressed per 10,000 population.

Results: During the study period, 30,399 surgical procedures for colorectal cancer were performed (colon 63%, rectum 36%, secondary malignant neoplasm 1%) with a SHR of 139.1; the number was higher in males (1.69 vs. 1.02; OR: 1.66; CI 95%: 1.62-1.7; p < 0.05). An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached a maximum value in 2007 (166.9; X2 trend: 46.73; p < 0.05) and during the second there was a falling tendency that reached its minimum value in 2015 (102.3; X2 trend: 429.79; p < 0.05). When the cancer sites were analyzed, it was seen that despite the peak in 2007, the rate of surgical procedures for the proximal colon during the last year was the same as the 2000 value (41.5); there was, instead, a relevant decrease in the rate of procedures on the distal colon and rectum which fell from 94.4 to 59.2 (–37.5%). The study also shows that there was no significant difference in the reduction in surgical procedures for CCR in LHU in which the screening program included a follow-up colonoscopy (SHR 2015: 139.8; –29%) with respect to those centers where it was not forseen (SHR 2015: 138.5; –28%).
Conclusion: Study findings confirmed that CRC screening was effective in reducing the number of oncological surgical procedures particularly with regard to the distal colon and rectum. Data analysis showed that the screening seemed to accelerate reaching the peak rate in surgical procedures that took place in 2007. After that time point the number of operations began to fall as far as the distal colon was concerned (it fell by 37.3%). Finally our data suggest that the real benefit in reduction of oncological surgery procedures is due to the first screening colonoscopy.

P1090 ETHNIC VARIATION IN ADENOMA DETECTION IN THE UK FLEXIBLE SIGMOIDOSCOPY BOWEL CANCER SCREENING PROGRAMME

Digestive Diseases Centre, University Hospital of Leicester NHS Trust, Leicester/United Kingdom

Contact E-mail Address: dennis.lim@uhl-tr.nhs.uk

Introduction: The NHS bowel scope screening programme was introduced in 2013 and 23% of adults aged 55 invited for a ‘one-off’ flexible sigmoidoscopy followed by a colonoscopy if significant adenomas are detected. University Hospitals of Leicester Bowel Cancer Screening Centre serves an ethnically diverse community with approximately 25% of the population eligible for sigmoidoscopy screening being British Asian Indians and 45% being British Whites. Within the faecal occult blood based bowel cancer screening programme we have previously reported a lower polyp detection rate (PDR) and adenoma detection rate (ADR) in British Asian Indians undergoing colorectal screening compared to White British. This study aims to evaluate PDR, ADR and cancer detection (CDR) in British Asian Indians taking part in the bowel scope screening programme.

Aims & Methods: Patients who underwent screening sigmoidoscopy between February 1st, 2015 and 6th Feb 2017 were included. All individuals participating in screening sigmoidoscopy routinely report their self-selected ethnic origin. This database was cross referenced with the endoscopic and histology findings from the ‘Exeter’ online database. The findings in British Asian Indians were compared with British Whites.

Results: A total of 4287 patients underwent screening sigmoidoscopy over the 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) and adenoma detection rate (ADR) was 500/4287 (11.7%), hyperplastic polyps were 642/4287 (15%), sessile serrated lesions were 13/4287 (0.3%), and other polyps were 14/4287 (0.3%) (Inflammatory polyps 13, Juvenile polyp 1). Cancer detection rate was 6/4287 (0.14%). During the period studied, 359 British white individuals (82%) and 778 British Asian Indians screened. Six cancers (CDR = 0.17%) were detected in British white (CDR = 0.01%) but none in British Asian Indians.

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared with British Whites. The study was not powered to detect a difference in CDR. Further long term evaluation of these differences is needed and may shed light on factors contributing to the development of bowel cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: We identified for the first time that DDX27 (DEAD box polypeptide 27) gene was amplified in colorectal cancer (CRC) by whole genome sequencing. Amplification of DDX27 was detected in 47% (47/100) of primary CRC tumors and positively correlated with its mRNA overexpression. DDX27 plays a pivotal oncogenic role in colorectal carcinogenesis by promoting cell proliferation and inhibiting apoptosis. In this study, we investigate its function, mechanism of action and clinical implication in CRC.

Aims & Methods: Downstream effectors and pathways of DDX27 were identified by promoter luciferase reporter assay, RT2 Profiler PCR array and western blot. The interacting partners of DDX27 were screened by BioID method and further validated using immunoprecipitation assay and immunofluorescence staining method. Clinical implication of DDX27 was assessed in two human CRC cohorts by quantitative PCR method and immunohistochemical staining of tissue microarrays.

Results: Promoter luciferase reporter assays revealed that DDX27 mainly activated nuclear factor kappa B (NF-kB) pathway in CRC cell lines (HCT116 and SW480). Ectopic expression of DDX27 promoted transcription of NF-kB signal targets including BCL2A1, BIRC3, CCL20, CXCL3, NFKBIA, TNF and TNFAIP3. Conversely, silencing of DDX27 showed an opposite effect on NF-kB signaling. Treatment of NF-kB inhibitors CAPE and JSH-23 abrogated the promoting effect of DDX27 on CRC cell growth. We revealed that DDX27 enhanced and prolonged NF-kB signaling via reducing the accumulation of nuclear IkB, which negatively regulates transcriptional activities of NF-kB and transport NF-kB proteins back to the cytoplasm. DDX27 overexpression markedly increased by endogenous immunoprecipitation assay and immunofluorescence staining. Knockdown of NPM1 abrogated DDX27-activating NF-kB signaling, as well as its tumor-promoting function. Kaplan-Meier curves showed that higher DDX27 expression was significantly associated with shorter survival in patients with CRC of two independent cohorts (N=199 for Beijing cohort using quantitative PCR method, and N= 275 for Shanghai cohort using immunohistochemical staining of tissue microarrays; both P < 0.05).

Conclusion: DDX27 plays an important oncogenic role in promoting CRC tumorigenicity via activation of NF-kB pathway. Higher expression of DDX27 is correlated with poor prognosis in CRC patients.

P1092 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Sugimura, M. Iwabuchi, K. Ukai

Gastroenterology, Sendai Medical Center Dept. of Gastroenterology, Sendai/Japan

Contact E-mail Address: msugimura@snh.go.jp

Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathological features are still not well defined and need further evaluation.

Aims & Methods: The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 3532 endoscopically resected specimens performed during January 2007 and December 2016 in our hospital. A total of 463 serrated lesions (8.7%) were classified into three categories: HP (hyperplastic poly), SSA/P (sessile serrated adenoma/polyp), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluated the morphological characteristics by using immunohistochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.

Results: Of these 463 lesions, a total of 241 (52.1%) were HP, 102 (22.0%) SSA/P, and 120 (25.9%) TSA. Male to female ratio (M/F) was 2.38 for HP, 0.98 for SSA/P, and 2.45 for TSA. Mean size of SSA/Ps (13.1 mm) and TSAs (10.4 mm) were significantly larger than that of HP (8.1 mm) (p<0.005, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 84% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinceme-shaped pit pattern as that of TSAs. Incidence of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 241), 2.9% (3 out of 102), and 4.2% (5 out of 120), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetric pattern, whereas most of those cells in TSA distributed in so-called ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were...

**Introduction:** It is generally accepted that exosomes, small, membrane-bounded vesicles are formed in multivesicular bodies (MVBs) which fuse with plasma membrane resulting in the release of individual exosomes into the extracellular space. Recently, sporadic in vitro observations of a novel, unconventional mechanism have been reported in which the exosome-like vesicles remain in one body during their secretion.

**Aims & Methods:** Our aim was to examine this phenomenon in migrating colorectal cancer (CRC) cells in situ. Immunohistochemistry (IHC) examination of migrating, individual cancer cells was performed in surgically removed, metastatic CRC samples (n = 6). We used epithelial cytoplasmic cytochrome (cytokeratin-18), and cell membrane (CD63) markers for the identification of migrating CRC cells as well as ALIX and CD63 proteins for the detection of exosomal transport. Samples were analyzed with confocal and stimulated emission depletion (STED) microscopy-based 3D reconstructions.

**Results:** 3D reconstructions showed ALIX-positive and CD63-positive exosome clusters (ECs) with 0.62 to 1.94 μm diameter (mean ± SD: 1.17 ± 0.34 μm) localized partially inside, and/or outside the cytoplasm in 85.96% (n = 98/114) of migrating CRC cells. E-cadherin HHC showed that ECs were not only captured during their exit from the cytoplasm and localized among plasma membrane proteins, but they were also detected extracellularly, in the plasma membrane-stroma interface. STED-microscopic images showed that released ECs were composed smaller, distinguishable ALIX-positive spheroids of 98 to 150 nm diameter (mean ± SD: 128.96 ± 16.73 nm), which fall into the size ranges of exosomes.

**Conclusion:** Our study demonstrates in situ for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular ECs. These structures might fundamentally contribute to the autocrine/paracrine regulation of cancer development, which effect may differ from that mediated by conventionally secreted exosomes.

Contact E-mail Address: j.h.vandemeer@amc.nl

**Introduction:** The semi-essential amino acid arginine is important for intestinal epithelial proliferation and is an essential dietary component delivered by solid food. In homeostatic proliferating adult intestinal enterocytes arginine is catalyzed, by the enzyme arginase 2. During embryonic development, the demand for arginine increases, due to rapid growth. Arginine is lacking from milk in the endogenous diet so the infant must synthesize arginine. We present studies on the role of arginase 2 in hyperproliferative epithelium in the rapidly growing intestinal tube. Neonatal enterocytes are capable of de novo synthesis of arginine from citrulline. The rate-limiting enzyme in this process is argininosuccinate synthetase 1 (ASS1). Similarly to postnatal development, hyperproliferative epithelium is a hallmark of tumorogenesis and wound healing.

**Aims & Methods:** The aim of this study is, to investigate, whether de novo arginine synthesis via ASS1 plays a role in intestinal carcinogenesis and repair.

**Results:** We performed immunohistochemistry on intestines from ACP-017 mice, and wild type mice. We observed that in control mice compared to the ACP-017 mice, argininosuccinate synthetase 1 expression was significantly reduced. Furthermore, knockdown of ASS1 decreases overall protein synthesis. Furthermore, knockdown of ASS1 results in compromised organoid growth. Our studies showed the three types of serrated lesions have their own characteristic markers and protein synthesis during intestinal carcinogenesis and repair.

**Conclusion:** ASS1 expression is highly increased in adenomas and hyperproliferative crypts during epithelial repair after mechanical wounding and irradiation wounds, compared to homeostasis. Variable expression of ASS1 is seen in different colorectal cancer cell lines, and expression correlates with resistance against arginine deprivation. In APC−/− organoids generated from the APC−/− genotype, ASS1 RNA and protein are highly expressed, with concomitant increase of intracellular arginine. Upon knockdown of ASS1 in in ACP−/− organoids, protein synthesis is significantly reduced and organoid growth is compromised. Furthermore, knockdown of ASS1 decreases overall protein synthesis.

**Disclosure of Interest:** G.R. van den Brink: G.R. van den Brink is an employee of GlaxoSmithKline. All other authors have declared no conflicts of interest.

Introduction: Less than a hundred polyps defines attenuated familial adenomatous polyposis (AFAP). APC or MUTYH involvement has been described in 60% of the cases. The natural history of AFAP without identified genetic defects is not enough evaluated. In our study we compare clinical and endoscopic features of polyposis in patients carrying APC or MUTYH mutation and wild type patients.

Aims & Methods: 102 cases (35 F, 67 M; mean age 51; range 28–78) of AFAP were registered at our Institution between 1996 and 2014. They had no cancer family history and presented more than 10 adenomas at index colonoscopy. Genetic testing for APC and MUTYH genes was performed. Patients were put in a program, after having cleaned the colon, consisting in colonoscopy after one year and then the colonoscopic interval was based on the number of polyps from 1 to 3 years. Odds Ratio test was used to compare APC or MUTYH mutated and wild-type patients.

Results: Out of 102 patients with AFAP we identified a genetic defect in 36 patients (35.3%; 12 with APC and 24 MUTYH) and 66 (64.7%) were wild-type. The mean endoscopic follow up was 10 years (2–31) in the mutated group and 9.7 years (2–23) in the wild-type group. Table 1 describes endoscopic and clinical features between the two groups. We observed some statistically differences between groups: the mutated group was younger than 50 years of age with a higher number of polyps, right colon was mainly involved and endoscopic follow-up was mostly every year. Patients of wild-type group never underwent colectomy during follow-up and they displayed few adenoma recurrences in 24% of cases. On the other hand 14% of mutated patients underwent colectomy for dense polyposis and 28% had more polyps than at index colonoscopy in 24% of cases. On the other hand 14% of mutated patients underwent colectomy for dense polyposis and 28% had more polyps than at index colonoscopy and 11% no polyps at all. These 11% displayed mutation in MUTYH.

Conclusion: We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Comparison of clinical and endoscopic feature between APC or MUTYH carriers versus wild-type patients.

Introduction: Besides local hypermethylation on promoters of certain tumor suppressor genes, global DNA hypomethylation is characteristic in various types of cancers including colorectal cancer (CRC). The DNA methylation level of long interspersed nuclear element-1 (LINE-1) repetitive retrotransposon sequences constituting 17% of the human genome can be used to estimate global methylation level.

Aims & Methods: We aimed to analyze the alterations of the global DNA methylation levels along the colorectal normal-adenoma-carcinoma sequence progression on the basis of LINE-1 methylation and to study the methyl-cytosine pattern in tissue samples. Genomic DNA was isolated from 10 colorectal adenoma, 10 CRC and 30 normal colonic biopsy samples. Bisulfite conversion of DNA samples was performed using E.Z. DNA Methylation-Direct Kit (Zymo). For methylation level quantification of the LINE-1 retrotransposable element, bisulfite-specific PCR (BS-PCR) was applied, and 146 bp long PCR products were sequenced on Pyromark Q24 system (Qiagen). Tissue localization of 5-methylcytosine (5-mC) in normal, adenoma and CRC tissues was analyzed by immunohistochemistry using mouse monoclonal anti-5mC antibody (GeneTex).

Results: According to the LINE-1 bisulfite sequencing results, significant (p < 0.01) global DNA hypomethylation was detected both in CRC (63.8 ± 8.7%) and adenoma samples (67.5 ± 5.1%) compared to normal tissue (72.1 ± 4.4%). 5mC labeling of both the epithelial and stromal components of normal samples was strong (scoring values: +2 and +3) with diffuse and nuclear staining. In adenomas, decreased nuclear 5mC staining (scoring value: +2) was detectable in the epithelium and the stroma compared to normal epithelium. In CRC samples significantly lower 5mC levels could be observed than in normal tissue samples (p < 0.05).

Conclusion: Global DNA hypomethylation could be shown in CRC compared to healthy normal tissue samples both by LINE-1 bisulfite-sequencing and by 5-mC immunohistochemistry. Genome-wide DNA methylation decrease occurs already in adenoma stage of colorectal carcinogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1098 CIRCULATING miRNA CHANGES IN HUMAN COLORECTAL CANCER DEVELOPMENT AND IN ANIMAL MODEL

Introduction: miRNAs have a critical relevance in regulation during tumorigenesis. The expression profiles of miRNAs alter along tumor progression moreover these miRNAs may spread into tumor macro- and microenvironment.
Extracellular miRNAs are stable and its expression is less characterized in plasma. Altered and overlapped miRNA profiles between tissue and plasma are less explored.

Aims & Methods: The present study was designed to characterize the tissue and circulating miRNA profile through colorectal adenoma-carcinoma sequence in humans and mice peripheral blood samples. The main purpose of our study was to determine the origin of detected miRNAs in tumor-adenocyst C57BL/6 and non-adenocyst CBAJ mice tumor models. To achieve that goal, human peripheral blood and biopsy of normal (N), tubular (AT), tubulovillous (TV) and colorectal cancer (CRC) volunteers and plasma were also collected two times a week over 45 days from C57BL/6-c38, CBAJ mice. MiRNAs were isolated and Affymetrix GeneChip miRNA array analysis was performed for screening of the altered miRNA profile. RT-qPCR method was performed for verification.

Results: In the case of human samples out of 1733 detectable miRNAs, 306 miRNAs were expressed in normal, 334 in adenoma and 321 in CRC. Characteristic miRNA expression alteration was observed in the comparison of AT (N vs. AT), and TV vs. TVs in plasma. In the case of N vs. CRC, overexpression of miR-612, miR-1296, miR-933, miR-937 and miR-1207 was validated by RT-PCR (p < 0.05). Partial co-expression of these miRNAs was observed in tissue as well as plasma. We identified high plasma levels of 94 miRNAs in CRC samples compared with healthy samples. A total of 176 miRNAs were listed in the latest tumor stages. Based on CBAJ-C38 mice model experiment where the injected tumorous cells could not adhere miR-676 found to be a host originated while miR-92a was a tumor-derived miRNA. MiR-676 and miR-92a shown significant overexpression (388 ± 37x p < 0.05) in plasma samples based on real-time PCR and microarray results.

Conclusion: Circulating miRNAs alteration could observe in animal models in and model systems. Cancer-associated miRNAs in the circulation may originate from the immunologic system or from other metastatic regions far from the primer tumor location.

Introduction: The mechanism of colorectal cancer (CRC) invasion and metastasis is still unclear. Epithelial-mesenchymal transition (EMT) is one of the key molecular steps in the process of distant metastasis. EMT is referred to conversion of cells with an epithelial phenotype into cells with a mesenchymal phenotype, which lead to loss of cell polarity, with acquisition of migratory and invasive property. MicroRNAs (miRNAs) (miR-126) is a non-coding RNA that negatively regulate gene expression at post-transcriptional phase. MicroRNA-126 (miR-126) originates from a common precursor structure located within the egfl7 gene, which acts as a tumor suppressive miRNA in various malignancies. Previous studies demonstrated significantly down-regulated in human CRC tissues and negatively related with patient's prognosis. MiR-126 was also low-expressed in high metastatic cell lines, and inhibited proliferation, invasion and metastasis of CRC in vitro. However, whether miR-126 can regulate the process of EMT in CRC is still unclear. Ras homolog A (Rhoa) is one of most characterized members of Rho GTPases which belong to Ras superfamily. Rhoa, as molecular switch, cycles between an active GTP bound state and an inactive GDP bound state. Rhoa and its components of signaling pathway are known to participate in a diverse array of cellular events related to invasion and metastasis of cancer cells. Our previous study found that miR-126 down-regulated RasA and ROCK activity in CRC cells. Whether Rhoa activity and Rhoa signaling pathway play an important role in miR-126 regulating EMT process, cell proliferation, migration and invasion of CRC remains unclear.

Aims & Methods: To identify Rhoa signaling pathway associated with the function of miR-126 overexpression or knockdown. Performed MTT, colony formation, wound-healing, migration, invasion assays and RT PCR, western blot analysis to study the functions of miR-126 in EMT, proliferation, migration, invasion and expression RasA signaling pathway of CRC cells. Constructed pDSRed2-V14Rhoa (constitutive active Rhoa, V14Rhoa) and pDRed2-N19Rhoa (Domain-negative, N19Rhoa) mutants, then transfected them into the CRC cell lines of miR-126 over-expression or knockdown (miR-126) activity. Pulldown assay detected Rhoa signaling activity after transfected. Then repeated the experiments above to investigate the biological behavior changes of CRC cells.

Results: MiR-126 promoted the expression of E-cadherin and suppressed the expression of SLUG, Snail, Vimentin, Fibronectin of CRC cells. MiR-126 also inhibited proliferation, migration and invasion of CRC cells, and negatively regulating Rhoa signaling pathway. V14Rhoa mutant effectively increased the activity of Rhoa and reversed the role of miR-126 by promoting EMT, proliferation, migration and invasion in miR-126 overexpressing HCT116 cells. Conversely, N19Rhoa mutant effectively decreased the activity of Rhoa and suppressed EMT, proliferation, migration and invasion in miR-126 silenced SW480 cells.

Conclusion: Rhoa signaling pathway was the key signaling pathway of miR-126 in suppressing the EMT, proliferation, migration and invasion of CRC cells.

P1110 DNA METHYLATION CHANGES PRECEDE AND CONTRIBUTE TO SPORADIC MUTATIONS IN COLORECTAL ADENOMA AND CANCER DEVELOPMENT THROUGH INDUCED GENOMIC INSTABILITY

2nd Dept. Of Medicine, Semmelweis University, Budapest/Hungary

Contact E-mail Address: mb@hel2.sote.hu

Introduction: Colorectal cancer development is characterised by sporadic mutations and epigenetic alterations. DNA mutations occur randomly and sporadically in growth-related genes, mostly on cytosome nucleotides. Active demethylation of cytosines in relation to RNA expression alterations may lead to genetic instability and DNA mutations. Whole genome DNA methylation and mutation analysis with RNA expression profiling data from CRC patients demonstrate the primary and secondary order of the epigenetic and genetic changes and their relation to the malignant phenotype development.

Aims & Methods: In this study we aimed the whole genome methylation analysis and targeted mutation analysis of colorectal cancer (CRC)-related genes (12) with upstream whole genomic mRNA expression evaluation. Special focus was set on the p53 pathway and the involved genes. Methyl capture sequencing (Illumina) was performed on normal (N), adenomous (Ad: 13) and colorectal cancer (CRC: 9) biopsy specimens. Methylation results were confirmed by in silico methylation studies' results (TCGA) and by methylation array-PCR (Quagen Methylation array). Specimens were further evaluated for 32 mutations of 12 CRC-related genes (APC, BRF, CTNNB1, EGFR, FBXW7, KRAS, NRAS, SMAD4, TP53, MSH6, PIK3CA, SMAD2, SMAD4, TP53) by new generation sequencing (Roche 454 Junior). mRNA expression evaluation was performed by whole genome expression analysis (HGU T3, Affymetrix). Tageted pathway analysis was performed for the p53 pathway. Bioinformatic analysis included overall survival time and methylation detection of top hyper/hypomethylated genes, methylation changes on the tumor mutation regions and related pathway gene promoters were evaluated by targeted analysis.

Results: Overall hypomethylation was observed on the N-Ad-CRC sequence in the gene body and non coding genomic regions. In Ad-N comparison e.g. p73, NFGR, PDGFRA genes were hypermethylated for their promoters, FMN1, SLIC6A7 genes were hypomethylated, respectively. In CRC-N comparison DK2, SDC2, SOX1 genes showed hypermethylation, while ERBB4, CREBS,CNTN1 genes were hypomethylated in the promoter regions. In silico analysis on the TCGA database yielded confirmatory results. The common hyper- and hypomethylated genes were also in correlation with methylation array results yielded by methylation specific PCR. A significant negative correlation of the top methylation changes could be demonstrated to the RNA expression. In the certain mutation hot spot, genebody regions significant DNA methylation alterations (mainly hypomethylation) were detected. APC, P53 and KRAS mutations were found in 30%, 21% of adenomas, and in 29%, 53%, 29% of CRCs, respectively. RNA expression profiling could not detect any significant quantitative changes related to these DNA sequence alterations. The p53 gene body was addressed by hypermethylation in adenomas. mRNA expression changes were observed in most of the p53 pathway genes showing promoter methylation alterations.

Conclusion: DNA methylation with consequent phenotypic effect can be observed in a high number of gene promoters and gene body regions through CRC development. The mutation hot spot areas of the most relevant colorectal cancer (APC, CTNNB1, EGFR, FBXW7, KRAS, NRAS, SMAD2, SMAD4, TP53) were completely methylated and the DNA methylation alterations without detectable quantitative RNA expression changes. p53 cancer pathway genes are highly methylated in promoters and gene body with corresponding expression changes. The tumor mutation hot spot areas in the p53 gene selection were hypomethylated and therefore unstable and methylated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal carcinoma is one of the leading causes of cancer-related mortality worldwide. Tumor associated macrophages (TAMs) are criticalstromal components intimately involved with the progression, invasion, and metastasis of cancer cells. Recently, increasing studies have demonstrated that microRNA-126 (miR-126) had an important role in colorectal cancer. The expression of miR-126 decreased significantly in colorectal cancer, particularly in high metastatic cell lines, indicating that miR-126 may inhibit tumor development and metastasis. However, the mechanism underlying miR126 inhibiting cancer is uncertain, and its function in cross-talk between colorectal cancer cells and TAMs are still in its infancy.

Aims & Methods: In this study, we investigate the cross-talk between cancer cells and TAMs in colorectal cancer microenvironment, and find out what role the miR-126-CXCL12-IL6 axis plays in it. Methods: (1)The effect of miR-126 on the growth and metastasis of cancer cells. (2) We build a co-culture system of TAMs and transferred cancer cells, and use AD를 기반으로한 tumour necrosis factor (TNF)를 통해 TAMs를 구축하고, 이를 통해 TAMs의 배양과 면역조절활성을 촉진했다. We detect expression of EMT associated factors and STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

Results: (1) miR-126 negatively regulate CXCL12 expression in post-transcript level; (2) Inhibiting miR-126 of colorectal cancer cells could promote TAMs recruitment and up-regulate inflammation factors IL1β and IL6 expression. However, blocking CXCL12/CXCR4 axis by AMD3100 could reverse this effect, vice versa; (3) Inhibiting miR-126 of colorectal cancer cells could recruiting TAMs, therefore down-regulate E-cadherin protein, up-regulate slug protein, and activate STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

Conclusion: Our results reveals a novel mechanism by that miR-126 repress recruitment and inflammatory factor secretion of TAMs through controlling secretion and paracrine signaling of CXCL12 to inhibit colorectal cancer growth and metastasis.

Introduction: Narrow Band Imaging (NBI) enable detection for vascular-rich small, flat lesion and recognition of mucosal surface compared with normal colonic mucosa and vascular pattern in colonoscopy. However, recent studies revealed no significant difference in overall adenoma detection rate with the use of NBI compared with white light imaging (WLI). Blue Laser Imaging (BLI) is next-generation of image enhanced endoscopy technique using LASER light source that were realized with lighting and image processing suitable for visualization of microvessels and structures in the superficial portion of the mucous membrane.

Aims & Methods: Our aim was to determine whether the use of BLI enhances the adenoma detection rate (ADR) and miss rate compared with WLI. A total of 163 patients who underwent screening or surveillance colonoscopy in Saga University Hospital were included. Three patients were excluded because of poor bowel preparation. One hundred and twenty-seven patients were randomized to tandem colonoscopy with BLI (BLI-WL group) or WLI followed by BLI (BLI-WLI group). Polyp (adenoma) detection rates, miss rates and the number of polyps (adenoma) detected per person (mean adenoma detection rate) were examined between the two groups.

Results: The BLI-WL group and WL-WL group comprised 64 and 63 patients, respectively. The proportion of patients with polyps (adenoma) was 62.5% in BLI-WL group compared with 63.5% in WL-WL group. There was no significant difference between two groups regarding ADR (1). The number of adenomas detected per person (ADR) of BLI-WL group and WL-WL group were 2.84 and 1.90, respectively. However, the polyp miss rate of BLI-WL group was less than that of WL-WL group (1.6% vs 10.0%; P=0.0014).

Conclusion: There were no significant difference in the overall polyp (adenoma) detection rate with BLI-WLI group or WL-WL group. However, miss rate was higher in WL-WL group compared with BLI-WL group (10.0% vs 1.6%; P=0.0014). Further, BLI detected more polyps per patient compared with WL group (2.84 vs 1.90). BLI may improve polyp miss rate and the number of polyps per subject (mean adenoma detection rate) in the colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.
CONCLUSION: Our results demonstrate that degree of ITH of KRAS/TP53 mutations is a predictor of colorectal cancer risk. Increased genetic variations in the microsurface structure may represent molecular subclones in early colorectal lesions and may be predictive of the malignant progression.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1106 THE DIAGNOSTIC VALUE OF HYPOXIA INDUCED EXOCYTOCELLULAR VESICLES IN COLORECTAL CANCER PATIENT PLASMA

Introduction: Hypoxia signaling has been enhanced to facilitate cell survival, chemoresistance, motility, tumour angiogenesis as well as cell survival and proliferation of putative cancer stem cells. One of the key players in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicle (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colorectal cancer in vitro.

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients’ plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs were quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs were determined by Agencourt A50. The study was aimed to determine whether EV number and size differ in CRC patient plasma compared to HD plasma, that might have diagnostic and prognostic value. (Financed by Latvian Council of Science 2021-0933)

Results: Statistically significant increase in the amount and size of EVs was observed in CRC plasma compared to healthy donors. In CRC group, the rate of distant metastasis or recurrence was 0.9% (10/1127). Among these 10 cases, 5 cases were developed from depressed-type lesions and one case was 10 cases, 5 cases were from protruded-type lesions. The rate of metastasis was 64.3% in depressed-type, 34.3% in flat-type and 38.4% in protruded-type. The rate of distant metastasis or recurrence was 0.9% (10/1127). Among these 10 cases, 5 cases were developed from depressed-type lesions and one case was developed from protruded-type lesions.

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCs arise via the adenoma-carcinoma sequence, 10-20% CRCs by sessile serrated adenomas (SSA). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged.

Aims & Methods: The study was aimed for molecular characterization of colon polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this prospective study. All patients underwent a complete hyperplastic polyp removed by standard endoscopic techniques. Up to 6 representative polyp biospies were collected and stored in a formalin medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (tNGS) was performed from formalin-fixed, paraffin-embedded tissue samples.

Aim: To correlate the number of CRC-related genes (38 targeted genes; GeneRead DNAseq Targeted Panels V2, Quagen®) on a MiSeq platform (Illumina®). Genetic and histopathological analysis was done blinded to the endoscopic and clinical data.

Results: In 100 patients, 234 polyps were removed. 121 polyps (54.0%) were sized <=10mm, 71 (31.7%) were >10mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.8%) were adenoma- and 110 polyps (49.1%) non-adenomatous lesions. No data were available.
samples of athletes during physical exercise (66.17/C6 stage. Based on our results, the above DNA analysis methods might contribute to hypomethylation could be observed only in CRC patients with advanced tumor CRC, IBD patients and also in healthy athletes during physical exercise. CfDNA P1109 ANALYSIS OF SFRP1, SFRP2, SDC2 AND PRIMA1 DNA hypomethylation was shown in CRC plasma samples with advanced tumor heights at 180 bp, 360 bp, 550 bp) was observed in each patient group. Global /C6 B. Wichmann2, Z.B. Nagy1, E. Markus1, K. Szigeti1, A´ . Nagy1, Z. Tulassay2, study certain DNA sequences of the promoter regions of SFRP1, SFRP2, SDC2 genes in biopsy and plasma samples of healthy, colorectal adenoma and CRC patients with colonic adenoma (20.61/C6 and 12.987 (1.637–100.00)). Contact E-mail Address: exzter1991@gmail.com Introduction: Cell-free DNA (cfDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in healthy people during physical exercise. Aims & Methods: We aimed to analyze cfDNA changes (quantity, fragment length, global DNA methylation level) in physiological conditions (during physical exercises) and neoplastic and inflammatory colorectal diseases. Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colonic adenomas (AD), 19 inflammatory bowel disease (IBD), and 16 normal (N) donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes before, during and after physical training. DNA was isolated with High Pure Viral Large Volume NA isolation Kit (Roche). cfDNA was quantified with Qubit fluorometry (Invitrogen). CDNA fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA demethylation was analyzed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Quagen). Results: High cfDNA amounts were observed in plasma samples of patients with colon adenoma (20.61 ± 10.70 ng/ml), colorectal cancer (24.13 ± 20.02 ng/ml) and IBD (22.27 ± 14.06 ng/ml) compared to healthy subjects (10.33 ± 3.22 ng/ml). Highly elevated cfDNA amounts were found in plasma samples of athletes during physical exercise (66.17 ± 29.00 ng/ml) while the cfDNA amount decreased after physical activity (51.87 ± 39.80 ng/ml). Characteristic cfDNA fragment length distribution pattern (with different peak heights at 180 bp, 360 bp, 550 bp) was observed in each patient group. Global DNA hypomethylation was shown in CRC plasma samples with advanced tumor stage (N= 17: 6.00%, AD: 79% ± 1.70%, advanced CRC: 70% ± 0.03%). Conclusion: cfDNA decreases after physical activity and higher cfDNA levels, observed only in patients with advanced tumor stage. Based on our results, the above DNA analysis methods might contribute to non-invasive detection for colorectal diseases. Disclosure of Interest: All authors have declared no conflicts of interest.

P1109 ANALYSIS OF SRFP1, SRFP2, SDC2 AND PRIMA1 PROMOTER METHYLATION IN CELL-FREE PLASMA DNA FOR NON-INVASIVE DETECTION OF COLORECTAL ADENOMA AND CANCER B.K. Bartak1, A. Kalmár1, B. Péteria,1 A.V. Introduction: Epigenetic instability, primarily aberrant DNA methylation seems to be a common phenomenon in colorectal cancer (CRC) influencing gene expression and contributing to tumor formation. In recent years, blood-based assays came into focus as potential screening tools for colorectal adenoma and cancer cases, as the analysis of the methylation status of circulating cell-free DNA (cfDNA) in plasma samples provides a good opportunity for cancer detection.

Aims & Methods: Our aim was to analyze the methylation pattern of four selected genes in biopsy and plasma samples of healthy, colorectal adenoma and CRC patients. Moreover, we aimed to examine the effect of methylation alterations on protein expression. Methylation (ML) PCR was used after bisulfite-conversion to study certain DNA sequences of the promoter regions of SRFP1, SRFP2, SDC2 and PRIMA1 in 32 biopy-plasma pairs and in 121 additional plasma samples.

Results: The methylation pattern of the four selected genes, demonstrated different methylation profiles for healthy, colorectal adenoma and CRC patients. Moreover, we examined the effect of methylation alterations on protein expression. Methylation (ML) PCR was used after bisulfite-conversion to study certain DNA sequences of the promoter regions of SRFP1, SRFP2, SDC2 and PRIMA1 in 32 biopy-plasma pairs and in 121 additional plasma samples.

Conclusions: Our findings suggest that SRFP1, SRFP2, SDC2 and PRIMA1 can be proven to be promising epigenetic biomarker candidates for colorectal adenoma and cancer diagnosis with high sensitivity and specificity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolomics, a dynamic portrait of the metabolic status of living systems, has demonstrated its great potential for use in the diagnosis of various cancers by applying advanced analytic techniques and bioinformatics tools. Recently, very few metabolic markers in CRC have been consistently discovered, but many metabolic profiles of CRC patients are being discovered in colorectal cancer remains poorly understood and warrants investigation due to its non-invasive sample method. In the last decade, several metabolomic approaches have been applied toward identifying metabolic alterations in CRC using variety of sample types including urine, tissue, serum, and feces. However, there are only few urinary metabolic studies and especially nuclear magnetic resonance (NMR) spectroscopy, which has several advantages including relative ease-of-use, high degree of reproducibility, easy-to-identify metabolites, high through-put, and non-destructive sample treatment, has not been applied to urine samples.

Aims & Methods: In this study, we investigate the differences in urine metabolic profiles of patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urinary metabolic study. In addition, we evaluate applicability as diagnostic tool of urine metabolomics for early detection of precancerous colorectal lesion with high sensitivity and specificity. Urine metabolic profiles of CRN patients from colorectal neoplasia (CRN; 36 advanced adenomas and 56 various stages CRC) and healthy controls (n=156) were analyzed by NMR spectroscopy. Healthy and CRN groups were statistically discriminated using orthogonal projections to latent structure discriminant analysis (OPLS-DA). The class prediction model was validated by three-fold cross-validation. The advanced adenoma and stage 0 CRC were grouped as pre-invasive CRN.

Results: After patients underwent endoscopic resection or surgical resection for CRN, advanced adenoma has been diagnosed in 36 patients, stage 0 CRC in 24 patients, stage I CRC in 8 patients, stage II CRC in 7 patients, stage III CRC in 13 patients and stage IV CRC in 4 patients. CEA and CA 19-9 levels for patient with stage I to IV CRC and healthy control were also assessed. Among patients with CA 19-9 level > 37 kU/L, 19-9 were in 42% of CRN patients and 52% of healthy controls, respectively. The sensitivity and specificity of CEA and CA 19-9 were 6.2% and 99.3%, respectively. The OPLS-DA score plot showed statistically significant discrimination between pre-invasive CRN as well as advanced CRC and normal with a Q2 value of 0.511. The predicted performance of the prediction validation study, the sensitivity and specificity for diagnosing pre-invasive CRN was 96.2% and 95%, respectively. The grades diagnosed by the PLS-DA model showed that area under the curve was 0.823 for tumor, 0.783 for alamine and 0.842 for aminosobutyrate. In multiple receiver operating characteristics curve analyses, tumorine, alamine, and aminosobutyrate were good discriminator for CRC patients.

Conclusion: NMR-based urine metabolic profiles significantly and accurately discriminate between patients with pre-invasive CRC as well as
advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urinary metabolomics as screening tool for accurate diagnosis of pre-invasive CRN.

Introduction: Symptoms alone are poor predictors of underlying colon pathology. Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), colorectal cancer (CRC), high risk adenoma (HRA, defined as ≥3 or any ≥1 cm) and inflammatory bowel disease (IBD). We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochemical test (FIT) is a good rule-out test for SBD. Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to the history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HMJacKarc (Kyowa Medex Co Ltd, Japan) with an analytic range of <10 to >400 μg Hb/g faeces. Referral rates with FIT were examined along with clinical findings at colonoscopy.

Results: 5,655 FIT tests were received. 76.2% had undetectable f-Hb, and 152 (2.7%) were untestable. 4,108 patients were referred of whom 2,338 (57%) returned a FIT. In 1,378 patients with a FIT result vetted to colonoscopy, 284 had SBD (20.6%), 86 CRC, 124 HRA and 74 IBD. 44% of patients examined along with clinical findings at colonoscopy.

Conclusion: A FIT test is an essential adjunct to the history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Introduction: The immunological screening test (FIT) for colorectal cancer (CRC) was introduced in January 2015 in Ile de France (15 million inhabitants) after Hemocult was abandoned due to its low sensitivity. The Hemocult (HC) launched in 2007 had reached less than 30% participation rate.

Aims & Methods: We report one-year on FIT in CRC screening in Ile de France and compare results to those with HC test for speculating on adjustment actions. The raw data were extracted by request from the registry of the screening structure (in various areas 75, 77, 91, 92, 94 and 95) covering a target population of 3026366 inhabitants. Rates of participation were calculated, and after one-year experience period, profiles of individual with positive tests, rates of those with negative colonoscopy, with polyps (all stages combined) and with high grade dysplasia (HGD) were described. Results were compared to those with HC from the launch to the end of the last campaign (Dec 2014) normalized for mean one-year output. The comparisons were made by an x2 test (qualitative variable) and multivariate stepwise analysis was performed for identifying predictive factors for cancer diagnosis.

Results: At the end of the HC-based screening campaigns 2014, 2.5 million individuals were annually invited and the participation rates since 2009, ranged from 28.5% to 24.6%, with females showing higher rates for participation (30.1% to 26.1%) than men (26 to 21.8%, p < 0.0001). During the first (2015) year FIT experience, the O Sensor device was used by 450120 (34% estimated participation rate) individuals (versus 294603 participants with HC in 2014 p < 0.00001; 24% participation rate) and the rate of positivity was 4.0% (versus 3.8% with HC; p < 0.00001). Among all positive FIT individuals, 93% underwent colonoscopies: 35% were normal (vs. 41%; p < 0.01), 13.2% presenting with cancer or HGD and 52% with polyps (vs. 37.7%; p = 0.00051). More women (52%) than men (45.5%) had to invitation to investigation rate in women (3.7%) was lower than in men (5.5%; p < 0.0001). More advanced polyps and cancer were found in men (14.5%) than in women (11.3%; p < 0.00001) with normal colonoscopies lower in men (24.2%) than in women (40.7%; p < 0.0001). The multiplicative value for FIT was significantly higher (p < 0.0001) in individuals with cancer +HGD (667; 9) or with polyps (374; 4) than in those with normal colonoscopy (440; 4). In multivariate analysis, risk factors for abnormal colonoscopies with cancer + HGD were male gender, FIT > 340 mg/mL and age > 63.5 yrs. More men than women with positive FIT test did not yet undergo colonoscopy.

Conclusion: FIT test has gained a better adhesion in Ile de France probably because to its simplicity and a wider distribution. The lower rate of normal colonoscopies and a higher positivity rate, this predictive value for cancer leads to more early lesions detected indicating its higher specificity. Men of 63.5 yrs old or more with Hemoglobin levels higher than 340 ng/mL are of very high risk of cancer and should be absolutely conducted to the colonoscopy in case positive FIT test. Introduction: Most T1 colorectal cancers (CRCs) undergo surgical colectomy in western countries with established clinical guidelines despite the low incidence (approximately 10%) of lymph node metastasis (LNM). Therefore, many patients with-out LNM undergo unnecessary surgeries.

Aims & Methods: To reduce unnecessary surgeries, we aimed to predict the risk of LNM in T1 CRCs by using artificial intelligence (AI). Data on 690 consecutive patients with T1 CRCs who had undergone colectomy between April 2001 and March 2016 were retrospectively analyzed. Data of a randomly selected 590 patients were used for machine learning for the AI model, which analyzed five clinicopathological factors: tumor location, lymphatic invasion, vascular invasion, tumor budding and histological grade. The remaining 100 patients served as a test set for validating the AI model and output the predicted LNM as positive or negative. To validate the AI model, sensitivity and specificity and

Introduction: Regular surveillance colonoscopy after colon cancer resection is recommended to detect metachronous adenoma and cancer. However, risk factors of advanced metachronous neoplasm during postoperative surveillance have not been fully evaluated yet.

Aims & Methods: This study aimed to assess the risk of advanced metachronous neoplasm during surveillance colonoscopy in patients who underwent curative colon cancer resection. The patients who underwent curative colon resection for non-metastatic colon cancer between January 2002 and December 2012 in a single tertiary center were retrospectively reviewed.

Results: A total of 728 patients were enrolled in this study. Surveillance colonoscopy was performed after perioperative clearing colonoscopy. Among the patients, 182 (61.6%) were male, and the median age was 65 years. On perioperative clearing colonoscopy, accompanying high-risk adenomas (≥3, size ≥10 mm, with high-grade dysplasia and villous histology) were detected in 95 patients (31.9%) and were significantly associated with old age (≥65 years), male sex, alcohol use, smoking, and stage 3 colon cancer (P < 0.05). During the postoperative follow-up periods (median, 5.35 years), advanced metachronous neoplasm was found in 45 patients (15.1%) during surveillance colonoscopy, including colon cancer in 4 patients (1.3%). In the multivariate analysis, distal colon cancer (distal to splenic flexure; odds ratio [OR] = 4.463; P = 0.002), accompanying high-risk adenomas on perioperative clearing colonoscopy (OR = 3.414; P = 0.001), and hypertension (OR = 2.344; P = 0.026) were significant risk factors of advanced metachronous neoplasm during surveillance colonoscopy.

Conclusion: Patients who had distal colon cancer, accompanying high-risk adenoma on perioperative clearing colonoscopy, and hypertension may need a shorter colonoscopic surveillance interval. A more tailored surveillance strategy is needed to improve overall outcome in patients who undergo curative colon cancer resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

4. Shaukat A, Mongin SJ, Geisser MS, et al. Long-term mortality after screen-
endoscopists with a higher ADR (3.45%). Hemostasis was easily achieved in both cases by clipping. No patient required blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumoperitoneum on CT scan. There was no perfora-
tion or delayed bleeding.

Conclusion: This study supports the existing data indicating acceptable rates of technical success and low incidence of adverse events with UEMR. The results of this study without cup were similar with the previous ones using cup. Further comparative studies with and without cup, using different settings and especially between UEMR and traditional EMR are needed.

P1117 ADENOMA DETECTION RATE INFLUENCES RISK 
PREDICTION OF METACHRONOUS ADVANCED COLORECTAL 
NEOPLASIA IN LOW-RISK PATIENTS
Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of 

Contact E-mail Address: ilonaelaona@hanmail.net

Introduction: Current guidelines recommend surveillance colonoscopy after 10 years or surveillance in 5–10 years in individuals with no or 1–2 non-advanced adenomas.

Aims & Methods: We hypothesized that risk of metachronous advanced colorectal cancer (ARC) differs based on clinical characteristics and colonoscopy quality. We identified 7,171 participants with no or non-advanced adenomas at first-screening colonoscopy. The risk of metachronous AN at surveillance colonoscopy 3–5 years later was investigated according to clinical characteristics and endoscopist adenoma detection rate (ADR).

Results: In multivariate analyses, strong associations between increasing age, male sex, current smoking, family history of colorectal cancer, follow-up interval, increasing number of adenoma, and low ADR were independent risk factors. Among patients with 1–2 small adenomas, women with age ≥60 years or men comprised a hidden-risk group, which had 5.3% risk of metachronous AN at surveillance. Women <60 years old with 1–2 low-risk adenomas had very low risk (1.2%) of metachronous AN as individuals with no adenoma. Furthermore, incidence of metachronous AN was significantly higher in individuals who were censored for endoscopies with an ADR (<32%) than in those screened by endoscopists with a higher ADR (≥32%) (3.2% vs. 0.6%, respectively; P = 0.001).

Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.

Introduction: The technique of endoscopic submucosal dissection has recently been improved, and large and complexed lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle traction (MR) sign are often difficult to be resected completely. We devised a new method called ‘Per Anal Endoscopic Myectomy’ for small lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer. 

Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM. We reviewed 55 cases of PAEM performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrous band with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases. 

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, and 3 cases with deep submucosal invasion were en bloc resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgical intervention or adjuvant chemoradiation. In surgical cases, they could permit anus-preservation.

Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable complete en bloc resection with accurate pathological diagnosis. No complica-
tions were recorded in our experiences. Further investigation into the sig-
nificance of PAEM would be needed.

P1119 LOCAL RECURRENT AFTER ENDOSCOPIC MUCOSAL RESECTION FOR HIGH-RISK LESIONS: MAY WE BETTER PLAN THE ENDOSCOPIC FOLLOW-UP ACCORDING TO PROCEDURAL AND PATHOLOGICAL AND HISTOLOGICAL CHARACTERISTICS?
C. Quondamcarlo, C. Lucidi, R. Lapenta
Gastroenterology, Regina Elena Cancer Institute, Rome/Italy

Contact E-mail Address: qcnnzia@ymail.com

Introduction: Endoscopic mucosal resection (EMR) is an increasingly used technique for the removal of large sessile and flat-laterally-spread colorectal lesions. At present, surveillance colonoscopies are ever performed to ensure detection and adequate treatment of residual or recurrent adenoma (RRA), which, occurring in 10–40% of non-pedunculated lesions, currently represents the main limitation of this technique. Fortunately, endoscopic detection of RRA in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up
colonoescopies and optimal time intervals are currently unclear. An adequate comprehension of the predicting factors of RRA would be very useful to try to prevent it, better plan surveillance intervals, establish role and timing of surgery and reduce costs.

Aims & Methods: Our aims were to assess the frequency of local recurrence after EMR of flat or sessile adenomas (to identify risk factors for recurrence), and to identify predictors of follow-up suggestions. We considered all consecutive patients undergoing EMR of flat or sessile adenomas ≥10 mm containing high-grade dysplasia or adenocarcinoma until pt1 from May 2015 to April 2016. EMR procedure was performed by 2 endoscopists with extensive EMR “inject and cut” experience and only lesions with a positive lifting sign were endoscopically treated. An endoscopic follow-up was performed at a planned interval of 3, 6 and 12 months by using high-definition instruments white light (HD-WL) and narrow band imaging (NBI) allowing an accurate and appropriate score assessment with the execution of biopsies when needed. Data collection included: (a) lesion size, morphology, Paris classification, pit pattern (kudo), technique of removal (en bloc vs piecemeal) and histology for all primary lesions and RRA; (b) Information on grading, grading, micronvasion, margins, submucosal exten- sion for all pt1 removed “en bloc”.

Results: 50 patients were included (mean age 63 ± 12 years, 54% females). The mean size of lesions was 21 mm (range 10–50 mm), 40% were sessile, 35% granular LST and the remaining 25% non-granular LST, the most frequent sites of location were sigmoidal colon (40%), ascending colon (25%) and cecum (12%). According to the morphological characteristics, 60% of lesions were removed “en bloc” and 40% “piecemeal”. Nodular lesions were used as propofol- laxis in 35% of patients and only in 1 for intraprocedural bleeding. No post-procedural bleeding or perforation occurred. APC has never been used. During the endoscopic follow-up a suspect early (3-months) RRA was documented and immediately treated in 16% and histologically confirmed only in 8%. At 6-month controls a RRA was again detected only in 2 of these patients. New cases of RRA were not found both at 6 and 12 month controls. Only 1 case of RRA was documented for lesions treated “en bloc” but this was the only one with histologically confirmed endoscopic stenting has not been ever used.

Conclusion: EMR results a technique safe and effective particularly for lesions removable “en bloc”: in this cases in fact the rate of RRA seems to be low and easily histologically predictable. Although factors related to RRA in “piecemeal EMR” appear to have a high rate of attention would be complicated in relation to determined morphological pattern and presence of in situ carcinoma. Moreover, RRA seems to be ever early suggesting a close follow up only in the first period.

P1120 TREATMENT STRATEGY FOR LOCAL RECURRENCES AFTER ENDOSCOPIC RESECTION OF COLORECTAL NEOPLASMS
Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka/Japan

Contact E-mail Address: sa.itos@scchr.jp

Introduction: Local recurrences after endoscopic resection (ER) frequently occur after colorectal neoplasms. Recently, the efficacy and safety of submucosal dissection (ESD) for local recurrences has been reported. However, an appropriate treatment strategy for these lesions including ESD remains unclear.

Aims & Methods: This study aimed to clarify the appropriate treatment strategy for local recurrences after ER. A total of 81 patients (81 lesions) who received treatment for local recurrences after ER for colorectal neoplasms between January 2010 and December 2016 were enrolled. Patients with pathological diagnosis of hyperplastic polypl, sessile serrated adenoma/polyp, and submucosal invasive cancer in their first ER were excluded. Seven patients who underwent surgery because of submucosal invasion or technically difficult locations were also excluded. Procedural outcomes, recurrence rate and disease control rate (DCR) were evaluated according to preoperative endoscopic diagnosis of recurrent lesions (adenomatous or carcinomas). The DCR was defined as proportion of patients who were diagnosed with curative resection after ER or received additional surgery based on pathological diagnosis after ER.

Results: Seventy patients were included allowing an adequate final analysis. Forty-nine patients diagnosed with adenomatous recurrences were treated by cold polypec- tomy in 15, by endoscopic mucosal resection (EMR) in 26, and by ESD in 8 patients. Cold polypectomy was applied only to diminutive (<5 mm) lesions and non-invasive carcinomas. The endoscopic resection rates of EMR and ESD were 53.8% and 100%, respectively (P = 0.03). Forty cases (7.7%) in the EMR group developed local recurrences, but additional ER achieved curative resection. The DCR of three methods were all 100%. Meanwhile, 23 patients diagnosed with carcinous recurrences were treated by EMR in 7 and by ESD in 18 patients. The en bloc resection rates of EMR and ESD were 28.6% and 36.3%, respectively (P = 0.017). Three cases (42.9%) in the EMR group developed local recurrences. One case required surgery because of invasive local recurrence, the second case required chemotherapy because of distant metastasis, and the third case was followed up to provide promising results.

Conclusion: The selection of ER for local adenomatous recurrences could be based on lesion size. On the other hand, ESD is desirable for local carcinous recurrences to achieve complete disease control.

Introduction: A self-expandable metallic stent (SEMS) placement is potentially a colostomy sparing option to manage a malignant colonic obstruction (MCO). However, in patients with coexisting peritoneal dissemination (carcinomatous adhesion), for example, insertion of a standard caliber colonoscope (SC) is impossible. Therefore, in such endoscopes equipped with a large working channel is suitable for through-the-scope (TTS) SEMS placement. Failure in stenting necessitates continuous tube drainage, stoma formation, or other surgical procedures and decreases quality of life (QOL). Our aim was the safety and efficacy of “Over-the-Catheter” Colonoscope Replacement technique (OTC-CR) detailed below, in palliative (not preoperative) SEMS placement for MCO. From Oct 2012 to Dec 2016, MCO patients were consecutively considered for decompression by SEMS placement until stoma formation was preferred. When a conventional TTS procedure was unsuccessful, specifically, when the MCO site was inaccessible with an SC (CF-H260AL, Olympus Medical Systems, Tokyo, Japan) with a 13.2 mm tip diameter and 3.7 mm working channel, needed for a 22 mm (not 18 mm) diameter and 3.7 mm working channel, needed for a 22 mm (not 18 mm) SEMS insertion.

All authors have declared no conflicts of interest.

*CROSS, ColoRectal Obstruction Scoring System (Reference 1)

Among 63 palliative MCO cases, initial attempt to place a 22 mm SEMS by TTS procedure was unsuccessful in 6 cases (Table), all of whom had peritoneal dissemination. The reasons for technical failures were; impossible insertion of an SCC to the stricture due to carcinomatous adhesions or narrowing in 5 cases and failure in passing GW through the stenosis due to a limited viewing angle to the stricture in one case. With OTC-CR, approach to the main stenosis with a thinner (alternative) scope, GW traverse, "over-the-catheter" replacement to the SCC, and a 22 mm SEMS placement were successful in all of the 6 cases with adequate clinical improvements (CROSS score change). Notably, ultimate TTS procedures were possible from reinserted SCC distant from the stricture in 3 cases. No adverse events occurred during the procedures.

P1123 RESULT OF THE FIRST ROUND OF THE COLORECTAL CANCER SCREENING PROGRAMME IN THE BALEARIC ISLANDS (SPAIN)

Contact E-mail Address: monica.florido@hcen.es

Introduction: Colorectal cancer (CRC) is the most common cause of cancer in western countries. In Balearic Islands 700 new cases per year are diagnosed. The cost-effectiveness of CRC screening programmes are clearly demonstrated in the studies and the important public health problem of CRC justifies the development of control strategies. The aim of this study is to present the results and impact during the first round of the program in Balearic Islands.

Aims & Methods: The first round includes the period from January 2015 through December 2016. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Mallorca), including 50% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,757 individuals. Exclusion criteria. Colonoecopy performed in the previous 5 years, previous diagnosis of CRC, follow-up colonoscopies because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochemical fecal occult blood testing (i-FOBT/OC-Sensor) was the screening method. The kit was delivered at pharmacies joined the program. The samples were deposited in urns placed in health centres. Participants who tested positive (≥100 ng/ml) were referred to pre-endoscopy evaluation and follow-up colonoscopy. The colonoscopies were performed according to the quality criteria of guidelines.

Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n=21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of those positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 60 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (≥5 adenomas or at least one ≥20mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment.

Conclusion: We observed an acceptable participation rate in the first round of the colorectal screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Introduction: The prevalence, gender distribution, and clinical presentation of irritable bowel syndrome (IBS) differ between Asian and Western countries. The densities of enteroendocrine cells are abnormal in Western IBS patients.

Methods: This study aimed at studying large-intestine enteroendocrine, Musashi 1(Msi 1; a marker for both intestinal stem cells and their early progeny), and neurogenin 3 (neuro 3; a marker for early intestinal endocrine cell progenitors) cells in Thai and IBS patients.
**Aims & Methods:** Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroendocrine), pancreatic polypeptide, somatostatin, Msi 1, and neurog 3. The densities of immunoreactive cells were determined with computerized image analysis (1).

**Results:** In both colon and rectum, the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Msi 1 and neurog 3 were unchanged in both the colon and rectum.

**Conclusion:** The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

to study the ability of STW 5 to modulate intestinal permeability under basal and repeated acute stress conditions.

Aims & Methods: C57 b16 mice were gavaged for 14 days with STW 5 (3 mL/kg). After 10 days of treatment, mice were subjected to water avoidance stress (WAS) during 4 consecutive days. In vitro permeability to FITC–Sulfonic Acid (F4A, 400 Da) and Horse Radish Peroxidase (HRP, 44KDa), total transit time and colonic transit (fecal pellet output - FPO) were measured at Day 0 (D0), D10 and D14 of IB treatment. Ex vivo permeability to FSA and HRP was assessed on jejunum, ileum, proximal colon and distal colon at D14 using Ussing chambers. Colonic transit time was measured at D10 and D14.

Results: In vivo permeability to FSA and HRP as well as total transit time were not modified by STW 5 in basal and WAS conditions. However, STW5 prevented the increase in permeability to FSA induced in the distal colon of control rats. Conversely, STW 5 prevented the increase in permeability to HRP induced by WAS in the jejunum and proximal colon. Furthermore, while STW 5 tended to increase colonic transit as compared to control in basal conditions, it prevented the increase in colonic transit induced by WAS. Finally, STW 5 did not modify the increase in permeability induced by WAS.

Conclusion: Our study suggest that STW 5 can prevent WAS induced changes in paracellular and transcellular permeability in specific regions of the gastrointestinal tract. Such effects could contribute to the therapeutic effects of STW 5 in irritable bowel syndrome and support novel therapeutic indications for pathologies in which barrier functions are altered.

P1129 ALTERING SPHINGOSINE-1-PHOSPHATE WITH AGING INDUCES MOTILITY DISFUNCTION OF COLON SMOOTH MUSCLE BY BKCA UPRREGULATION IN RATS
S. Xiaoze
The First Affiliated Hospital Of Nanjing Medical University, Nanjing Medical University, Nanjing/China

Contact E-mail Address: shenxiaozue0606@163.com

Introduction: Large conductance Ca2+ - activated K+ channel (BKCa channel) was shown to play critical roles in regulating smooth muscle contractility by modulating membrane potential, at the same time, age-associated changes in BKCa expression may contribute to the development of motility disorders of the gastrointestinal tract. Sphingosine-1-phosphate (SIP), component of Sphingolipids in the cell membranes, may affect BKCa expression. Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats.

Aims & Methods: Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats. Forty Sprague-Dawley rats at the same age were randomly divided into five groups. After different times of administration, finally they were divided into different-aged: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested in colonic tissues of rats with varying ages by immunohistochemical, RT-PCR and western blot. SIP levels in colonic tissue were tested by LC-MS/MS analysis. Primary cultured colonic smooth muscle cells (SMCs) from normal adult rats were used in complementary in vitro studies. In the presence and absence of SIP with different concentrations, the expression of BKCa, P-MLC level, single-channel activity, intracellular Ca2+ mobilization were tested. At the same time, in the presence and absence of SIP, SMCs were transfected with anti-SIP antibody. BKCa siRNA transfection was used to investigate whether P-MLC expression and intracellular Ca2+ mobilization were affected by BKCa expression in SMCs. The expression and phosphorylation of Akt, JNK, ERK, NK-FκB, and PKC were examined by western blot analysis to investigate the effect between SIP and BKCa.

Results: Aged rats showed prolonged colonic transit time and weakness of circulatory muscle contraction compared with the young (10 weeks old) SD rats. LC-MS/MS analysis exhibited that the levels of SIP were significantly greater in the CSM of aged rats, demonstrating that SIP varies depending on age. BKCa (a- subunit and β subunit) levels in CSM were shown to increase in an age-dependent manner from 10- to 80-week-old rats by mRNA, protein and immunohistochemical, but P-MLC expression decreased. In colon SMCs by BKCa siRNA transfection, we found P-MLC levels increased. Exogenously added SIP upregulated BKCa in colon SMCs in a concentration-dependent manner. Intracellular Ca2+ mobilization though inhibiting SIP was measured and induced the decline of P-MLC. Our results also proved that SIP upregulated BKCa through the Akt/ERK/JNK pathways. The expression of BKCa decreased by treatment with inhibitor of Akt/ERK/JNK pathways or siRNA.

Conclusion: The results of our study showed that altered SIP due to aging upregulates BKCa via the Akt/ERK/JNK mediated pathway in CSM. BKCa upregulation inhibits Ca2+ influx and MLC phosphorylation and thereby reduces the contractile force. These findings are consistent with previous reports and offer the first evidence for the mechanism of the contractile dysfunction of CSM observed in older individuals, which may be implicated in age-associated gastrointestinal motility disorders.

P1130 DIABETES-RELATED ALTERATIONS IN THE EXPRESSION OF THE INFLAMMATORY CYTOKINES, TUMOR NECROSIS FACTOR ALPHA AND INTERLEUKIN 6 IN THE MYERIC GANGLIA AND ITS MICROENVIRONMENT OF DIFFERENT INTESTINAL SEGMENTS
I. Chandrakumar, D. Mezei, B. P. Barta, Z. Szalai, N. Bödi, M. Bagyanszki

Introduction: Growing amount of evidence has indicated that increase of the hyperglycaemia-induced oxidative stress and decreased effectiveness of the endogenous antioxidant protection play the major role in the initiation of diabetes-related neural damage. Using a streptozotocin-induced diabetic rat model we recently demonstrated that nitricergic myenteric neurons, which are key regulators of peristalsis, display different susceptibilities to diabetic damage and also to 10% treatment in the ileum and proximal colon segments. On these results we suggested the importance of the molecular differences in the neuronal microenvironment in the pathogenesis of diabetic nitricergic neuropathy.

Aims & Methods: Aim to reveal the quantitative differences in the expression of the pro-inflammatory cytokines like tumor necrosis factor alpha (TNFα) and interleukin 6 (IL6) in the myenteric ganglia and its microenvironment of the different intestinal segments, quantitative immunogold electron microscopy was used. Ten weeks after the onset of diabetes, segments from the duodenum, ileum and proximal colon of control and diabetic, and control rats were processed for post-embedding immunohistochemistry.

Results: The density of TNFα- and IL6-labelling gold particles was strictly region-dependent, with increasing to the distal part of the gastrointestinal tract of TNFα. In diabetic rats, the number of TNFα gold particles was significantly increased in the duodenal, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myenteric ganglia of different gut regions. The diabetes-related alterations of TNFα- and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNFα- and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we presume that regionally alterations in the TNFα and IL6 expression are correlated with the diabetes-related region-specific nitricergic myenteric neuropathy.

Aims & Methods: Gene and protein expression of SEMA3A and its receptor NRP1 was investigated in distal colon from postnatal day 1 (P1) to adulthood by qRT-PCR and Western blot respectively. The cellular distribution of SEMA3A and NRP1 was performed at P7 and P36 in whole mount distal colon tissue by double immunofluorescence for SEMA3A or NRP1 with specific markers for ganglion cells and enteric neurons (Hu, TuJ-1, and muscle cells a-SMA). The impact of SEMA3A on neuronal outgrowth was assessed in cultures of enteric neurons cocultured with SEMA3A-transfected COS-7 cells.

Results: A peak of mRNA expression for SEMA3A and NRP1 was observed in distal colon of newborns at P7, corresponding to a stage of intense neural circuit remodeling. At the protein level, NRP1 was also found to be predominantly expressed during the early postnatal period. Immunohistochemistry for colon tissue indicated that SEMA3A immunoreactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NRP1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-expressing COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

Conclusion: This study shows the expression of SEMA3A and its receptor NRP1 in the ENS during early postnatal period. By controlling axonal outgrowth, SEMA3A might be an important factor to restrict the axonal trajectories in the appropriate paths between ganglia.

Introduction: Objective means of evaluating of the defecatory process include anorectal manometry (HRM), balloon expulsion test (BET) and imaging of the defecatory process (X-ray defecography, dynamic transpelvic ultrasound (DT-PUS) or MR defecography). These tests have a place in the evaluation of suspected evacuatory dysfunction (ED), fecal incontinence (FI) and chronic pelvic pain (CPP). Test choice may influence subsequent patient management; however, there is only limited information regarding the agreement between HRM, DT-PUS and BET.

Aims & Methods: The aims of this study were to compare the diagnostic yield and agreement between different tests of evacuation and to define the relation between the diagnoses of evacuation dysfunction to objective evacuation failure. 63 consecutive patients (60 females, mean age 51ys) were prospectively evaluated with HRM, BET and PUS. Inter test agreement for the diagnosis of anismus was assessed using the Kappa statistic. Correlation between anismus to evacuation failure (assessed by PUS) was also assessed.

Results: 36 patients were assessed for ED, 6 for CPP and 21 for FI. Anismus was diagnosed in 26 patients by HRM and 45 patients by DT-PUS. All cases of anismus diagnosed by HRM or DT-PUS had a positive BET. The Kappa agreement for the diagnosis of anismus between HRM and DT-PUS was poor (0.143 ± 0.01). 9 patients had significant pelvic floor anatomic pathology (4 rectal prolapse, 6 pathological pelvic descent, 4 enterocele and 3 rectoceles >3.5cm). There was a moderate correlation between diagnosis of anisms on DT-PUS to failure to evacuate the rectum (r = 0.636). The correlation between rectal evacuation on DT-PUS to the diagnosis of anismus on manometry was weak (r = 0.296).

Conclusion: There is considerable disagreement between the results of various evacuatory tests, and between the diagnoses of evacuation dysregulation to failure of rectal evacuation. Therefore, more than one test should be applied in order to evaluate the defecatory dysfunction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1134 DIAGNOSTIC USE OF ENDOSCOPIC FULL-THICKNESS WALL RESECTION (EFTR) IN PATIENTS WITH SYMPTOMS OF CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIP0)
P.V. Valli1, D. Pohl2, M. Fried1, R. Caduff2, P. Bauerfeind2

Introduction: Complex gastrointestinal motility disorders such as chronic intestinal pseudo-obstruction (CIP0) or Hirschsprung’s disease (HD) are challenging to diagnose and treat appropriately. Thorough assessment of patient history, radiographic exams, endoscopy and motility measurements aid in diagnosis and, subsequently, in grouping, yet underlying histology is the cornerstone to enable a more distinct diagnosis of neuromuscular GL disorders. Traditionally, surgical procedures have been performed to obtain specimen suitable for accurate histologic analysis.

Aims & Methods: We performed endoscopic full-thickness resection (eFTR) using a full-thickness-resection device (FTRD) under moderate propofol sedation in four patients with suspected severe neuromuscular gut disorders including CIP0.

Results: Patient 1: A 21-year-old male patient with cerebral palsy suffering from acute small bowel ileus with a history of laparotomy, detorquation and appendectomy after colic volvulus at the age of 15. Histologic analysis revealed irregular configuration of the myenteric plexus, but primary neuro- myopathic disease such as HD were ruled out. GL dysmotility due to cerebral palsy syndrome was suspected. Patient 2: After a life-long history of recurrent obstipation, colonic dilatation, ileus symptoms and various colonic segment resections, diagnostic eFTR was performed in a 55-year-old female patient. The diagnosis of hypoganglionosis was established by LDH histochemical and by immunohistochemical reactions with Calretinin and Map-2 Kinase. Patient 3: A 19-year-old male patient with a history of a sigmoid volvulus and massively dilated large bowel segments. Enzyme histochemistry excluded HD upon histopathological analysis. The inner muscle layer showed fibrosis, eosinophilic leiomysitis and lymphocytic ganglionitis. Congenital CIP0 was diagnosed due to degenerative leiomysitis. Patient 4: A 56-year-old male patient with acute ileus and a year-long history of constipation and abdominal pain. Histopathological analysis
revealed hypogangloniosis, severe fibrosis of the inner muscle layer and reduced ICC networks (4.6 and 3.9 for YH1282 0.3, 0.5, 1, 2 and 3 mg, respectively, 4.0 prucalopride and 2.6 placebo. The proportion of responders (defined as those with a ≥1 point reduction in PAC-SYM from baseline) was similar between the treatment groups (87.5%, 100.0%, 100.0%, and 100.0% in 0.3, 0.5, 1 and 2 mg, respectively, with the exception of the 3 mg group (80.0%), compared with that in the prucalopride (83.3%) and placebo groups (28.6%). The mean stool con- stipation (STC).

P1137 HEALTHCARE PROFESSIONALS FAIL TO PROVIDE ADEQUATE SUPPORT ABOUT OPYIOTINDUCED CONSTIPATION TO STRONG-OPIOID Users.

Introduction: Constipation is a common side effect of opioid use. Available laxa- tive therapies for opioid-induced constipation (OIC) leave the patient with signif- icant residual symptoms, which may lead them to adjust or stop their opioid intake in order to have a bowel movement, unless effectively counselled.

Aims & Methods: This subgroup analysis of an international survey investigated counselling resources, information-seeking, and sources of support in subjects with constipation caused by the use of strong opioids (e.g. buprenorphine, fen- tanyl). This was a quantitative, questionnaire-based, online survey conducted in France, Germany, Italy, Spain and the UK among respondents aged ≥40 years with largely non-cancer-related chronic pain, treated long-term with strong opioids and having constipation (N=2016). The survey assessed past medical history, opioid use, treatment-related symptoms, and effects on quality of life.

Results: In general, respondents find it difficult to combine pain management relief and constipation and discontinued having to balance between them (36%). Approximately one-fifth (22%) of respondents were very or somewhat dissa- tisfied with the effectiveness of their current constipation treatment and only 43% strictly adhered to prescribed treatment regimens, with 32% researching other treatment options. A significant number of respondents (44%) admitted that their constipation becomes so bothersome that they have to combine different meth- ods to relieve it, and 40% often cut down their opioid medication or even skip it entirely (9%) to relieve constipation. To manage their constipation, respondents regularly used a variety of approaches, including dietary measures (48%), exercise (23%) and single (32%) or multiple (15%) laxative treatments. Only 45% of respondents reported that their healthcare professionals (HCPs) had warned them about constipation as a potential side effect of opioid use. Almost two-thirds of respondents (63%) reported that their HCP was the main information source on opioid-induced constipation. Although 58% of respondents stated that they would have liked their HCP to provide more information about OIC, 48% preferred to deal with constipation on their own, rather than discuss it with their HCP. Other common sources of information were online search engines (44%) and online health forums (29%). Less than half of respondents (43%) strictly adhered to prescribed treatment regimens, with 32% researching other treatments.

Conclusion: A proportion of patients are not satisfied with their current constipa- tion treatment and they sometimes find balancing the need for adequate pain relief with constipation side effects challenging; consequently, many fail to adhere to their prescribed treatment regimens, or resort to using suboptimal strategies, such as reducing their opioid intake, to relieve constipation. Despite this dissat- isfaction, many HCPs are not counselling patients adequately about constipa- tion as a common potential side effect of opioid use. While most patients would like to have more support from their HCP, nearly half prefer to deal with con- stipation on their own, perhaps due to embarrassment or resignation.

Introduction: Three-dimensional high-resolution anorectal manometry (3DHARM) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastrointestinal tract.

Our aim was to evaluate children after surgery for ano-rectal disorders using 3DHARM.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age, 7 years) after surgery for ano-rectal disorders at the Departments of Pediatric Gastroenterology, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung’s disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after procotocolectomy for other reasons (PC). In all children conventional manometric parameters were compared to the design and conduct of the study, data analysis and medical writing.

Introduction: Linaclootide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aims & Methods: A multicentre, observational, prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Score Severity Scale (IBS-SSS) score from baseline at 52 weeks after linaclotide initiation. Consenting patients (n=202) were recruited; 185 (92%) were female. At baseline, median age was 44.9 (range 18–77) years; 84 (42%) reported concomitant laxative use.

Results: 202 patients were recruited; 185 (92%) were female. At baseline, median age was 44.9 (range 18–77) years; 84 (42%) reported concomitant laxative use.

Change in IBS-SSS score at 52 weeks from start of linaclotide

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of faecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria (n=13) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12 and 20/28. All the samples were stored at −80°C until analysis. Faecal concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-caproic acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28, assessing the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 1).

P1141 HEALTHCARE RESOURCE USE IN PATIENTS WITH IRRITABLE BOWEL SYNDROME WITH DIARRHOEA BASED ON A SURVEY OF PHYSICIANS IN THE UNITED KINGDOM

A. Marciniak1, D. Collomb2, S. Baker3, R. Goosy4
1Allergan plc, Marlow/United Kingdom
2Kantar Health, Epsom/United Kingdom

Contact E-mail Address: Anne.Marciniak@Allergan.com

Introduction: Irritable bowel syndrome with diarrhoea (IBS-D) is a chronic gastrointestinal disorder associated with significantly increased healthcare resource use (HCRU) and a substantial economic burden. In clinical practice, adequate relief (AR) of symptoms is an important measure of treatment effectiveness. However, the difference in HCRU related to IBS-D between patients with AR and those with inadequate relief (IR) has not yet been assessed.

Aims & Methods: This objective of this study was to quantify the HCRU in patients with AR of IBS-D symptoms compared to patients with IR. An online survey assessing HCRU was distributed to general practitioners (GPs) recruited from market research panels in the UK in August 2016. GPs opted-in to complete the survey via an email link and were screened before being invited to complete the main survey. Screening criteria included having seen patients with a chronic gastrointestinal condition in the past three months, having seen patients with IBS-D in the past 3 months and having decided on what treatments were prescribed for patients with IBS. The survey was a 15-minute web-based survey, including 12 questions collecting information on the use of medical services and procedures amongst patients with IBS-D for the first year following diagnosis and for subsequent years. Respondents were required to answer the survey considering patients who had AR of IBS-D symptoms and those who did not (IR), based on the respondents’ own assessments. Statistical analyses included t-tests for two independent samples comparing mean scores for those with IR vs those with AR during the first year after diagnosis at a 5% risk level, with p < 0.05 denoting significance.

Results: The online survey was completed by 50 GPs, with responses from 46 GPs included in this analysis (four responses were excluded due to data quality reasons). The reported total number of medical visits was significantly higher for patients with IR vs patients with AR during the first year after diagnosis (mean 10.11 vs 5.20; p < 0.001), with similar results seen for subsequent years (mean 8.20 vs 4.38). Significantly higher numbers of GP office visits, outpatient visits and emergency room visits were reported for patients with IR, with the greatest difference seen for GP office visits (2.37 more visits/year on average; incremental 4-week increase of 0.182; p = 0.003) [Table]. Similarly, the total reported mean number of procedures was significantly higher for patients with IR vs patients with AR (8.11 vs 4.52; p = 0.046), with number of colonoscopies having the greatest difference between the two groups (2.17 vs 0.91; 1.26 more procedures/year on average; incremental 4-week increase of 0.097; p = 0.008). Similar results were seen for the subsequent years after diagnosis, with patients with IR having more medical procedures compared to patients with AR (4.08 vs 2.56).

Conclusion: Our results reveal differences in faecal fermentation products between patients with IBS and healthy donors, and suggest that FMT may act to normalise such alterations of gut microbial functions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Concentrations (mmol/kg) of short-chain fatty acids (SCFAs) in faecal samples collected from donors and patients with irritable bowel syndrome (IBS) before and after faecal microbiota transplantation (FMT).

Data are presented as mean ± SEM. Comparison: Kruskal-Wallis multiple comparisons test with Dunn’s post test. *Donors at the beginning of the study vs. patients on FMT day before faecal installation. **Donors at the beginning of the study vs. patients 1 week after FMT. ***Donors at the beginning of the study vs. patients 3 weeks after FMT. ****Donors at the beginning of the study vs. patients 12 weeks after FMT. *****Donors at the beginning of the study vs. patients 20/28 weeks after FMT.

Conclusion: GPs reported that patients with IBS-D considered as having IR of symptoms had increased HCRU, including more GP office visits and more colonoscopies, compared to patients with AR. These results highlight that IR is potentially an important driver of increased HCRU in patients with IBS-D, emphasising that effective treatments that provide AR may reduce HCRU and the associated economic burden.

P1143 LINACLOTIDE ACCELERATES COLONIC TRANSIT AND IMPROVES COLONIC CONTRACTILITY IN IBS WITH CONSTIPATION

A. D. Farmer1, A. R. Hobson1
1Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom
2Functional Gut Clinic, London/United Kingdom

Contact E-mail Address: a.farmer@qmul.ac.uk

Introduction: Linaclootide, a guanylate cyclase-C agonist, stimulates intestinal fluid secretion and decreases visceral hypersensitivity and is licensed for use in irritable bowel syndrome with constipation (IBS-C). There is a relative paucity of data comparing the effect on gastrointestinal (GI) motility.

Aims & Methods: We aimed to compare the effect of linaclootide on segmental and pan-enteric motility in IBS-C. 14 patients with Rome III defined IBS-C (3 male, mean age 37 years, range 20–64) underwent a wireless motility capsule (WMC) study. Baseline and post treatment data were compared using change from baseline as the primary outcome.

Results: Changes in GI motility are shown in Table 1. Linaclootide improved VDVAS-I and VDVAS-U (130.7±20.8 vs. 106.5±33, p = 0.03 and 113±22 vs. 85.8±33, p = 0.01) and quality of life (58.4±21.2 vs. 68±17.6, p = 0.02).

Conclusions: Linaclootide improved VDVAS-I and VDVAS-U and quality of life. Due to the small number of patients, these results require confirmation in larger studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1144 RELATIONSHIP BETWEEN RIFAXIMIN THERAPY AND SEHCAT TEST IN PATIENTS WITH DIARRHEA-PREDOMINANT IRITRIBULE BOWEL SYMORDM OR FUNCTIONAL DIARRHEA

Gastroenterologia, Hospital Universitari de Bellvitge, Hospitalet de Llobregat/Spain

Contact E-mail Address: alexandruarzucerulla@gmail.com

Introduction: Rifaximin is used as prophylaxis against endoscopy related infections. However, the role of rifaximin in patients with IBS-D or Functional Diarrhea (FD) is undefined. The role of rifaximin in reducing bile acid malabsorption (SeHCAT) has not been described. We aimed to assess the effect of rifaximin in patients with IBS-D or FD.

Aims & Methods: a) To determine if SeHCAT test result improves in patients with IBS-D or FD.

Results: Forty-one patients were included. BAD was present in 23 patients (56%). No clinical differences were found between BAD and non-BAD patients at study entry. Rifaximin resulted in a significant improvement in the number of daily stools (Δ = 1.5; P < 0.01), daily watery stools (Δ = 2.1; P < 0.01), Bristol scale (Δ = 1.1; P < 0.01), abdominal pain (Δ = 0.5; P < 0.01), distension (Δ = 0.3; P < 0.01), urgency (Δ = 0.7; P < 0.01) and in the IBS-SS (Δ = 78; P < 0.01). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment and 10.7% after treatment; P = 0.4).

Conclusions: Rifaximin treatment confers significant clinical improvement irrespective of the presence of BAD. Rifaximin treatment does not affect SeHCAT test.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Aims & Methods:** To evaluate IR in patients treated with ELX in a post hoc analysis from two randomised, double-blind, placebo-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BID) ELX (75 or 100 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had adequate [satisfactory] relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders. Patients answering “No” were considered to have had inadequate relief (IR). This analysis evaluated the number of consecutive weeks that patients reported IR over Weeks 1–12 and 13–24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

**Results:** Overall, 2429 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p = 0.001] and 56.3% [p = 0.001] vs 41.8%, respectively) and at 26 weeks (51.5% [p < 0.001] and 49.0% [p = 0.004] vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IR of IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–<5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

**Conclusion:** In this post hoc analysis of the pooled ELX Phase 3 studies, ELX-treated patients experienced fewer consecutive weeks of IR compared to those receiving PBO, within both Weeks 1–12 and 13–24 of treatment. As IR is thought to increase healthcare resource use and subsequent healthcare costs associated with IBS, further prospective study of the impact of ELX on AR and any subsequent reduction in healthcare costs is required, including the relationship between the number of consecutive weeks of IR and patients’ behaviour towards healthcare resource use.

**Introduction:** Adequate relief (AR) of irritable bowel syndrome (IBS) symptoms is a commonly used global outcome measure to assess treatment benefit in both clinical trials and real-life clinical practice. Conversely, inadequate relief (IR) is considered an important driver for patients to use healthcare resources such as general practitioner or gastroenterologist consultations. Eluxadoline (ELX) is a mixed μ-opioid receptor (OR) and κ-OR agonist and δ-OR antagonist approved for the treatment of IBS with diarrhoea (IBS-D) in the US and Europe.

**Aims & Methods:** Evaluate IR in patients treated with ELX in a post hoc analysis from two randomised, double-blind, placebo-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BID) ELX (75 or 100 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had adequate [satisfactory] relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders. Patients answering “No” were considered to have had inadequate relief (IR). This analysis evaluated the number of consecutive weeks that patients reported IR over Weeks 1–12 and 13–24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

**Results:** Overall, 2429 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p = 0.001] and 56.3% [p = 0.001] vs 41.8%, respectively) and at 26 weeks (51.5% [p < 0.001] and 49.0% [p = 0.004] vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IR of IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–<5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

receptor antagonist, is approved for the treatment of IBS-D in adults, based on two large, Phase 3 clinical trials when evaluated in the primary composite response endpoint of simultaneous improvement in abdominal pain and stool consistency over 26 weeks.

**Aims & Methods:** These post hoc analyses of two double-blind, placebo-controlled, Phase 3 clinical trials of eluxadoline (IBS-3001 and IBS-3002) aimed to assess responder and non-responder rates over 4-week intervals for eluxadoline vs placebo, and the proportion of responders/non-responders who continued or discontinued treatment. Patients meeting Rome III criteria for IBS-D were randomly assigned to twice-daily treatment with eluxadoline (75 or 100 mg) or placebo. Patients rated IBS symptoms daily, including worst abdominal pain (WAP; 0–10 scale, with 0 = no pain and 10 = worst imaginable pain), stool consistency (Bristol Stool Form Scale [BSFS]), and Global Symptom Score (GSS; 0–4 scale, where 0 = no symptoms and 4 = very severe symptoms). A responder for a 4-week interval was defined as a patient with a simultaneous daily improvement ≥30% in WAP score vs baseline and BSFS score <5 with ≥50% of days demonstrating a response and a minimum of 20 days of diary data. The intention-to-treat (ITT) analysis set included all patients randomised to a treatment group. For these analyses, patients with baseline GSS ≥3 (severe or very severe symptoms) and self-reported inadequate symptom control with loperamide were classified as having severe IBS-D.

**Results:** Of the 2423 patients in the pooled Phase 3 ITT population, 249 were classified as having severe IBS-D. Over Weeks 1–4, 26.8% and 30.3% of patients with severe IBS-D were responders with eluxadoline 75 and 100 mg, respectively, vs 8.1% of patients on placebo (Table). Higher proportions of patients were responders with eluxadoline vs placebo over each subsequent 4-week interval, with response rates observed at Weeks 1–4 consistently maintained across all subsequent 4-week time intervals. With both eluxadoline and placebo, proportions of responders discontinuing were <2% across each 4-week interval, and discontinuation rates in non-responders were higher than in responders (Table). Similar findings were observed in the ITT analysis set: over Weeks 1–4, 22.7% and 24.6% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 12.5% of patients on placebo. Over Weeks 21–24, 28.1% and 30.2% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 20.1% on placebo. Discontinuation rates among responders with both eluxadoline and placebo remained <1% across all 4-week time intervals.

C, patients continuing on treatment; DC, patients discontinuing from treatment.

**Conclusion:** Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has no post hoc evidence to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileocaecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

**Aims & Methods:** We aimed to compare the effect of a low FODMAP diet vs the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (verbal descriptor scale on pain and 10

**Results:** After screening, 32 patients (23 female, median age 37 years, range 18–65) were randomized. Baseline symptom severity and demographics were similar between the two groups. Relative to baseline, there was a reduction in the change in ileocaecal pH with the low FODMAP diet group compared to the m-NICE group (3.37 ± 0.3 vs 0.005 ± 0.4, p = 0.047) suggesting reduced fermentation. Changes in GI motility are shown in Table 1.

**Table 1:** Changes in segmental/whole gut transit times and ileal/mucosal motility, relative to baseline between the low FODMAP and m-NICE diets. Both the low FODMAP and NICE diets improved VDVAS-I and VDVAS-U (−18 ± 17 vs. −9 ± 14 and −16 ± 16 vs. −9 ± 14, respectively). Similarly, both reduced somatic symptoms (−1 ± 1.4 vs. −0.8 ± 1.8, p = 0.07) and improved quality of life (9.5 ± 10.2 vs. 4.4 ± 9.8, p = 0.23).

**Conclusion:** The low FODMAP diet reduces caecal fermentation in comparison to the NICE diet as indexed by a reduction in the change in pH across the ileocaecal junction. Both diets improved GI and extra-GI symptoms as well as quality of life. Neither diet has a demonstrable differential effect on ileal/colic contractility or segmental/whole gut transit times. It is therefore plausible that the efficacy of the low FODMAP diet in IBS-M is via mediated by alterations in the microbiota.

**P1148 THE LOW FODMAP DIET REDUCES CAECAI FERMENTATION COMPARED TO TRADITIONAL DIETARY ADVICE: A RANDOMISED CONTROLLED TRIAL**

A. D. Farmer1, N. Saint2, A. R. Hobson3
1Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom
2Functional Gut Clinic, London/United Kingdom

**Introduction:** Diet reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, mono-saccharides, and polyols [FODMAPs]) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileocaecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

associated with triggering gastrointestinal symptoms in irritable bowel syndrome (IBS).

**Aims & Methods:** This study aimed to assess whether oral α-galactosidase co-ingestion with foods high in GOS and low in other FODMAPs would reduce symptoms and breath hydrogen production in a double-blind, placebo-controlled trial. Monash University Ethics Committee. Patients meeting the Rome III criteria for IBS who produced >10 ppm hydrogen on two consecutive breath samples following 10 g frucitol were randomized to either placebo or enzyme (α-galactosidase) and followed for 7 days. Participants were randomly assigned to full-dose enzyme (300 GALU α-galacto-sidase) and placebo (150 GALU α-galactosidase) and placebo (glucose). Following a 3-day low-FODMAP run-in period, participants consumed pretreatment diets high in GOS for a further 3 days. Gastrointestinal symptoms were measured daily using a 100 mm visual-analogue-scale. Breath samples were taken hourly on the second last day and analysed as area-under-the-curve.

**Results:** Thirty-one participants with IBS (20 IBS-D, 4 IBS-C, 7 IBS-M) completed the study. The addition of high GOS foods resulted in a significant increase in overall symptoms (median [IQR] 13.0 [5.5–22.0] to 35.5 [12.8–54.0] mm; p = 0.000, Wilcoxon signed-rank test). No significant increase in overall symptoms was seen with the full-dose enzyme (14.0 [3.5–24.0] vs 14.7 [2.3–32.7] mm; p = 0.422). Ten participants exhibited GOS-sensitivity (>10 mm increase in overall symptoms). Of those, full-dose enzyme reduced overall symptoms (24.5 [17.5–35.8] mm vs 5.5 [1.5–15.0] mm; p = 0.006) and bloating (20.5 [9.5–42.0] vs 6.5 [2.0–15.8]; p = 0.017). Breath hydrogen production was minimal with no differences seen between placebo and 5248 ± SD 3339 ppm (12 h) and full-dose (5585.5 ± 3205; p = 0.597, paired samples t-test).

**Conclusion:** An oral α-galactosidase supplement taken with high GOS foods provides a clinically significant reduction in symptoms in IBS-susceptible individuals. However, the office-based point-of-care test may not be related to reduced gas and distention, rather suggesting a role of alterations to the microbiota. Future analysis of the faecal microbiota may provide insight for the mechanism of action. This strategy can be easily translated into clinical practice. A prospective case-control study involving high GOS foods with IBS as an adjacent therapy to the low-FODMAP diet.

**Contact E-mail Address**: a.albuquerque.dias@gmail.com

**Introduction:** Anal squamous intraepithelial lesions are pre-cancerous lesions of anal squamous cell carcinoma and are largely related to human papillomavirus infection. Immunosuppressed patients have a higher prevalence of these lesions. There are some studies in renal transplant recipients, but no information exists regarding prevalence in liver transplantation.

**Aims & Methods:** Our aim was to evaluate the prevalence of anal squamous intraepithelial lesions in liver transplant recipients compared with healthy subjects. We conducted a retrospective case-control study involving liver transplant recipients that were compared with a healthy control group. All patients were admitted to the anal cytology. Those with abnormal cytological results, namely high-grade squamous intraepithelial lesions (HSIL), atypical squamous cells which cannot exclude high-grade squamous intraepithelial lesions (ASC-H), low-grade squamous intraepithelial lesions (LSIL) and atypical squamous cells of undefined significance (ASC-US), were submitted to high-resolution anoscopy with biopsies of any suspicious lesion.

**Results:** A total of 59 liver transplant recipients and 57 controls underwent anal cytology. In the liver transplant group, 37 (65%) were men, with a mean age of 54 ± 10 years. The most common indication for transplantation was alcoholic cirrhosis in 26 patients (44%), the majority of the patients were only on tacrolimus (n = 65, 39%), and had been transplanted a mean of 8 ± 5 years ago. In the healthy control group, 36 (65%) were men, with a mean age 59 ± 11 years. Regarding anal cytology, 10 (17%) of liver transplant recipients had abnormal results, 7 patients had ASC-US, 1 patient ASC-H and 2 patients HSIL. In the control group only 1 patient (2%) had an ASC-US result (p = 0.005). Anal squamous intraepithelial lesions were confirmed in 7/10 of liver transplant patients and 0/1 in control group (p = 0.013) by high-resolution anoscopy with biopsies. Smoking was the only risk factor for abnormal anal cytology (OR = 5.9, 95% CI = 1.224–28.121, p = 0.057).

**Conclusion:** Liver transplant patients have a higher risk of anal squamous intraepithelial lesions and screening should be considered especially in smokers.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Gastrointestinal mediated food allergy (GMA) is a common disease that has increased recently. The scientific research on this disease has increased, however its diagnosis still remains difficult to date. Diamine oxidase (DAO) is an enzyme that deactivates histamine, the main mediator in allergic reactions, through oxidative deamination. It has been shown that the enzymatic activity of DAO is diminished in the colonic mucosa of patients with GMA. Up to now no studies concerning the expression of DAO in the upper gastrointestinal tract (GIT) of patients with GMA have been published. Therefore, the objective of this study was to analyse the immunohistochemical staining of DAO and its localisation in the upper GIT of patients with or without GMA.

Aims & Methods: The study was retrospective. The GMA group consisted of 21 patients with gastrointestinal food allergy. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO. The expression of DAO was semi-quantitatively analysed with the following scale based on the staining intensity of DAO (SI-DAO): 0 = none, 1 = low, 2 = medium, 3 = high intensity. The localisation of DAO was also examined vertically from the epithelium to the submucosa in all examined tissues. The analyses were performed twice by the same examiner in two separate points of time. Furthermore, the tissue samples were immunohistochemically stained for MBP and CD117 in order to count the number of eosinophils and mast cells respectively. Two measurements were performed inside an area of 100μm² in the lamina propria (LP); one in the subepithelial superficial lamina propria (SLP) and one in the deeper lamina propria (DLP). The average of these two measurements constituted the number of these cells for each tissue.

Results: Immunohistochemical analysis found DAO in all segments of the upper GIT, but the SI-DAO was overall low. Across the upper GIT the median SI-DAO in the CG was 1.1 (range 0.9–1.3). The SI-DAO did not differ between the examined tissues. The SI-DAO was also low in the GMA group (median 1.0; range 0.8–1.3) and it was statistically significantly lower compared to the controls (median vs. 1.1; p < 0.04) only in duodenum, in the GMA group the SI-DAO in the esophageal region of the cardia and in corpus was significantly higher than in duodenum (see Table 1). The strongest DAO-staining was detected in the subepithelial lamina propria (SLP) of all tissues. A strong inverse correlation of the SI-DAO to the number of eosinophils across the upper GIT was observed only in the GMA group (r = -0.89, p = 0.02). An inverse correlation of the SI-DAO with the number of mast cells was also observed in both groups, but this result was not statistical significant (GMA: r = -0.71, p = 0.11; CG: r = -0.6, p = 0.14).

Conclusion: The above findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, the assessment of DAO staining for DAO only in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

Introduction: Chronic atrophic gastritis (CAG) is claimed to be a pre-cancerous condition for gastric cancer, being serological markers like serum pepsinogens and gastrin-17 (G-17) proposed as non-invasive useful tools. OLGA histological classification has been proposed as of prognostic value. Aim of the study was to assess, by using serological markers, the prevalence of CAG in general population and to correlate with the results with OLGA classification.

Aims & Methods: One thousand and nine hundred consecutive patients (M = 915; mean age = 53.5, range = 27–82) showing upper-gastrointestinalal (GI) troubles entered the study. Exclusion criteria were: previous history of upper-GI neoplasms, previous surgery, concomitant Proton Pumps Inhibitor (PPI) therapy. All patients underwent a blood sample for GASTROPanel® (BioHit Oy, Finland) based on: pepsinogen I (PGI), pepsinogen II (PGII), gastrin-17 (G-17) and IgG against Helicobacter pylori. (Hp-IgG). The normal values are: PGI: 30–120 μg/L, PGII: 2–15 μg/L, G-17: 1–9 pmol/L, Hp-IgG:<8 (IU/mL) as well as high levels of G-17 (G-17>15 pmol/L) were considered diagnostic for CAG. Eighty-three patients with serology suggestive for CAG underwent upper endoscopy and histology according with OLGA staging. The relationship between PG-I, PG-II and the different OLGA stages was statistically analyzed.

Results: Eighty-three (M = 44, mean age = 61, range = 49–82) out of 1900 investigated patients showed CAG (4%). Of the 83 CAG patients, 19.2% was classified as OLGA 2, 56.6% as OLGA 3 and 24.2% as OLGA 4. The relationship between PG-I levels and OLGA stage shows a statistically significant difference between the stages OLGA 0, 1, 2 and the stages 3 and 4 (PG-I mean values: OLGA 0: 72.45 μg/L, OLGA 1: 85.95 μg/L, OLGA 2: 47.38 μg/L, OLGA 3: 16.00 μg/L, OLGA 4: 10.10 μg/L; p<0.001). The relationship between OLGA stages and G-17 serum levels shows a statistically significant difference (G-17<15 pmol/L mean values: OLGA 0: 4.6 pmol/L, OLGA 1: 5.2 pmol/L, OLGA 2: 2.65 pmol/L, OLGA 3: 44.6 pmol/L, OLGA 4: 38.5 pmol/L; p < 0.01 by comparing OLGA 0–1 against OLGA 2–4) (p < 0.02).

Conclusion: The prevalence of CAG assessed by serological markers is low in the studied population (4%). The majority of patients (56.6%) were classified in the OLGA 2 stage. Both PG-I and G-17 showed a statistical significant relationship with the more severe degrees of CAG.

Disclosure of Interest: All authors have declared no conflicts of interest.
L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group I human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.

Aims & Methods: One hundred fourteen consecutive patients (M=43, mean age 64.9 years) (with diagnosis of CAG) by means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen 1 <25 µg/l gastrin-17 >14 pmol/l) - GastroPanel®, Boehr, Ohy, Finland) entered the study. Forty-one patients (11 M, mean age 49.4 ± 21 years, range 27–71 years) were treated with L-cysteine (100 mg 3 times daily, with meals) for 24 months (Group 1). As a control group we enrolled 73 CAG patients (M=32, mean age 55.3 ± 11 years, range: 32–77 years) followed up for 24 months without any related therapy (Group 2 - patients with gastritis, early satiation, nausea, bloating) were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0–3 for each symptom, min. 0 = no symptoms; max. 12 = full symptomatology).

Results: The initial symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.9; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01). Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous Helicobacter pylori infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

Conclusion: The administration of L-cysteine to subjects affected by moderate–severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1155 PROGNOSTIC SIGNIFICANCE OF SERUM INFLAMMATORY MARKERS IN GASTRIC CANCER
A. Powell1, D. Parkinson2, N. Patel3, C. Brown2, W. Lewis4

Introduction: Despite undergoing potentially curative resection a significant proportion of patients develop cancer recurrence. Several cellular and humoral components of systemic inflammatory response have been reported and associated with poor outcome. To date, no study has comprehensively examined the relationship between readily available markers of inflammation and survival in gastric cancer.

Aims & Methods: Patients undergoing surgery for stage I-III gastric cancer between 2004-2016 at a regional unit were identified. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological factors were recorded from reports issued at the time of resection. The modified Glasgow Prognostic Score (based on CRP and Albumin), Neutrophil-Lymphocyte Ratio, Platelet-Lymphocyte Ratio and Neutrophil-Platelet ratio were calculated. Pathological variables including TNM stage, differentiation and vascular invasion were also recorded. Survival endpoints of overall survival (OS) and disease-free survival (DFS) were used.

Results: 331 patients were identified and 291 patients underwent potentially curative resection for gastric cancer. On univariable DFS analysis, female gender, proximal location, T-stage, N-stage, TNM, vascular invasion, poor differentiation, lymph node ratio, R1 status, platelet count and mGPS were significantly associated with poor survival. On multivariable DFS analysis, mGPS (HR 2.51, 95% CI 1.35–4.65; p < 0.01) with 10 codes and implementation of the upper GI endoscopy. For each test-case, the odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for aspirin, proton pump inhibitors, omeprazole, omeprazole + hydrochloride, respectively. The odds ratios of all the upper GI mucosal injuries were the highest in the patients with anticoagulants, and the ratios were relatively low in those with NSAIDs and COX-2 selective inhibitors. The odds ratios tended to increase with the number of prescribed

Conclusion: Rebleeding in UGB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall and Blatchford were predictors for in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. The UGB risk scores AIMS 65 and Rockall showed poor predictive ability for acute rebleeding in the rebleeding patients’ group and was similar for Blatchford score (based on AURG).

P1157 A CASE-CONTROL STUDY ON THE RISK OF UPPER GASTROINTESTINAL MUCOSAL INJURIES IN SUBJECTS PRESCRIBED NSAIDS AND ANTI-THROMBOTIC DRUGS USING THE LARGE ORGANIZED DATABASE OF CLAIMS IN JAPAN (APPROMINATELY 3.7 MILLION POPULATION ON AN ACCUMULATED BASIS)

Introduction: Upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We conducted a case-control study to risk upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

Aims & Methods: The medical claims database developed by Japanese Medical Data Center (JMDJC) Co., Ltd. was selected as data source in this present retrospective observational study. The JMDJC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database from January 2009 to December 2014. The evaluated upper GI mucosal injuries were peptic ulcers (143,271 cases), upper GI bleeding (10,545 cases) and gastroesophageal reflux disease (GERD: 154,755 cases) with diagnosis by ICD-10 codes and implementation of the upper GI endoscopy. For the each test-case, ten controls who matched age, sex and diagnosis month were identified from the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injuries caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antplatelet drugs (except low-dose aspirin) and anticoagulants.

Results: The odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antplatelet drugs, and anticoagulants, respectively. In the medical claims data prescribed the incidence of peptic ulcers (p < 0.0001 in each). The odds ratios of upper GI bleeding were 1.76, 1.62, 1.96, 1.82 and 2.38, and those of GERD were 1.54, 1.41, 1.89, 1.67 and 1.91, and these odds ratios were statistically significant in each medicine group with GI bleeding and GERD (p < 0.0001 in each).
medicines (1 agent <2 agents <3 agents, peptic ulcer: 1.38 < 2.49 < 4.52, upper GI haemorrhage: 10.74 < 3.55 < 7.77, GERD: 1.61 < 2.96 < 5.88, respectively). The upper GI mucosal injuries were exacerbated in complication of lifestyle-related diseases, including hyperlipidaemia and diabetes mellitus.

Conclusion: Prescribing NSAIDs and anti-thrombotic medicines was associated with increased risks of developing upper GI injury. The present case-control study utilizing the large organized database of claims in Japan provided precise clinical evidence for safety management of medical drugs in the clinical settings in Japan.

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increasingly recognized as valid alternative therapy to reduce thromboembolic risk in patients with non valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy. Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrence in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding patients who were proprosed to undergo LAAO to debate the reversibility profile of each lesion in an organ by organ and lesion by lesion approach to stratify the risk of bleeding individually. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleeding risk by etiology. The reversibility profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy treatment (surgery, radiotherapy, embolisation) to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodyplasia (23%) for the midgut, these latter being responsible for 5% of all GI bleeding causes. The rate of bleeding recurrence under OAC treatment is 5-7% for stomach, 20-55% for duodenal lesions, 74-77% vs. upper GI (23-35%). 31.8% were related to aspirin/non-steroidal anti-inflammatory drug use. 48-52% had high risk (Forrest 1a-2b) lesions, of whom 38/48 (79.2%) received dual endoscopic therapy and 6/48 (12.5%) received adrenaline monotherapy. 10.85% received the recommended adrenaline volume of 15 mL. Of 90% prescribed intravenous proton pump inhibitor infusion, 85% did not complete the full 72-hour duration. Rebleeding occurred in 12 patients (13.2%) after a median of 3 days post endoscopy. 10 (83.3%) underwent repeat OGD. 2 (16.7%) underwent CT embolisation, whilst 3 (25.0%) underwent surgery. Aspirin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleed planning was documented on the endoscopy report in 33.0%. Regarding H. pylori, 51% underwent assessment with endoscopy, 10 (76.9%) had positive results of whom 7 (70%) received eradication. 12/23 (52.2%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anemia at discharge and at 6 months were 83.5% and 62.9% respectively, with iron therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to assure the management of PUD. Interestingly, rates of anemia at discharge and on follow-up are high. Such patients may benefit from iron replacement at discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1159 AN AUDIT INTO THE MANAGEMENT OF BLEEDING PEPTIC ULCER DISEASE

K. Siao1, A. Vijayan2
1Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom
2Postgraduate School of Medicine, Birmingham/United Kingdom

Contact E-mail Address: keith.siao@ucl.ac.uk

Introduction: Peptic ulcer disease (PUD) accounts for 25–56% of acute upper gastrointestinal bleeding (AUGIB) and is associated with high mortality.

Aims & Methods: In line with international guidelines, we aimed to audit our practice of bleeding PUD at a district general hospital within the West Midlands, UK. We retrospectively identified all patients with AUGIB who had inpatient endoscopic confirmation of PUD between November 2012–2014. We scrutinised endoscopy and case records to assess management related to PUD, in addition to follow-up records with the general practitioner.

Results: We identified 91 patients (median age 78.4, 65.9% male), of whom 65.7% were admitted with AUGIB, whereas 36.3% developed bleeding during their hospital stay. The majority of bleeding was duodenal (74.7%) vs. gastric (25.3%). 31.8% were related to aspirin/non-steroidal anti-inflammatory drug use. 48 (52.7%) had high risk (Forrest 1a-2b) lesions, of whom 38/48 (79.2%) received dual endoscopic therapy and 6/48 (12.5%) received adrenaline monotherapy. 10.85% received the recommended adrenaline volume of 15 mL. Of 90% prescribed intravenous proton pump inhibitor infusion, 85% did not complete the full 72-hour duration. Rebleeding occurred in 12 patients (13.2%) after a median of 3 days post endoscopy. 10 (83.3%) underwent repeat OGD. 2 (16.7%) underwent CT embolisation, whilst 3 (25.0%) underwent surgery. Aspirin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleed planning was documented on the endoscopy report in 33.0%. Regarding H. pylori, 51% underwent assessment with endoscopy, 10 (76.9%) had positive results of whom 7 (70%) received eradication. 12/23 (52.2%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anemia at discharge and at 6 months were 83.5% and 62.9% respectively, with iron therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to assure the management of PUD. Interestingly, rates of anemia at discharge and on follow-up are high. P1161 COMPARISON OF RISK-SCORING SYSTEMS IN PREDICTING NEEDS OF INTERVENTION AND CLINICAL OUTCOMES OF UPPER GASTROINTESTINAL BLEEDING

M. Ooi, W. Low, R. Bryant, N. Q. Nguyen
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marioo_ali@yahoo.com

Introduction: There are several risk-scoring systems available to assist the management of upper gastrointestinal bleeding (UGIB). The aim of this study is to compare the performance of pre-endoscopy (pre-RS), post-endoscopy Rockall score (post-RS), GBS and AIMS65 scores in predicting the need for intervention in patients admitted to hospital for UGIB.

Aims & Methods: Data related to the three scoring systems were collected prospectively in consecutive patients who were admitted with acute UGIB to the Royal Adelaide Hospital over 24 months. The performance of the three scoring systems was evaluated using receiver operating characteristic (ROC) curves, in predicting the outcomes was assessed for the need for endotherapy, rebleeding risk, transfusion requirement, survival and intervention and death. All patients received high dose acid suppression therapy.

Results: Of the 280 patients (93M; 66.4 ± 0.6yrs) who presented with UGIB, 622 (402M; 65.7 ± 0.6yrs) underwent endoscopy with 123 (38%) required endoscopic therapy, 42 (13%) repeated endo-therapy and 12 (3.7%) surgery for haemostasis. 155 (89M; 68.8 ± 0.6yrs) patients were treated conservatively due to medically unwell status (n = 50), known diagnosis (n = 25), known diagnosis but contraindicated for intervention (n = 17), and suspected MWT (n = 28). Death occurred in 33 (8%) patients, of which 10 (2.4%) were related to bleeding. Patients who required endoscopic or surgical intervention had higher GBS, pre-ERS, post-ERS and AIMS65 scores (P < 0.001). On ROC analyses, GBS and post-RS were superior to pre-RS and AIMS65 in predicting the need for (1) endotherapy (AUC: 0.75 and 0.78 vs. 0.65 and 0.59, P < 0.01), (2) repeated endoscopy due to re-bleed (AUC: 0.66 and 0.65 vs. 0.56 and 0.60, P = 0.03), and (3) blood transfusion (AUC: 0.83 vs. 0.72 and 0.70, P < 0.01). The scoring systems performed equally well in predicting the need for surgery (GBS vs. Rockall vs. GBS AUC: 0.72 vs. 0.67 vs. 0.71) and death (AUC: 0.75 ± 0.72 vs. 0.69).

Conclusion: Although GBS performs equally well for predicting need of surgery and death, it is superior to both Rockall and AIMS65 scores in predicting the need for endotherapy, repeated endoscopy, and blood transfusion in patients with acute UGIB. These findings suggest that GBS is the best performed risk scoring system in the evaluation of patients with UGIB.

P1162 STEROID ADMINISTRATION IS AN INDEPENDENT RISK FACTOR FOR REBLEEDING IN HEMORRHAGIC DUODENAL ULcer WITH A DOSE-RESPONSE RELATION

Division Of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai/Japan

Contact E-mail Address: waku-style@festac.ocn.ne.jp

Introduction: Hemorrhagic gastroduodenal ulcer is commonly seen in routine clinical practice, and there have been many studies investigating risk factors for rebleeding. However, few studies have evaluated hemorrhagic gastric ulcers (HGU) and hemorrhagic duodenal ulcer (HDU) separately. Furthermore, the relation between steroid administration and rebleeding in hemorrhagic gastroduodenal ulcer (HGU) and hemorrhagic duodenal ulcer (HDU) remains unclear. Aims & Methods: The aim of this study was to clarify the difference of rebleeding between HGU and HDU, and associated factors for rebleeding of HGU and HDU. Between March 2005 and September 2016, 176 consecutive patients with hemorrhagic gastroduodenal ulcer (106 with HGU and 70 with HDU), who underwent endoscopic hemostasis, were enrolled in this study. Regular dose proton pump inhibitor was administered to all patients after the diagnosis of hemorrhagic gastroduodenal ulcers. Rebleeding was defined as hematemesis or melena with ulcers confirmed by endoscopy or a decrease in the hemoglobin level >2 g/dl in the presence of endoscopically proven ulcers. First, we compared the rebleeding rate between HGU and HDU. Subsequently, associated factors for rebleeding of HGU and HDU were calculated by logistic regression analysis individually. The estimated factors were age (<65 vs ≥65 years), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulbs in HDU), underlying comorbidities (ischemic heart disease, liver cirrhosis, hyper-tension, diabetes mellitus, and hyperlipidemia), number of ulcers (multiple/ single), hemostasis method (pure ethanol injection therapy/other therapies), antiplatelet therapy, anticoagulation therapy, NSAID administration, steroid administration, antacid administration in the initial ulcer bleeding, hypoalbuminemia (serum albumin level ≤2.5 g/dl), and hemodialysis. We further investigated the detailed association between steroid administration and rebleeding in HDU, including dose-response relation.

Results: The rebleeding rate of HGU and HDU were 5.7% and 22.9%, respectively, which was statistically significant (P = 0.001). There was no missing data in the estimated factors. Although no factor was associated with rebleeding in HGU, multivariate logistic regression analysis revealed that the independent risk factors for rebleeding in HDU were multiple ulcers [odds ratio (95% confidence interval)] = 24.2 (2.76–213), P = 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. Regarding the detailed dose of steroid administration, multivariate logistic regression analysis showed that middle (≥10 mg ≤14 mg) or high (≥10 mg ≤14 mg) dose prednisolone (≥20 mg in prednisolone) (5.27 [3.19–8.71], P = 0.006) was a significant risk factor for rebleeding of HDU, with a dose-response relation (P = 0.0015).

Conclusion: HDU developed significantly higher rebleeding after endoscopic hemostasis, compared with HGU. In addition to multiple ulcers and hemodialysis, we firstly demonstrated by multivariate analysis that steroid administration is an independent risk factor for rebleeding of HDU after endoscopic hemostasis, with a dose-response relation.

P1163 EFFICACY AND SAFETY OF BIO-INSERT MINERAL SMECTITE IN CONTROLLING GASTROINTESTINAL HEMORRHAGE: AN ANIMAL PILOT STUDY

1 The First Affiliated Hospital with Nanjing Medical University, Nanjing/China
2 Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kiri9178@sina.com

Introduction: Gastrointestinal bleeding is common in clinics, especially after endoscopic operation. Besides from hemoclip, APC or electrocoagulation, more novel hemostasis approaches should be developed to improve endoscopic bleeding management. Granular smectite is bioinert mineral and efficient for curing diarrhea. Inspired by its dehydration and tissue-covering effect, this pilot study was to investigate its efficacy and safety for controlling hemorrhage in rats.

Aims & Methods: 32 rats were divided into four equal groups. For hemorrhage model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smectite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology. Results: Smectite demonstrated the best hemostasis effect, and its mean coagulation time was 1.45 ± 0.026 min. Commercial hemostatic chitosan styptic powder need 2.5 ± 0.04 min for complete clotting, while Starch group was 4.25 ± 0.056 min and 4.1min saline group was 4.025 ± 0.0108, (p = 0.05). Similarly, smectite led to less blood (0.6188 ± 0.034 g), while rats lost 2.3288 ± 0.123 g blood (p < 0.05) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively 2.0862 ± 0.061 g and 1.2925 ± 0.0238 g. Histopathologic results confirmed that smectite was biocompatible to tissue.

Conclusion: The mineral smectite powder was the superior candidate for hemostasis treatment in vivo. Compared with common polysaccharide agents, smectite could induce faster coagulation and reduce blood loss. More importantly, bioinert smectite was biocompatible and even promoted the wound healing. For gastrointestinal application, smectite powder could be delivered through endoscopic spray tube, while its inspiring efficacy required more endoluminal hemostasis tests.

P1164 PREDICTORS OF LIFE THREATENING MUCOSAL ULCERATION AFTER VARICEAL SCLEROTHERAPY

A. S. Hanafy
Internal Medicine, Zagazig University, Zagazig/Egypt

Contact E-mail Address: dr_amr_hanafy@yahoo.com

Introduction: Life-threatening bleeding could occur early after variceal sclerotherapy in cirrhotic patients.

Aims & Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with variceal sclerotherapy (esophageal varices: EV = 653, 87.3%) and (gastric varices: GV = 95, 12.7%) Zagazig University hospital-endoscopy unit- Internal medicine department, in the period from October 2014 till July 2016. 150 patients (20%), mean age 46.2 ± 9.4 years (EV = 129, GV = 21) developed bleeding due to sclerotherapy induced ulcers confirmed by endoscopy 6.4 ± 2.1 days after the procedure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryptogenic in (1%). A case-control study was performed comparing these

A572 United European Gastroenterology Journal 5(5S)
patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due sclerostatic ulceration. Results: Bleeding occurred 64.2 ± 2.1 days (2-10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin ≥ 2.5 g/dl [OR 1.3], total bilirubin ≥ 1.6 mg/dl and platelet ratio index (APRI) > 1 [OR 1.2], low prothrombin concentration < 50% [OR 1.5]. Intraprocedural factors as amount of ethanolamine > 15.5 ml [OR 2.6], amacarate > 3.5 ml [OR 2.9]. Post-procedural factors within 24 hours after endoscopy; leukocytosis > 12,000 cell/µl [OR 1.9], drop of hemoglobin > 10% of the pre-endoscopic value [OR 3.2], prolonged INR > 1.55 [OR 1.2]. Conclusion: Bleeding related to sclerosant ulcers is not uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Carbonell N, Pauwels A, Serfaty L, Fourdan O, Levy VG, Poupon R. Aims & Methods: This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (>18 years) met the Rome III criteria among the patients visited the gastroenterology department for dyspepsia. Exclusion criteria were prior surgery to the upper gastrointestinal tract, history of ulcer disease, erosive GERD, history of malignancy, and severe comorbidity. Healthy control group who had no clinical history of gastroduodenal related disorder and no abnormal finding on endoscopy recruited from health examination center for screening. The Pittsburgh Sleep Quality Index was used to assess sleep disturbance. Hospital anxiety and depression scale was used to identify anxiety and depression.

Results: This study included 160 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than health controls (7.8 ± 4.3 vs 5.6 ± 3.1, p = 0.000). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18.4%, p < 0.000). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, p < 0.0001). The independent risk factors for sleep disorder in multivariate analysis were FD (OR 1.80, p = 0.017), BMI (OR 1.17, p = 0.053), age (OR 1.03, p = 0.000), and depression (OR 2.91, p = 0.000). Conclusion: FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

References
as a predictor among individuals with FGIDs (Table 1). Epigastric symptom severity was predicted by worry and psychological attribution of symptoms among FGID individuals but no psychological trait predicted symptom severity among non-FGID individuals (Table 1).

**Conclusion:** A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be more clearly driven by the non-FGID subgroup, among whom psychological attributes for symptoms and problem-focused coping are positively related to later symptom burden. For epigastric symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the commonly reported associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** martin.jerzej@homolka.cz

**Introduction:** In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between achalasia and neurologic symptoms in their personal and family history. Those neurological diseases might have common features. For example, a number of genetic variations have been shown to increase the risk of both conditions (e.g. HLA-DQB1-insertion on chromosome 6 may be strongly associated with both achalasia and with neurodegenerative/demyelinating diseases). Several other findings (e.g. inflammatory infiltrates, occipital hyperintensities, periventricular lesions) have been noted in patients with achalasia (dysphagia, regurgitation, chest pain).

**Aims & Methods:** The aim of our prospective study is to examine a prevalence of neurodegenerative/demyelinating diseases in a cohort of consecutive patients with confirmed esophageal achalasia. Achalasia was diagnosed by high-resolution manometry, endoscopy and esophageal manometry. A total of 140 consecutive patients with esophageal achalasia have been questioned about the occurrence of neurological diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were referred for a detailed clinical neurological examination. MRI imaging of the brain and electrophysiological study. A total of 106 patients with a neurodegenerative/demyelinating disease have been questioned by using a questionnaire about the occurrence of symptoms typical for achalasia (dysphagia, regurgitation, chest pain).

**Results:** A total of 51 out of 140 patients (36.4%) exhibited some neurologic symptoms—most often visual disturbances in 17 patients (33.3%) and limbs paresthesia in 12 patients (23.5%). Among patients with a presence of neurologic symptoms, 5 patients (3.6%) had definitely been diagnosed with a neurodegenerative/demyelinating disease (multiple sclerosis - 2 patients, Lebert optic neuropathy - 1 patient, Parkinson’s disease - 1 patient and Allgrove syndrome - 1 patient). Furthermore, 7 patients with a positive questionnaire had been diagnosed with other neurological diseases (tetany n = 2, carpul tunnel syndrome n = 3, epilepsy n = 2). Fourteen patients (27.4%) among those with neurological symptoms (vs. 0 out of 89 patients without neurological symptoms) had a positive family history of a neurodegenerative or a demyelinating disease. Among 106 patients with a neurodegenerative/demyelinating disease, 30 of them (28%) described dysphagia as a part of their personal history. These patients will be examined by oesophageal manometry.

**Conclusion:** Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11) and epigastric symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Epigastric: FGID: OR = 1.58, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs.

**Contact E-mail Address:** j.ruffle@kcmu.ac.uk

**Introduction:** Visceral pain is a complex percept influenced by numerous factors. Of these, differences in the autonomic nervous system (ANS)—in particular, parasympathetic cardiac vagal tone (CVT)—has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible anti-nociceptive. Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

**Aims & Methods:** To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21–53 years)), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distention. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the commonly reported associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

*P1169 HIGH RESTING PARASYMPATHETIC CARDIAC VAGAL TONE CONFERS A UNIQUE FUNCTIONAL BRAIN NETWORK DURING ACUTE OESOPHAGEAL PAIN*
Aims & Methods: We evaluated a prototype 36 channels W-HRM reused catheter allowing to measure 3-D pressure vector volume analysis of lower esophageal sphincter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24h impedance-pH monitoring performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n = 39), SS-HRM (n = 33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 ml water, five times solid food and multiple water swallow with 200 ml of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

Results: There was significant difference between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integrale (DCI) and DCI-expanded, LES resting pressure, % of ineffective peristalsis, and esophageal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

Conclusion: While RDC test cannot be used to determine EGJOO cause, patients with POP or OS during RDC had more severe dysphagia than those without. In patients with POP, the highest DCI might be secondary to obstruction. Further prospective studies should determine if RDC test could help to select patients who might benefit from treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1170 RAPID DRINK CHALLENGE (RDC) TEST DURING OESOPHAGEAL HIGH RESOLUTION MANOMETRY (HRM) IN PATIENTS WITH OESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION
D. Biasutto, F. Mion, A. Garros, S. Roman Digestive Physiology, Lyon I University and Hospices Civils de Lyon, Lyon/France

Contact E-mail Address: d.biasutto@unicampus.it

Introduction: Oesophageo-gastric junction outflow obstruction (OGJOO) is of unclear significance. It may be secondary to an incomplete form of achalasia, a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO. From a database of 3222 consecutive oesophageal HRM performed from 01/2012 to 03/2017, we extracted patients with OGJOO according to the Chicago Classification v3.0. HRM protocol consisted of 10 5-ml water swallows in supine position and RDC test (200-ml free drinking) in sitting position. Distal contractile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesophageal pressurization (POP; homogeneous oesophageal pressurization >30 mmHg) were reported for 5-ml swallows. POP and oesophageal shortening (OS) were analysed during RDC. Symptom severity was assessed with Eckardt score. Causes of OGJOO were determined by reviewing patients’ chart for previous history, complementary work up and treatment. Quantitative data were expressed as median (range) and qualitative data as percentage. They were compared using non-parametric and Chi square tests.

Results: 75 patients (29%) (29 males, mean age 62 years (25–92)) were included. The dominant symptom was dysphagia (69%), regurgitation (9%), chest pain (5%), other (13%), no symptom (3%). The causes of EGJOO were previous oesophago-gastric surgery (43%), incomplete achalasia (7%), mediastinal neoplasia (7%), miscellaneous (19%) and unknown (25%). RDC test was successfully performed in 70 patients (93%) and associated with POP and OS in 41% and 13% respectively. Dysphagia as dominant symptom was more frequent (79% vs 59%, p = 0.057) and more severe (Eckardt score 5 (1–11) vs 3 (0–10), p = 0.01) in patients with POP during RDC compared to those without. The same observation was achieved in patients with OS vs those without (dysphagia 100% vs 62, p = 0.02 and Eckardt score 6 (2–10) vs 1 (0–11), p = 0.02). Manometric parameters were reported in the table. The causes of OGJOO were similar in patients with and without POP during RDC (previous oesophageo-gastric surgery 34% and 51% respectively, achalasia 14% and 2%, mediastinal neoplasia 3% and 7%, miscellaneous 10% and 22%, unknown 35% and 17%). OS was not observed in patients with unknown cause of EGJOO vs 20% of patients with an identified cause (p = 0.09).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1171 THE NORMATIVE VALUES OF A NEW 36 CHANNELS WATER PERFUSION ESOPHAGEAL MOTILITY CATHETER
S. Bor, S. Kipcak Gastroenrology Sec., Ege Refflux Study Group, Ege University, izmir/Turkey

Contact E-mail Address: kipcaksezgi@gmail.com

Introduction: High resolution manometry (HRM) is performed with solid-state catheters (SS) in many centers. However according to Chicago classification, very limited data from healthy volunteers are available for some catheters and starting from IRP, numerical values are crucial for the diagnosis. Because of the cost of the SS-HRM catheters many centers especially from developing countries use water perfusion HRM (W-HRM) catheters up to 24 channels and normal values are even more limited.

Aims & Methods: We evaluated a prototype 36 channels W-HRM reused catheter allowing to measure 3-D pressure vector volume analysis of lower esophageal sphincter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24h impedance-pH monitoring performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n = 39), SS-HRM (n = 33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 ml water, five times solid food and multiple water swallow with 200 ml of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

Results: There was significant difference between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integrale (DCI) and DCI-expanded, LES resting pressure, % of ineffective peristalsis, and esophageal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

Conclusion: Water perfusion HRM catheter exhibits significantly lower values especially for IRP, DCI, LES resting pressure. Centers which are working with water perfusion catheters should not accept universal normal established with solid state catheters and need to work on their normative values. The ineffective peristalsis pattern is common with water perfusion catheters.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: The Chicago Classification (CC V3.0) defined the presence of esophageal motor dysfunction in patients (EGJ-OO) when the value of integrated relaxing pressure (IRP) is higher than 15 mmHg during high-resolution manometry (HRM). Both low-volume (10 ml) multiple rapid swallow (MRS) and high-volume (200 ml) rapid drinking test (RDT) were never evaluated to detect the inhibition of esophageal body in patients with EGJ-OO.

Aims & Methods: The aim of this study was to compare the efficacy of MRS and RDT in evaluating the esophageal body inhibition during repetitive swallow in patients with EGJ-OO and in patients with functional heartburn (FH) considered as control group. From a larger group of patients evaluated for dysphagia with negative upper endoscopy, we enrolled consecutive patients with EGJ-OO, and as control group, patients with functional heartburn (FH) defined according to the Rome IV criteria. EGJ-OO was defined according to CC V3.0. HRF performed according to the Italian guidelines. All patients underwent 3 MRS (10 ml of water in 5 swallow in less than 10s) and 1 RDT (200 ml of water freely drunk). The mean DCI of MRS and the DCI of RDT were compared with DCI of 10 single swallows (SS) mean value. The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with EGJ-OO (18 females; mean age 49.5 ± 12.4 yrs) and 30 patients with FH (17 females; mean age 41.2 ± 13.6). Impedance and pH 24-h analysis was performed to select patients with FH (normal AET and number of reflux and lack of reflux-symptom correlation). During HRM the mean DCI resulted similar in patients with EGJ-OO compared to FH (p = 0.101). One-hundred and eighty MRS and 60 RDT were evaluated. The lack of body inhibition was found in 11% (20/180) during MRS and in 53% (16/30) during RDT in EGJ-OO. No patients in FH showed lack of body inhibition during both MRS and RDT. All results are reported in Table 1.

Conclusion: Patients with EGJ-OO showed less peristaltic reserve during MRS and RDT. The RDT evidenced more frequently lack of body inhibition in patients with EGJ-OO.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The aim of this study was to compare the diagnostic value of MRS and RDT in patients with IEM. From a larger group of patients evaluated for heartburn/wk with poor response to standard dose proton pump inhibitors, we enrolled consecutive patients with IEM and with functional heartburn (FH). FH were enrolled as controls. IEM was defined according to the CCV3, and FH were defined according to the Rome IV criteria and with normal peristalsis. HRF was performed according to the Italian guidelines. All patients underwent 3 MRS (10 ml of water in 5 swallow in less than 10s) and 1 RDT (200 ml of water freely drunk). All patients underwent 24-h impedance and pH recording (MII-pH). Mean DCI of MRS and DCI of RDT were compared with mean DCI of 10 single swallows (SS). The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with IEM (18 males and 12 females; mean age 45.7 ± 11.4 yrs) and 30 patients with FH (15 males and 17 females; mean age 41.2 ± 13.6). The MII-pH showed higher acid exposure time (AET) and number of reflux events in IEM than in FH (p < 0.005). Mean DCI of SS resulted lower in patients with IEM compared to FH (p < 0.05). One-hundred and eighty MRS and 60 RDT were evaluated. DCI of MRS was lower than 450 mmHg-s-cm in 39% (35/90) of IEM patients, and in 7% (6/90) of FH (p < 0.005). DCI of RDT was lower than 450 mmHg-s-cm in 77% (23/30) of IEM patients, and in 50% (15/30) of FH (p < 0.05). The MRS/RDT ratio resulted >1 in both groups. All results are reported in Table 1.
Introduction: Oesophageal diverticula are rare diverticula of the gastrointestinal tract known to be associated with oesophageal motor disorders.

Aims & Methods: The aim was to study manometric abnormalities associated with oesophageal diverticula, using both wet and solid swallows. Patients underwent high resolution oesophageal manometry (HRM) in the upright position. 18 patients with oesophageal diverticula were found and were free of previous surgery. Traction diverticulum was excluded in all patients. We also included 10 healthy controls. HRM was performed using wet (5 mL of water) swallows in both groups, followed by solid (meat) swallows in patients. Mean age of the control group and diverticulum were 50 years old while 70 years old for patients.

Results: The main reported symptom was dysphagia (76%). HRM found 11 (61%) patients with an oesophageal motor disorder, including 2 oesopha- gistric junction outflow obstruction (OGJOO), 4 achalasia (subtypes 2; n = 2; sub- type 3; n = 2), 4 distal esophageal spasms (DES) and 1 jackhammer oesophagus, and was normal in 7 (39%) patients. In those patients with normal findings, solid swallows identified 4 (57%) additional motor disorders, including 2 OGJOO, 1 jackhammer oesophagus and 1 DES. Provocative testing using solid swallows confirmed the diagnostic yield by 22% in overall patients and by 57% in patients with normal manometry using wet swallows only. Mean pressure slopes at mid-oesophagus and oesophageal diverticulum were greater in patients than healthy controls (p < 0.05 for wet swallows), as previously reported. Other metrics are summarized in the table.

Conclusion: While more than one-third of HRM using wet swallows were normal, provocative testing using solid swallows increased the diagnostic yield of the procedure by more than 50% in these patients. Analysis of pressure slopes confirmed the association of propagating peristalsis with the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The management of achalasia targets relieving the obstruction at the esophagogastric junction (EGJ) by pneumatic dilation (PD), laparoscopic Heller myotomy (LHM) plus a fundoplication variant (Dor, Toupet and more rarely Nissen/Nissen-Rossetti). However, effective ablation of the LES barrier can induce gastroesophageal reflux disease (GERD). Recently, new metrics to evaluate EGJ function with high resolution manometry (HRM) have been intro- duced, such as EGJ contractile integral (EGJ-CI). Currently there are few data investigating how achalasia treatments impact EGJ function based on these metrics.

Aims & Methods: We aimed to assess the EGJ-CI metric in achalasia before and after different treatments, to verify if post-operative changes in this metric corre- lated to symptom relief and iatrogenic GERD following surgical treatments. Methods Between 2014 and 2015, we enrolled consecutive achalasia patients. All patients underwent clinical evaluation with Eckardt and GERDQ score, as

Introduction: Jackhammer esophagus is a rare esophageal motility disorder. Little is known about its physiopathology; however, an excess of cholinergic drive has been suggested as an important etiologic factor. Multiple rapid swallowing (MRS) is an adjunctive test in order to evaluate integrity of inhibitory and excitatory neural pathways. In healthy subjects body motility inhibition is appropriate; data are shown as median-IQR range.

Methods: The data of consecutive patients who underwent G-POEM by a single expert endoscopist from October 2015 to November 2016 was collected. Procedures were performed, similar to POEM for achalasia, including initial mucosal incision, creating a submucosal tunnel, full-thickness (pyloro)myotomy, and closure of the mucosal entry. Patient demographics, etiology, Gastroparesis Cardinal Symptoms Index (GCSI) and gastric emptying scintigraphy (GES) were recorded before and after the procedure. Treatment outcomes and procedure related adverse events were also evaluated.

Results: A total of fourteen patients with refractory functional delayed gastric emptying refractory to medical therapy. We herein report our initial experience of G-POEM in an Asian population with focus on technique in addition to safety and efficacy of this promising endoscopic therapy.

Aims & Methods: We aimed to determine whether epigastric pain syndrome (EPS) accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by Japan Pancreas Society (JPS) using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (FPS; n=49), EPS with pancreatic enzyme abnormalities (n=41) and EPS without pancreatic enzyme abnormalities (n=42) based on Rome III criteria. Gastric motility was evaluated using the 13C-acetate breath test. Early chronic pancreatitis was diagnosed by endosonography and graded from 0 to 7.

Results: The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly (p=0.0018) higher than the ratio of female EPS patients (20/40) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly (p=0.002 and p=0.001, respectively) increased compared to those (19.75±1.01 and 18.3±3.01, respectively) in EPS patients without it. Interestingly, AUCσ and AUCσ values (24.85±1.31 and 24.86±1.27, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p=0.002 and p=0.001, respectively) increased compared to those (19.75±1.01 and 18.3±3.01, respectively) in EPS patients without it.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Results: The endoscopic follow-up was planned every month. After 1 months, 18–23 cm esophageal region has healed to be normal. Within 6 months, the stricture process was exactly delayed as expected. The patient stated his symptom was remarkably improved. Gastroscopy revealed the esophageal implanted lesion was covered with an epithelium and the luminal surface was flat, without ulceration.

Conclusion: Autologous esophageal mucosa transplantation might facilitate tissue re-epithelialization, reduce pathological fibroplasia, and be helpful for managing or preventing esophageal strictures. More clinical controlled trials are required to provide evidenced-based recommendation and promote its clinical application.

Aims & Methods: We aimed to compare the prevalence of FD in patients with OSA and healthy volunteers. A total of 60 consecutive OSA patients (defined as Ephysworth sleepiness scale > = 10, and apnea-hypopnea index > = 10/hour during polysomnography; mean age: 47.6 years, male: 83.3%) and 60 healthy age-and-sex-matched volunteers were recruited in a prospective case-control study. Questionnaires were applied for the diagnosis of functional gastrointestinal disorders (FGIDs) according to Rome III criteria. Anxiety and depression were evaluated using the Hospital Anxiety and Depression Scale (HADS), sleep quality was evaluated by the Pittsburgh Sleep Quality Index, and fatigue was assessed by the Multidimensional Fatigue Inventory (MFI-20) Chinese version.

Results: The prevalence of FD was 28.3% and 8.5% (17 vs 5, P = 0.005), and the prevalence of symptomatic gastro-esophageal reflux disease was 18.3% and 5% (11 vs 3, P = 0.023) in the OSA group and healthy volunteer group, respectively. OSA patients had higher anxiety and depression symptom scores, worse sleep quality, and more fatigue compared with healthy volunteers. In the multivariate logistic regression analysis, the risk of having OSA (odds ratio 4.99, 95% CI 1.01–24.1, P = 0.049) and depression (odds ratio 4.91, 95% CI 1.44–16.71, P = 0.011) were independently associated with FD.

Conclusion: To our best knowledge, this is the first study showing that OSA is independently associated with functional dyspepsia. Sleep disturbances previously attributed to psychological comorbidities in FGID may in fact arise from undiagnosed OSA. We recommend screening for OSA as part of the management of FD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Functional dyspepsia (FD) is commonly associated with sleep disturbance, which has been attributed to comorbid anxiety, depression and bothersome gastrointestinal symptoms. However, it is unclear whether obstructive sleep apnea (OSA) is specifically associated with FD.

Aims & Methods: We aimed to compare the prevalence of FD in patients with OSA and healthy volunteers. A total of 60 consecutive OSA patients (defined as Ephysworth sleepiness scale > = 10, and apnea-hypopnea index > = 10/hour during polysomnography; mean age: 47.6 years, male: 83.3%) and 60 healthy age-and-sex-matched volunteers were recruited in a prospective case-control study. Questionnaires were applied for the diagnosis of functional gastrointestinal disorders (FGIDs) according to Rome III criteria. Anxiety and depression were evaluated using the Hospital Anxiety and Depression Scale (HADS), sleep quality was evaluated by the Pittsburgh Sleep Quality Index, and fatigue was assessed by the Multidimensional Fatigue Inventory (MFI-20) Chinese version.

Results: The prevalence of FD was 28.3% and 8.5% (17 vs 5, P = 0.005), and the prevalence of symptomatic gastro-esophageal reflux disease was 18.3% and 5% (11 vs 3, P = 0.023) in the OSA group and healthy volunteer group, respectively. OSA patients had higher anxiety and depression symptom scores, worse sleep quality, and more fatigue compared with healthy volunteers. In the multivariate logistic regression analysis, the risk of having OSA (odds ratio 4.99, 95% CI 1.01–24.1, P = 0.049) and depression (odds ratio 4.91, 95% CI 1.44–16.71, P = 0.011) were independently associated with FD.

Conclusion: To our best knowledge, this is the first study showing that OSA is independently associated with functional dyspepsia. Sleep disturbances previously attributed to psychological comorbidities in FGID may in fact arise from undiagnosed OSA. We recommend screening for OSA as part of the management of FD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1186 SARCOPENIA AS A LEADING RISK FACTOR FOR EROSIv EsOPHaGAL REFlUX DISEASE: A LARGE-SCALE CROSS-SECTIONAL STUDY

T. Kim, T.J. Kim, H. Lee, J.J. Kim
Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack836@naver.com

Introduction: Obesity is an established risk factor for reflux esophagitis. Yet, the association of sarcopenia and obesity status with reflux esophagitis remains unclear. We aimed to study the association between obesity, sarcopenia, and reflux esophagitis and the risk of reflux esophagitis in a large number of asymptomatic men and women.

Aims & Methods: We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations below the mean for healthy young adults. Participants were categorized into four groups according to obese and sarcopenic status: normal, obese, sarcopenic, and obese and sarcopenic obese.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese [adjusted odds ratio (aOR), 1.38; 95% confidence interval (CI), 1.26–1.52], sarcopenic (aOR, 2.02; 95% CI, 1.48–3.29), and obese and sarcopenic obese participants (aOR, 1.68; 95% CI, 1.39–2.03) than in normal participants. The ORs comparing sarcopenic and sarcopenic obese participants to obese participants were 1.59 (95% CI, 1.06–2.38) and 1.32 (95% CI, 1.02–1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: This study suggests that sarcopenia, regardless of obesity, is more harmful context for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1188 ONE DRINK CAN INCREASE A RISK FOR ESOPHAGEAL, STOMACH AND COloRECTal CANCER IN A COHORT OF 23,323,730 KOREAN ADULTS

Y.J. Choi, D.H. Lee
Internal Medicine, Seoul National University Bundang Hospital, Seongnam/Korea, Republic of

Contact E-mail Address: olivo06@naver.com

Introduction: Epidemiologic findings of low-volume alcohol consumption in relation to gastrointestinal cancers including gastric cancer are inconsistent.

Aims & Methods: The association between alcohol intake and esophageal, gastric and colorectal cancer risk was examined in a population-based prospective cohort of 23,323,730 adults in Korea who had undergone a biennial evaluation provided by the National Health Insurance Corporation between the years 2009 and 2012.

Results: After median 5.4 years of follow-up, 9171 esophageal, 135,382 gastric and 154,970 colorectal cancer cases were identified. Cox proportional hazards regression models were used to estimate hazard ratios (HR) and corresponding 95% confidence intervals (95% CI). Light drinking as well as moderate to heavy alcohol consumption significantly increased the risks of the three gastrointestinal cancers (HR 1.31, 95% CI, 1.16–1.49; HR 1.51; 95% CI, 1.43–1.60; HR 1.10; 95% CI, 1.06–1.09; HR 1.12; 95% CI, 1.11–1.14) compared with non-drinkers after adjusting for age, sex, smoking, exercise, income, body mass index, and diabetes. For esophageal cancer, there was a dose-dependent linear relationship. However, no association was observed between prediagnostic alcohol consumption and all cause mortality.

Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Some studies have suggested the central obesity as a risk factor for gastroesophageal reflux diseases (GERD). However, the associations between visceral adipose tissue (VAT) and the locations of erosions and symptoms of GERD have been controversial.

Aims & Methods: The study was designed to evaluate the influences of visceral fat on the locations of erosions and symptoms of GERD. The subjects who underwent abdomen computerized tomography and esophagogastroduodenoscopy for routine checkup at the same day were collected from January 2007 to October 2016. 177 subjects who had erosive esophagitis (LA class A to D) were enrolled. Questionnaires including gastrointestinal symptoms were written before examinations. The abdominal obesity was measured by evaluating visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), ratio of VAT to SAT, total adipose tissue (TAT), body mass index (BMI) and waist circumference (WC).

Results: Lesser curvature (LC) side of esophagogastric junction (EGJ) was the most frequent site of mucosal breaks (103 cases, 58.2%) followed by posterior wall side (71 cases, 40.1%), anterior wall side (25 cases, 14.1%) and fundus side (16 cases, 9.0%). Mucosal breaks on the LC side were frequently observed in male subjects (61.3% vs. 36.4%, p = 0.04) and WC (89.0 ± 11.8 vs. 85.0 ± 9.1, p = 0.01) were significantly higher in LC group. Moreover, VAT, ratio of VAT to SAT, and SAT were significantly higher in LC group. In the multivariate analysis, a higher VAT area (odds ratio (OR) 3.47, 95% confidence interval 1.38 to 8.73, 1st quartile vs. 4th quartile, p < 0.01) and ratio of VAT to SAT (OR 2.99, 95% CI 1.15 to 7.60, 1st quartile vs. 4th quartile, p = 0.02) were strongly associated with the mucosal breaks in LC.
P1190 A LESS COMPETENT OESOPHAGO-GASTRIC JUNCTION IS ASSOCIATED WITH OESOPHAGEAL ACID HYPERSENSITIVITY EVEN IN HEALTHY CONTROLS

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach mucosa. However, gastro-oesophageal reflux disease (GERD) caused by acidic reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the OGJ, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett’s oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [4]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal sensitivity in relation to OGJ competence, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett’s oesophagus (mean age: 64.2 ± 7.7 years) and 12 healthy controls (mean age: 54.9 ± 10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the filling and emptying of an attached polyurethane bag with water, stimulation with electrical current, and infusion of acid. Using this probe, mechanical distension of the bag, thermal stimulation at increasing temperature, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test) were performed. All stimulations were stopped when the subject felt moderate pain, equal to seven on a 0–10 visual analogue scale validated for visceral pain. Data were analysed using multi-level, mixed-effects regression analysis in Stata 12.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter function. The association between lowered acid volume was associated with greater distensibility index (P = 0.03) and with lower pressure (P = 0.03) in the OGJ in all subjects analysed together and separately in healthy controls (P = 0.006 and 0.03 respectively). Performing separate analyses in patients with BO, these associations were not present (all P > 0.7). Sphincter function was associated with neither oesophageal sensitivity to mechanical, heat, nor electrical stimulation (all P > 0.13).

Conclusion: Oesophageal acid sensitivity increased with a more incompetent OGJ. Based on this and previous findings, we suggest that even in some healthy controls, a modest degree of OGJ incompetence allows gastric acid to reflux. This may again lead to low-grade oesophageal inflammation and mucosal damage, thereby evoking acid hypersensitivity. The latter mechanism probably constitutes a reflux protective mechanism towards acid reflux.

Disclosure of Interest: B.P. McMahon: Barry P McMahon holds a minor share in Crospon Inc., Galway, Ireland who manufactures the EndoFLIP probe. All other authors have declared no conflicts of interest.

4Local Health Unit Of Parma, Public Health Department, Occupational Health And Safety Service, Parma, Italy, University Hospital, Parma (Italy), Parma/C6

Aims & Methods: In this study, we analyzed serum levels of gastrin-17 (G-17) and IgG against (Hp-IgG). The normal range is 5-30 U/L; the diagnosis of gastroesophageal reflux disease is made when G-17 > 30 pmol/L; the diagnosis of chronic atrophic gastritis (CAG) was made when PGI was > 50 pg/mL; the diagnosis of CAG before performing endoscopy could address to a better bioptic sampling and CAG before performing endoscopy could address to a better bioptic sampling and CAG before performing endoscopy could address to a better bioptic sampling.

Results: Four hundred and eighty eight patients were classified as affected by Hp-related non-atrophic gastritis (26%). 547 patients were classified as normal (29%). 83 patients were classified as CAG (4%). In 96% out of the 488 patients with Hp-related non-atrophic gastritis (26%); 547 patients were classified as normal (29%). 83 patients were classified as CAG (4%). In 96% out of the 488 patients with Hp-related non-atrophic gastritis the diagnosis was confirmed by esophagogastroduodenoscopy in 313 patients. Positive Demester score in 170 out of 221 patients at 24 hours pH-metry or presence of typical symptoms in 91% out of the 782 patients diagnosed as GERD subjects, the diagnosis was made by means of HP measurement in between the both groups have not been found statistically significant difference (p > 0.05) (Table 1). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, aphonia, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = -0.273) (p < 0.003) has been determined.

Conclusion: The frequency and severity of gastroesophageal reflux symptoms in the non-obese is closely related with body fat composition as those in the obese. Increase in abdominal and visceral fat composition may cause high risk of gastroesophageal reflux disease in individuals irrespective of their obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Prevalence of obesity and the obesity-related diseases have been increasing in recent years(1). In the studies conducted there are views claiming that visceral fat-related central obesity causes digestion system diseases and increase in the number of gastroesophageal reflux symptoms in particular (½).

Aims & Methods: In this study, we analyzed serum levels of gastrin-17 (G-17) and IgG against (Hp-IgG). The normal range is 5-30 U/L; the diagnosis of Hp-related non-atrophic gastritis was made by means of HP measurement in between the both groups have not been found statistically significant difference (p > 0.05) (Table 1). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, aphonia, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = -0.273) (p < 0.003) has been determined.

Conclusion: The frequency and severity of gastroesophageal reflux symptoms in the non-obese is closely related with body fat composition as those in the obese. Increase in abdominal and visceral fat composition may cause high risk of gastroesophageal reflux disease in individuals irrespective of their obesity.

Introduction: Gastroesophageal reflux disease (GERD), is characterized by frequent relapses after withdrawal of therapy and no prognostic markers of relapse are available to predict the outcome of the patients. Gastrin-17 (G-17) has been proposed as a non-invasive marker of reflux disease as well as a good marker of response to the therapy. Pepsinogen I (PG I) and Gastrin-17 (G-17) are claimed to increase in a statistically significant manner after proton pump inhibitors (PPIs) therapy. Aim of the study was to assess the prognostic value of G-17 and PG I levels in order to select out GERD patients more prone to develop an early reflux relapse in a prospective open study.

Aims & Methods: We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28–74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6–8 weeks, assessing at the end of the therapy the symptoms’ modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, registering the GERD relapse episodes; only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

Results: One hundred eighty five patients were asymptomatic after the 6–8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. 19 subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 96±g/L, G-17 19±pmol/L; after therapy: PG I 164±g/L, G-17 19±pmol/L; p<0.001; second group: baseline PG I 98±g/L, G-17 16±pmol/L; after therapy: PG I 116±g/L, G-17 6.3±pmol/L; p<ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

**Introduction:** Atrophic body gastritis (ABG) is characterized by loss of oxyntic glands with consequent reduced acid secretion, hypergastrinaemia and, in a later stage, pernicious anemia (PA). Up to 40% of ABG patients complain of dyspepsia. Despite hypochlorhydria, in 21% of autoimmune gastritis (AG) patients, gastro-esophageal reflux (GER) symptoms have been reported and in one third of them (mostly non-acidic reflux) has been documented at pH-monitoring. At present, data regarding endoscopic and histopathologic AG-related esophageal findings in this setting are lacking.

**Aims & Methods:** Aim of this study was to assess the occurrence of GER symptoms and endoscopic-histopathologic esophageal findings in ABG patients. During 12-months, 35 consecutive ABG patients (80% female; median age 60 yrs (27–81); BMI 25.7 kg/m2 (18.2–32.3); fasting gastrinemia 329 pg/ml (215–1476); pepsinogen I 10 ng/ml (0–44); positive Ab against parietal cells 716# (235–1476) were included. Histology, performed using a picture of esophagitis according to LA classification or a positive DeMeester score (> 14) was recorded in GERD group. Finally, patients showed a positive upper-GI endoscopy and were enrolled in the study, according with presence of upper-GI troubles like epigastric pain, fullness, nausea/vomiting, as well as related risks factors, such as smoking habits. All patients showed a positive upper-GI endoscopy and were enrolled in the study, according with presence of upper-GI troubles like epigastric pain, fullness, nausea/vomiting, as well as related risks factors, such as smoking habits.

**Results:** A thousand and six hundred consecutive dyspeptic patients (M = 766; mean age: 51.5 years; range: 27–79 yr) were enrolled in the study, according with presence of upper-GI troubles like epigastric pain, fullness, nausea/vomiting, as well as related risks factors, such as smoking habits.

**Conclusion:** As a new diagnostic tool, MI needs validation studies and our results failed to show additional diagnostic value in non-erosive patients compared to healthy controls. Since regular catheters are failed, new balloon-shaped catheters should be validated. BI might be a better tool to discriminate NERD from controls. This implicates that the esophageal epithelial resistance is impaired in this particular group compared to controls.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In China, 13.6% of gastrointestinal outpatients suffer from gastro-esophageal reflux disease (GERD), among which only 36.9% undergo endoscopy [1]. For patients with symptoms of GERD, empirical proton pump inhibitor (PPI) treatment is recommended as a diagnostic test of GERD and as a therapeutic trial to control symptoms by Chinese GERD consensus guidelines [2].
Currently, there are no real-world data assessing the efficacy of short-term empirical treatment with PPIs in GERD patients in China.

Aims & Methods: This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empirical treatment with PPIs. Responders were defined as having heartburn/regurgitation on ≤1 day during the prior 7 days, assessed by the Gerd-Q questionnaire. Outpatients aged between 18 and 65 years with a Gerd-Q score ≥8 were enrolled if they were prescribed standard-dose PPIs as empirical treatment and were not planned to have an endoscopy within 4 weeks of enrollment. The PPI regimen prescribed was decided completely at the physicians’ discretion. Patient demographics, diagnosis, prescribed PPI regimens, Gerd-Q score and symptom frequency were recorded. Data were collected at baseline, 2 weeks and 4 weeks after initiating PPI treatment. Results from the full analysis set (FAS) are presented.

Results: A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years, the mean body mass index was 23.4 ± 3.3 kg/m², and 50.3% of the patients were male. The mean duration of GERD was 0.8 ± 2.6 years, with a mean baseline Gerd-Q score for the week before screening of 10.5 ± 1.9. During the 4 weeks’ treatment, the proportion of patients receiving at least 19 days of PPI was 99.5%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (rabeprazole, lansoprazole, pantoprazole and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥2 PPIs in the duration of the study. A total of 787 (79.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI, 70.7%–77.0%] (Table 1). Among the 818 patients who completed 2 weeks’ treatment, the responder rate was 37.0% [95% CI, 33.5%–40.4%]. The overall median time to response was 1.12 days (95% CI, 1.12–1.15). Over the study duration, patients’ Gerd-Q score demonstrated a decreasing trend. The proportion of patients with a Gerd-Q score ≥8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

Conclusion: In Chinese clinical practice, short-term PPI empirical treatment effectively improves symptom control in GERD patients and gains a satisfactory overall responder rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The use of PPIs represents the main treatment in gastroesophageal reflux disease (GERD), having demonstrated its effectiveness both in the control of inflammation and symptomatology. However, between 10–20% of patients present persistent symptoms or lesions despite the treatment.

Aims & Methods: The aim of the study was to assess the presence of acid reflux in patients submitted to our department with the diagnosis of refractory GERD, due to low or no response to PPIs. This was a retrospective study including 190 patients (55 men, 135 women) referred to our service with the diagnosis of GERD from January 2008 to December 2015. Based on the diagnostic criteria, two groups were made. Group 1: included 63 patients (33.2%) diagnosed of GERD due to typical symptomatology and at least one positive complementary test (24-H pHmetry). All of them underwent a 24-H pHmetry study with a dual channel, esophageal and gastric, on-PPI treatment. In 17 patients the pHmetry was performed with multichannel intraluminal impedance (15 cases) or Bilitec (2 cases). Group 2: included 127 patients (66.8%) who had been diagnosed of GERD only on the basis of typical symptoms; all of them underwent esophageal double channel 24-H pHmetry off-PPI. All of the studies (24-hour pHmonitoring or multichannel intraluminal impedance-pH studies) (MARK III, Delta and Digitrapper pH-Z, Synectics, Gyen, Medtronic) were performed according to standard technique.

Results: Pathological reflux was present in 91 patients (47.9%), 24 from group 1 and 67 from group 2. Pathological acid reflux was therefore ruled out as a cause of symptoms in 52.1% of all cases studied: 60 patients (47.2%) from group 2, and 36 patients (61.9%) from group 1. In addition, out of the 24 patients with pathological reflux in group 1 (true refractory patients), 9 had an incomplete response, with a percentage of time with pH < 4 less than 7.5% (mild reflux), which probably was not the cause of the symptomatology.

Conclusion: Proton pump inhibitors (PPIs) are the drugs of choice in the treatment of GERD. However, its efficacy may be compromised for a variety of reasons including: non-compliance, bioavailability, episodes of nocturnal acid break-through, poor gastric emptying, etc. In most of the patients referred for
studying with the diagnosis of refractory reflux to PPIs, this diagnosis had only been based on OHR, intractable symptoms. When the diagnosis is exclusively clinical, about a half (47.2%) of the patients with persistent symptoms on double doses of PPIs, considered as GERD patients refractory to PPIs, have an incorrect diagnosis (patients do not have pathological reflux). More than half of the patients (61.9%) who have a diagnosis of GERD confirmed by complementary tests that do not respond to treatment with PPIs, acid reflux is not the cause of their symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1204 LOW-FODMAP DIET resulted effective in reducing symptom perception in patients with functional heartburn

Introduction: Recently, low-FODMAP diet has been proposed as potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia.

Aims & Methods: The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper pathophysiological tests (oesophageal manometry and impedance and pH monitoring, MII-pH) at Gastroenterology Unit in University of Pisa. We excluded patients older than 75 and younger than 18, those with primary oesophageal motor disorders and with previous abdominal surgery. Medical history, volup-
tuary habits and response to proton pump inhibitor (PPI) treatment were recorded. By means of MII-pH we splitted patients in two populations: NERD group (abnormal esophageal acid exposure or number of refluxes) and FH group (normal esophageal acid exposure and number of reflux, no symptom-reflux correlation and no heartburn relief during PPI treatment). All enrolled patients were evaluated with validated questionnaires (Likert andVAS) to evaluate heartburn occurrence pre- and post a nutritional approach with low-FODMAP diet for 6 weeks.

Results: We included 31 patients (20 female; mean age 49.1 yrs; mean BMI 24.4) into the study. NERD group was composed of 13 patients (6 female; mean age 48.7 yrs; mean BMI 22.5). FH group was composed by 18 patients (11 female; mean age 50.9 yrs; mean BMI 23.9). All patients showed symptom improvement regarding bloating, abdominal pain and stools composition (p < 0.001) after low-FODMAP diet (see Table 1). Moreover, we observed a very important improvement of heartburn in the FH group (from 8.4 ± 2.5 to 2.3 ± 1.1; p < 0.001 on VAS scale) compared to the NERD group (7.2 ± 2.2 a 6.9 ± 1.9; p = 0.624 on VAS).

Legend: BSC = Bristol Stool Classification; *=statistically significant (p < 0.05)

Conclusion: This pilot study showed that a low-FODMAP diet was able to reduce heartburn perception in patients with FH and who did not obtain any symptom relief with PPI treatment. Larger prospective randomized controlled trial is mandatory to further explore these findings.

Introduction: Because of a higher prevalence of BE in males, recommendations in current guidelines are mainly based on male BE patients and make no difference in gender according to gender. Nevertheless, it is unknown whether female BE patients have the same neoplastic progression and acceleration rate as male patients.

Aims & Methods: The aims of this study were (1) to evaluate the difference between males and females in probability of and (2) time to neoplastic progression, as well as (3) gender differences in stage distribution of neoplastic progression in surveilled BE patients. In this multicenter prospective cohort study we included 729 patients with BE who met the inclusion criteria of a segment of ≥2cm and confirmed intestinal metaplasia. Endoscopic surveillance was performed according to the American College of Gastroenterology guidelines. Cox regression modelling as well as accelerated failure time modelling were used to estimate differences in probability of and time to neoplastic progression to HGD, EAC and both HGD and EAC between sexes, respectively. All models were adjusted for age, presence of esophagitis and length of BE. In case of a limited number of events, descriptive statistics were used.

Results: 532 males (73%; median age 58 years, IQR 51–67) and 197 females (median age 64 years, IQR 57–70) were included with a median follow-up of 8.2 years (IQR 5.3–10.3). High-grade dysplasia (HGD) was detected in 35 males versus 4 females, EAC in 12 males versus 5 females. The total number of patients with neoplastic progression was 56 (8%), which was twice as high among males compared to females (HR 1.90, 95% CI 1.02–3.92). Especially the risk of HGD was higher in males than in females (HR 3.34, 95% CI 1.17–9.50). The ratio HGD/EAC in males was 2.92, in females 0.80. Apparently in females propor-
tionally more EAC was identified compared to males. Though these data might suggest accelerated neoplastic progression rates in females, time to event was significantly shorter for males in HGD (HR 0.45, 95% CI 0.22–0.94). There was no difference for overall neoplastic progression (AR 0.59, 95% CI 0.16–1.90). Stage distribution as shown in Table 1, females tend to have a higher stage of neoplastic progression than males.

Conclusion: The risk of HGD and overall neoplastic progression and acceleration rate of HGD development is higher in male BE patients compared to females. On the other hand descriptive statistics show proportionally more EAC in females as well as an advanced stage of EAC at diagnosis. Further research into the differ-

Introduction: Given its proven safety and efficacy, RadioFrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett’s Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. The CryoCryoballoon Ablation system (FCBA; C2 Therapeutics Inc. Redwood City, CA, USA) is another ablation method -based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. FCBA comprises a handheld, through-the-scope system with a conformable balloon that is simultaneously inflated and cooled using nitrous oxide, resulting in ice patches of approximately 2cm2 on the targeted mucosa. Previous studies applying FCBA to limited areas of BE (1 to 2 small BE islands per patient) have shown promising results. Data on
efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

Aims & Methods: Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE <6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGĐ) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including the initial BE. Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal stricture or other adverse events.

Results: We enrolled 20 patients with dysplastic BE (85% male, mean age 66 (±8) years), with a median BE length of 2.2 cm (IQR 0–6; 1–3) and with a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoballoon and 8 (40%) had undergone previous circumferential RFA. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 83–98), this included 3 patients (15%) with a complete 100% regression. All biopsies confirmed squamous regeneration with out evidence for subsquamous BE. No significant esophageal strictures or other complications were noted.

Conclusion: Our multicenter, prospective trial shows that a single treatment with Focul CryoBalloon ablation therapy is safe, well-tolerated and effective for eradication of dysplastic BE.

Disclosure of Interest: All authors have declared no conflicts of interest.

A1. Baseline characteristics
- Male gender, n (%) 17 (85%) 29 (83%) 0.84
- Age, mean (SD) years 65 (±8) 66 (±8) 0.66
- Worst diagnosis prior to FCBA
  - LGD, n 10 (50%) 19 (54%) 0.54
  - HGD, n 1 (5%) 6 (17%) 0.05
  - EAC, n 9 (45%) 10 (29%) 0.05
- Prior treatment
  - ER, n 10 (50%) 17 (52%) 0.92
  - Circumferential 10 (50%) 23 (66%) 0.33
- BE length
  - Prior to FCBA
    - Circumferential, cm 2 (1–2) 1 (1–3) 0.72
  - Maximum pain scores on day 1 to 14 post treatment
    - Maximum VAS, median (IQR)
      - Day 1 2 (0–4) 3 (1–7) 0.06
      - Day 2 1 (0–4) 3 (1–6) 0.02
      - Day 3 1 (0–3) 3 (1–4) 0.03
      - Day 4 1 (0–2) 2 (1–4) 0.05
      - Day 5 0 (0–2) 2 (1–5) <0.01
      - Days 7 to 9 0 (0–1) 2 (0–4) <0.01
      - Days 10 to 14 0 (0–0) 1 (0–2;3) <0.01

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared with RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1207 CRYOBALOON ABLATION OF DYSPLASTIC BARRETT’S ESOPHAGUS CAUSES SHORTER DURATION AND LESS SEVERE POST-PROCEDURAL PAIN AS COMPARED TO RADIOFREQUENCY ABLATION

S. Van Munster1, A. Overwater2, J.J. G.h.m. Bergman1, B.L.a.m. Weusten2
1Gastroenterology And Hepatology, AMC, Amsterdam/Netherlands
2Dpt. Of Gastroenterology And Hepatology, Universy Medical Center Utrecht, Utrecht/Netherlands

Introduction: Radiofrequency ablation (RFA) is safe and effective for eradication of dysplastic Barrett’s Esophagus (BE), but may be associated with significant post-procedural pain. As an alternative, cryobalisation using the Focal Cryo Balloon Ablation system (FCBA) has recently been developed, which ablates BE by freezing it using nitrous oxide. Early uncontrolled studies suggest comparable safety and efficacy of FCBA and RFA in eradicating dysplastic BE. This study compared cryoballoon endpoints like pain management with FCBA versus RFA, to determine post-ablation pain and its determining factors.

Methods: Fifty-five patients were included (35 with focal RFA; 20 with CBA) and were enrolled in a prospective multicenter, non-randomized, open-label study. Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. All AUC curves were significantly smaller after FCBA compared to RFA: for maximum VAS score (12.3 vs 26.7, p < 0.01), for odynophagia (11.6 vs 26.7, p < 0.01), for pain in rest (7.8 vs 20.5, p < 0.01), for use of analgesics (0.9 vs 3.1, p < 0.01) and for dysphagia (2.6 vs 8.2, p < 0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p < 0.01). After 4 (IQR 1–10) days, half of the FCBA patients reported a pain score of 0, whereas this was 13 (IQR 10–15) days for RFA compared to 8 (IQR 0–11) days for RFA patients (p < 0.01).

Results: We enrolled 20 patients with dysplastic BE (85% male, mean age 66 (±8) years), with a median BE length of 2.2 cm (IQR 0–6; 1–3) and with a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoballoon and 8 (40%) had undergone previous circumferential RFA. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 83–98), this included 3 patients (15%) with a complete 100% regression. All biopsies confirmed squamous regeneration with out evidence for subsquamous BE. No significant esophageal strictures or other complications were noted.

Conclusion: Our multicenter, prospective trial shows that a single treatment with Focul CryoBalloon ablation therapy is safe, well-tolerated and effective for eradication of dysplastic BE.

Introduction: Radiofrequency ablation (RFA) with endoscopic mucosal resection is recommended for Barrett’s Oesophagus (BO) related neoplasia. In this study, we evaluated RFA treatment outcomes for BO stratified according to baseline histology, i.e. low-grade dysplasia (LGD), high-grade dysplasia (HGD) and intramuscular carcinoma (IMC). We retrospectively reviewed the treatment outcomes of patients with dysplastic BO between January 2007–2017. Patients received 3-monthly RFA until endoscopic and histologic remissions were achieved. Outcomes measured were: 1) complete remission of dysplasia (CRD) and intestinal metaplasia (CRIM), 2) stricture rate, and 3) durability of CRD and CRIM. Patients on active treatment protocol were excluded.

Results: We identified 113 patients who completed RFA treatment (21 LGD, 46 HGD and 46 IMC). There were no significant difference between the groups in the age, gender, circumferential and maximum length of BO, and stricture rate. CRD and CRIM were achieved in 94.7% and 78.8% of patients, respectively. When stratified according to baseline histology, there was no significant difference in CRD rate among LGD (95.2%), HGD (95.7%) and IMC (93.5%) (p = 0.89). Similarly, there was no significant difference in CRIM rate among LGD (71.4%), HGD (76.1%) and IMC (84.8%) (p = 0.31). CRD durability at 12 and 36 months (n = 107) were 99.0% and 97.0%, respectively. CRD durability (n = 89) at 12 and 36 months were 98.5% and 92.7%, respectively. When stratified according to baseline histology, CRD durability at 12 and 36 months for LGD and IMC were 100% at both time points, and 97.7% and 93.6% for HGD, respectively (log rank p = 0.31). CRIM durability at 12 and 36 months for LGD, HGD and IMC were 100%, 96.4%, 100%, and 100%, 88.5%, 95.5%, respectively.

Conclusion: The treatment outcomes for BO were similar in patients with different baseline histology. Our results showed that once CRD and CRIM were achieved, these were durable over time.

P2109  IS IT REASONABLE TO PROPOSE AN ENDOSCOPIC MUCOSAL RESECTION FOR BARRET’S OESOPHAGUS WITH HIGH-GRADE DYSPLASIA ON THE BIOPSY?

J. Gonzalez1, J. Casanova1, A. Benezech1, E. Bories2, S. Garcia3, M. Giovannini4, M. Barthet1

Introduction: Endoscopic mucosal resection (EMR) is currently the first-line treatment for high-grade dysplasia (HGD) in Barret’s esophagus (BE). Despite improvements in the characterization of dysplasia, the management depend on the pathological analysis of biopsies previously performed. However, the level of concordance between cytologists in such situation remains low. The aim of this study was to evaluate the discordance between biopsy sample (BS) and EMR specimen in case of HGD, as well as cytologists’ inter and intra-observatory variability.

Aims & Methods: This was a retrospective study including a prospect histological relecture (BS and specimen) in two expert centers. The inclusion criteria were BE with HGD on pre-operative biopsies resected by the endoscopist. The initial biopsies from other centers were collected and re-examined by our cytologists. The BS discordant with EMR specimens were recorded in a numeric file (Teleslide) and a second lecture was carried out by 2 experts and 2 fellows (1 of each per center). Five diagnoses were considered: no metastasis (no BE), metaplasia without dysplasia, LGD, HGD, Adenocarcinoma. Concordance statistics tests were performed to assess the variability between BS and EMR specimen and among the cytologists and the pathologists. Results: Between January 2005 and December 2015, 87 patients have undergone EMR for HGD on biopsies, in both centers. Among them, 41 (47%) had a discordant result between biopsy and resection specimen. The histological diagnosis was BS HGD and EMR no BE in 6 cases (16.4%), BS LGD and EMR HGD in 4 cases (4.6%) and one patient had no metastasis. Finally, 33 patients could be analyzed, 29 men and 4 women, with a mean age of 63 years old. The length of BE according to Prague classification was C3-M5, with relief achieved in 63.6% of the cases. A mean number of 1.4 endoscopic session was performed, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months.

Conclusion: The discordance rate between initial diagnosis of HGD on BS and final diagnosis of EMR was 47%. BE extent is high, around 47%. The intra and inter observer concordance is insufficient, even in expert tertiary centers. Thus, the question about performing EMR based on random biopsies rather than endoscopically performed biopsies is to be raised. The BS discordant with EMR specimen were recorded in a file and concordance statistics tests will be performed to assess the variability between BS and EMR specimen as well as cytologists’ inter and intra-observatory variability.

Introduction: Non-neoadjuvant chemoradiotherapy (CT-RT) before esophagectomy is standard management for locally advanced squamous cell carcinoma (SCC) of the esophagus and in several cases, it can lead to complete response (CR).

Aims & Methods: The aims of this study were to identify possible immunological predictive factors for neoadjuvant CT-RT failure after neoadjuvant chemoradiotherapy (nCRT) and to identify distinct clusters associated with response to therapy. Based on these subgroups, we will develop a subtype classifier that might improve stratification of patients for (targeted) therapies and subsequently improve outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal adenocarcinoma (EAC) is a highly aggressive malignancy with poor prognosis. Advances in therapy have led to incremental improvements in overall outcome in EAC, but over- and undertreatment of unidentified subgroups of patients might undermine these benefits (Courrech Staal et al. 2010). The biological diversity of EAC complicates patient selection and treatment stratification and impedes the development of new targeted agents. Further insight into the heterogeneous molecular pathology of EAC and a possible relation to outcomes and response to current treatment strategies is urgent.

Aims & Methods: We included ~75 patients with EAC and functional adenocarcinoma (FAC). Most patients underwent neoadjuvant chemo-radiotherapy (nCRT) with carboplatin and paclitaxel. Pre-treatment tissue samples of the tumor and healthy adjacent mucosa were collected during upper gastrointestinal endoscopy. RNA was extracted from all tumor biopsies and a subset of matched healthy biopsies. Samples were sequenced using Illumina sequencing technology. Count files were obtained, which served as input into the R language and environment for statistical computing for further analyses.

We performed unsupervised hierarchical clustering on the tumor RNA profiles to identify distinct subtypes. We performed K-means clustering with software package clusterProfiler (Yeung et al. 2007) for further analyses.

Results: We could identify three distinct subtypes with a metabolic, immune and cell cycle regulating signature respectively. The subtype with the immune signature was associated with tendency to poorer response to therapy. We will develop a subtype classifier to perform subtype prediction in an independent patient cohort from the TCGA database (The Cancer Genome Atlas Research 2017).

Conclusion: Our studies support the existence of three distinct EAC/junctional subtypes associated with different response to therapy. Based on these subgroups, we will develop an EAC subtype classifier that might improve stratification of patients for (targeted) therapies and subsequently improve outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

analyzed by cell counting kit-8 assay. Cell cycle and apoptosis were evaluated by flow cytometric analysis. Protein levels of p53 were determined by western blot analysis. Differences between groups were tested for significance using Student’s-t test (two-tailed).

Results: ESCC tissues examined in this study showed an obvious increment in TRPM2-AS expression when compared to normal tissues. Meanwhile, TRPM2-AS expression was positively related to lymph nodes metastasis, TNM stage and clinical stage. And upregulated TRPM2-AS expression was turned to be remarkably correlated with the shorter survival of ESCC patients which could act as an independent risk factor for both overall survival time and disease-free survival. In addition, overexpression of TRPM2-AS could promote the proliferation and inhibit the apoptosis of ESCC cells, while knockdown of TRPM2-AS had a reverse function. Furthermore, downregulation of TRPM2-AS enhanced the expression of p53 in ESCC cells.

Conclusion: This study suggested that long non-coding RNA TRPM2-AS could be a potential oncogene of ESCC. TRPM2-AS expression might be served as another potential therapeutic target and prognostic biomarker. In addition, our study suggested that the overexpression of TRPM2-AS contributes a lot to inhibiting apoptosis of ESCC by regulating the expressions of p53 in vitro, which may be a potential oncogene and therapeutic target for ESCC.

Introduction: Esophageal adenocarcinoma (EAC) is an increasingly common cancer with a poor prognosis. EAC is the final step of a pathway starting with esophageal reflux disease, intestinal metaplasia, and dysplasia. The expression of cytotoxic protein p53 and the expression of p53 in the esophageal cancer tissue is significantly lower than in the normal mucosa of healthy patients. This may be one of the mechanisms of immune escape of cancer cells in the esophageal cancer. Aims & Methods: The aim of this study was to investigate the role of CD80 in the inflammatory environment of EAC. The expression of p53 in cancer and from healthy esophagus was obtained during esophagectomy from patients affected by EAC. Fresh biopsies were obtained from patients who underwent endoscopy for screening or follow-up. Immunohistochemistry for CD80 was performed. Fresh biopsies were analyzed by flow cytometry to quantify the expression of CD80, its receptor CD28 and the lymphocytes activation marker CD3. ESCC and esophageal epithelial cells and CD80 infiltrating lymphocytes, respectively. A model of reflux induced esophageal metaplasia was created with a esophagostoma/xenografting: C57BL/6 mice were randomized to receive or not intraperitoneal injections of anti-CD80 antibody. The esophago-gastric specimens were collected 32 weeks after randomization and analyzed in a blinded fashion. Non-parametric statistical analyses were used.

Results: Flow cytometric analysis of esophageal biopsies from healthy controls, Barrett esophagus, dysplastic esophageal and esophageal adenocarcinoma reveals that the expression of the cytotoxic molecule CD80 by epithelial cells peaks during metaplasia in the inflammatory esophageal carcinogenesis. In the mice that received antiCD80 antibodies the rate of dysplasia in the fore stomach was significantly higher (5.7) compared to that observed in vehicle-treated wild type mice (1.6). Conclusion: The human and the in vivo data that we obtained suggest that in inflammation-driven esophageal carcinogenesis there is evidence of an active immune surveillance process mediated by the overexpression of CD80 costimulatory molecules such as CD80 and CD86 in the esophageal cancer tissue. This may be one of the mechanisms of immune escape of cancer cells in the esophageal cancer. Aims & Methods: The aim of this study was to evaluate the effect of the interplay between dysregulation of oncogenes and oncosuppressor genes within the tumor and immune microenvironment on EAC prognosis. Mucosa samples from EAC tissue were obtained during esophagectomy from 169 consecutive patients operated. Immunohistochemistry for MLH1, MSH2, MSH6, PM2, CMCy, p16, HER2 and nuclear p53 expression was performed. CD8 infiltration, CD8 and NK cells cytolytic activity (CD107) of tumor infiltrating lymphocytes and migratory enhancing cells across the tumor microenvironment (TME) were assessed by immunohistochemistry. Mutational analysis for BRAF was performed. Cox proportional hazard models were created to investigate the role of each marker adjusted for cancer stage. The association between each marker and the presence of nodal metastasis was assessed by an exact test.

Results: In our EAC patients’ series, one patients had BRAF mutation (V600E) and 5 of them had microsatellite instability. CD107 overexpression within the cancer was associated with the presence of nodal metastasis (p = 0.029). In patients with nodal metastasis, nuclear p53 overexpression revealed to be an independent predictor of early recurrence with [HR = 2.995 (95% CI = 1.122 – 7.986) p = 0.029] as well as cancer stage [HR = 2.903 (95% CI = 1.669 to 5.186) p < 0.01]. On the other hand nuclear p53 overexpression also tended to be an independent predictor of overall survival [HR = 2.359 (95% CI = 0.961 to 6.963) p = 0.06] while cancer stage confirmed to be the main survival predictor [HR = 1.889 (95% CI = 1.081 to 3.214) p = 0.025].

Introduction: Altered glucose metabolism has become a recognised feature of tumor cells, which is characterized by an increased glucose uptake and preferential dependence on glycolysis for energy production. As a consequence, cancer cells produce large amounts of lactate, which is pumped out the cytosol by monocarboxylate transporters (MCTs), mainly MCT 1 and 4. MCT inhibition has previously been related to increased apoptosis in cancer cells, but this aspect has not been investigated in esophageal adenocarcinoma (EAC) yet.

Aims & Methods: We aimed to: 1) characterize the expression of MCT 1 and 4 in human samples of EAC and to evaluate in vitro the effect of extracellular glucose concentration and pharmacological inhibition of MCT1 on lactate concentration, intracellular pH (pHi), and cell apoptosis, MCT1 and MCT4 expression was analyzed by immunohistochemistry in human samples of EAC. For the in vitro study, two different EAC cell lines were used: OE33 (ECACC), established from an EAC of the lower esophagus and OAC5M1C (ECACC), obtained from a lymph node metastasis derived from an EAC, MCT1 and MCT4 expression and localization were assessed by immunohistochemistry in both cell lines. The MCT1 selective inhibitor AZD9395 (0, 10 and 100 nM) was added to the culture medium under a normoxic and hypoxic atmosphere in standard (11 mM) or high (30 mM) glucose content in the media. Apoptosis was determined by flow cytometry (Annexin V-FITC and propidium iodide). Intracellular lactate concentration was evaluated in a colorimetric assay. pH was evaluated by flow cytometry with the probe SNARF-1 AM. Experiments were performed at least in triplicate. Statistical analysis was performed by student’s t-test. Results: MCT1 and MCT4 expression was found in all the EAC samples evaluated. MCT1 expression was confined to tumor cells, with 62% of the biopsies showing moderate or intense staining, whereas MCT4 was expressed in both tumor and stromal cells, with 40% of moderate/intense stained samples. Both MCT1 and MCT4 expression was significantly downregulated in OE33 cells and only in a small population of the metastatic cell line. High extracellular glucose concentration increased intracellular lactate levels in OE33 cells but not in the metastatic line, and did not have any effect either in pH and apoptosis under any of the conditions evaluated (normoxia and hypoxia) in both cell lines. Treatment with AZD9395 (10 and 100 nM) increased intracellular lactate concentration in OE33 and OAC5M1C cells, but this increase was higher (600–700%) in the metastatic cell line than in OE33 cells (50–70%). Under normoxic conditions AZD9395 significantly increased pH of both cell lines whereas hypoxic atmosphere had no effect on metastatic cells. The highest concentration (100 nM) of the MCT1 inhibitor significantly...
increased apoptosis of OACM5.1C cells whereas did not affect apoptosis of OE3.1 cells.

Conclusion: Metastatic and non-metastatic esophageal adenocarcinoma cells exhibit different glycolytic metabolism and response to pharmacological inhibition of MCT1, which increases apoptosis in metastatic cells. Further preclinical studies are required to be defined the potential of blocking lactate transporters on the treatment of metastatic EAC.

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumothorax, sometimes requiring emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 lesions were treated with ESD. Esophageal perforation was defined as cases with lack of data. The primary outcome was determination of the predictive factors for esophageal perforation in patients who received esophageal ESD. The secondary outcome was clinical outcomes. Perforation was defined as a hole in the hold dissected wall exposing the mediastinal cavity. Logistic regression multivariate logistic analysis with generalized estimating equations were used to analyze repeated measures data.

Results: A total of 549 cases with 927 lesions were evaluated. Of those, perforation occurred in 15 cases (2.7%) with 15 lesions (1.6%). A lesion diameter (Odds ratio; OR = 1.05, 95% confidence interval: CI: 1.02-1.07, p < 0.001) and the proximity of the tumor to a previous ESD scar (OR = 6.66, 95% CI: 1.80–24.6, p = 0.004) were both associated with perforation using crude logistic regression analysis. Multivariate logistic regression analysis also showed that a lesion diameter (OR = 1.05, 95% CI: 1.03-1.07, p < 0.001) and the proximity of the tumor to a previous ESD scar (OR = 13.0, 95% CI: 2.48-67.9, p = 0.002) were independent predictive factors for perforation.

Conclusion: Larger size and the proximity of the tumor to a previous ESD scar increased the likelihood of perforation in patients who received esophageal ESD.

P1217 SAFETY, EFFICACY AND OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE TREATMENT OF EARLY BARRETT’S NEOPLASIA

M. Omote, M. Konradsson, P. Elbe, M. Nilsson, M. Lindblad, I. Rouvelas, F. Bäldqua-Silva
Gastrocentrum, Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: masami.negoi@jcr.or.jp

Introduction: Endoscopic submucosal dissection (ESD) was developed in Japan for the treatment of large gastrointestinal neoplasias and has progressively been adopted in the West. Currently, early Barrett’s neoplasia is mainly treated with endoscopic mucosal resection (EMR) and/or radiofrequency ablation, being the ESD is not performed in this context not well-established yet. Our aim is to evaluate the safety, efficacy and outcome of ESD for the treatment of early Barrett’s neoplasia.

Aims & Methods: Fifty consecutive ESD cases of early Barrett neoplasia were performed in 42 patients in our center between 2011 and 2016. All ESDs were performed under full narcosis after multidisciplinary team conference discussion and patient’s consent. The primary endpoint was the rate of endoscopic resection. Secondary endpoints included rate of R0 and curative resection, a comparison of pre- and post- ESD histology, procedure time, procedure-related adverse events, and rate of remission at follow-up. This study was approved by the Stockholm Regional Ethical Committee.

Results: Mean age was 67 years (range 46–84), being 74% male and 72% long segment BE. The mean specimen size was 52 mm (range 16–150 mm). ESD resections included less than 25% of the 25–50%, 50–75% and 75–100% of the mean circumference in 4/3/12 of the cases, respectively. En bloc, R0 and curative resection were obtained in 96% (48/50), 80% (40/50) and 70% (35/50) of cases, respectively. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleeds treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality was 0%. In 15 cases of LGD, there was submucosal invasion on the ESD specimen. In 14/50 of the resected specimens there was submucosal neoplasia. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleeds treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality was 0%. The patients with 15 non-curative cases, 2 patients went through further ESD, 1 received chemoradiotherapy and 2 patients are under surveillance. In the 10 esophagectomy cases, 4 patients had AC in the remnant Barrett’s esophagus and 2 patients had lymph node metastasis. Complete resection was 364 patients with ESCC (425 lesions) who underwent endoscopic resection from January 2000 through July 2015, a total of 93 patients (93 lesions) had a histopathological diagnosis with submucosal or lymphovascular invasion. Among these 93 patients, 41 received additional CRT (CRT group), and 52 were followed without CRT(follow-up group). CRT comprised cisplatin plus 5-fluorouracil and radiation therapy. Additional CRT after endoscopic resection in patients with esophageal cancer was a 22 mm (6 to 55) in the CRT group and 25 (3 to 47) in the follow-up group (p = 0.63). The tumor invades the MM in 9 patients, the SM1 in 3, and the submucosa to a depth more than 200μm (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group (p = 0.91). Lymphatic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group (p < 0.01). Vascular invasion was positive in 27 patients in the CRT group and 29 in the follow-up group (p = 0.32). Involved margin of the submucosal or lymphovascular invasion was found in 7 in the CRT group and 9 in the follow-up group (p = 0.07). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhea 2.4% (1), anorexia 17.9% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and in 7 in the follow-up group (p = 0.15). In 2 patients with recurrence in the CRT group, lymph-node metastases were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer (p = 0.43). The overall survival (OS) rate at 2 years was selected radio-positive (93.8%) in the follow-up group (p = 0.02). Disease-free survival (DFS) rate at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group (p = 0.02).

Conclusion: Additional CRT after endoscopic resection in patients with esophageal cancer who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preservation strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
found in 100% (35/35) of patients with curative resection at median follow-up of 2.5 years (range 4–64 months).

Conclusion: In the proper setting, ESD is safe and effective for the treatment of early Barrett’s neoplasia with high en bloc and complete resection rates and good curative rate. ESD enables full pathological assessment in lesions not suitable for en bloc resection with EMR. There were no recurrences in the curette cases, which increases the role of ESD for the management of early Barrett’s neoplasia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P2129 ENDOSCOPIC EVALUATION AT THE PRIMARY SITE OF CTI ESOPHAGEAL CANCER AFTER PROTON BEAM THERAPY AND CLINICAL RESULTS OF SALVAGE ENDOSCOPIC THERAPY FOR LOCAL RECURRENCE

D. Satou1, A. Motoi2, T. Kojima1, Bandou1, K. Horii1, T. Kodota1, Y. Yoda1, K. Iwata1, Y. Ono1, T. Akimoto1, Y. Yano1

3Gastroenterology And Oncology, National Cancer Center Hospital East, Kashiwa/Japan
4Division Of Radiation Oncology, National Cancer Center Hospital East, Kashiwa/Japan

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site.

Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation of the primary lesion of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was 60 Gray- Equivalent (GyE). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows: disappearance of tumor lesion and ulcer, and absence of cancer cells in biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows: endoscopic resection (ER) for T1a, esophagectomy or photodynamic therapy (PDT) for T1b or deeper depending on patient’s condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and those with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 43 patients (98%) had a depressed component in endoscopic evaluation. Recurrence occurred in 100% of the patients with clinical stage II, III, and IV. The median follow-up of the patients with local recurrence was 257 days (range, 111–722 days). The endoscopic finding from CR was 257 days (range, 111–722 days). The endoscopic finding from CR was 257 days (range, 111–722 days).

Aims & Methods: The aim of this study was to investigate the clinical outcomes of electron beam therapy (EBT) and conventional esophageal squamous cell carcinoma (HNSCC) patients in an oncology tertiary center. From 2010 to 2016, 3280 endoscopies were performed in patients with HNSCC and in 1887 chromoscopy with Lugol and NBI were performed. A total of 26 SENS, submitted to ESD, in 25 patients were retrospectively analysed.

Results: The median tumor size was 4.37 cm (±1.83). The en bloc resection were 100% and free margin (R0) were 92.3%. The two patients with positive margins had a depressed component in endoscopic evaluation. Recurrence occurred in 11.5% (3/26) and one of these cases was successfully treated by endoscopic submucosal dissection (ESD).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCC, curative endoscopic treatment can be performed. ESCC mainly occurs in developing countries, often with limited endoscopic expertise and resources, like Central and Eastern Asia and Eastern and Southern Africa. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a new endoscopic ablation therapy that comprises a therapeutic cryoballoon catheter with a conformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm2. FCBA is easy to use and requires no capital equipment. Early studies for FCBA for Barrett’s esophagus have shown promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

Aims & Methods: In this ongoing multi-center prospective trial in China, patients with one flat type (Paris O-Hb) unstained lesion (USL) on Lugol’s chromoscopy, <6cm in length and <50% of circumference, with a confirmed diagnosis of Moderate or High Grade Intraepithelial Neoplasia (MGIN/HGIN) were
Aims & Methods:
Phenotypic diagnosis of endoscopic (EUS) is the standard modality for qualitative diagnosis of submucosal tumors (SMTs) and determining the depth of invasion of esophageal cancer. Standard EUS, however, comprises a continuous water-filling or water-filled balloon method, which creates some problems for some patients (feeling of swallowing difficulty, vomiting, aspiration caused by balloon compression). Aspiration of water is especially problematic during the diagnosis of lesions in the cervical or upper thoracic esophagus. To resolve such disadvantages, we recently reported a method that includes probe EUS with a jelly-filling technique (EUS-J) for evaluating superficial esophageal squamous cell carcinoma (SCC). The procedure is characterized by filling the esophageal lumen with a water-soluble lubricating jelly (K-Y lubricating jelly; Johnson & Johnson, Tokyo, Japan) that is used for routine endoscopy and is harmless to humans. In the current study, we retrospectively evaluated the usefulness of EUS-J with water-soluble lubricating jelly for lesions located in the cervical and upper thoracic esophagus.

Aims & Methods: Patients with an esophageal SCC or SMT in the cervical or upper thoracic esophagus were included. EUS-J with water-soluble lubricating jelly was performed using a high-resolution probe. Before examination, several 5-mL syringes containing the Water Soluble Lubricating Jelly were prepared. We enrolled 80 patients with early esophageal cancer (EAC) treated by endoscopic submucosal dissection (ESD) in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroids injection, endoscopic transplantation following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroids injection combination therapy for the prevention of post-ESD stenosis. Results: 1. Clinical outcomes: In EUS-J, the stenosis rate was 29.8%, and the ulcer healing period was 97.5 days. In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis.

Aims & Methods: A total of 2850 patients who were diagnosed with EGC underwent endoscopic resection either by esophagectomy or endoscopic submucosal dissection (ESD). We analyzed the surgical and oncological safety of these procedures.

Contact E-mail Address: TRISTAN82@yuhs.ac

Introduction: The patients with early gastric cancer (EGC) who have undergone non-curative endoscopic resection (ER) need additional surgery. Our previous study reported short-term data about 29 days were optimal time when considering surgical outcome. (Ann Surg Oncol. 2014 Jan;21(1):1232-9.) This study is a long-term follow-up study to evaluate the impact of previously proposed optimal time interval from ER to additive surgery by on the surgical and oncological outcomes. Results: A total of 2850 patients who were diagnosed with EGC underwent ER at the Severance and Gangnam Severance Hospitals, Seoul, Korea, between January 2007 and December 2014. We analyzed totally 302 (10.6%) patients who underwent additive gastrectomy after non-curative ER. The patients were divided into 2 groups according to the time interval point, as the earlier operation group (group A) and the later operation group (group B). The time interval point, at which operative time and estimated intraoperative blood loss (EBL) of the earlier operation group and the later operation group...
showed the greatest disparities, was evaluated. We retrospectively evaluated long-term follow-up study for oncological outcomes about follow-up duration, loco-regional recurrence, distant recurrence.

**Results:** The median follow-up duration is 40.36 ± 20.74 months in all patients. Based on the previous our study, we divided patients two groups who underwent operation before 29 days and after 29 days. Of the 302 patients, 133 were in Group A (≥29days) and 169 in Group B (>29days). There were more differences between two groups about ASA score, ER Specimen size, intra-op. transfusion, POD/discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous our study the operative time, EBL, tumor size was significantly longer and more in Group A compared with group B. There were totally 7 patients loco-regional and distance recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

**Conclusion:** Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that adding surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA**

T. Wakasuki, S. Furutachi, H. Yamashita
Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

**Contact E-mail Address**: t.wakasuki4503@yahoo.co.jp

**Introduction:** This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful Helicobacter pylori eradication, we often observe multiple reddish depressed lesions and “patchy redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crest (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intraperithelial microinvasion (IEMI)”, and 2) “Over flow”, Over flow is that the endoscopic finding that the structure of the lesion called “patchy redness” or “map-like redness” in the gastric mucosa.

**Aims & Methods:** The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. This is a retrospective control study. There were 234 cases of EGC performed endoscopically in Japan.

**Characteristics**

<table>
<thead>
<tr>
<th>Group</th>

**Contact E-mail Address**: smaxavier@gmail.com

**Introduction:** Iron deficiency anemia (IDA) may be the only sign of gastrointestinal (GI) malignancy. The identification of predictive factors of GI malignancy in patients with IDA could help the physician to establish patients’ priority to endoscopic assessment, contributing to an earlier diagnosis.

**Aims & Methods:** Retrospective study of 344 patients submitted to endoscopic assessment for IDA. Included adult patients with IDA and excluded patients with GI or extra-GI bleeding, total gastrectomy, exclusively vegetarian diet or intake of synthetic iron records.

**Results:** Included 121 patients with mean age of 68.5 ± 17.0 years and 54.5% females. GI malignancy was identified in 14.9% of patients (gastric in 12, colonic in 6 patients). A statistically significant association was found between the presence of GI mucosal findings and IM (p < 0.001), gender (72.2% vs 40.8%, p = 0.01), IM symptoms (61.1% vs 11.7%, p < 0.01), weight loss (61.1% vs 5.8%, p < 0.01), need for hospitalization (88.9% vs 49.5%, p < 0.01), iron serum levels and transferrin saturation (97.0 ± 10.1 mg/L vs 30.4 ± 18.9 mg/L, p < 0.01), transferrin saturation showed a weak discriminative capacity (AUC = 0.67, p = 0.01) however, values of transferrin saturation ≤11% had a sensitivity of 94.4% and a negative predictive value of 97.1% for GI malignancy (CI 95% 95.7–98.8). The association remained significant after adjusting for IDA symptoms. The prevalence of GI malignancy was highest in females (89.7% vs 57.6%, p = 0.01) and 6.1% in patients with values over 11% have a very low probability to have GI malignancy.

**Conclusion:** All patients with IDA the diagnosis of GI malignancy is established in a significant percentage of patients and patients with symptoms, weight loss or with need for hospitalization should be given priority in the performance of endoscopic examinations. Transferrin saturation may help the physician establishing the urgency of endoscopic assessment, since patients with values over 11% have a very low probability to have GI malignancy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Detection of gastric cancer in its early stage is pertinent in reducing specific mortality. However, early detection of gastric cancer has not been achieved in many countries where the incidence of gastric cancer is high. In order to overcome this problem, we developed an e-learning system for international endoscopists to improve endoscopic diagnosis of early gastric cancer. However, it has not been investigated whether such learning system is useful in clinical practice.

**Aims & Methods:** The objective of this trial is to investigate whether the intensive on-site TTT course is useful for increasing early detection rate of gastric cancer in Chinese high-volume endoscopy center. Five Chinese doctors (the TTT group) who were invited to the TTT course and the other five age and experience-matched Chinese doctors (the non-TTT group) in the same facility who did not attend any learning program during the same period. Lectures of the TTT course included the detection of early gastric cancer by screening endoscopy using white-light endoscopy alone and the feature of the detected subtle gastric mucosal lesion using white-light endoscopy or magnifying endoscopy with narrow-band imaging. Contents used in the lecture had been reported to be useful by an e-learning trial [1, 2]. All the instructions were given by an experienced Japanese endoscopist (K. Yao) who constructed the e-learning system [1, 2]. Endoscopists also received on-site hands-on training in addition to the theoretical training. Furthermore, we held case conferences in order to share common experiences. During the period, the number of both newly detected early gastric cancers and screening gastroscopy procedures was recorded. The primary end-point is to compare the early detection rate between the TTT and the non-TTT group.

**Results:** The data obtained from the 275 consecutive cases of screening gastroscopy procedures by the TTT group endoscopists and from the 323 consecutive cases of screening endoscopy procedures by the non-TTT group endoscopists were analyzed. In the TTT group, four cases with early gastric cancers were detected and no early gastric cancer was detected. The early detection rates of
the TTT and the non-TTT group were 1.5% and 0%, respectively. There was a significant difference in early detection rate between the TTT and the non-TTT group (Fisher’s exact test, P = 0.046).

Conclusion: This clinical trial clearly showed that the systematic intensive TTT course is useful for improving early detection rate of gastric cancer in clinical practice compared to the usual examination for patients of endo-highvolume endoscopy center. (NCT02358578)

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities about the outcome of the ESD and surgery after 10 years.

Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement, 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy. Long-term overall and disease-specific survival rates, development of new lesions, and complications were analyzed.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58.5 ± 11.7, P = 0.001) and female distribution was higher in surgery group (30.5% vs. 38.9%, P = 0.001). In the ESD group, diabetes was more frequent (12.9% vs. 7.1%, P = 0.001). Overall survival rate was similar (96.2% vs. 96.7%, P = 0.136), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, P = 0.037, log-rank test). During 10 years’ follow-up period, new lesions were observed in 3.6% of the ESD group and in 13% of the surgery group (P < 0.001). ESD group showed less complications (4.5% vs. 16.3%, P = 0.001) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, P < 0.001).

Conclusion: Although the development of new lesions were more frequent than surgery, ESD was similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1229 HEMATOLOGISTS SHOULD ORDER ENDOSCOPIC EXAMINATIONS TO EXPERTS OF ENDOSCOPY IN CASE OF ENDOSCOPIC CHECK-UP OF GASTROINTESTINAL MALIGNANT LYMPHOMA
T. Yamasaki, T. Sakurai, J. Mitobe, M. Mitsuogna, M. Saruta
Department Of Gastroenterology And Hepatology, The Jikei University, Tokyo, Japan

Contact E-mail Address: tacusan.yamasaki@gmail.com

Introduction: Gastric malignant lymphoma (ML) is most popular lymphoma of the gastrointestinal tract. Especially we often see gastric ML lymphoma in cases of H. pylori (HP) infection positive, and we also sometimes find out HP negative gastric MALT lymphoma. Since gastric carcinoma (GC) is more common rather than gastric MALT lymphoma, typical endoscopic diagnostic characteristics of GC are established on usual endoscopic examination for most of gastroenterologists. On the other hand, endoscopic characteristics of gastric MALT lymphoma on usual endoscopy have not been established for most of gastroenterologists.

Aims & Mete: Objective of this study is to estimate the difficulty on endoscopic diagnosis of gastric MALT lymphoma for 24 gastroenterologists (12 experts and 12 trainees of endoscopy) on usual endoscopic examination. We investigated a total of 72 gastric MALT lymphoma cases in our hospital and other 7 hospitals. We estimated total number of endoscopic examinations to achieve diagnosis of gastric MALT lymphoma endoscopically and histologically. In addition, we had analyzed the difference of abilities to diagnose of gastric MALT lymphoma between experts and trainees on endoscopic examinations using past endoscopic profiles (248 profiles).

Results: The average number of endoscopic examinations up-to diagnose gastric MALT lymphoma was 3.4 times (from 1 to 7 times) on whole endoscopies after first appearance of lymphoma. Though average total number of endoscopic examinations of experts was only 1.2 times, on the other hand average total number of endoscopic examination of trainees was 5.4 times. There was a significant difference between experts and trainees of endoscopy on average total number of endoscopic examinations (p = 0.022). Major reason of misdiagnosis was insufficient recognition of endoscopic appearances of ML on endoscopic trainees. Typical representative appearances of gastric MALT lymphoma were erosions, ulcers and surface irregularities. Since these lesions are also appeared as typical appearances of GC and gastritis, most of non-expert of endoscopy cannot distinguish the difference of GC, ML and gastritis due to those similarities. That is, even if typical appearance of non-expert could not diagnose gastric MALT lymphoma, but expert could diagnose minimal lesions of ML at first endoscopy. Especially HP positive gastric MALT lymphoma was similar to gastritis and GC on endoscopic findings, most of non-expert could not diagnose exactly.

Conclusion: There was significant difference between specialists and trainees. Therefore, hematologists should order endoscopic examination to experts of endoscopy knowledgeable of ML in case of endoscopic check-up of gastrointestinal malignant lymphoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastrointestinal subepithelial tumors include potentially malignant tumors. When considering the diagnostic yield for subepithelial tumors, it is important to evaluate whether the samples obtained are adequate for histological analysis, as immunohistological analysis is indispensable for a definitive diagnosis. However, it may be difficult to make a correct histological diagnosis with only the endoscopic ultrasonography-guided fine-needle aspiration (EUS- FNA). Therefore, there has been an interest in exploring an alternative modality for tissue sampling as mucosal-incision assisted biopsy (MIAB) based on the endoscopic submucosal dissection.

Aims & Methods: The aim of this study was to compare the usefulness of EUS-FNA and MIAB in the histological diagnosis of gastrointestinal subepithelial tumors (SET). We performed the retrospective study comparing 37 patients who underwent either EUS-FNA (n = 18) or MIAB (n = 19). Diagnostic yield, feasibility and safety of both EUS-FNA and MIAB were compared.

Results: The location of the SET was esophagus (n = 6), stomach (n = 29), and duodenum (n = 2). The diagnostic histology were gastrointestinal stromal tumors (n = 10), leiomyoma (n = 17), aberrant pancreas (n = 3), poorly-differentiated carcinoma (n = 2), metastatic carcinoma (renal cell carcinoma, n = 1), and no-diagnosis (n = 4). There were no significant differences in the clinical characteristics including sex and age of the patients in the EUS-FNA and MIAB group. In EUS-FNA group, the histological diagnostic rate was 72.2% in EUS-FNA and 78.9% in MIAB (p = 0.429). Diagnostic yield was 72.2% of the EUS-FNA and 94.7% of the MIAB (p = 0.0897).

Conclusion: No complications were found in either method.

Aims & Methods: The aim of this study was significantly different in MIAB than in EUS-FNA. However, the mean diameter of the tumor was significantly smaller in MIAB than in EUS-FNA the higher diagnostic yield in MIAB than in EUS-FNA.

Introduction: The gastrointestinal tract (GIT) is the most commonly extranodal site affected in lymphomatous pathology. Infection with Helicobacter pylori, human immunodeficiency virus and Epstein Barr and immunosuppression have been studied as possible risk factors. The diagnosis is often late, presenting at an advanced stage, with limited therapeutic options.

Aims & Methods: The objective of this study was to characterize the anatomical distribution, clinical manifestations, risk factors and prognosis of GI lymphomas. Retrospective study of patients diagnosed with GI lymphomas between 1997 and 2016.

Results: During the 20 years, 127 GI lymphomas were identified. The mean age at diagnosis was 58.2 years, and 60% of the patients were male. The most commonly affected organ was the stomach (65.3%) and the most common subtypes were diffuse large B-cell (48.8%) and MALT (27.6%). Most symptoms at the time of diagnosis, with fatigue (54.3%) being the most common. For coagulation of blood vessels or bleeding, it is not required to replace SB which is used cutting and coagulation.

Conclusion: This short insulated scissors-type knife (SBf) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

Introduction: Previous studies have shown that non-cardiac gastric cancer had no associations with the obesity even if cardiac or gastroesophageal junctional cancer was related with the obesity. These studies have included high portion of advanced gastric cancer. Patients with most advanced cancer already experienced weight loss.

Aims & Methods: We evaluated the effect of body mass index (BMI) on early gastric cancer in patients undergoing endoscopic treatment for early gastric cancer. A total of 748 patients with early gastric cancer undergoing endoscopic treatment (endoscopic submucosal dissection) including age and sex matched healthy controls consist of this case-control study. Body mass index was classified into underweight (BMI < 18.5), normal (BMI 18.5–23), overweight (BMI 23–25), and obese (BMI ≥ 25) by Asia-Pacific guideline. Adjusted analysis using odds ratio (OR) and 95% confidence interval (CI) was performed to evaluate the effect of BMI on early gastric cancer.

Results: The mean age was 57 years and male sex was 60% (n = 447). BMI was higher in gastric cancer compared to healthy control (24 vs 23, P < 0.001). The OR of gastric cancer was increased according to the BMI increase; 1.57 (95% CI, 0.89–2.79, P = 0.12) in normal BMI, 1.88 (95% CI, 1.06–3.35, P = 0.03) in overweight, and 2.28 (95% CI, 1.29–4.06, P = 0.005) in obese persons comparing to underweight. The BMI trend < P < 0.03 when comparing BMI > 25 vs BMI ≤ 25.

Conclusion: The early gastric cancer was strongly associated with the increased BMI and its effect has dose-dependent pattern.

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features (1-3). However, the molecular biological features of GAFG have not been well elucidated.

Aims & Methods: We evaluated clinical and molecular characteristics of GAFG in comparison with conventional gastric adenocarcinoma. Among 831 patients with gastric adenocarcinoma who underwent surgery or endoscopic resection in Division of Gastroenterology, Juntendo University School of Medicine between January 2010 and December 2016, we enrolled 13 cases of GAFG, defined as an extremely well differentiated adenocarcinoma with expression of pepsinogen-I and/or H+/K+-ATPase 1). To clarify current mutations of GAFG, next generation sequencing (NGS) was performed for all cases of the tumor and normal tissue formalin-fixed paraffin-embedded samples, using Ion PGM™ system with the Hotspot Cancer Panel v2 targeting 50 genes (Thermo Fisher Scientific). We also carried out immunohistochemical staining including MUC2, MUC5AC, MUC6, and CD10, and analyzed association among genetic alterations and mucin phenotype.

Results: Clinicopathologically, all patients (62.9% (range 43–80), 8 male, 5 female) had submucosal invasive adenocarcinoma with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm. Neither local recurrence nor metastasis was detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm. Neither local recurrence nor metastasis was detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm. Neither local recurrence nor metastasis was detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm. Neither local recurrence nor metastasis was detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm. Neither local recurrence nor metastasis was detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm. Neither local recurrence nor metastasis was detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had submucosal invasive adenocarcinomas with no H. pylori infection; the mean depth of the submucosal invasion was 288.4 (50–700) µm.}

Conclusion: The present clinical and comprehensive genetic analysis identified that GAFG had significantly higher expression of MUC5AC (55 µM, p < 0.001) in GAFG. Furthermore, the frequency of TP53 mutation was significantly lower (7.7% vs. 47.8%, p < 0.05) in GAFG. However, there were no significant differences in the frequencies of KRAS and STK11 mutations. In addition, all lesions showed negative staining for E-cadherin (i.e., immunohistochemical staining for MUC5AC and/or MUC6) and there were no significant differences between genetic alterations and mucin phenotype.

Introduction: Runx-related transcription factor 3 (Runx3) is a transcription factor playing an inhibitory role in the malignant behavior of gastric cancer. Long non-coding RNAs (LncRNAs) exert their functions mainly by binding with corresponding transcription factors. Among Runx3 transcription factors are the most common ones. However, the LncRNAs that could bind with and affect the expression or activity of Runx3 are still unclear.

Aims & Methods: Potential Runx3-binding LncRNAs were screened by an online program software RNAiPath v4.0 and validated by Runx3 immunoprecipitation assay. Specific HOTIAR binding site with Runx3 was confirmed further by RNA Pull down. The E3 ubiquitin ligase isoforms in the ubiquitin-proteasome degradation of Runx3 were recognized through co-immunoprecipitation assay.

Results: The expressions of HOTIAR and Runx3 were measured in human gastric cancer tissues and correlated with each other.

Aims: The potential role of HOTIAR and Runx3 in gastric cancer through LKB1-mediated AMPK activation was validated by bisulfite genomic sequencing (BGS), western blot and siRNAs targeting either HOTIAR or Mex3b could enhance the stability of Runx3 by impairing its ubiquitination. In addition, HOTIAR was negatively associated with the protein level of Runx3 in gastric cancer tissue.

Conclusion: HOTIAR induction leads to suppression of the ubiquitin-proteasome degradation of Runx3 by enhancing its interaction with a E3 ubiquitin ligase Mex3b in gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Promoter hypermethylation plays a vital role in cancer development through transcriptional silencing of tumour suppressor genes. Using Infinium Human Methylation 450 BeadChip (450K) array, we first identified calcium binding protein 39-like (CARB3L) to be preferentially methylated in gastric cancer (GC) and it may function as a potential tumour suppressor gene.

Aims & Methods: In this study, we aim to investigate the biological function, molecular mechanism and clinical implications of CARB3L in GC. Clinical relevance was validated by bisulfite genomic sequencing (BGS), western blot and immunohistochemistry (IHC). In vitro functional assays were carried out by cell viability, colony formation, apoptosis, cell cycle, cell invasion and migration assays in GC cell lines. In vivo tumorigenesis was evaluated in an orthotopic nude mouse model. Pathway analysis was performed using RNAseq and Phospho-kinase Antibody Array. The interaction of CARB3L with its protein partners was determined by co-immunoprecipitation assay.

Results: CARB3L mRNA was down-regulated in 13 out of 14 GC cell lines. Silencing of CARB3L was associated with promoter hypermethylation, and demethylation 5'-treatment using Azadecoxycytidine (5-Aza) restored the expression of CARB3L. In human GC, CARB3L mRNA and protein level (p < 0.0001)
were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort (n = 48 pairs) and TCGA cohort (n = 450). CAB39L hypermethylation was correlated with poor overall survival in Chinese cohort (n = 87, p < 0.005) and validated in TCGA cohort (n = 354, p < 0.005), which suggesting that CAB39L might function as a tumour suppressor. The functional importance of CAB39L in GC was therefore confirmed. Ectopic expression of CAB39L in three GC cell lines (AGS, BGC823, MKN45) suppressed cell proliferation in MTT (p < 0.01) and colony formation assays (p < 0.0001). CAB39L induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-3, caspase-9, p21 and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CAB39L in wound healing and gel invasion assays, respectively. Conversely, CAB39L knockdown in MKN28 demonstrated opposite effects. Orthotopic mouse model also showed inhibited tumorigenicity with CAB39L-overexpressing BGC823 cells. Mechanistically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CAB39L in GC. Consistent with our RNAseq data, a monoclonal anti-AMPK Antibody Array indicated AMPK is the key active kinase; whilst ERK1/2 was the most strongly down-regulated in CAB39L over-expressing GC cells, suggesting that CAB39L up-regulates AMPK concomitant with down-regulation of ERBB2/ERBB4 signalling. Moreover, co-immunoprecipitation experiments revealed a direct interaction between CAB39L and LKB1, a bona-fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPK/β cascade in GC cells expressing CAB39L, whose opposite effect was observed in CAB39L silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. Combination of novel tumour suppressor silenced by promoter methylation in GC, CAB39L inhibits gastric tumorigenesis via LKB1-mediated activation of AMPK/β. CAB39L methylation may serve as an independent prognostic biomarker for GC patients.

Kang: No conflicts of interest. P.W.Y. Chiu: No conflicts of interest. E. Ng: No conflicts of interest. J. Yu: No conflicts of interest. PKNOX2 via activating p53 signaling pathway, as determined by western blot analysis. Moreover, p53 transcriptionally and coordinately up-regulated in PKNOX2-overexpressing cells, leading to tumour suppression.

Conclusion: PKNOX2 functions as a novel tumour suppressor silenced in GC by promoter methylation. Its tumour suppressive effect is mediated via IGFBP5 and the activation of p53 signaling pathway. Promoter methylation of PKNOX2 may be a useful biomarker for predicting patient prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The relationship between Helicobacter pylori (H.p.) eradication and atrophic changes is debated. Although some studies report a partial restauration of gastric mucosa by l-cysteine, it is not clear if cysteine has a protective role or if finding reflects gastric mucosal healing. L-cysteine, reducing acetaldehyde production after food intake, has been proposed for prevention of gastric carcinogenesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-cysteine administration in CAG by means of PGI and gastrin 17 (G17) serum levels

Aims: To test gastric function in patients with chronic atrophic gastritis (CAG) in response to l-cysteine therapy.

Methods: We recruited 62 patients with chronic atrophic gastritis (H.p.) for whom symptoms regressed after H.p. eradication. PGI and G-17 serum levels were measured before and after 3, 6, 12, 24, 36 months of therapy. The subgroup of patients allocated in the pilot to DA OGD did have a quicker exit from the pathway, at 12.4 days [95% CI 6.5,18.3] compared to 14.8 days [95% CI 12.9,16.6] on the DTT OGD group. The pilot overall detected 8 cancers (4.2%). The standard 2WW path way detected 55 (12.8%). OG cancers were 4 in the DA OGD (4%) and 14 of the DTT OGD (10.2%). A further 10 non-OG cancers were detected in the DTT group after clinicians requested further investigations to determine the cause of their symptoms. Those patients allocated to OPD first by either GP or hospital were as likely to have cancer as those having OGD, with 4.3% of those in the pilot having acancer detected this way, but none OG cancer, and 10.3% found to have cancers in the standard 2WW group following investigation directed after clinic visit. Of these 65% were cancers other than OG cancers and would not be detected on OGD alone.

Conclusion: OG as a sole investigation for symptoms has its utility in excluding or detecting OG cancer. A high proportion of cancers detected via 2WW criteria were not OG and would not be detected in the pathway. The standard pathway is the gold standard option, although many cancers other than OG cancers may still be missed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Signaling pathway mediated by androgen receptor (AR) plays an important role in the progression of gender-related tumors, such as hepatocellular carcinoma, prostate cancer. Gastric cancer (GC) is the third cause of cancer related death all over the world, and its incidence in male is also much higher than female. However, the molecular mechanisms of AR in gastric cancer are still poorly characterized.

Aims: To investigate the role of AR in gastric cancer, we identify the transcriptional downstream targets of AR by chromatin immunoprecipitation. We detected mRNA and protein expression level of AR and its target in paired GC samples by RT-PCR and western blot. The biological functions of AR signaling pathway in GC cell lines were determined by colony formation and invasion assay.

Results: CCRK was demonstrated as the direct target of AR by chromatin immunoprecipitation. AR expression was elevated in most (6/7) GC cell lines compared with the immunortalized gastric cell line GESI. CCRK was upregulated in all (7/7) tested GC cell lines. The correlation of AR and CCRK expression was statistically significant. Higher mRNA level of both AR and CCRK were detected in GC tissues compared with the adjacent normal tissues (P < 0.01). Ectopic re-expression of AR or CCRK by stable transfection promoted colony formation and invasiveness (P < 0.05). Consistently, the numbers of colony formation, migrated cells and invasive cell were reduced by knockdown of AR or CCRK in GC cell lines.

Conclusion: Our results demonstrate that AR directly regulates CCRK expression in GC. AR and CCRK gene may act as a potential oncogene in gastrocarcino genesis by playing an important role in promoting of cell proliferation, migration and invasion, which may partially explain the higher prevalence of gastric cancer among males.

P1243 FLYING OFF COURSE WITH A 2WW DIRECT ACCESS TO TEST PILOT: NOTTINGHAM’S EXPERIENCE OF THE SUSPECTED UPPER GASTRO-INTESTINAL CANCER PATHWAY CHANGE WITH GP VETTING AND OGD BOOKING
N. R. Lewis, J. Catton, E. James
Trinity Oesophago-gastric unit, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

Contact E-mail Address: nina.lewis@nhs.nhs.uk

Introduction: Timely progress through diagnostic pathways is a leading quality measure for NHS cancer services. A hypothesis of sooner diagnosis being achievable with direct access to hospital tests from primary care is a core part of CRUK ACE program (1), and in the context of UGI cancer pathways, there is known wide variation of direct access (DA) OGD (2). This pilot evaluates the efficacy and utility of DA OGD or clinic (DA OPD) for GP concerns a patient may have with OG cancer. Comparison was made with the standard 2WW pathway, where allocation to OGD or OPD first is performed by OG consultant.

Methods: Pilot and UGI standard 2WW referrals 01/01/16-01/08/16 were identified from Cancer Centre records.

Results: 192 patients were in the pilot pathway, 430 via the standard 2WW. GP were more likely to allocate patients to 2WW (52%) compared to the 32% having DTT OGD allocated by the hospital. Despite under-utilisation of protected slots for DA OGD, time to DA OGD compared to DTT did not differ (11.0 days [95% CI 10.5,11.2] versus 12.4 days [95% CI 11.0,13.9]). The same was found for OPD. The time on pathway was not different in the pilot group at 16.8 days [95% CI 4.9,28.6] compared to 17.9 days [95% CI 16.9, 18.9]. The subgroup of patients allocated in the pilot to DA OGD did have a quicker exit from the pathway, at 12.4 days [95% CI 6.5,18.3] compared to 14.8 days [95% CI 12.9,16.6] on the DTT OGD group. The pilot overall detected 8 cancers (4.2%). The standard 2WW path way detected 55 (12.8%). OG cancers were 4 in the DA OGD (4%) and 14 of the DTT OGD (10.2%). A further 10 non-OG cancers were detected in the DTT group after clinicians requested further investigations to determine the cause of their symptoms. Those patients allocated to OPD first by either GP or hospital were as likely to have cancer as those having OGD, with 4.3% of those in the pilot having acancer detected this way, but none OG cancer, and 10.3% found to have cancers in the standard 2WW group following inves tigation directed after clinic visit. Of these 65% were cancers other than OG cancers and would not be detected on OGD alone.

Conclusion: OG as a sole investigation for symptoms has its utility in excluding or detecting OG cancer. A high proportion of cancers detected via 2WW criteria were not OG and would not be detected in the pathway. P1244 WHAT IS THE YIELD OF ROUTINE D2 BIOPSIES IN THOSE PRESENTING WITH WEIGHT LOSS AT GASTROSCOPY?
M. Yalchin, S. Zonoozi, M. Hussein, N. Jayasooriya, K. Besherdas
Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Coeliac disease is a common cause of malabsorption in Western countries. The gold standard method of diagnosing coeliac disease is by way of duodenal biopsy. Weight loss is a symptom of malabsorption. Patients referred for upper gastrointestinal endoscopy with symptoms of weight loss commonly undergo duodenal biopsy to assess for presence of coeliac disease. We hypothesise that those patients with weight loss and who routinely have duodenal biopsies very rarely have coeliac disease unless there are other pointers towards malabsorption.

Aims: A single-centre, retrospective analysis of consecutive patients with weight loss undergoing upper gastrointestinal endoscopy for the primary indication of weight loss was undertaken within a large associate teaching hospital within North London from 2005–2016. Of these patients, we reviewed those that had duodenal (D2) biopsies and the results. If they proved abnormal, we looked back for additional markers of malabsorption, clinically and biochemically.

Results: 142 consecutive patients, 65 were Male, 77 were female, underwent OGD for weight loss. Out of this cohort, 62% (n = 88) had a duodenal biopsy. 89% (n = 78) of these had a normal biopsy. 11% (n = 10) had an abnormal biopsy,
The ratio of the proportion of all cancer death to the proportion of all cancer digestive cancers accounted for 23–24% of all cancer deaths from 2010–2015, but in 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 24% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Aims & Methods: We obtained the total annual funding for cancer (including the five most common digestive cancers) from 2008 to 2015 using a public database of research funded by US federal agencies. We calculated funding in 2015 constant USD using the Consumer Price Index. Cancers and deaths estimated by the American Cancer Society were used to calculate funding per death or case for each cancer. For comparison, we also extracted data for the three most common cancers (breast, lung, prostate) and all cancers combined. As funding for research in the United States was boosted by the American Recovery & Reinvestment Act in 2009–2010 and declined thereafter, we analyzed trends in funding and disease burden from 2010–2015 using the Spearman correlation.

Results: In 2015, 8 billion USD in federal funding was issued to all cancer research and 658 million USD to the five common digestive cancers. The five digestive cancers accounted for 23–24% of all cancer deaths from 2010–2015, but only 16% of all cancer funding in 2015. The ratio of the proportion of all cancer death to the proportion of all cancer funding, a marker of funding disparity, was 2.9. In comparison, breast cancer accounted for 7% of cancer deaths in all years, 11% of funding in both 2010 and 2015, and had lower proportional death than proportional funding (ratio = 0.8). Prostate cancer likewise had lower proportional death than funding (ratio = 0.9). Funding disparity, measured by proportional death and funding, was highest for esophageal and gastric cancer among digestive cancers and for lung cancer overall. The relative distribution of deaths and cancer funding more or less remained unchanged between 2010–2015, but increased for the other digestive cancers during the study period. Funding per death among digestive cancers in 2015 was highest for liver cancer and lowest for esophageal cancer. Funding per death for breast cancer was more than 5-fold the funding per all cancers. For colorectal cancer, funding per death for digestive cancers decreased by 20% for esophageal cancer, 24% for colorectal and gastric cancer, and 28% for liver cancer; funding per death for pancreatic cancer was not available. Prostate cancer was not available for liver and colorectal cancer (p < 0.05 for both). Over the same period, funding per incident case decreased by 15% for esophageal cancer, 21% for colorectal cancer, 34% for gastric cancer, and 37% for liver cancer; funding increased for pancreatic cancer by 6%. Statistically significantly high trends were observed for liver (p < 0.01), colorectal, and gastric (p < 0.05) cancer. Despite the larger relative funding decrease for liver cancer, it remained the best-funded digestive cancer relative to both incident case and death. Liver cancer received more than 2.5-fold funding per incident case than colorectal and gastric cancer in 2015. Gastric cancer was the only digestive cancer to measure in the bottom two for both funding per death and per incident case.

Conclusion: From 2010 to 2015 in the US, federal research funding relative to the burden of cancer decreased for all digestive cancers except pancreatic cancer. Although a similar trend was observed for all cancer research, there appears to be a funding disparity for digestive cancers—especially gastric cancer—compared to breast cancer and all cancers combined. Greater investment and more equitable funding allocation may improve digestive cancer outcomes.

Introduction: Helicobacter pylori infection induces aberrant DNA methylation in the gastric mucosa. We evaluated the effect of Helicobacter pylori eradication on promoter CpG island hypermethylation in gastric carcinogenesis.

Aims & Methods: H. pylori-positive patients with gastric adenoma or early gastric cancer who underwent endoscopic resection were enrolled. According to H. pylori eradication after endoscopic resection, the patients were assigned to H. pylori eradication or non-eradication group. H. pylori-negative gastric mucosa from normal participants provided the normal control. CpG island hypermethylation of tumor-related genes (p16, CDH1, and RUNX-3) was evaluated by quantitative MethyLight assay in non-tumorous gastric mucosa. The gene methylation rate and median values of hypermethylation were compared after one year by H. pylori status.

Results: In H. pylori-positive patients, hypermethylation of p16 was found in 80.6% of CDH1 in 80.6% of RUNX-3 in 48.4%. This was statistically higher than normal control (p16, 10%; CDH1, 44%; RUNX-3, 16%) (p < 0.05). In the H. pylori eradication group, methylation rates of p16 and CDH1 decreased in 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after H. pylori eradication. The non-eradication group hypermethylation did not change after eradication.

Conclusion: H. pylori infection was associated with promoter hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1247 CURCUMIN DOWNREGULATES INTERLEUKIN (IL)-17 BY INCREASING THE EXPRESSION OF INDOLEAMINE 2,3- DIOXYGENASE (IDO) IN HELICOBACTER PYLORI-INFECTED HUMAN GASTRIC MUCOSA

T. Larussa, R. Liprotiti, S. Gervasi, E. Suraci, R. Marasco, M. Imeneo, F. Luzza

Introduction: IDO promotes the effector T-cells apoptosis by catalyzing the rate-limiting first step in tryptophan (Trp) catabolism. We demonstrated that the high expression of IDO in H. pylori-infected human gastric mucosa attenuates Th1 via the T-helper response of the anti-inflammatory T2 type, and anti-inflammatory properties of the nutraceutical compound curcumin suggest its use as an anti-H. pylori agent, but mechanisms that underlie its helpful activity are still not clear.

Aims & Methods: Five antral biopsies were taken from 22 patients (10 M, median age 47.5 yrs, range 20–74) who underwent gastrointestinal dyspeptic symptoms: 1 for urease quick test (Eurospital, Trieste, Italy), 2 for histology (Giemsa staining for H. pylori), and 2 for organ culture. A C4-urea breath test was also performed (at least two tests positive and all the three tests negative to be considered as H. pylori-negative for colonized or uninfected). Biopsy samples were immediately placed in an organ culture chamber, treated with and without curcumin 200 μM (Sigma, St. Louis, MO, USA) for 20 hours and evaluated for the expression of IDO and IL-17 by Western blotting. Levels of IL-17 were also measured in culture supernatant by ELISA. Further antral biopsies from a subgroup of 14 patients were treated with curcumin in addition with the IDO inhibitor 1-methyl-L-Trp (1-MT, Sigma, St. Louis, MO, USA) and the expression of IL-17 was assessed in total RNA extracts by Western blotting. The ratio of IDO expression by Western blotting in the presence compared to the absence of 1-MT was evaluated by densitometry, while data from ELISA were normalized on protein content. Values were given as means ± SD arbitrary units (a.u.) and pg/mL, respectively. Data were analysed using the Mann–Whitney U test.

Results: In gastric biopsies cultures from H. pylori-infected patients (n = 13), IDO significantly increased in curcumin-treated compared with untreated samples (1.26 ± 0.64 a.u. vs. 0.87 ± 0.61, p = 0.02). Levels of IL-17 were significantly lower in curcumin-treated compared with untreated samples, both in gastric biopsies (0.53 ± 0.26 a.u. vs. 0.85 ± 0.31 a.u., p = 0.02) and culture supernatant (22.91 ± 13.72 pg/mL vs. 40.46 ± 21.69 pg/mL, p = 0.04)). In the subgroup of H. pylori-infected patients (n = 9), samples treated with curcumin in addition to IDO inhibitor 1-MT, IL-17 expression was significantly higher compared with untreated samples with as well those treated with curcumin alone (1.44 ± 0.52 a.u. vs. 0.91 ± 0.34 a.u. and vs 0.78 ± 0.21 a.u., p = 0.04 and p = 0.01, respectively). Both IDO and IL-17 expression were very low in untreated H. pylori-infected samples and did not significantly change when treated with curcumin alone or in addition to IDO inhibitor 1-MT.

Conclusion: Curcumin is capable of down-regulating IL-17 production in H. pylori-infected human gastric mucosa. This effect is, at least in part, mediated by increasing IDO expression. This endorses the potential role of curcumin in dampening H. pylori-induced immune-mediated inflammatory cytokine production.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Alterations in salivary microbiota have been linked to elevated inflammatory responses and has been reported in patients with inflammatory bowel disease and pancreatic cancer. As yet, the potential association between salivary microbiota in patients with gastrointestinal disease has not be determined.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with H. pylori-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We excluded patients with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy, and who have recent exposure to antibiotics or acid suppressive therapies. Unstimulated saliva samples were obtained from subjects during fasting state prior to endoscopy. Using qPCR, salivary microbiota were obtained for determination of HP statuses by rapid urease test and histology. Another gastric biopsy was obtained for characterization of gastric microbiota. Serial salivary samples were obtained from HP-infected subjects 8-week after completing HP eradication therapy. Bacterial DNA was extracted for 16S rRNA sequencing by using the MiSeq Platform (Illumina). OTU clustering was performed and taxonomy assigned to the Greengene and HOMD database. Alpha and beta diversity were determined using Linear Discriminant Analysis Effect Size (LEfSE) was used to identify differentially expressed bacterial DNA in different groups.

Results: We enrolled 16 subjects with confirmed HP gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher salivary microbial diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is Helicobacteraceae (55.2%) whereas Helicobacteraceae constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in saliva microbiota are Prevotellaceae (23.9%) and Neisseriaceae (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the Bacteroidetes and Spirochaetaceae, and a decrease in Flavobacteriaceae families. HP eradication therapy resulted in a significant reduction in the relative abundance of family Flavobacteriaceae in Flavobacteriales. Family Helicobacteraceae also decreased in number.

Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with Helicobacteraceae dominating the gastric microbiota. HP-infected subjects had a distinctive microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigation.

Introduction: Seroconversion of Helicobacter pylori occurs more often in seronegative adults living with a H. pylori-infected family member or in those with a history of upper gastrointestinal endoscopy. Nonetheless, there are controversies on alcohol drinking and development of a positive seroconversion was found in Korea, but an inverse correlation was found in Japan.

Aims & Methods: In this study, we tried to elucidate the risk factors for seroconversion including alcohol drinking. Korean adults who showed negative finding for the serum anti-H. pylori IgG assay were analyzed. Subjects were included if they underwent serum anti-H. pylori IgG assay, serum pepsinogen assay, and upper gastrointestinal endoscopy annually at our center. Subjects were excluded if they had a history of H. pylori eradication or gastrectomy.

Results: Of the 211 seronegative subjects, 26 (12.3%) subjects showed seroconversion-positive responses at the mean follow-up of 39.0±19.1 months. Subjects with seroconversion showed a higher body mass index (p = 0.033), heavier alcohol drinking (p = 0.001), more intake of nonsteroidal anti-inflammatory drug (p = 0.015), and longer follow-up period (p = 0.038). On multivariate analysis, heavy alcohol drinking [odds ratio (OR) = 6.867, 95% confidence interval (CI) = 2.089–22.577, p = 0.002] and social drinking (OR = 5.306, 95% CI = 1.410–17.913, p = 0.013) were independent risk factors for seroconversion.

Discussion: In Korean adults, the amount of alcohol drinking positively correlates with seroconversion in H. pylori-seronegative subjects. Although seroconversion does not indicate an active H. pylori infection, our study findings suggest that drinking is a significant risk factor for new H. pylori infection in Korean adults.

Helicobacter pylori gastritis is distinct from autoimmune gastritis.

Aims & Methods: The aim was to define features of change of level of interleukin-10 (IL-10) and interleukin-18 (IL-18) in patients with chronic gastritis associated with Helicobacter pylori infection depending on existence or lack of a gene of a cagA in a microorganism genome. 40 patients with the chronic gastritis associated with Helicobacter pylori have been examined. Expression was made for specification of a condition of stomach mucosa and taking biopsy from stomach antrum (2 biopates) for the purpose of verification of Helicobacter pylori infection. Detection of a microorganism was made by rapid urease test, a histologic method and molecular-genetic research—the polymerase chain reaction (PCR) with definition of genes of urease (ureC, ureA). Besides, the PSR method presence of a cagA gene in a genome of Helicobacter pylori was detected. All patients were divided on two groups: with cagA (+) strains and with cagA (−) strains. Levels of interleukins 1-β, 4-8 decided by immunofluorescent analysis (the Vektor-Best sets, Russia).

Results: cagA gene was detected in 30 patients (cagA(+) group) and absence in 10 patients (cagA(−) group). In cagA(+) patients mean level of interleukin-1-β was 395.6 pg/ml, but in cagA(−) patients—311.2 pg/ml (p < 0.05). Level of interleukin-4 in cagA(+) patients was 2.4 pg/ml but in cagA(−) patients—0.32 pg/ml (p < 0.05). Level of interleukin-18 in cagA(+) patients was 21.6 pg/ml, but in cagA(−) patients—83.4 pg/ml (p < 0.05).

Conclusion: presence in a genome of Helicobacter pylori cagA gene is accompanied by reliable increase in level of pro-inflammatory cytokines (IL-1β, IL-8) and decrease in level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during Helicobacter pylori infection.

eradication therapy of H. pylori increased remarkably from 48.4% in 2012 to 76.5% in 2016. The success rate was 76.5%. The success rate of conventional PPI regimen was 75.8% (846/1116), and that of the vonoprazan regimen was 85.1% (74/87). The success rate of vonoprazan regimen was significantly higher than that of the PPI regimen (Fisher's exact test: p < 0.05). The success rate of H pylori eradication in 2nd line treatment was 84.7% (210/248). The success rate of H pylori eradication in patients who received the conventional PPI regimen was 84.4% (35/224), and that in patients who received the vonoprazan regimen was 87.5% (21/24).

Conclusion: Vonoprazan is considered to be useful for H pylori eradication instead of a PPI in first line treatment.

Introduction: Clarithromycin (CLA)-containing quadruple therapy, i.e. concomitant therapy (CT), and bismuth-containing quadruple therapy (BQT) have been sequentially proposed for eradication of H. pylori infection. Both treatments are reported to have an eradication rate higher than 90%. International guidelines recommend that choosing one regimen vs the other should be based on knowledge of patient's previous antimicrobial exposure or allergy to amoxicillin, and patient's wish.

Results: The eradication rate was 85.1% (74/87). The success rate of vonoprazan regimen was 87.5% (21/24). The success rate of conventional PPI regimen was 84.4% (35/224), and that in patients who received the vonoprazan regimen was 87.5% (21/24). The success rate of H pylori eradication in 2nd line treatment was 84.7% (210/248). The success rate of H pylori eradication in patients who received the conventional PPI regimen was 84.4% (35/224), and that in patients who received the vonoprazan regimen was 87.5% (21/24).
such as erosion and diarrhea were reported in 6.6% (9/136) of patients in VPZ, in 7.7% (5/65) in RPZ and in 6.1% (28/456) in LPZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

P1257 CAN TWO WEEK BISMUTH BASED QUADRUPLE THERAPY FOR RESISTANT H. PYLORI INFECTION STILL BE USED IN THE UK?
H. Logan-Ellis, L. Bengaid, R. P. H. Logan
Gastroenterology, King’s College Hospital, London/United Kingdom

Contact E-mail Address: hughloganellis@khs.nhs.uk

Introduction: Eradication of H. pylori infection cures peptic ulcer disease (PUD); however, first-line treatment strategies are not ideal and many patients require repeated courses of treatment. We, and others, have recently documented that currently, within the UK, less than 30% of patients with proven PUD, are subsequently documented to have been cured by H. pylori eradication.

Methods of analysis and inclusion criteria were based on PRISMA recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been analyzed ad proportions-percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odds ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software.

Results: Two week standard bismuth based quadruple therapy achieved a remarkable eradication rate in real life, irrespective as first treatment or as a salvage therapy, in both naïve and previously treated patients. We targeted a real-life effectiveness and safety of this therapeutic regimen in a large population of patients who were infected by H. pylori, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The new bismuth-containing quadruple therapy is currently advised as salvage/treatment regimen in patients infected by resistant H. pylori. Aims of this study was to assess the real-life effectiveness and safety of this therapeutic regimen in a large population of patients who were infected by H. pylori.

Aims & Methods: Consecutive dyspeptic H. pylori-positive patients were enrolled, both naïve for treatment and already unsuccessfully treated. Patients were treated with Pylera® (3-in-1 capsules containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg and tetracycline 125 mg) 3 capsules four times a day plus omeprazole 20 mg or esomeprazole 40 mg two times a day for 10 days. Eradication was confirmed using a urea-breath test (at least 30 days after the end of treatment). Efficacy and safety were assessed.

Results: Three hundred and twenty patients were included in the study: 131 (40.9%) patients were naïve, and 189 (59.1%) patients with previous failure treatment. Of H. pylori eradication was achieved in 99 (93.4%), 95% confidence interval (CI) was 92-96%. No difference in eradication rate was found either between naïve and previously treated patients (95.4% vs 92.1%, P = 0.336).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1258 MAY PROBIOTICS MONOTHERAPY ERADICATE HELICOBACTER PYLORI? A SYSTEMATIC REVIEW WITH POOLED-DATA ANALYSIS
G. Losurdo, R. Cubisino, M. Barone, M. Principi, E. Ierardi, A. Di Leo
Emergency And Organ Transplantation, University of Bari, Bari/Italy

Contact E-mail Address: giuseppedolos@alice.it

Introduction: Despite several evidences in literature have demonstrated a role for probiotics as adjunctive treatment for Helicobacter pylori (H. pylori) eradication, national and international guidelines as well as meta-analyses suggest that only co-administration of probiotics may have a beneficial effect on the prevention of side effects and eradication rates. Herein, we performed a systematic review with pooled-data analysis aimed to clarify whether probiotics alone may eradicate the bacterium.

Aims & Methods: Methods of analysis and inclusion criteria were based on PRISMA recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been analyzed ad proportions-percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odds ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software.

Results: Two week standard bismuth based quadruple therapy achieved a remarkable eradication rate in real life, irrespective as first treatment or as a salvage therapy, for the majority of clinical trials and open label pilot studies were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean eradication rate was 14%, with a 95% CI of 2-23% (p=0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacteria in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1-31%). Multiflavum combinations were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI 16-43%). In the comparison probiotics versus placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97-47.36 (p = 0.005). Finally, probiotics induced a mean reduction in delta values of 8.61% (95% CI = 8.01 -11.34, p < 0.0001).

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: One hundred and forty five patients with peptic ulcer disease and naïve to Clarithromycin were randomly divided into two groups to receive either 10-day standard triple therapy (Pantoprazole 40 mg, Amoxicillin 1 g and Clarithromycin 500mg, all given twice daily) or 10-day Levofloxacin-containing triple therapy (Pantoprazole 40 mg BD, Amoxicillin 1000 mg BD and Levofloxacin 250 mg tid). Eight weeks after the treatment, H. pylori eradication was assessed by 13C- urea breath test.

Results: One hundred and thirty three patients completed the study. According to intention to treat analysis, H. pylori eradication rates were 75.7% (95% confidence interval CI: 65.7%-85.7%) and 58.5% (95% CI = 47.1%-70%) in standard and Levofloxacin-containing therapies, respectively. Also, per-protocol eradication rates were 83% (95% CI: 74%-92%) and 61% (95% CI = 49%-73%), respectively. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

Conclusion: Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen do not seem to be suitable options for first-line H. pylori eradication in Iran. We suggest using Clarithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1261 EFFICACY AND TOLERABILITY OF REBAMIPIDE IN TRIPLE THERAPY FOR ERADICATION OF HELICOBACTER PYLORI: A RANDOMIZED CLINICAL TRIAL
S. S. Vyalov
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Rebamipide is an orally prostaglandin E2 and I2 synthesis inducer. A latest clinical trial showed that the adhesion of H. pylori to stomach wall was reduced by rebamipide. This could improve eradication rates by increasing the availability of Helicobacter to antimicrobial.

Aims & Methods: We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of H. pylori infection. Subjects comprised patients undergoing eradication therapy for H. pylori infection in our clinics. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple eradication were excluded. Written informed consent was obtained for each patient. This trial was performed as a randomised open-label study, where the permission of institutional review board was granted ethical approval (approval: 1610-013), and was registered in the University Hospital Medical Network Clinical Trials Registry (UMIN-CTR) as number UMIN 000025390.

Results: For RBD therapy group and STD therapy group, the eradication rates were 94.0% (95% confidence interval, 85%-100%) and 82% (95% confidence interval, 74%-95%) respectively, and the rates of side effects were 8.5% (95% confidence interval, 7.0%-26.5%) and 29% (95% confidence interval, 17.5%-41.0%) respectively. Each group showed statistically significant difference in eradication rates. The RBD group revealed trends of high eradication rates and low rates of side effects.

Conclusion: The findings suggest that rebamipide is effective in eradication of H. pylori infection, significantly improve eradication rate in triple therapy. The advantage of rebamipide has efficacy and good tolerability.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chemotherapy-induced mucositis is a common complication during anticancer treatment. Epicallocatechin-3-gallate (EGCC), derived from green tea, has been shown to have antioxidant effects and immunomodulatory activities. However, studies on EGCC for chemotherapy-induced mucositis have been scarce.

Aims & Methods: In this study, we aimed to prove the protective effect of EGCC in murine chemotherapy-induced mucositis model. Twenty-four 8-wk-old male C57BL/6 mice were randomized to 4 groups: control, EGCC, 5-Fluorouracil (5-FU), EGCC plus 5-FU. Mucositis was induced by intraperitoneal injection of 5-FU (400 mg/kg). EGCC (50 mg/kg) was administered orally for 5 days from the day before administration of 5-FU. After 6 days of 5-FU injection, the mice were sacrificed. Histopathological examination was performed with whole blood from Inferior vena cava of mice. The end points were villus height, villus/crypt ratio, histologic characteristics, and mRNA expression of tumor necrosis factor (TNF-α), and interleukin (IL)-6.

Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 K/µL, Control, 5.317 K/µL), indicating sufficient 5-FU effect. Histologic findings showed that crypt dilatation, villus stunting, and villus atrophy were reduced in EGCC plus 5-FU group than in 5-FU group (Figure 1). Quantitative analysis (Figure 1) revealed that EGCC group (352 µm, 5-FU, 319 µm, and villus/crypt ratio (EGCC plus 5-FU, 3.26; 5-FU, 2.31) in EGCC plus 5-FU group, compared with 5-FU treated group, were significantly higher. mRNA expression of TNF-α was significantly lower in EGCC plus 5-FU group compared with 5-FU group (P < 0.05)(Figure 2). Figure 1. Effects of EGCC administration on chemotherapy-induced mucositis in mice jejunum (A) Control (B) 5-Fluorouracil (5-FU) group with significant villus atrophy and crypt dilatation (c) EGCC group (d) EGCC plus 5-FU group with mild villus destruction and less crypt dilatation. Figure 2. mRNA expression of TNF-α. EGCC plus 5-FU group showed significantly lower 2’dctd than 5-FU only group. (** P < 0.05)

Conclusion: EGCC derived from green tea reduced 5-FU induced intestinal mucositis, suggesting a possibility for novel treatment of chemotherapy-induced mucositis.

Introduction: Proton pump inhibitors (PPIs) have become one of the most commonly prescribed medicine due to their strong effects of suppressing gastric acid and high curative effects for acid related diseases. On the other hand, their side effects have been attracting more attention. One of them is the increased incidence of infectious intestinal diseases. Those are mostly reported by clinical publications, and the exact mechanism has not been clarified. To investigate whether PPIs can increase the susceptibility to peroral enteropathogenic bacterial infection, we used Citrobacter rodentium (C. rodentium), a well-known mouse typhoidal associated pathogen, which is used for the model of human enterohe-morrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) infection: the major causes of food poisoning.

Aims & Methods: To investigate whether LAZ can influence the steady-state intestinal environment, C57BL/6J mice were divided into two groups, and 8 mg/kg/day of lansoprazole (LAZ group) or saline (control group) were administered intraperitoneally for two weeks. The ileal contents and feces were collected before and after LAZ administration. Genomic DNA of the gut microbiota was isolated by 16s ribosomal RNA (16sRNA) gene sequencing, and the metabolites were analyzed by a CE-TOFMS platform. To examine the changes of immune cell distribution by LAZ, hematopoietic cells in the lamina propria were analyzed by flow cytometry. The changes of gene expressions of the ileum tissues were measured by QRT-PCR. Two anti-inflammatory metabolites were analyzed by a CE-TOFMS platform. To examine the changes of immune cell distribution by LAZ, hematopoietic cells in the lamina propria of intestinal villi were isolated and their gene expressions were measured by RT-qPCR.

Results: At steady-state, no prominent change of metabolites and gut microbiota were observed in the feces of LAZ group. On the other hand, the changes of short chain fatty acids, such as butyrate and propionate, were decreased in the ileum of LAZ group. The result of 16sRNA analysis also showed that the composition of ileal microbiota were different between LAZ and control group. However, it did not show the change of the immune cell distribution in the intestine.

The gene expression levels in the ileum were not altered either. Interestingly, the ileal microbiota of LAZ group became similar to that of the feces. As mice have a habit of coprophagia, it was assumed that perorally invaded bacteria could survive and pass through the stomach due to suppression of gastric acid by LAZ. Accordingly, in the LAZ group, infectious inflammation was established by less numbers of C. rodentium inoculation, indicating that PPIs could raise the susceptibility to peroral enteropathogenic bacterial infection.

Conclusion: Our data showed that administration of PPIs could alter the intestinal environment such as microbiota and luminal metabolites. However, neither the gene expressions nor distribution of immune cells in the intestinal tissue were affected. It was assumed that the increased risk of peroral enteropathogenic bacterial infection was not because of the immunological modification by PPIs, but it was mainly because of the increased number of pathogenic bacteria passing through the stomach.

Introduction: Acetyl salicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal injury have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an in vitro model. However, there are the thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

Aims & Methods: This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups: group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polysorbate-80 (P80) alone, group 3: ASA alone, and group 4: P80 plus ASA. CMC and/or 20 mg/kg ASA was injected into the proximal duodenum of rats. P80, an emulsifier, which has been reported to reduce mucous thickness [2], was administered via drinking water for 2 weeks before ASA treatment. Indeed, P80 also reduced the thickness of mucous layer in our analyses. One hour after ASA treatment, Evans blue was injected into a vein of rats to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological assessment. To further investigate the importance of mucus, redbanipide (Reb, 300 mg/kg) or saline were orally administered for one week prior to P80 or ASA treatment. Reb is a gastric mucous-protective drug widely used for the treatment of gastric ulcer, and increases mucous secretion by small intestinal goblet cell.

Results: Evans blue method suggested that high-dose ASA (200 mg/kg) induced severe intestinal lesions, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly enhanced Evans blue exudate and severe mucosal lesions in jejunal sections at these concentrations, suggesting the pivotal role of mucus in these lesions. Moreover, pre-administered Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions by P80, indicating that mucus is inevitable in the protection of ASA-induced small intestinal mucosal injury.

Conclusion: Prevention increasing therapy might be a useful strategy for the prevention of ASA-induced small intestinal mucosal injury.

Introduction: Intestinal mucosal injury is a severe side-effect of chemotherapy with current deficiency in effective treatments.

Aims & Methods: This study investigated three prebiotics, galacto-oligosaccaride (GOS), mannan-oligosaccharide (MOS) and fructo-oligosaccharide (FOS) for their potential to reduce the severity of 5-Fluorouracil (5-FU)-induced intestinal mucositis in rats. Female Dark Agouti rats (n=8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU: 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. Crypt depth, villus height and histological severity scores were quantified in haematoxylin & cosin stained sections. Sucrase and myeloperoxidase [MPO] activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids (VFAs), acetic, propionic, isobutyric, butyric, isovaleric and valeric acid were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p < 0.05 was considered statistically significant.

Data are expressed as mean ± standard error of the mean.

Results: %Bodyweight loss was significantly decreased in all treatment groups following 5-FU injection. This was only seen in rats treated with MOS or FOS, and pre and post 5-FU compared to saline treated controls (p < 0.05).

Ileal villus height was significantly higher in GOS treated rats pre 5-FU (284.16 ± 11.95 μm) compared to respective water controls (240.40 ± 8.83 μm; p < 0.05). Ileal villus height and crypt depth was significantly decreased in all treatment groups after 5-FU injection (p < 0.05) and prebiotic treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p < 0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre-5-FU compared to water controls (p < 0.05). Pre 5-FU treatment with GOS significantly increased the fecal VFAs acetic acid (16.76 ± 1.22 mM/L) and propionic acid (4.60 ± 0.99 mM/L) compared to saline treated controls (7.73 ± 0.92 mM/L and 3.05 ± 0.28 mM/L respectively; p < 0.05). MOS and GOS treatment also significantly increased fecal acetic and propionic acid post 5-FU compared to water control (p < 0.05).

Conclusion: Our study has found that prebiotics, MOS, GOS and FOS modified some parameters of intestinal health and immune regulation in healthy rats; however, these prebiotics were not protective against 5-FU induced intestinal damage. Furthermore, our findings have demonstrated that prebiotic treatment significantly increases VFA production, suggesting functional changes to the intestinal microbiome. Further studies are indicated to investigate prebiotics, both alone and in combination, during the repair phase of intestinal mucositis, and to determine their effect on gut microbial composition.

Introduction: Food allergy is characterised by a T helper type-2 immune response against a food antigen, manifesting as symptoms including nausea, diarrhoea, vomiting and anaphylactic events. It is estimated that 10% of the Australian population have a food allergy, and common allergens include cow’s milk, shellfish and peanuts. Epidemiological studies have identified antibiotics as a significant risk factor for food allergy in infants.

Aims & Methods: We examined how the broad spectrum antibiotic amoxicillin influenced mucosal immune responses to peanut proteins and the development of peanut allergy in mice. Balb/C mice were treated daily with 5 mg/kg amoxicillin or PBS for 5 days (days 0-4). On days 5 and 6 animals received 0.2 mg peanut extract or PBS vehicle by oral gavage. Animals were rechallenged with peanut or peanut gavage on days 11 and 13 and sacrificed on day 16. Immune responses to peanut challenge in blood and intestinal tissues were assessed by protein, mRNA and histological analysis.

Results: The proportion of circulating eosinophils was increased in the blood of mice treated with both antibiotics and peanut. Histological examination revealed an increase in small intestinal eosinophils, predominantly at the villous tips, indicating recruitment to the mucosa. RNA and protein analysis revealed an increase in IL-5 associated with increased Nod-Like Receptor Protein 3 (NLRP3) inflammasome activation.

Conclusion: These studies demonstrate that antibiotic treatment prior to food antigen challenge can lead to altered mucosal immune homeostasis, facilitating IL-5-mediated eosinophil recruitment, characteristic of allergic responses. Importantly, we have demonstrated an adjuvant-free model of food sensitisation and small intestinal eosinophilia. These findings contribute to a better understanding of how disruption of mucosal homeostasis by antibiotics contributes to the development of allergic sensitisation and reaction.

Introduction: Crohn’s disease has been thought to be caused by abnormal immune responses affecting many parts of digestive tract in which Th1 cells and their cytokines and chemokines play an important role. The recruitment of Th1 cells is regulated by interaction of their expression of chemokine receptor CXCR3 and its ligands. There have been many IBD murine models showing the increase of CXCR3 expression and its roles on the disease promotion. However, there are limited evidences in the roles of CXCR3 in human IBD. In fact, a small study in large bowel in a cohort of 10 Crohn’s disease patients showed lower expression of CXCR3 on T lymphocytes, compared to colon cancer patients. In terms of inhibition of T lymphocyte migration into intestine in IBD patients, anti a4b7 (Vedolizumab) therapy is currently shown to be effective.

Aims & Methods: Our study aimed to assess expression of CXCR3 on different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 expressing integrins. Total of 56 duodenal biopsies were obtained from CD (n = 15), functional dyspepsia (FD)/irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and gentle but complete cell dissociation. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistically significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (p ≤ 0.05) compared to 61.6% in control group (FD/IBS deficiency). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different subsets of T-cells, whereas the related disease CXCR3 was seen in CD8+ lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients’ small intestine may have protective role. This propose further study to clarify.

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been mainly focused on prevention and treatment of its complications; every day, we find more publications on the use of adjuvants to decrease its duration. Probiotics have gained greater importance because some of them report benefits. We look for Clinical Practice Guidelines (CPG) that recommend their use in AGE in children. The AGREE II instrument was developed to address the issue of variability in guideline quality, so it is a tool that assesses the methodological rigour and transparency in which a guideline is developed.

Aims & Methods: To assess the methodological quality of clinical practice guidelines (CPG) on the use of probiotics in infant diarrhea. The search was conducted in December 2016, of CPG based on the evidence, the last 10 years and as contaminants in drinking water, has become a public health problem. Most of these substances are considered as endocrine disruptors and their daily occurrence is likely to be severe and irreversible consequences. Indeed, preliminary studies have shown that chronic exposure to low doses of chlorpyrifos (CPF) causes intestinal imbalance (dysbiosis) in vitro.

Aims & Methods: The objective of this study is to evaluate the preventive potential of a probiotic (mulin) in co-exposure with the CPF on the intestinal dysbiosis, the bacterial translocation and the integrity of the intestinal mucosa. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial
P1273 SYSTEMATIC REVIEW AND META-ANALYSIS: PREVALENCE OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN CHRONIC LIVER DISEASE

A. Shah1, P. Ghasemiz2, E. Shanahan3, G. Macdonald4, L. Fletcher5, M. Morrison6, M.P. P. Jones7, G. Holtham7

4Psychology, Macquarie University Psychology, North Ryde/Australia

Introduction: Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the sequence of events leading to translocation remains unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which an excessive and/or abnormal type of bacteria is present in the small bowel has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Aims & Methods: Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘cirrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

Results: The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath tests, four xylose breath tests, five studies utilised culture methods and one quantitative PCR. Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9–40.9) versus 9.8% (95% CI 7.5–12.8) in controls. Four studies reported SIBO in CLD was increased as compared to controls (RR = 7.15, 95% CI 4.9–10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.6–43.8) compared to 7.3% (95% CI 4.9–10.8) in controls. Eight studies researchers used a combination of methods to detect SIBO. The prevalence of SIBO in CLD was 35.8% (95% CI 32.6–39.1) compared to 8.0% (95 CI 5.7–11.0) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in CLD was 68.3% (95% CI 59.6–76.0) vs 7.94% (95% CI 3.44–12.73) in controls.

Conclusion: Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting that culture tests for small intestinal bacterial overgrowth (SIBO) detected in patients with CLD are more sensitive than other methods. Given the levels of SIBO detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

### Introduction
In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with 'constipating' conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

### Aims & Methods
Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathscreen microlyser (Quinton, USA). Gastrointestinal symptoms were assessed utilising the Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS). The association between methane exhalation and symptoms during the 2 weeks prior the test were evaluated using non parametric test.

### Results
100 consecutive patients (55%), aged 52.2 ± 15.7 yrs (mean ± SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and methane baseline values were highly correlated (r = 0.96, p < 0.001). Methane peaks (and baseline) were inversely correlated with the SAGIS diarrhoea score (r = −0.35, p < 0.01, Figure 1). Contrary to current opinion, CH₄ exhalation was not associated with constipation (r = −0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all >0.3, p all <0.04).

### Conclusion
There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ production microbes modulate human gut function.

| A. Schiepatti, F. Biagi, M. Zuffada, G. Maiorano, G.R. Corazza University of Pavia, Pavia/Italy Contact E-mail Address: salamina@hotmail.it Introduction: Small bowel villous atrophy (VA) is mainly related to coeliac disease (CD) that develops in HLA-DQ2 and DQ8 positive patients and improves on a gluten-free diet. Other forms of VA unrelated to CD are common variable immune-deficiency, autoimmune enteropathy, small bowel malignancies, medication-related enteropathies, HIV, tropical sprue, and giardiasis [1–3]. There are also forms of VA which in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two forms of VA in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two forms of VA in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two
P1279 SYSTEMATIC REVIEW OF THE ECONOMIC BURDEN OF CELIAC DISEASE

Aims & Methods: Searches of Medline, Embase, EconLit, the Cochrane Library, and conference abstracts systematically identified literature published in English during the last 10 years assessing direct and indirect costs, cost-effectiveness analyses, and indirect utility measures (HUIs) for CD in North America and Europe. Results: Of 33 studies meeting criteria for inclusion, most (20) were from Europe, and most (18) reported or modeled costs associated with screening and diagnosis. Cost per positive CD diagnosis of screening patients already undergoing upper gastrointestinal biopsy for other indications, such as anaemia or irritable bowel syndrome, ranged from approximately $1,300 in Canada to more than $44,000 in the Netherlands (costing year not reported). In these populations, screening was judged to be cost-effective with various strategies combining diagnostic modalities, including serology then biopsy, compared to no screening. Strategies using either endoscopy/biopsy or serology alone were not considered cost-effective. Direct annual excess costs to a US payer per diagnosed CD patient ranged from $3,068 to $7,879 (US$2007) to $6,821 to $11,231 for a person without CD, chiefly due to outpatient care, with higher costs among patients with poor disease control. High use of outpatient care is also reflected in studies of HRI, although hospitalization, emergency visits and medication use are also more common in individuals with CD than in controls. After initiation of a gluten-free (GF) diet, patients visit primary care providers less often, but use more medications. Patients often pay out of pocket for gluten-free (GF) foods, which cost 240–518% more than gluten-containing equivalents. Three studies on absenteeism from Scandinavia found fewer days missed from school and work following diagnosis and initiation of a GF diet. Conclusion: Most economic studies of CD have focused on the cost of screening and diagnosis, especially in Europe. Methods of screening generally are considered cost-effective when they combine diagnostic modalities, such as serology then biopsy, in people being evaluated for symptoms. Much of the cost to a payer of managing CD derives from outpatient care, especially for patients with poorly controlled disease. Patients on a GF diet lose fewer days from work or school but pay high costs for GF foods.

7. Introduction: Strict gluten-free diet (GFD) in celiac disease is burdensome and difficult to maintain, which might predispose to poor dietary adherence and impaired quality of life. We aimed to evaluate adult patients’ experience of living with celiac disease diagnosed in childhood, and identify factors associated with possible life restrictions caused by the disease. Aims & Methods: 232 adults (women 69%, median age 27.0 yr) with a childhood diagnosis of celiac disease fulfilled a questionnaire evaluating their experiences about dental health and lifestyle, possible co-morbidities, adherence and attitudes towards GFD and long-term follow-up of celiac disease. In addition, they completed validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for gastrointestinal symptoms and quality of life. Patient records were used to confirm clinical and histological presentation at diagnosis and other relevant medical data.
8. Results: Altogether 108 (47%) out of the 232 responders felt that celiac disease restricts their daily life. This was experienced especially when eating in a restaurant (52%) and visiting a friend (30%). Patients reporting restrictions had more often anemia (38% vs 22%, p = 0.013) and severe symptoms (16% vs 6%, p = 0.047) at diagnosis, whereas the groups did not differ in age, gender or other clinical and histological presentation. Current age (OR 1.5; p = 0.015) and time from initial diagnosis (18.6 vs 17.9 yr, p = 0.468) were also comparable, as well as were self-experienced general health and concern about health, presence of co-morbidities and complications, smoking, physical exercise, socioeconomic status, membership of celiac society and presence of celiac disease in relatives. There was also no difference in specific gastrointestinal symptoms as measured by GSRS scores, but patients considering the disease restrictive reported more overall symptoms possibly related to celiac disease than those without restrictions (32% vs 17%, p = 0.007). Furthermore, diagnosis was more common (93% vs 82%, p = 0.770) than experienced adhering to the diet more challenging (somewhat difficult 33% vs 7%, p < 0.001) and had significantly lower PGWB vitality scores (median 17 vs 18, p = 0.023).
9. Conclusion: Almost half of the patients diagnosed in childhood experienced celiac disease to cause marked restrictions in adulthood. This was associated with current symptoms, lower vitality scores and difficulties to maintain GFD. Patients with severe symptoms and anemia at diagnosis might require special attention and tailored follow-up in these circumstances.

P1280 PNPLA3 RS738409 POLYMORPHISM PREDICTS THE DEVELOPMENT AND THE SEVERITY OF HEPATIC STEATOSIS, BUT NOT METABOLIC SYNDROME, IN PATIENTS WITH CELIAC DISEASE

Aims & Methods: We aimed to evaluate the role of PNPLA3 rs738409 in the development of MS and HS in CD patients after starting GFD. From June 2014 to September 2016 we consecutively enrolled all patients referred to academic gastroenterological centre, suffering from CD, with our without HS. All patients underwent anthropometrics and serological investigations, ultrasonography (US) evaluation to assess the degree and severity of HS and genotyping of PNPLA3 rs738409 polymorphism. Results: Finally, 370 subjects were enrolled (136 with HS and 234 without HS). Among the 194 subjects with HS (52.4%), G genotype was found in 138 subjects (37.3%), while 38 individuals (10.2%) showed the GG genotype. At binary logistic regression, only G and GG alleles were predictive for the development of HS (OR 1.97; p < 0.01 for G carriers and OR 6.9; p < 0.001 for GG carriers), while BMI (OR 3.8; p < 0.001) and waist circumference (OR 2.8; p = 0.03) at CD diagnosis were the only independent factors for the development of MS. The intergroup comparison among HS patients showed that
the severe grade of HS was more frequently observed in GG than in CC carriers (74% vs 11.3%, p < 0.001, OR 21.8).

Conclusion: PNPLA3 G and GG carriers with CD have higher susceptibility to hepatic steatosis, but not to metabolic syndrome. Moreover, patients with GG alleles display a more relevant disease in terms of severity of HS based on US evaluation.

Introduction: Parenteral support (PS) volume needs vary depending on disease severity in patients with intestinal failure associated with short bowel syndrome (SBS-HF). Patient classification has focused on the diagnosis that led to resection and the remnant bowel anatomy.

Aims: To identify the stage that grading severity of SBS-HF is based on magnitude of PS volume needs led to this clinical trial data post hoc analysis of patients with SBS-HF based on their baseline PS volume. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of teguglutide (TED) 0.05 mg/kg/day in patients with intestinal failure associated with short bowel syndrome (SBS-HF). Three baseline PS volume groups were evaluated: Group I, <9 L/week; Group II, >9 L to <18 L/week; and Group III, >18 L/week.

Results: The predominant diagnosis leading to SBS-HF in Group I (12:28:43%) and Group II (15:41:37%) was vascular gut complications; in Group III (18:41:36%), Crohn’s disease. Baseline PS volume and TED-induced volume reduction (% change) at Week 24 was highest in Group III (Table). Evaluation of individual patient response showed a close, linear, and significant correlation between absolute PS volume reduction at Week 24 in relation to TED treatment and daily volume at baseline (y = 0.387x + 90.03, R² = 0.61; P < 0.0001). Statistical correlation was observed in the placebo group (y = 0.06x+220.15, R² = 0.02; P = 0.36). Adverse events were reported by 93% (Group I), 80% (Group II), and 71% (Group III) of TED patients.

P1287 LACTULOSE, LACTOSE AND FRUCTOSE INGESTION INDUCES SPECIFIC PATTERNS OF GASTROINTESTINAL SYMPTOMS IN CHINESE SUBJECTS WITH FUNCTIONAL DYSPEPSIA AND IRRITABLE BOWEL SYMPTOMS

V. Tan1, N. H.S. Chu1, C. K. Yao1, P.R. Gibson2

Introduction: Prevalence rates of Functional Dyspepsia (FD) in East Asia are three times higher than Irritable Bowel Syndrome (IBS) rates. Many researchers have suggested that IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

Aims & Methods: We aimed to compare patterns of gastrointestinal (GI) symptoms in Chinese subjects with FD or IBS during provocative hydrogen breath testing (HBT) with lactulose, lactose and fructose. Subjects fulfilling the ROME III classification of FD and IBS, and control subjects with no known GI disorder were recruited. All subjects underwent HBT with lactulose (10 ml), lactose (25 g) and fructose (25 g). Subsequent breath tests were performed after a washout period of at least one week. Breath tests were performed after an overnight fast, with the patient sedentary. Breath samples taken every 15 minutes for 3 h. GI symptoms were recorded during these 3 h visits and a telephone follow-up 24 h later.

Results: A total of 353 subjects completed at least one breath test examination and 313 subjects completed all three breath tests. 16%, 55% and 29% were control, FD and IBS subjects, respectively. All study subjects were ethnic Chinese, the mean age was 53 (Range: 18-76) y and 27% [95% CI; 23–32%] were male. 85% [95% CI, 82-89%] of subjects were hydrogen-producers and 100% methane-producers. Symptoms were induced in a relatively low proportion of healthy controls. Both FD and IBS subjects experienced similar proportions of epigastric pain on consumption of lactulose, lactose and fructose. See Table 1. Subjects with FD experience more belching than subjects with IBS when lactulose [58 vs. 42%, p = 0.011] and lactose [62 vs. 46%, p = 0.014] were ingested, respectively. Subjects with IBS experience significantly more “lower GI” symptoms of abdominal pain and development of loose stools when lactulose was ingested when compared with subjects with FD. In general subjects with IBS experienced both epigastric pain and abdominal pain when any of the three carbohydrate solutions were ingested. Healthy controls experienced minimal symptoms.

Conclusion: Chinese subjects commonly co-produced hydrogen and methane. Ingestion of poorly absorbed sugars induces symptom patterns in patients with FD in similar proportions. Chinese IBS subjects commonly experienced epigastric and abdominal pain. Reducing poorly absorbed short-chain carbohydrates (FODMAPs) might be efficacious in FD as it is in IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel disease (IBD) and mesenteric vascular (Vasc) disease are underlying conditions for intestinal failure associated with short bowel syndrome (SBS-IF). Fluid balance, urine production, and parental support (PS) are variable among patients with SBS-IF.

Aims & Methods: This is a post hoc analysis of the impact of teduglutide (TED) on fluid composite effect (FCE = sum of urine volume output increase, oral fluid intake reduction, and PS volume reduction) in patients stratified by diagnosis. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS–IF. Three groups were evaluated: SBS-IBD, SBS-Vasc, and Other.

Results: The SBS-IBD group included more patients with stoma (95%: SBS-Vasc, 9%; Other, 41%) and fewer with colon-in-continuity (11%: SBS-Vasc, 78%; Other, 62%). At Week 24 (Table), PS volume reductions were significantly higher in SBS-IBD patients treated with TED vs placebo (P = 0.02) and vs TED patients in the SBS-Vasc (P = 0.04) and Other (P = 0.02) groups. Change in FCE was greater in SBS-IBD patients treated with TED vs placebo (P < 0.02) and vs TED patients in the SBS-Vasc (P < 0.01) and Other (P < 0.05) groups.

Conclusion: TED had the largest absolute effect on FCE in the SBS-IBD group; TED effect on FCE was not as major in SBS-Vasc or Other patients at Week 24. This research was funded by Shire International GmbH, Zug, Switzerland.

Disclosure of Interest: P.B. Jeppesen: I have served as a consultant and on the speaker bureau for Shire. S.M. Gabe: I have served as a consultant for Shire. K. Iyer: I have served as a consultant for Shire. U. Pape: I have received grant/research support from and served as a consultant for and on the speaker bureau for Shire. D.L. Seidner: I have served as a consultant for Shire. H. Lee: I am an employee for Shire. C. Olivier: I am an employee for Shire.
were evaluated: Group 1 (no colon/stoma present/no colon-in-continuity), Group 2 (≤50% colon/stoma to colon-in-continuity), and Group 3 (other bowel anatomies). Clinical response was defined as ≥50% reduction from baseline in weekly parenteral support (PS) volume at Weeks 20–24. Data presented as mean (SD).

**Results:** The predominant diagnosis in Group 1 was Crohn’s disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12, 9.9 [2.1]; Week 24, 2.5 [2.1] compared with Group 1 (Week 12, –5.5 [3.8]; Week 24, –6.4 [4.5] or Group 3 (Week 12, –2.7 [12]; Week 24, –5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, P = 0.001; Group 2, 56% vs 40%, P = 0.36; Group 3, 57% vs 29%, P = 0.035). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

**Conclusion:** Patients with SBS – IF in Group 1 had the highest baseline PS volumes, and responders most frequently to TED with PS volume reductions, compared with patients in Group 2 or Group 3. This research was funded by Shire International GmbH, Zug, Switzerland.

**Contact E-mail Address:** sakaguchi-tky@umin.ac.jp

**Introduction:** Sporadic non-ampullary duodenal epithelial tumors (SNADETs) are rare, accounting for less than 1% of gastrointestinal neoplasms, and thus the mechanism behind the pathogenesis and carcinogenesis of these neoplasms is still poorly understood. However, with the overall increase of small bowel cancer in recent years, there is an increasing need to clarify the morphology of SNADETs. This study was conducted with the objective of identifying genetic markers and pathways specific to superficial SNADETs through gene-expression analysis.

**Aims & Methods:** This was a prospective pilot study on patients with a diagnosis of superficial SNADETs who were treated at the Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Hospital, Tokyo, Japan. Adenoma and adenocarcinoma, all patients were subjected to endoscopic evaluation to preclude ampullary lesions, and had a preoperative histologic diagnosis of either adenoma or adenocarcinoma. Patients with familial polyposis were excluded. Immediately before resection of the target lesions, a single biopsy sample from the duodenal tumor and a paired sample from the surrounding normal duodenal mucosa was endoscopically obtained from each patient, followed by RNA extraction. Gene expression profiling with an oligonucleotide microarray was performed in a training set of 4 matched tumor-normal tissue superficial SNADETs pairs. Genes and pathways that demonstrate differences between pairs were identified, followed by a set-level gene enrichment analysis with a pre-validated curated gene set. Results were confirmed with rt-PCR in all other independent SNADETs pairs.

**Results:** From Nov 2014 to Jan 2016, a total of 12 consecutive patients were enrolled in this study. One patient was excluded due to a post-treatment diagnosis of familial polyposis. In a training set of 4 tumor-mucosa pairs, 626 probes (168 up-regulated, 458 down-regulated) which consistently demonstrated over a 2-fold expression difference between tumor and normal mucosa in all matched pairs were identified. RT-PCR of genes most highly differentially expressed between the tumors and normal mucosa was performed in the 4 pairs in the training set as well as 7 independent patients. Consistent gene expression patterns concurrent with microarray results were demonstrated in all pairs, confirming the results of this study. Gene set enrichment analysis of the training set using a curated data set demonstrated a strong association between SNADETs and colorectal adenomas (p < 0.0001) and APC down-regulation (p < 0.00001). No other significant associations were demonstrated.

**Conclusion:** Superficial SNADETs demonstrate gene expression characteristics that strongly resemble familial colorectal adenomas. Gene expression characterization of these lesions has also demonstrated the significant role of APC down-regulation in the pathogenesis of SNADETs, suggesting that an adenoma-carcinoma sequence similar to colorectal neoplasms may be seen in SNADETs. Further analysis of genes which may play a key role in the carcinogenesis of these neoplasms is required.

P1293 INK TATTOOING FOR BALLOON-ASSISTED
ENTEROSCOPY–TIME WELL SPENT?
C. Römmele1, A. Ebigbo1, H. Messmann1, S. Gölder1
1
Department Of Internal Medicine Iii, Klinikum Augsburg, Augsburg/Germany
Contact E-mail Address: christoph.roemmele@klinikum-augsburg.de
Introduction: Balloon-assisted enteroscopy is a well-established tool in the diagnosis and therapy of small bowel diseases. Ink tattooing of the small bowel is
used in some centers to mark pathologic lesions or the depth of small bowel
insertion.
Aims & Methods: The purpose of this study was to determine the safety, the
detection rate within a surgical operation or video capsule endoscopy and the
clinical relevance of ink tattooing during balloon-assisted enteroscopy (BAE).
Between 01.01.2010 to 31.12.2015 229 BAE were performed in 156 patients (pts)
at the endoscopy unit of Klinikum Augsburg. We performed a retrospective
analysis of all 81 (52%) patients who received an ink tattooing during BAE.
Results: Main indications for BAE were known angiodysplasia (37 pts), suspected bleeding of the small intestine (32 pts) and anemia (19 pts). Other indications were known or suspected tumor of the small intestine (17 pts) and Crohn’s
disease (3 pts). In 27 patients no pathologic findings were found. In 41 patients an
active bleeding, angiodysplasia or hemangioma were found and further therapeutic interventions were performed. Tumor/polyps (11 pts), inflammatory
lesions (7 pts) and ulcerative diverticula (1 pts) were other findings. In all 81
patients ink tattooing of the small intestine was performed with no complications. 46 (57%) of 81 patients received a follow-up mainly due to re-bleeding. 5
Patients underwent surgery directly after enteroscopy with ink-tattooing and
therefore received no follow-up. In total 26 (32%) patients received a capsule
endoscopy after BAE at our hospital. The ink tattooing could be detected via
capsule endoscopy in 19 of these 26 patients (73%). The ink tattooing of the
previous antegrade BAE could be detected via retrograde BAE only in 2 of 11
(18 %) patients. Nine patients received a second ink-tattooing of the small intestine within these examinations without any complications. Ink tattooing had no
clinical relevance or therapeutic consequence in 62 of the 81 (72%) patients
within the observation period. 5 of these 62 Patients received no further diagnostic or therapeutic steps due to their clinical situation. In 9 patients ink tattooing influenced the choice of approach (antegrade versus retrograde) for reenteroscopy after a video capsule endoscopy. In 7 patients the ink tattooing
was used for intraoperative localization and in 3 patients for intraoperative
localization as well as for enteroscopy. The intraoperative detection rate of the
ink tattooing was 100%.
Conclusion: Ink tattooing of the small intestine is a minimally invasive and safe
endoscopic procedure to mark the depth of scope insertion or a pathologic lesion
during balloon-assisted enteroscopy. It is a useful tool to avoid unnecessary
examinations and aids the intraoperative localization of pathologic lesions. A
complete enteroscopy of the small intestine via BAE from retrograde and antegrade is achieved rarely in our setting.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1294 THE ROLE OF CAPSULE ENDOSCOPY IN THE DETECTION
OF SMALL BOWEL TUMOURS IN A LOW-RISK POPULATION;
A SINGLE-CENTRE EXPERIENCE

Introduction: Small bowel tumours (SBT) are very rare and generally grow insidiously, with alarm symptoms such as obstruction and overt GIB often occurring
at a later stage of disease. The introduction of small bowel capsule endoscopy
(SBCE) has enabled earlier detection of SBT and has been shown to affect the
therapeutic course. However, the reported frequency of small bowel malignancies
diagnosed by SBCE is highly variable.
Aims & Methods: We aimed to review the frequency of small bowel tumours
diagnosed by SBCE in a high-volume tertiary centre, and to assess the clinical
presentation and outcome of patients. A retrospective review of the database in
our institution was undertaken. All patients who had undergone SBCE from
2011–2016 were identified. All patients had undergone SBCE using the standard
protocol. The Given SB3 Pillcam was used for the majority of procedures from
2014 onwards and the SB2 was used prior to 2014. All videos were analysed by
experienced gastroenterologists and reported using the Rapid reader software
system (Given Imaging, Covidien, Medtronic, Yoqneam, Israel). SBCE reports
for all indications were reviewed and all patients with reports suggestive of a
small bowel tumour were included initially. A chart review was then performed

United European Gastroenterology Journal 5(5S)
and information was obtained on patient demographics, clinical presentation/
indication for SBCE, laboratory markers, previous endoscopic or radiological
procedures, further endoscopic or surgical interventions carried out, and final
histological diagnosis. Only patients who went on to have a histological diagnosis
of a small bowel malignancy were included in the final analysis.
Results: A total of 1670 SBCEs were carried out.The overall indications for
SBCE were as follows: suspected small bowel Crohn’s disease 34% (n ¼ 568),
iron deficiency anaemia/obscure occult GIB 41% (n ¼ 685), obscure overt GI
bleeding 16% (n ¼ 267), non-specific abdominal pain 6% (n ¼ 100), known or
suspected polyposis syndrome 2% (n ¼ 33) or Coeliac disease 1% (n ¼ 17).
In total 1% (n ¼ 19) of SBCE reports identified a possible small bowel tumour.
Of these, a final histological diagnosis of a small bowel malignancy was made in
14 patients. Of the 5 patients with a benign diagnosis, one patient was diagnosed
with myoepithelial hamartoma, two patients an adenomatous polyp, one a lymphangioma, and one ganglion cells only. Of the 14 patients diagnosed with a
small bowel malignancy, the majority, 71% (n ¼ 10) were female and the mean
age was 58 years (18–90). The indication for referral in 12 (86%) patients was
obscure gastrointestinal bleeding, with occult bleeding in 57% (n ¼ 8) and overt
bleeding in 29% (n ¼ 4). Only one patient was referred for SBCE due to abnormal imaging and the other patient had persistent diarrhoea. The mean length of
time from presentation to diagnosis of their small bowel tumour by SBCE was
18.8 months (16–24). Patient’s mean Haemoglobin at diagnosis was 10.6 g/dL
(7.4–12.4). Only 3 patients had a recognised risk factor,2 with coeliac disease and
1 patient had previous colorectal cance. In 79% (n ¼ 11) of all patients, SBCE
was the first investigation suggestive of a small bowel tumour. In all, 7 (50%)
patients underwent cross sectional imaging prior to SBCE, of which 3 (42%) had
a reported no small bowel abnormalities. All patients had undergone at least one
negative upper and lower endoscopy prior to referral, and SBCE was the third
investigation in 50% (n ¼ 7) of patients. After SBCE, 60% (n ¼ 8) of patients
underwent a double balloon enteroscopy (DBE) for further evaluation of findings and to obtain tissue samples. In terms of histological diagnoses, adenocarcinomas were found in 43% (n ¼ 6), Neurendocrine tumours in 29% (n ¼ 4),
Gastrointestinal stromal tumours (GISTs) in 14% (n ¼ 2), and lymphoma in
14% (n ¼ 2). All patients eventually underwent surgical resection of their small
bowel tumours and 80% (n ¼ 11) patients remain well at present, after a mean
follow up time of 15.2 months (2–36).
Conclusion: SBT are rare but accounted for 1% of significant SBCE findings in
our cohort. The lack of concordance between SBCE and cross sectional imaging
suggests this modality should remain an early diagnostic test in OGIB.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The western diet (WD) high in fat and fructose is considered one of
the most relevant cause of metabolic disorders and cardiovascular diseases
(CVD). The aim of this study was to evaluate whether daily vitamin D3 supplementation is able to modulate hepatic steatosis, or restore insulin resistance and
the metabolic alterations contributing to CVD and hearth failure (HF) caused by
a westernized diet, in a rat model without specific vitamin D deficiency.
Aims & Methods: Eighteen adult male Wistar rats were divided into 3 groups,
each of 6 rats, fed with: Group 1: Standard Diet, 3.3 kcal/g (SD); Group 2:
Western Diet, 5.6 kcal/g, (WD) containing 13 IU/day/rat of vitamin D3; Group
3: Western Diet þ Vit D (WD Vit D) containing 23 IU/day/rat of vitamin D3.
The experiment was conducted for 6 months. Standardized tail-cuff blood pressure (BP) measurements of conscious rats and transthoracic echocardiography
were performed in basal condition (Time 0), and after 3 and 6 months of diet.
Hepatic steatosis and collagen myocardial fibrosis were assessed using standard
methods. Serum insulin and 25(OH)D3 concentrations were determined using
rat-specific ELISA kits. Insulin resistance was determined according to the
Homeostasis Model of Assessment (HOMA-IR) method.
Results: In WD rats the percentage of hepatocytes with steatotic vacuoles was
61%, while in WDVitD group was only 27%. In WD group HOMA-IR
was significantly higher than in SD (41.9  8.9 vs 6.17  1.3, p 5 0.01) and it
was reduced by vitamin D supplementation in WDVitD group (41.9  8.9 vs
19.4  5.2, p 5 0.05). At baseline, no differences in systolic blood pressure
(SBP) were detected among the three groups showing normal systolic blood
pressure. SD did not increase SBP, significantly, during the study period. On
the contrary, WD, enhanced SBP by 27  12% p 5 0.001 at 3 months, and by
47  11%, p 5 0.001 at 6 months. At the end of the study, SBP resulted to be
higher in WD group (117  3 mmHg) compared with both SD (84  3 mmHg,
p 5 0.001) and with WDVit.D (101  4 mmHg, p 5 0.01). During the study
period, WD group showed a significant increase of left ventricular mass
(LVM) (52  25% at 3 months p 5 0.05, and 123  43% at 6 months
p 5 0.001, vs basal conditions,). Supplementation of VitD abolished the WDinduced increase of LVM (25  19% at 3 months, and 34  20% at 6 months,
p 5 0.05 vs baseline respectively). At the end of the study LVM resulted to be
higher in the WD group in comparison to both SD and WDVitD groups, while


Introduction:

Gastro balloons (IGB) are an emerging option for overweight and obese patients with a body mass index (BMI) greater than 31 kg/m2 and they provide greater efficacy with lower risks than do conventional surgical procedures. The balloon treatment is based on gastric space-occupying effects that increase the feeling of satiety and may also effect gut neuroendocrine signaling. However, widespread use of current generation IGBs has been limited by several factors: placement and removal endoscopies require sedation, special training and equipment; patients lost to follow-up are susceptible to IGB deflation and unplanned passage into the gastrointestinal tract. The ElipseTM is the world’s first IGB that does not require endoscopy or anesthesia.

Aims & Methods:

We conducted a study to prospectively analyze the safety and effectiveness of IGB ELIPSE in overweight adults. Six patients, 1 male and 5 female (average age 40, mean BMI 40 kg/m2), were included in this study. Each patient swallowed Elipsetm balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 ml of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct positioning of the device. All patients were followed up by a nutritionist with a specific semiliquid diet.

Results:

All 6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 kg). In all of the patients, the balloon remained full throughout 16 weeks, self-emptied, and were passed spontaneously without needing endoscopic removal.

Conclusion:

This study demonstrates the efficiency, security and simplicity of the Elipse™ system. Moreover, we highlighted the non necessity of deep sedation for IGB placement and removal. All patients were followed up by a nutritionist with a specific semiliquid diet. All patients had a significant weight loss (about 16 kg). In all of the patients, the balloon remained full throughout 16 weeks, self-emptied, and were passed spontaneously without needing endoscopic removal.

P1298 CHANGE OF VITAMIN D AND BONE MINERAL DENSITY AFTER BARIATRIC SURGERY IN CHINESE POPULATION

M. Han1, W. Lee2

1Internal Medicine, Min-Sheng General Hospital, Taoyuan/Taiwan

2Surgery, Min-Sheng General Hospital, Taoyuan/Taiwan

Contact E-mail Address: minghun@ms18.hinet.net

Introduction: Bariatric surgery is an effective treatment for morbid obesity. In Taiwan, the number of patients who received bariatric surgery increased gradually. However, for long-term follow-up, nutritional deficiency may develop in patients who received bariatric surgery. The aim of our study is to evaluate the change of Vitamin D and bone mineral density after bariatric surgery in Chinese population. This prospective cohort study included 50 patients (aged 20 to 65 years old) who received bariatric surgery at one teaching hospital in Taoyuan, Taiwan. Patients with osteoporosis before surgery were excluded in this study. Baseline (2012-2014) and one year after bariatric surgery (2013-2015), venous blood was collected from each patient for assessment of the Calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm2) was also measured at lumbar spine (L2-L4) by dual energy x-ray absorptiometry (DEXA).

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy, 24 patients received laparoscopic mini-gastric bypass (MGB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodenal-jejunal bypass with sleeve gastrectomy (DBJ-SG).

The characteristics of the study population was shown in Table 1. The differences of mean for calcium, vitamin D, PTH and BMD after bariatric surgery were 0.16 mg/dl (P < 0.05), 8.6 pg/ml (P < 0.05) and -0.04 g/cm2 (P = 0.14) respectively.

Conclusion: One year after bariatric surgery, the prevalence of osteoporosis and osteopenia was low. The serum Vitamin D level increased significantly but no significant change of BMD was noted. Further longitudinal studies are warranted to clarify the long-term effect of bariatric surgery on BMD in Chinese population.
P1300 INTRAGASTRIC BALLOON: A LARGE BRAZILIAN MULTICENTRIC STUDY OVER 10,000 CASES AND 20 YEARS OF EXPERIENCE

Introduction: The intragastric balloon has been used for more than 20 years in Brazil as an endoscopic device for assisting weight loss, and some intercurrences were observed during more than 10,000 procedures performed. With the assistance of a multidisciplinary team the results have been satisfactory.

Aims & Methods: To assess the efficacy and complications of the weight loss with IGB in patients seen at the 07 private centers. A total of 10,255 patients with IGB implanted from 1997 to 2017 were analyzed from a prospective fed database. A liquid filled IGB with a volume in-between 620 to 700 ml was used. Initial BMI started at 27 kg/m² (as approved by Brazilian health authorities) and were followed up by a multidisciplinary team during implant. IGB maximum period implant was 09 months. Statistical analysis was performed according to sex and degree of excess weight (overweight and grade I, II and III). Data were assessed using Student t-test, and Tukey post-test. The level of significance was set at p < 0.05.

Results: 492 patients (4.8%) were excluded from the final analysis associated with weight loss: 226 (2.2%) due to early removal–These were analyzed in relation to the previous consultation with psychologist and 88% did not undergo nutritional monitoring during the use of IGB, 108 (1.04%) due to patient refusal–These were analyzed in relation to the psychological and degree of excess weight (overweight and grade I, II and III). Data were assessed using Student t-test, and Tukey post-test. The level of significance was set at p < 0.05.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first IGB was 96.35 months (± 75.82) and average weight at the first IGB was 135.9 kg (± 37.28). The mean age was 31.13 years. The patients showed a significant weight loss, with a success rates according to the following criteria:

- 14.4% of the weight loss. Of the 554 patients APC, 51 (9.2%) required dilatation balloon due to significant stenosis at least one. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastric enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The weight regained has been a described growing problem in patients after bariatric surgery and this weight regained is multifaceted and originated from dilation of Gastrojejunostomy (GJ). For the patients with significant weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroenteric anastomosis in patients who have undergone RYGB for morbid obesity and regained weight associated to dilation of the GJ. From Jan-2014 to April-2017 554 RYGB subjects were analyzed. We divided the patients that regain a dilated anastomosis (>18 mm) and at least 2 procedures were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilation, although some studies use smaller diameters such as 12mm similar to that created mainly in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic diameter was measured using a 33 mm long Fouchet bougie and an additional dilator with a maximum of 03 applications. APC set was at 2-3 mL with 65-85W. GJ diameter target was 8-12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (± 75.82) and average weight at the first APC was 135.9 kg (± 37.28). The mean age was 31.13 years. The patients showed a significant weight loss, with a significant stenosis at least one. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastroenteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Contact E-mail Address: hanna.dale@outlook.com

Introduction: Non-coeliac gluten sensitivity (NCGS) is a new entity with unknown prevalence and mechanisms, and there is a need for a standardized procedure to confirm the diagnosis. The objective of this study was to characterize the response to a gluten challenge, when performed according to the updated Salerno criteria.

Aims & Methods: Twenty patients (14F/6M, age range: 21–62 y) with suspected NCGS, without coeliac disease and wheat allergy, were included while on a gluten-free diet. All patients went through four periods of double-blinded provocation with gluten and placebo containing muffins. They were instructed to eat two muffins a day (11 g gluten) for four days, followed by a three days’ wash-out. Gastrointestinal symptoms were recorded with questionnaires at baseline and after each provocation, while fatigue and quality of life were registered at baseline and end of the trial.

Results: Four out of twenty patients (20%) correctly identified the two periods when they received muffins containing gluten, hence were diagnosed with NCGS. The diagnosed group tended to show higher symptom scores than the not-diagnosed group both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten (p = 0.029). Symptom severity at baseline was significantly correlated with fatigue (r = 0.63, p = 0.003) and reduced quality of life (r = 0.76, p = 0.0001).

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear difference between the diagnosed and the not-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1304 THE ROLE OF BILE ACIDS AND GUT MICROBIOTA IN CORONARY ARTERY DISEASE: RESULTS OF THE MABAC STUDY IN HUMAN (MICROBIA ATEROMA ET BILE ACID IN CORONARY DISEASE)

Contact E-mail Address: henri.duboc@gmail.com

Introduction: By targeting specific receptors into the vascular system, bile acids (BA) are cholesterol derivatives that are now considered as hormones. BA regulates the basal energy expenditure and glau-copeptide metabolism. In animal models of atheroma development (ApoE-/- and Ldl-/- mouse model) a powerful anti-atherosclerotic effect of circulating BA has been evidenced: BA are metabolites of the gut microbiota, suspected to play a role in the development of atherosclerosis. This study examined whether variations in BA or in the gut microbiota composition can be described in the human Coronary Artery Disease pathophysiology.

Aims & Methods: Consecutive patients undergoing coronary angiography between February and May 2015 were enrolled. To avoid physiological or induced variations in circulating BA or in the gut microbiota, highly restrictive exclusion criteria were applied. Circulating and faecal BA were quantified by high pressure liquid chromatography and tandem mass spectrometry. The faecal microbiota composition was assessed by 454 pyrosequencing of the total bacterial DNA.

Results: 80 patients were prospectively included of 406 screened, and divided in two groups: with (n = 45) and a group without (n = 35) CAD. The mean serum concentration of total BA was 1.02 ± 0.16 μmol/l in patients with, versus 2.16 ± 0.38 μmol/l in patients without CAD (P = 0.005). This decrease, (adjusted for gender and age) was an independent predictor of CAD (odd ratio = 0.51; 95% confidence interval 0.31, 0.85; P = 0.0) The BA concentrations in feces were similar in both groups. There was no group-specific pattern in the fecal microbiota. In a subgroup of 17 patients, one month of statin therapy increased the serum BA concentration from 0.68 ± 0.08 to 1.37 ± 0.21 μmol/l (P = 0.01).

Conclusion: There was no specific microbiota signature associated with CAD. However, the decreased serum BA concentration was a strong predictor of CAD in humans. With respect to the powerful anti-atherosclerotic effect of BA in animal models, and their role in human lipid metabolism and diabetes, this study unraveled the existence of a new metabolic disturbance associated with CAD.

P1305 LOW FODMAP DIET: REINTRODUCTION PHASE DOES NOT MODIFY EFFICACY, BUT BEWARE OF REAL TRIGGER FOODS!

1 Ospedale Di Cisanello Pisa, Pisa/Italy
2 O.U. Reumatologia, Ospedale Di Cisanello Pisa, Pisa/Italy
3 Department Of Translational Research And Of New Surgical And Medical Technologies, University of Pisa, Pisa/Italy
4 O.U. Gastroenterology, Ospedale Di Cisanello Pisa, Pisa/Italy

Contact E-mail Address: mbellini@med.unipi.it

Introduction: The low-FODMAP diet (LFD) is used to treat patients with irritable bowel syndrome (IBS) even if some nutritional concerns have been raised. It starts with an elimination phase and is followed by a reintroduction phase to verify the “trigger” foods in foods in order to suggest a definitive and less restrictive diet tailored to the patient.

Aims & Methods: The aims of this study were to evaluate: 1) the effects of FODMAP reintroduction on a) body composition and nutritional status, using Bioelectrical Impedance Vector Analyses (BIVA), b) abdominal symptoms, c) quality of life, d) anxiety/depression, e) sleep quality. 2) if the patients’ perception of the “trigger” foods was accurate.

Results: Neither change of blood tests at T1 nor variations of anthropometric data and BIVA were reported at T1 and in comparison with T0. A significant improvement in abdominal symptoms (IBS-SSS), anxiety and quality of life, was recorded at T1, this remaining unchanged also at T2 (p < 0.0001). Depressive improvement improved at T2 (p < 0.01 vs. T0). Sleep quality improved at T1 (p < 0.05 vs. T0) and at T2 (p < 0.001 vs. T0). Normal BSC faces were reported by 38 patients at T0 to 60 patients both at T1 and T2. The degree of symptom relief with the diet was 1.5 ± 0.6 at T1 and 1.6 ± 0.7 at T2 and the degree of satisfaction was high.
both at T1 (8.4±1.6) and T2 (8.2±1.7). When starting, LFD patients considered all foods containing simple sugars (67%), fructans (27%), fructose (17%), galacto-oligosaccharides (GOS) (17%) and polyols (5%); the reintroduction phase (T2) enabled us to detect lactose in 70%, fructans in 30%, fructose in 37%, GOS in 33% and polyols in 27%, as real triggers. The agreement (Cohen’s kappa) was moderate for lactose (k: 0.50), fair for fructans (k: 0.39) and fructose (k:0.32) and poor for polyols (k: 0.16) and GOS (k: 0.01).

Conclusion: Not only did reintroduction not affect the improvements achieved during the elimination phase, but it also precisely identified the foods responsible for the remaining manifestations. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underlines the fact that LFD has to be administered and carried out under the guide of an expert nutritionist.

Introduction: Fructose malabsorption (FM) is a frequent finding in patients with abdominal symptoms due to high levels of fructose in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the main fructose transporter GLUT5 in the duodenum.

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as controls. The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endogenous hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression patterns of GLUT5 were correlated with clinico-pathological patient characteristics.

Results: The expression of GLUT5 did not differ significantly between patients with FM complete diet responders (n = 183) and healthy controls (n = 42). Also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H2 increase and AUC measured in fructose breath testing from patients not responding to the diet (n = 40). However, in patients with CD (n = 29) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls (p = 0.009). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression (rs = 0.563, p = 0.001).

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult patients with FM. The symptoms induced by FM could be associated with mechanisms known to the pathology of the fructose bowel syndrome. However, in secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functional gastrointestinal disorders.

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. Symptom relief due to a low FODMAP diet has especially been investigated in patients suffering from irritable bowel syndrome (IBS) and has proven to reduce gastrointestinal symptoms in up to 86% of patients with IBS. In addition, there is evidence for an association between gastrointestinal symptoms and joint hypermobility (JH). However, there is no clear data regarding response rates to a diet low in FODMAPs in patients suffering from JH. In this study we aimed to assess and compare the response to a diet low in FODMAPs in JH positive and JH negative patients with FGIDs.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by physicians using Brighton score and rated positive for scores ≥ 4.9 points. Patient received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) were male. Median age was 35 [range 18–81]. Females were more likely to exhibit JH compared to males (38.62 [61.3%] vs. 6.22 [27.3%]; p = 0.006). Global symptom response rate to a diet low in FODMAPs was 64/84 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%], p = 0.005, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36.39 [92.3%] vs. 28/38 [73.7%]; p = 0.036).

Conclusion: Our data indicate an association between global symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An understanding of structural pathophysiologies of JH positive patients with intestinal permeability causing gastrointestinal symptoms in JH positive patients and limiting response to low FODMAP diet should be considered. Our findings represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

Introduction: Gastrointestinal symptoms are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber.

Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI symptoms and duodenal physiology, we conducted a single-blind, randomized, single-center study. Healthy adults with baseline fiber intake ≥14 g/1000 calories/day; ≤10% daily calories from added sugar; ≥5 servings of fruits and vegetables/day; and ≤13% daily calories from saturated fat were recruited. Exclusion criteria included known GI disease or symptoms, antibiotic/probiotic use within 4 weeks of the study, pregnancy, and vulnerable adults. At baseline visit, participants completed a symptom and demographic questionnaire and underwent esophagogastroduodenoscopy (EGD) with duodenal biopsies and aspirates. Symptoms associated with constipation, straining, incomplete evacuation, hard stools, abdominal pain associated with bowel movements, diarrhea, bloating, nausea/vomiting, heartburn, fatigue, and appetite. All participants consumed a 7-day standardized diet with typical United States dietary habits, consisting of 50% carbohydrates (35% fat, 15% protein). The diet was low in fiber (<10 g/1000 calories/day) and high in simple sugar (>50% daily carbohydrates). After dietary intervention, participants filled out four symptom questionnaires and underwent repeat EGD and duodenal biopsies and aspirates. Before and after the diet, quantitative aerobic and anaerobic cultures were performed on duodenal aspirates. Duodenal biopsies were mounted in an using chamber. Intestinal permeability was evaluated using transepithelial electrical resistance (TEER) and FITC flux (4KDa; a measure of paracellular transport). Secretory responses were quantified in voltage clamp mode by measuring baseline short circuit current (Isc) and change in Isc (ΔIsc) to response in increasing concentrations (0.003–300 μM) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data were presented as mean ±SEM. Data were analyzed using paired-t test unless specified and p < 0.05 was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were recruited. Average BMI was 23.1 ± 2.9 kg/m2. At baseline, 83% of participants were asymptomatic. After dietary intervention, all participants endorsed at least one new symptom and 9/10 participants endorsed multiple (≥2) new symptoms. At baseline, 4/10 participants had positive duodenal cultures (> 100,000 CFU/mL), anaerobic) despite having no symptoms. Of the 6 who had no growth initially, I developed bacterial overgrowth following intervention. There was no significant difference in TEER (26.45 ± 1.98 vs 26.18 ± 2.45 Ohms/cm²); FITC flux (217 ± 34.72 vs 217.6 ± 42.57 ng/ml) or baseline Isc (48.27 ± 0.63 vs 51.58 ± 2.82 μA/cm²) before and after dietary intervention. Interestingly there was a significantly lower ΔIsc response to increasing concentrations of 5-HT after dietary intervention (P < 0.05, two-way ANOVA).

Conclusion: A low-fiber, high simple sugar diet led to gastrointestinal symptoms in healthy adults with high-sugar, low-fiber diets. A significant decrease in 5-HT evoked secretory response in the duodenum, suggesting a potential role for dietary modulation of host secretory pathways. There was no correlation with quantitative bacterial cultures and there was no overall significant change in intestinal permeability. Diet may mediate these
P1309 STRESS AND STRESS-RELATED PEPTIDE AMPLIFY THE ANOREXIC ACTIONS OF CHOLECYSTOKININ

Gastroenterology And Hepatology, Saitama medical University, Kawagoe/Japan

Contact E-mail Address: yamaguoata80@yahoo.co.jp

Introduction: Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dyspepsia (FD) have hyper sensitivity to CCK. And revells of CCK inbrad was shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticosterone-releasing factor (CRF) or urocortin (UCN1) injection intraperitoneal (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amount of the mixture (food and glass beads) left in the stomach was measured at 2 hours after the perorally injection of mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 1 and 2 hours after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (100ug/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. C-Fos expression of the neurons in the nucleus of soritary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorectic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

P1310 PEPTIDE TYROSINE-TYROSINE (PYY) ENHANCES EFFECTS OF CHOLECYSTOKININ (CCK) ON GASTRIC MOTILITY AND FOOD INTAKE IN RATS

E. Hosomi1, N. Yamaguchi1, K. Maewaza1, M. Ochiai1, S. Ro1, K. Chieko1, K. Takayama1, K. Yakabi1
Gastroenterology And Hepatology, Saitama medical University, Kawagoe/Japan

Contact E-mail Address: hosomi@saitama-med.ac.jp

Introduction: Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PYY) have been investigated to appetite and gastric emptying. Both peptides raise in blood by feeding, and maintain high levels simultaneously for 1–2 hours. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

Aims & Methods: In this study, we undertook to elucidate whether CCK and PYY have the interaction to decrease food intake. Study on gastric emptying. Male SD rats were fasted overnight, and 1 mL of mixture of food and glass beads was given into the stomach and then PYY or CCK followed by PYY was IP injected into the rats left in the stomach after the injection was measured and gastric emptying rate was calculated. Study on appetite. PYY or CCK was IP injected to the rats just before setting food to eat. The amounts of food were measured at 1 and 2 hours after the injection. To clarify the involvement of the brain in the interaction between CCK and PYY, c-Fos expression was examined.

Results: CCK (0.5–10 nmol/kg) dose-dependently inhibited gastric emptying (p < 0.001). CCK 10 nmol/kg maximally inhibited food intake (p < 0.01). PYY 25–2500 pmol/kg significantly inhibited gastric emptying for 1 or 2hrs after the injection (p < 0.001). PYY 250 pmol/kg significantly inhibited food intake for 1 hour after the injection (p < 0.01). The combination of CCK 10 nmol/kg and PYY 250 pmol/kg inhibited gastric emptying more than CCK alone (p < 0.001) or PYY alone (not significant). PYY and CCK additively inhibited food intake when PYY was injected 20 minutes later from CCK injection. PYY significantly amplified c-Fos expression induced by CCK in the nucleus of soritary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) in the brain.

Conclusion: The combination of PYY with CCK amplified the suppression of gastric emptying and food intake for 1 hr after the injection (p < 0.05). After the injection, CCK and PYY might strengthen the inhibition of food intake through the activation of satiety center in the brain, that is important for terminating food intake and adjusting energy intake.

Introduction: Transcriptions factors belonging to the p53 family (p53, p63, p73) respond to cellular stress signals by inducing an accurately defined set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 proteins can exert carcinogenic or tumor-suppressive functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. It is known that expression patterns of microRNAs can be controlled by the p53 family. Depending on disease and cellular origin different sets of p53-induced microRNAs have been identified. We undertook to elucidate whether CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (100ug/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. C-Fos expression of the neurons in the nucleus of soritary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorectic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

P1312 IGFBP2 IS REGULATED BY THE P53 FAMILY OF TRANSCRIPTION FACTORS IN HEPATOCELLULAR CARCINOMA

D. Gschwend1, M. Lohe2, E. Aschenbrenner3, K. Pollinger1, S. Schlösser1, C. Kunst1
1Department For Internal Medicine I, University Hospital Regensburg, Regensburg/Germany

Contact E-mail Address: dana.gschwend@stud.uni-regensburg.de

Introduction: p53 transcription factors (p53, p63, p73) respond to cellular stress by transcriptional regulation of specific sets of genes. In hepatocellular carcinoma (HCC) and other tumors p53 family members exert carcinogenic or tumor-suppressive effects. Depending on their spacial and temporal expression microRNAs can exert cancerogenic or tumorsuppressive functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. The observed synergistic effect of p53 and HCC-relevant target genes on microRNA expression might provide new options for the development of therapeutic and prognostic markers in HCC.

Conclusion: All authors have declared no conflicts of interest.
potential p73 BS reduced luciferase activity by 85%. CHIP analyses verified binding of p73 to the putative p53-binding sites of IGFBP4. Conclusion: These results clearly identify IGFBP4 as novel target gene for pAp73 and p53 in HCC. We demonstrate for the first time an interaction of pAp73 with IGFBP4 and therefore an important, so far unknown link between the p53 family member and the IGF pathway. p53 proteins exert predominantly tumor-inhibiting effects, whereas the IGF axis is of critical importance for proliferative events. The particular ratio of both important signaling seems to be decisive for tumor characteristics and treatment response. Our results therefore not only expand our knowledge of signaling pathways, but also indicate that fine-tuning of these signaling pathways provides new therapeutic options in clinical management of HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1315 IDENTIFICATION OF P73 AS A NOVEL TRANSCOCRATOR OF IGFBP4 GENE EXPRESSION IN HEPATOCELLULAR CARCINOMA

G. Gooswind1, S. Heckel2, E. Aschenbrenner1, K. Pollinger1, S. Schlosser1, C. Kunst1, M. Müller-Schilling2

1Department For Internal Medicine I, University Hospital Regensburg, Regensburg/Germany

Contact E-mail Address: sebastian-heckel@outlook.de

Introduction: Members of the p53-family, including p53, p63 and p73, are known for their involvement in the regulation of cell cycle, cell senescence and apoptosis. In their role as transcription factors and depending on their splice variants with transactivation domain (TA) or dominant negative (DN) - p53 and its siblings are capable of activating or inhibiting the transcription of specific target genes. We previously identified the gene for Insulin-like Growth Factor Protein 4 (IGFBP4) as p53-family family network and IGF signaling. Since in an independent study we identified and IGFBP4 we enhance our knowledge in a so far unknown association of p53-family members and IGFBP4.

Aims & Methods: The aim of the study was to characterize the regulatory influence of p53 family members on the IGFBP4 gene. Hep3B cells were transfected with pAp53, -pAp63, -pAp73, -pDNp63, and -pDNp73. Transcriptional regulation of IGFBP4 was determined by real time qPCR. Intracellular and extracellular IGFBP4 protein levels were examined by Western Blotting and ELISA. TransSAC database analysis was performed to identify potential p53-family binding sites in the IGFBP4 locus. Identified sequences were cloned, deleted, and analyzed by luciferase reporter assays to evaluate binding of p53-family members.

Results: IGFBP4 expression was increased by more than 30-fold in TA-pAp73-transfected Hep3B cells, by more than 15-fold in DNp63- and by 3-fold in pAp53-transfected cells. Induction of intracellular IGFBP4 protein was detected in all transfected Hep3B cells, whereas extracellular IGFBP4 levels were only measurable after TA-pAp73 and DNp63 transfection. Database analysis identified 2 putative p73 binding sites within intron 1 of the IGFBP4 gene. Intron 1-dependent luciferase activity was increased by up to 20-fold in TA-pAp73-transfected cells. This induction was reduced by up to 70% when one of the putative binding sites was deleted.

Conclusion: These results identify the IGFBP4 inhibitor hypothesis as novel target gene for pAp73 and IGFBP4 and enhance our knowledge in a so far unknown association of p53-family network and IGF signaling. Since in an independent study we identified IGFBP2 as a novel p53-family target gene, these results highlight the link between p53-family-mediated transcriptional mechanisms and IGF-dependent cell proliferation. We therefore suppose that the particular balance of these pathways decides on growth, cancerogenesis and treatment response.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1314 MONITORING OF LIVER FUNCTION IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE IN COMBINATION WITH METABOLIC SYNDROME

A. Ksenyiychuk, E. Skyjarov, N. Kurlaøy, A. Bochar

Therapy #1 And Medical Diagnostics, LNMU by Danylo Galytskyi Dept. of Therapy, Lviv/Ukraine

Contact E-mail Address: akskris@mail.ru

Disclosure of Interest: U3C-methacillin breath test (13C-MBT) is used to specify the detoxification function of the liver by determination its metabolic capacity and degree of hepatocytes recovery.

Aims & Methods: The study involved 113 patients with MS aged from 37 to 82 years. The average age was 55.8±5.3. There were 75 men and 38 women. The criteria, which has been examined for the functional state of the liver was 13C-MBT. The control group included 25 patients with a BMI of 25-30 kg/m2 without severe concomitant diseases. Indicators of 13C-MBT were metabolic rate, cumulative dose of 13C-methacelin on 40 and 120 minutes. Also evaluation was carried by mathematical deduction which measured the liver dysfunction stage.

Results: The data showed normal detoxification liver function in patients without MS (20.11% ±0.55). The results were below normal in patients with BMI higher than 25.25 kg/m2, which indicated that there were initial changes in the functional state of liver. In patients with steatosis - cumulative dose on 120 minute was 15.12%±0.49, which corresponded to a moderate reduction of detoxification function with the mass of function hepatocytes 50-100%. The data of 13C-MBT in patients with steatohepatitis showed pronounced changes of the liver detoxification function (8.88±0.64%). All indicators at steatosis group have indicated the moderate decline detoxification function with the level of function hepatocytes 50-100%.

Conclusion: In assessing to the data of 13C-MBT, main attention is paid to mathematical calculation of CO2 labeled methacetin. It allows to identify the early stages of the liver detoxification function violation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1316 NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH 2 TYPE DIABETES MELLITUS AND CORONARY HEART DISEASE AGAINST THE BACKGROUND OF METABOLIC SYNDROME. HOW TO DIAGNOSE?
K. Aksentiychuk, E. Sklyarow, N. Kurylak, A. Bochar
Therapy, #1 And Medical Diagnostics, LNMU by Danylo Galytskyi Dept. of Therapy, Lviv/Ukraine
Contact E-mail Address: akskris@mail.ru

Introduction: It is known that nonalcoholic fatty liver disease (NAFLD), which develops in progress of body mass index (BMI) from 19% to 35%, using instrumental and laboratory methods, which include an ultrasound, the determination of the transaminase levels, steatostest, 13C-methacetin test. However, these research methods do not allow to clearly differentiate steatosis from the steatohepatitis, that reduces their credibility.

Aims & Methods: 163 patients (75 men, 88 women) with 2 type diabetes mellitus and coronary heart disease with metabolic syndrome, were examined. The average age of patients was 55.8 + 9.2 years. The presence of steatosis was diagnosed as steatosis group, 66 - steatohepatitis group. In 25 patients liver pathology was not found, which identified as a control group.

For verification of steatosis and steatohepatitis diagnosis the level of ALT, diameter of vena portae and data 13C-methacetin breath test were evaluated.

Results: The rate of liver metabolism based on 13C-methacetine test results in patients without NAFLD was 22.0 ± 0.66%, in patients with steatosis - 17.1 ± 0.84%, steatohepatitis - 14.3 ± 0.62%. Cumulative dose of methacetin on 120 minute was 20.2 ± 0.46% in patients without pathology of liver, 16.1 ± 0.49% in patients with steatosis, 11.4 ± 0.36 in patients with steatohepatitis. ALT level in control group was 0.4 ± 0.05 mmol/l, with steatosis 0.84 ± 0.06 mmol/l, with steatohepatitis 6.9 ± 0.08 mmol/l. The diameter of vena portae in control group was 11.2 ± 0.26 mmn, in group of steatosis 11.9 ± 0.21 mm, in patients with steatohepatitis 13.7 ± 0.15 mm. There were investigated, that the rate of metabolism and its cumulative dose on 120 minute has decreased in steatohepatitis group in comparison of the control group, with simultaneous significant increasing of ALT level and diameter of the portal vein. However, a significant reduction of the metabolism rate of methacetin and the cumulative dose 13CO2 in the background of the increase of a diameter of vena portae correlated with a great severity of steatohepatitis group.

Findings: We found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of 13CO2 on 120 minute in patients with steatohepatitis. Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 0.68 mmol/l) and the diameter of the portal vein (13 mm).

Conclusion: The differentiation between steatosis and steatohepatitis should be moderate with the speed of a metabolism, a cumulative dose of methacetine on 120 minutes of MBT and vena portae diameter. The sensitivity of the method is based on the definition of the three proposed indicators - ALT level, total concentration of 13C-methacetin on 120 minute and the portal vein size, which is 75% for steatosis, and 76% for steatohepatitis.

Introduction: Liver fibrosis (LF) is a progressive pathological process resulting in accumulation of excess extracellular matrix proteins. A metalloprotease BMP1-3 is produced in the liver. Administration of BMP1-3 isoform circulates in the plasma and its neutralization resulted in an effective inhibition of the fibrosis progression. Administration of BMP1-3Ab was accompanied by antifibrotic therapy.

Aims & Methods: In our experiments the presence of BMP1-3 was immunohistochemically demonstrated in both healthy and cirrhotic liver suggesting that at least a part of circulating BMP1-3 is produced in the liver. Administration of BMP1-3 Ab reduced the amount of fibrosis which may progress from simple steatosis to NAS, cirrhosis and hepatocellular carcinoma (HCC). Our results suggest that neutralization of BMP1-3 is a promising therapeutic approach in preventing the liver fibrosis progression.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1318 LIVER TRANSIENT ELASTOGRAPHY IN NON-ALCOHOLIC FATTY LIVER DISEASE: IS THERE ANY PREDICTIVE ROLE IN THE DEVELOPMENT OF COLORECTAL POLYPS?
M. Gravito-Soares1, E. Gravito-Soares2, D. Gomes3, A. Simão1, L. Tome4

4Contact E-mail Address: ms18498@gmail.com

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational study. NAFLD was defined according to transient elastography by Fibroscan®, between 01/2015-02/2017. Exclusion criteria: age <18 years, absence of total colonoscopy with good preparation <3 years, inflammatory bowel disease, hereditary polyposis syndromes and personal/family history of colorectal polyps/neoplasia. Compared patients with colorectal polyps(cases) and without colorectal polyps(controls).

Results: Of the 237 NAFLD patients who performed Fibroscan®, 103 underwent total colonoscopy. The prevalence of colorectal polyps was 28.2% (n = 29): 19.4% (20/103) hyperplastic, 16.5% (17/103) adenoma and 4.8% (5/103) advanced adenoma/adenocarcinoma. The mean age was 58.32 ± 5.51 years (vs70.9 ± 10.53 p = 0.059), with men predominant (51.7% vs63.5%; p = 0.272), mostly located in the left colon (55.2% vs44.8%; p = 0.314) and number and mean size of 1.64 ± 0.88 and 6.90 ± 0.46 mm, respectively. After multivariate analysis, the presence of colorectal polyps was associated with F4 liver fibrosis (34.5% vs14.9%; p = 0.026; OR = 3.01) and obesity (BMI > 30 kg/m²; 55.2% vs29.7%; p = 0.016; OR = 2.91); hyperplastic polyps were associated with liver fibrosis for a cut-off value of 6.96 kPa (AUROC 0.689 ± 0.008; S = 85.7%; Sp = 51.2%); mainly F4 (42.8% vs14.6%; p = 0.004; OR = 4.38), hyperuricemia/gout (23.8% vs8.5%; p = 0.040; OR = 3.35) and peptic ulcer disease (9.5% vs1.2%; p = 0.043; OR = 8.53); adenoma was associated with liver steatosis (88.2% vs83.7%; p = 0.024; OR = 3.50), F4 liver fibrosis (41.2% vs16.2%; p = 0.006; OR = 3.24) and obesity (85.8% vs33.6%; p = 0.040; OR = 2.39); advanced adenoma/adenocarcinoma was associated with F4 fibrosis (20.0% vs1.2%; p = 0.02; OR = 12.24), hyperuricemia/gout (40.0% vs10.3%; p = 0.044; OR = 0.040; OR = 1.50) and dilated cardiomyopathy (20.0% vs11.0%; p = 0.003; OR = 1.24).

Conclusion: More than 1/4 of the patients with NAFLD have colorectal polyps, being 16.5% adenoma and 4.8% advanced adenoma/adenocarcinoma. Obesity and liver steatosis are independent risk factors for colorectal adenoma. Liver fibrosis, especially F4 is an independent risk factor for all types of colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1319 „SUBTRACTED ADULTHOOD MASS INDEX“ (SAMI)- A NEW INDEX TO PREDICT NAFLD RISK IN NON-OBSE INDIVIDUALS
A. Kyak1, S. Eltorb1, M. Sarsc2, O. Sayghi2, N. Tözün3

Contact E-mail Address: atakiyak@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinicopathological entity from which may progress from simple steatosis to NAS, cirrhosis and hepatocellular carcinoma (HCC). Obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be a sine qua non for the presence of NAFLD. Recent studies suggested that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research; the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasonography(USG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the USG was defined as the diagnostic between the HP level in liver, morphometric analysis and elastography of the liver.

Conclusion: Our results suggest that neutralization of BMP1-3 is a promising therapeutic approach in preventing the liver fibrosis progression.

Disclosure of Interest: All authors have declared no conflicts of interest.
limit for hepatosteatosis. The beginning of adulthood was taken as 20 years old. Exclusion criteria were: HbA1c or anti-HCV positivity, alcohol use, liver disease, pregnancy, cancer treatment, renal insufficiency, being younger than 25 years old. Patients were evaluated for the presence of diabetes, hypertension or cardiovascular disease and ALT, AST, fasting plasma glucose and cholesterol values were recorded. Statistical evaluations were done with IBM SPSS.

NAFLD evaluation with SAMI 3 cut-off value

| SAMI > 3 | 144 | 38 |
| SAMI < 3 | 25 | 77 |

Sensitivity: 85.2%
Specificity: 66.95%
PPV: 79.12%
NPV: 75.49%

Results: Among 362 participants 169(46.7%) were men with an average age of 44.81 ± 10.73. 78 (21.6%) participants were overweight, the average age of the group being 46.78 ± 9.12. Out of 78 obese individuals 73 (93.5%) were NAFLD(+). The average age of the 284 (78.4%) non-obese subjects was 44 ± 11.05. Among non-obese people 169(59.5%) were NAFLD(+) and average age was 48.07 ± 10.13 with a SAMI > C6 people was 38.729. Non-obese NAFLD(+) patients reported they had gained significant amount of weight during their adulthood. This information led us to create, a new index named “Subtracted Adulthood Mass Index” (SAMI) to estimate the risk of NAFLD development in non-obese individuals. SAMI is calculated by dividing the difference between the subject’s current weight and his/her weight at the age of 20 years to his/her height squared(kg/m²). SAMI values for non-obese attendants were calculated. When the cut-off value was set as SAMI 4 kg/m², sensitivity was 76.3%, specificity was 79.1, positive predictive value was 84.3% and negative predictive value(NPV) was 69.4%. At a cut-off of SAMI 3 kg/m² sensitivity was 85.2%, specificity was 66.9%, PPV was 79.1%, and NPV was 75.4%.

Conclusion: In this pilot study, we found that weight gain in adulthood is an important predictor of NAFLD development in non-obese individuals. The new index named SAMI can correctly identify non-obese people under the risk of developing NAFLD. Cut-off value of SAMI has been set as 3.5 kg/m². We also observed that NAFLD prevalence increases as SAMI value goes up. We propose that SAMI is appropriate for clinical use to estimate the risk of NAFLD in on-obese individuals.

Contact E-mail Address: guttmann.sarah@ukmuenster.de

Introduction: Cisplatin-treated cancer patients often face therapy failure caused by acquired cisplatin resistance. Development of resistance was previously associated with modulation of transporters mediating cellular copper metabolism. Overexpression of the Wilson disease protein ATP7B, a TGN copper transporter, was proposed to increase cellular cp efflux.

Aims & Methods: The human hepatoma cell line HepG2 was compared with a HepG2-variant lacking functional ATP7B expression (KO) in regard to cp sensitivity. Hepatoma cell lines were generated that displayed cp resistance by step-wise increasing cp concentrations. Cells were examined via growth, cell viability assay (MTT) and analysed for apoptosis (Annexin V staining). Inducively coupled plasma mass spectrometry was used to determine intracellular cp level. Gene expression analysis (RT-qPCR) was carried out to determine the expression of various transporters. Overexpression of individual transporter genes in siRNA treatment was used for confirmation of the data.

Results: Treatment of HepG2 and KO cells with various cp concentrations revealed no significant differences in cell viability and intracellular cp accumulation when examining KO cells that lack ATP7B can adapt to high cp levels, a cp resistant subtype (CpR) was generated. Cp resistance was confirmed by viability assays and increased intracellular cp load. Gene expression analysis of more than 16 transporters demonstrated an upregulation of metallothionein 1 (MTT: 8.91 ± 4.4) and a downregulation of organic cation transporter 3 (OCT3: -5.17 ± 2) compared to control cell lines. Weaning and regrowth of the CpR cell line in the absence of cp revealed a stable phenotype of resistance in the cells.

Conclusion: We suggest that ATP7B does not seem to be involved in cp resistance, at least in hepatic cells. OCT3 represents a novel marker of cp resistance. OCT3 expression could be a valuable tool for improved prognosis of cisplatin therapy.

Contact E-mail Address: kawaguy222@gmail.com

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738409 in the PNPLA3 gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD).1,1 However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-densyTM, which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90min.

Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the PNPLA3 gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-densy fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5’-cctctctctgctttgacag-3’ and 5’-ggggctgcctggaaagga-3’ respectively. PCR consisted of initial denaturation for 1 min at 95°C, and 60 cycles of denaturation at 95°C for 1s and annealing at 61°C for 30s. After completion of the PCR, we analyzed melting temperatures. The SNP genotypes were determined by monitoring the change in fluorescence intensity with increasing temperature. The results obtained with the QP method were compared with those obtained with the conventional DS method. Then, we analyzed 73 patients with NAFLD according to PNPLA3 genotype in terms of alanine aminotransferase (ALT), aspartate aminotransferase to platelet ratio index (APRI), Fibroscan value, and cumulative hepatocellular carcinoma (HCC) development rate.

Results: The genotypes obtained with the QP method were identical to those obtained with the conventional DS method. In 73 patients with NAFLD, the frequency of the PNPLA3 genotypes CC, CG and GG was 21 (28.8%), 24 (32.9%) and 28 (38.4%), respectively. Serum ALT, APRI and Fibroscan value according to PNPLA3 genotypes CC, CG and GG were 26 (14-59), 32 (11-113) and 46 (17-175) U/L, 0.3 (0.1-1.0), 0.5 (0.2-6.8) and 0.7 (0.2-3.1), and 4.4 (2.7-25.1), 5.6 (2.5-26.5) and 6.6 (3.6-38.6) kPa, respectively (p=0.001, p=0.001 and p=0.033 by Jonckheere-Terpstra test). HCC developed in none of the patients with CC genotype, one (4.2%) with CG and four (14.3%) with GG. The cumulative HCC development rate in patients with GG genotype was significantly higher than that in those with CC + CG genotype (p=0.043 by log-rank test).

Conclusion: The i-densy using the QP method can automatically, quickly and easily identify PNPLA3 genotypes in real-world clinical settings. These findings indicate the feasibility of personalized medicine for NAFLD.

Copper metabolism and suggests a new role of MDR1 in the pathogenesis of WD. Our analysis of long-term Cu exposure presents new insights in from a WD patient and from the rat animal model confirmed our observations. The intracellular Cu load was significantly affected by siRNA and verapamil indicating by siRNA and drug activation (verapamil). Notably, cell viability and gained resistance (CuR). Characterization of CuR cells revealed increased survival gain resistance (CuR). Characterization of CuR cells revealed increased survival.

Aims & Methods: We aimed to examine the efficacy of orlistat versus placebo in reducing liver fat content by the magnetic resonance imaging (MRI) based on chemical shift imaging. A total of 51 NAFLD patients diagnosed by MRI were randomly assigned to receive trice-daily 120mg oral Orlistat or placebo for 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received.

Results: Parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), fasting plasma insulin (FPI), homeostasis model assessment IR (HOMA-IR). The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique in two-point chemical shift-faceted fat-water separation method. The chi-squared and paired t test were used to compare mean differences between fat fractions between two groups.

Conclusion: Orlistat was higher in Orlistat group (31.38 ± 3.19) than that of the placebo group (26.78 ± 3.02; p < 0.001), while the baseline characteristics including liver fat fraction and the proportion of hypertension, hyperlipidemia, diabetes mellitus type 2, and obesity were similar. Compared to baseline, end-of-treatment liver fat content was significantly lower in the Orlistat arm (19.38% ± 9.52% to 11.56% ± 7.49%, change was 7.72 ± 6.39%; P = 0.001) but not in the placebo (16.05% ± 8.7% to 14.17% ± 9.58%, change was 1.43 ± 9.54%; P = 0.640) arm. Change of BMI was the only independent factors correlated with reduction of liver fat content (β = 0.522, p = 0.006).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1323 LONG-TERM COPPER EXPOSURE OF HEPATIC CELLS LACKING FUNCTIONAL ATP7B
Transplantationsklinik, Universitätsklinikum Münster, Münster/Germany

Contact E-mail Address: guttmann.sarah@ukmuenter.de

Introduction: Copper transporter ATP7B is essential for hepatic Cu homeostasis and loss of function is associated with the inherited autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and brain. Understanding of molecular mechanisms involved in Cu homeostasis is essential to improve therapeutic options. The molecular impact following long-term Cu elevation in hepatic cells lacking functional ATP7B has not been explored.

Aims & Methods: HepG2 cells lacking functional ATP7B (KO) were used for generation of a copper resistant subline (CuR). Cell growth, cell viability (MTT) and intracellular Cu load (atomic absorption spectroscopy) was assessed. RT-qPCR was performed to quantify the expression of genes related to Cu homeostasis genes. Functional analysis of candidate genes was assessed via siRNA transfection. Additiona...
Conclusion: We conclude that Fibroscan® represents an eligible tool to diagnose liver diseases in Austrian bank employees. Compared to the previous work of Bedogni et al. FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FibroScan®CAP is more sensitive than ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis.

Aims & Methods: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA)) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolomic profile identified four metabolites that are associated with severe fibrosis: 1,25(OH)2vitamin D, (p = 0.003), isosoprophatidyl-letanolamine LPE 0:22:6 (p = 0.05), Lysocephatidylcholine LPC 18:2 (p = 0.003), and high levels of butenyl carnitine (p = 0.04). Of these, LPE was the strongest predictor of severe fibrosis (AUROC-0.795, Sensitivity (Se) = 88.33%, specificity (Sp) = 78.79%), but the others molecules were also significantly associated with severe fibrosis: vitamin D (AUROC = 0.776), butenyl carnitine (AUROC = 0.737), LPC 18:2 (AUROC = 0.768). As the metabolomics permits the evaluation of all these molecules the same time, we can use them combined in order to increase the diagnostic accuracy. In our case, the combined use of the four metabolites determined an AUROC of 0.839, with Se of 100% and Sp of 68.5%.

Conclusion: In metabolomics, we can identify patients with fatty liver and severe fibrosis who are significantly exposed to a progressive disease and a higher mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1327 CHRONIC RENAL FAILURE IS ASSOCIATED WITH THE DEVELOPMENT OF NAFLD/NASH
S. Gehring¹, P. Di Fazio², T. M. Gress³, T. T. Wisniowski¹
¹Gastroenterology, Philipps University, Marburg/Germany
²Department Of Visceral Thoracic And Vascular Surgery, Philipps University Marburg, Marburg/Germany
³Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektiologie, Philipps Universität Marburg, Marburg/Germany

Contact E-mail Address: sonjagehring@gmx.de

Introduction: Chronic renal failure (CRF) is frequently associated bone metastasis particular in case of hemodialysis. Younger studies suggest an association of low vitamin D levels with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH), as well as metabolic syndrome, and diabetes mellitus. Unfortunately, a causality could not yet be proven.

Aims & Methods: Our aim was to identify patients on higher risk to develop NAFLD/NASH in a selected patient cohort being admitted for renal disorders.

176 patients, admitted to the department of nephrology of the University Hospital Marburg for renal disorders whose plasma vitamin D concentration, phosphate and parathormone levels and liver enzyme levels had been quantified beforehand, were enrolled and a retrospective investigation of laboratory parameters (including electrolytes, hormones, and vitamins) and pre-existing medical conditions (including high blood pressure, diabetes, hyperlipoproteinaemia, and more) followed. Appropriate statistical test were used to characterise the cohort (ANOVA; MANN-Whitney-U; FISHER-EXACT) using SPSS™. Other hepato-pathies were excluded. Steatosis was assessed by ultrasonography.

Results: Patients were divided into 4 groups according to plasma vitamin D levels (normal > 25 ng/ml; low < 25 ng/ml) and transaminase levels (AST/ALT > GT > 30 U/l; normal; AST/ALT > GT < 30 U/l). Low 1,25-hydroxyvitamin D levels correlated significantly with high creatinine, urea, and LDL levels, while low 25-hydroxyvitamin D levels correlated with high cholesterol and triglyceride levels, suggesting a relationship between low vitamin D levels and fat metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was significantly related with the development of NAFLD/NASH with significantly higher levels of AST/ALT and gGT, hyperparathyreodism and hyperphosphate-mia. Transaminases were significantly lower if Vitamin D was supplemented.

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present. Supplement of Vitamin D saves from NAFLD/NASH. The correlation of hyperparathyreodism and NAFLD/NASH has to be further investigated in larger patient groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1328 NONINVASIVE DIAGNOSTICS OF NONALCOHOLIC FATTY LIVER IN PATIENTS WITH TYPE 2 DIABETES MELLITUS
K. Aksentiyevych1, E. Sklyarova2, A. Bochar2
1Therapy #1 And Medical Diagnostics, L/NU by Danilo Galyszkij Dept. of Therapy, Lviv/Ukraine

Introduction: Usually for the determination of nonalcoholic fatty liver disease (NAFLD) there are instrumental and laboratory techniques, including ultrasound diagnosis, determination of amino transferases, steatotest, 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prediction of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis oftenly with subsequent liver parenchyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Aims & Methods: The study involved 65 patients with type 2 diabetes and coronary heart disease with metabolic syndrome, aged 37 to 82 years (mean age 53.82 ± 3.46), 29 men, 36 women. According to the ultrasound, the stage of fatty infiltration were differentiated by such criteria for steatosis as diffuse liver parenchyma and expansion of portal vein (13 mm or more in diameter).

Results: For steatosis and steatohepatitis determination the ALT monitoring was used, where the level exceeding 0.68 mmol/l signed to steatohapatitis, and below 0.68 mmol/l - to steatosis. Portal vein diameter size above 13 mm subscribed in infiltration were differentiated by such criteria for steatosis as diffuse liver parenchyma and expansion of portal vein (13 mm or more in diameter).

Conclusion: Differentiation between steatosis and steatohepatitis should be performed in the early stages of disease.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1329 NON-OBESIVE FATTY LIVER DISEASE IN TYPE 2 DIABETES: NOVEL CONDITION OR SIMILAR TO TYPICAL NAFLD STATE?
N. Kobyliak1, N. Bosak2, G. Mykhalchyshyn1, D. Kyriienko3, O. Dynnystk
1Endocrinology, Bogomolets National Medical University, Kyiv/Ukraine
2Bogomolets National Medical University, Kyiv/Ukraine
3Kyiv City Clinical Endocrinology Center, Kyiv/Ukraine

Introduction: Non-alcoholic fatty liver disease (NAFLD) is hepatic counterpart of the metabolic syndrome in close relation to obesity and encompasses a disease spectrum spanning simple steatosis through nonalcoholic steatohepatitis (NASH) with or without liver fibrosis, and hepatic neoplasms including carcinoma [1]. Clearly, not all obese subjects develop NAFLD and NAFLD can also be found in non-obese patients. Globally, the reported prevalence of non-obese NAFLD varies widely, ranging from 3% to 30% [2]. Today remains unclear how patients without obesity should be managed and therefore it is important to understand the clinical and pathological conditions of non-obese NAFLD.

Aims & Methods: In this study, we investigated the liver stiffness and liver fat content in addition to other clinical and metabolic parameters in type 2 diabetes patient with non-obese and obese NAFLD detected on ultrasoundography (US). In this cross-sectional study, 245 T2D patients with age of 40–80 years from the Kyiv City Clinical Endocrinology Center were selected. Inclusion criteria were: age ≥ 18 years, presence of T2D in association with fatty liver disease. The diagnosis of fatty liver was based on the results of abdominal ultrasoundography, which was done by trained technicians with Ultima PA (Radmir Co., Kharkiv, Ukraine). Of 4 known criteria (hepatic echo contrast, liver brightness, deep echo enhancement, and vascular blurring), the participants were required to have hepatic parenchymal hypoechoic contrast and liver brightness to be given a diagnosis. According to body mass index (BMI) value patients were assigned else to NAFLD group (n = 157, BMI ≥ 30.0 kg/m2) or to non-obese NAFLD (n = 88, BMI < 30.0 kg/m2) group.

We performed 10 valid measurements of liver stiffness (LS) measured by trans- Wave Elastography (SWE) in every patient, and a median value was calculated, the result being measured in kPa. Also in all patient we calculated fatty liver index (FLI). FLI a validated prediction score for hepatic steatosis severity designed Bedogni et al [3]. Changes in transaminases activity, serum lipids and cytokines (TNF-α, IL-1β, IL-6, IL-8, INF-γ) levels were evaluated.

Results: Non-obese NAFLD patient had higher LS (7.52 ± 0.2 vs 6.87 ± 0.09, p = 0.001) values measured by SWE, which were accompanied with increased transaminases activity; for ALT 42.1 ± 3.17 vs 35.8 ± 1.28 (p = 0.028) and for AST 40.81 ± 2.68 vs 34.31 ± 1.33 (p = 0.016) respectively. In contrast to non-obese group patient in NAFLD group had significantly higher FLI (68.59 ± 1.09 vs 68.06 ± 1.98, p < 0.001). Markers of chronic systemic inflammatory state were also significantly higher in NAFLD obese as compared to non-obese patient: IL-1β 44.64 ± 2.0 vs 31.02 ± 1.78 (p < 0.001); TNF-α 54.11 ± 2.20 vs 42.28 ± 1.81 (p = 0.001); IL-8 29.18 ± 1.27 vs 22.05 ± 0.99 (p = 0.001) and INF-γ 195.60 ± 9.47 vs 132.47 ± 5.74 (p = 0.016) respectively. Changes of IL-6 between groups were non-significant.

Conclusion: At present, the clinical-laboratory characteristics of non-obese NAFLD are not fully understood. Therefore, we found that non-obese NAFLD associated with higher liver stiffness values and transaminases activities. Our other hand, patient with obese NAFLD are characterized with more pronounced liver fat content and elevation of markers of chronic systemic inflammatory state.

Contact E-mail Address: eshraghia@yahoo.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is usually considered as the hepatic manifestation of metabolic syndrome and obesity. However, a subgroup of NAFLD patients are lean. Some studies have reported severe liver fibrosis in lean NAFLD and these patients are still at risk for development of liver cirrhosis.

Aims & Methods: This study aimed to investigate the prevalence and risk factors of lean NAFLD in a cluster of Iranian population. Study population was recruited from Kavar cohort study which has been started from 2006 in Kavar town, a small town near Shiraz. The study sampling was performed between September 2011 and September 2015 among adult subjects (age >18 years) who underwent voluntary hepatobiliary ultrasound. NAFLD was diagnosed using abnormal sound and absence of chronic liver diseases such as autoimmune hepatitis, hepatitis B or C viruses induced hepatitis, hepatobiliary cancers, Wilson’s disease, >10 g/day alcohol consumption, and receiving some specific medications known to cause hepatic steatosis (like amiodarone, valproic acid, etc). Lean individuals were defined as those with body mass index (BMI) <25 kg/m². Student’s-t test was used for comparisons of continuous variables and Chi-square test was used for comparison of categorical variables. Receiver operating characteristics (ROC) curve analysis using area under curve (AUC) was used for analysis of optimum cutoff values for BMI and waist circumference in association with lean NAFLD.

Results: 1343 individuals were included. 165 individuals (12.3%) was diagnosed to have NAFLD. 129 individuals (9.6%) had mild NAFLD and 36 individuals (2.7%) had moderate NAFLD. None of the participants had severe NAFLD. In univariate analysis, history of diabetes mellitus (DM) (OR = 2.25; 95% CI: 1.15-4.40, P = 0.015) and metabolic syndrome (OR = 2.80; 95% CI: 1.74-4.48, P < 0.001) were associated with NAFLD. Higher BMI and waist circumference, higher systolic and diastolic blood pressure, higher serum triglyceride, cholesterol, fasting plasma glucose (FPG) and alanine aminotransferase (ALT) were associated with NAFLD (P < 0.03). In multivariate regression analysis, higher BMI and waist circumference, higher serum ALT, FPG and cholesterol were independent predictors of NAFLD in our study population (Table). A cutoff value of 22.3 kg/m² for BMI was predictor of NAFLD (sensitivity = 72%; specificity = 60%; AUC = 0.728, P < 0.001). A cutoff value of 79.5 cm for waist circumference was predictor of NAFLD in our study population (sensitivity = 80%; specificity = 68%; AUC = 0.753, P < 0.01). Table: Multivariate regression analysis showing independent risk factors for lean NAFLD.

Conclusion: Lean NAFLD was prevalent in our study population and was associated with metabolic risk factors. BMI and waist circumference can be used for prediction of lean NAFLD.

Introduction: While some studies have evaluated the ability of new “real-time” elastography devices such as 2-D Shear Wave Elastography (SWE) and Virtual Touch Quantification (ARTI) in predicting the presence of high-risk gastroesophageal varices, no study has explored the potential role of another point-shear wave technique, ElastPQ, in the assessment of clinically significant portal hypertension.

Aims & Methods: The aim of our study was to identify a liver stiffness cut-off value measured by ElastPQ and/or laboratory parameters that could help identify patients who can undergo endoscopic screening endoscopy. We recently proposed Baveno VI criteria which recommends a liver stiffness value <20kPa measured by transient elastography in combination to a platelet count >150,000/μl. Data were collected on 1385 patients who underwent ElastPQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a liver stiffness value of ≥7 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. We choose this specific liver stiffness cut-off value in order to highlight partially advanced fibrosis and cirrhosis, based on the limited literature available on this specific elastographic technique. Exclusion criteria were history of decompensated liver disease, evidence of porto-spleno-mesenteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 184 patients (114 [62%] hepatitis C, and 160 [87%] Child-Pugh A). Varices were present in 36% cases, with 10% prevalence of high-risk varices. According to ROC curve analysis liver stiffness measurement and...
platelet count were evaluated as predictors of high-risk varices. Overall 74/184 (40%) met the new “BAVElastPQ” criteria (that is, liver stiffness <12 kPa and platelet count >150,000/µl). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high-risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value of 0.51 and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients with high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new p-SWE technique such as ElasIPQ in the non-invasive assessment of clinically significant portal hypertension, similarly proposed Baveno VI criteria though using ElasIPQ as an alternative to transient elastography.

Introduction: Inhibitors of PPIs are commonly prescribed and predispose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake, infection and hepatic encephalopathy at hospitalization. Statistical analysis was performed using chi-square and PPS 21, considering statistical significance p < 0.05.

Results: 386 patients, 321 males (83.2%), mean age 60.3 ± 12.1 years. Main etiologies of cirrhosis were alcohol (67.4%), alcohol plus hepatitis C (16.3%) and hepatitis B virus (5.2%). Hepatic encephalopathy was present in 222 (57.5%) of the patients and 26.9% had PPI intake. In univariate analysis hepatic encephalopathy was associated with infection (p < 0.001), gastrointestinal bleeding (p < 0.001) and Model for End-Stage Liver Disease (MELD) (p < 0.001). There was no association between hepatic encephalopathy and PPI intake (p = 0.057), gender (p = 0.228) or age (p = 0.352). In multivariate analysis, hepatic encephalopathy maintained association with infection (p < 0.001), gastrointestinal bleeding (p < 0.001) and MELD score (p = 0.001).

Conclusion: In our series, PPI intake was not associated with hepatic encephalopathy development in cirrhotic patients.

Introduction: The incidence of bacterial infections in cirrhotic patients is significantly higher than that observed in general population, being one of the most important causes of decompensation. In theory, the final result of an infectious disease depends of three major factors: the antibiotic resistance of the bacteria and the degree of virulence or pathogenicity of the bacteria; and finally the patient status in relation to risk factors such as immune status, age, diet and stress. There are conflicting results regarding the clinical outcome of multidrug-resistant (MDR) bacterial infections in cirrhotic patients.

Aims & Methods: Our aims within this study were to 1) analyze the incidence of MDR bacteria in patients with decompensated cirrhosis at admission (less than 24 hours after hospitalization), 2) to study its impact on 30 and 90-day mortality, and 3) to identify independent risk factors for 30 and 90-day mortality. We conducted a retrospective cohort study which evaluated all admissions due to decompensated cirrhosis in one center between 2010 and 2015. MDR bacterial infections, its acquisition site and the antibiotic resistance patterns were defined according with the European Centre for Disease Prevention and Control (ECDC) criteria.

Results: A total of 681 hospitalizations were evaluated and 41% had a bacterial infection at admission. The 30 and 90-day mortality rate was 14.7% and 38.1%, respectively. The most common infection was spontaneous bacterial peritonitis (SBP; 40.5%), followed by urinary tract infection (UTI; 25%). About 55.6% of the patients had a microbiological documented infection (MDI). MDR bacteria were identified in 18.6% of all bacterial infections, matching 34.5% of the nosocomial acquired infections and 8.3% of the community-acquired (CA) infections. Of patients in whom MDR by a MDI was documented, no infections, no difference was noticed between non-MDI, non-MDR bacteria or MDR bacteria matching 30 (p = 0.801) and the 90-day (p = 0.525) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SpO2 were independently associated with 30 and 90-day mortality. Higher INR and age were independently associated with 90-day mortality.

Conclusion: The presence of bacterial infection, independently of the antibiotic profile, was associated with a worse prognosis in cirrhosis. In patients with documented infections, no differences was noticed between non-MDI, non-MDR bacteria or MDR bacteria matching 30 (p = 0.801) and the 90-day (p = 0.525) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SpO2 were independently associated with 30 and 90-day mortality. Higher INR and age were independently associated with 90-day mortality.

P1334 STATIN THERAPY IN THE REDUCTION OF PORTAL HYPERTENSION IN PATIENTS WITH LIVER CIRRHOSIS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

J.G. E. Cataluna, J. G. Cervantes
Institute Of Digestive And Liver Diseases, St. Luke’s Medical Center - Quezon City, Quezon City/Philippines

Contact E-mail Address: doycataluna@yahoo.com

Introduction: Statins have been shown to decrease intrathoracic vascular resistance and improve portal blood flow, reducing portal hypertension. The objective of this research was to perform a meta-analysis of randomized controlled trials (RCTs) to determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among adult patients with liver cirrhosis.

Aims & Methods: The objective of this research was to perform a meta-analysis of randomized control trials (RCTs) and determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among adult patients with liver cirrhosis.

Results: Three trials comprising of 98 patients met the inclusion criteria. In the random-effect model, the weighted mean difference was 0.76 mmHg, favoring statin therapy over placebo. There was no evidence of significant heterogeneity (I2 = 0%, Q = 0%).

Conclusion: Statin therapy reduces portal hypertension as measured by the HVPG among adult patients with liver cirrhosis. The findings of this study reinforce the promising role of statins in decreasing portal hypertension. Further RCTs with larger population and with longer duration of follow-up as well as the use of different statin drugs to explore further on the class effect are recommended.

Introduction: The place of noninvasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research topics.

Aims & Methods: The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV). Material and method We did a prospective multicentre study, from September 2016 to December 2016, which included all patients with perfectly compensated HCV liver cirrhosis, diagnosed by means of elastography, ultrasound, endoscopic and biological criteria prior to interferon-free treatment. All patients were evaluated by upper gastrointestinal endoscopy, transient elastography and CRBPs tests. By using these criteria we classified the patients in: probably without EV (lower stiffness: LS < 20 kPa and thrombocytes > 150,000/mm³), probably with EV (LS ≥ 25 kPa and the “gray zone” in between these criteria.

Results: Out of 403 patients, 127 (30.7%) had LS < 20 kPa, 89 (22%) had LS between 20–25 kPa, 190 (47.3%) had LS ≥ 25 kPa, 120 (29.7%) had thrombocytes > 150,000/mm³, while 283 (70.3%) had thrombocytes < 150,000/mm³. For the subgroup probably with EV, the Baveno VI criteria had PPV = 84.6% (Se = 90.7%, Sp = 74.6%), NPV = 26.8% for predicting the presence of esophageal varices, while for the subgroup probably without EV had NPV = 80.3% (Se = 50.2%, Sp = 58.6%, PPV = 75.6%). The subgroup that had LS < 20 kPa and thrombocytes > 150,000/mm³, was composed of 60 patients. Using these criteria, only classified 80% patients, with a Se = 80%, Sp = 28.3%, PPV = 59%, NPV = 61.2%, AUROC = 0.70, CI (= 0.68-0.71). The best cut-off value for TE for predicting the presence of EV of any grade in our group was >23 kPa, AUROC 0.79 (Se = 68.8%, Sp = 56.9%, PPV = 44.7%, NPV = 78.4%).

Conclusion: By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

Introduction: Non-invasive fibrosis scores (NIFs) are increasingly replacing liver biopsy as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using ANOVA and Pearson’s correlation coefficient. Results: A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

Aims & Methods: We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained. Healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained. Within the CLD cohort, sensitivity 97.7% and specificity 72.7% for detecting the presence of MHE were reported. 78 patients had a positive PHES test and the Stroop test was performed on all patients. Both tests were compared and correlation coefficients calculated. Results were compared amongst patient groups using a student t-test, where p < 0.05 was considered significant. ROC analysis was used to establish a standard local cut-off for a positive Stroop test.

Results: A total of 96 patients (51 men) were recruited. Overall, the mean age was 51.7 ± 16.6 years; mean years spent in education 13.8 ± 4.2. In all there were 35 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the controls, 23/35 (66%) vs. 28/61 (46%), p = 0.06. Within the CLD cohort, 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4/35 (11%) vs. 3/61 (5%) (p = 0.009). In total, 39 patients had an on time of >187 seconds as a positive cut-off for our PHES test, sensitivity 97.7%, specificity 72.7%, positive likelihood ratio 18.9, negative likelihood ratio 0.02. However, mean Stroop on-off times were similar, 190 ± 130 s as a positive cut-off for the Stroop test, sensitivity 59%, specificity 88%, positive likelihood ratio 2.4, negative likelihood ratio 0.12. However, neither age nor years of education correlated with performance on the PHES test (r = 0.087, r = 0.12, respectively).

Introduction: Minimal Hepatic Encephalopathy (MHE) is present in more than 30% of patients with chronic liver disease (CLD), and is associated with a poor prognosis including a higher incidence of falls, RTAs and overall mortality. Detection of MHE is often difficult due to time constraints associated with the current gold standard, the psychometric hepatic encephalopathy score (PHES), which includes five paper-based tests. A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

Aims & Methods: We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using ANOVA and Pearson’s correlation coefficient. Results: A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

**Aims & Methods:** We hypothesized that probiotic bacteria repress intestinal pathogen growth and that can translocate through a weakened gut barrier and cause severe infections. Therefore, we conducted a randomized, double-blind, placebo-controlled trial to test the effects of the multispecies probiotic Ecologic Barrier (Winclove, Amsterdam, The Netherlands)/Omnibiotic Hetox (Allergosan, Graz, Austria) on microbiome composition, predicted metagenome functions, and tight gut barrier.

**Conclusion:** This is the first study investigating the efficacy of the Stroop test in Ireland. It was quicker and easier to perform compared to PHES test. Age and years in education had a greater impact on the Stroop test, which may affect its application and interpretation. While our ROC analysis suggests a similar cut off to previously published values, there is significant variability and local validation is likely to be required. Overall the comparison with the gold standard PHES was poor. However, there were no false negative Stroop tests suggesting it may be a convenient filter test for MHE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and strengthen the gut barrier.

**Aims & Methods:** Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecologic Barrier (Winclove, Amsterdam, The Netherlands)/Omnibiotic Hetox (Allergosan, Graz, Austria) on microbiome composition, predicted metagenome functions, and tight junction function in cirrhosis patients. A once daily dose of the probiotic mixture (1.5x10^10 CFU) or placebo was administered to 58 patients with Child's A cirrhosis. We analysed the stool microbiome prior, immediately after the intervention and six months following end of treatment. Hypervariable region 1–2 of the bacterial 16S rDNA was sequenced and predictive communities were identified using Ada Boost Classifier. Functional predictions were analysed by Phylogenetic Investigations of Communities by Reconstruction of unobserved States (PICRUSt). Zonulin and calprotectin were assessed in stool as markers for gut permeability and intestinal inflammation, respectively.

**Results:** A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: Lactobacillus brevis and Lactococcus lactis increased significantly and Enterococcus durans decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUSt) and calprotectin did not show any differences during intervention.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Diabetes mellitus (DM) is a growing disease worldwide. Some previous studies have reported negative impact of DM in patients with chronic liver disease.

**Aims & Methods:** This study aimed to investigate the prevalence of DM in patients with liver cirrhosis and its impact on post-liver transplant short-term and long-term outcomes. In a cross-sectional study patients with liver cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥126 mg/dL or random plasma glucose ≥200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

**Results:** 1014 patients were included in the study. 259 patients (25.5%) found to have DM. Prevalence of DM was significantly higher among patients with cirrhosis due to non-alcoholic steatohepatitis (NASH) (P < 0.001). Portal vein thrombosis (PVT) was significantly higher among cirrhotic patients with DM (OR = 1.79; 95% CI: 1.18–2.70; P = 0.005). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05).

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Rejection episodes (OR = 1.38; 95% CI: 0.47–4.11, p = 0.129) and acute kidney injury (OR = 0.96–1.84, p = 0.07) after liver transplantation were not statistically different in patients with and without DM. Using Kaplan-Meier method, mean post-liver transplant survival was 50.04 ± 0.67 months in cirrhotic patients without DM and 45.26 ± 0.14.6 months in cirrhotic patients with DM (p < 0.001). Post-liver transplant survivals at 6 months, 1 year and 4 years were outlined in Table. In patients with DM, presence of hepatocellular carcinoma (HCC) (OR = 4.61; 95% CI: 1.64–7.98, p = 0.002), acute kidney injury within 30 days after transplant (OR = 2.65; 95% CI: 1.02–4.10, p = 0.042) and pre-transplant PV (OR = 2.51; 95% CI: 1.16–5.14, p = 0.019) were independent predictors of mortality after liver transplantation.

Table: Post-liver transplant survival at 6 months, 1 year and 4 years in patients with and without DM

<table>
<thead>
<tr>
<th>Conditions</th>
<th>6 month survival</th>
<th>1 year survival</th>
<th>4 year survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>With diabetes</td>
<td>81% ± 2.5%</td>
<td>79.1% ± 2.6%</td>
<td>75.9% ± 2.8%</td>
</tr>
<tr>
<td>Without diabetes</td>
<td>90.6% ± 1.1%</td>
<td>87.8% ± 1.2%</td>
<td>85.4% ± 1.3%</td>
</tr>
</tbody>
</table>

Conclusion: Diabetes mellitus is prevalent in patients with liver cirrhosis especially among those with NASH. Patients with DM may have lower post-transplant survival and need more intense follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P3140 VALIDATION OF THE BAVENO VI CRITERIA ON A COHORT OF CIRRHOTIC PATIENTS

I.M. Ratiu1, R. Lupusoru1, N. Baltes1, I. Sporea1
1Department Of Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania
2Gastroenterology, Pediatrics, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: ratiu_iulia@yahoo.com

Introduction: The Baveno VI guidelines propose that cirrhotic patients with a liver stiffness measurement (LS) <20 kPa and a platelet count >150 000/μL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.

Aims & Methods: The aim of the study was to validate the Baveno VI criteria. We did a retrospective study, from 2009–2014. We took all the patients with transient elastography data. Inclusion criteria was a LS >12 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of chronic liver disease. Varies were graded as low risk (grade <2) or high risk (grade ≥ 2).

Results: The study included 774 patients (hepatitis C virus 40.5%, hepatitis B virus 16.1%, 31.6% etanovics, 11.8% etiology, and 47.5% were Child Pugh N 7% were cardiae, 13.85% were premalignant cirrhosis and in 5% of cases the etiology was unknown. In univariate analysis, hypernatremia (p < 0.0001), hyperpotassemia (p < 0.0001), hypoalbuminemia (p < 0.0001), high values of creatinine (p < 0.0001), high values of creatinine (p < 0.0001) were strongly associated with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinine and bilirubin (all p-values <0.05) had an AUROC = 0.78, CI (0.75–0.81), p < 0.0001. Using this factors as predictors, by multiple regression analysis we obtained in the initial group the following score: ABCPS score = 0.04 + 0.03*Albumin + 0.05 + 0.02*Creatinine + 0.04 + 0.04*Bilirubin + 0.05 + 0.28*Potassium + 0.04*0.07*Sodium.

Conclusion: Prevention and prompt treatment of kidney injury, hypernatremia, hyperpotassemia, can improve survival. ABCPS score can be an uselfull score to rule out patients with high mortality rate.

Introduction: Bariatric surgery provides a durable method of weight loss but is associated with serious adverse events. Some studies report an increase in drug-induced acute liver injury following bariatric surgery.

Aims & Methods: We aimed to assess if bariatric procedures increase the risk of acute liver failure in a large inpatient cohort. We retrospectively analyzed discharge data on patients who developed acute liver injury (ALI) using the Nationwide Inpatient Sample (NIS) database from 2010-2013. Discharges with an IC-9 code indicating ALI were included. The primary outcome was ALI in patients with a history of bariatric surgery compared to all other patients with an ICD-9 code indicating ALI. Secondary outcomes were mortality in the two cohorts, and independent socio-demographic and medical risk factors for mortality in each cohort. Variables tested include age, gender, race, income, Charlson criteria, hospital factors and medical comorbidities including Malnutrition, HTN, Anemia, CKD, Diabetes, CHF, Coagulopathy, Alcoholism, HBV and HCV. Univariate and multivariate logistic regression analyses were performed to identify independent predictors.

Results: During the study period, a total of 437,390 patients were diagnosed with acute liver injury and were included in the study, of which 3,799 had previously undergone bariatric surgery. In the post-bariatric cohort, mean age was 58.7 years and 77% were women. The prevalence of acute liver injury in all inpatient admissions for that time period was higher in patients with history of bariatric surgery (0.85%) than in non-bariatric patients (0.75%), p < 0.001. Patients with history of bariatric surgery displayed odds ratio of 1.52 of developing ALI when compared to patients with no history of bariatric surgery (0.85%) than in non-bariatric patients (0.75%), p < 0.001. Admissions for that time period was higher in patients with history of bariatric surgery. In the post-bariatric cohort, mean age was 58.7 years and 77% were women. The prevalence of acute liver injury in all inpatient admissions for that time period was higher in patients with history of bariatric surgery (0.85%) than in non-bariatric patients (0.75%), p < 0.001. Admissions for that time period was higher in patients with history of bariatric surgery. In the post-bariatric cohort, mean age was 58.7 years and 77% were women. The prevalence of acute liver injury in all inpatient admissions for that time period was higher in patients with history of bariatric surgery (0.85%) than in non-bariatric patients (0.75%), p < 0.001. Admissions for that time period was higher in patients with history of bariatric surgery.
P1344 LONGITUDINAL MONITORING OF LIVER STIFFNESS BY ACOUSTIC RADIATION FORCE IMPULSE IMAGING IN PATIENTS WITH CHRONIC HEPATITIS B RECEIVING ENTECAVIR

Introduction: Acoustic radiation force impulse (ARFI) imaging measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naive patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly validated during antiviral therapy in CHB patients.

Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions.

Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransaminase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet and cholinesterase. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS value (change threshold ¼ 15%) was significantly correlated with the changes in histological fibrosis staging (r ¼ 0.63, P < 0.001).

Conclusion: In CHB patients, LS assessed by ARFI was significantly reduced during antiviral therapy. Longitudinal monitoring of LS might be a promising noninvasive assessment of fibrosis regression during long-term antiviral therapy in CHB. Further studies on large populations are warranted.

P1346 ANTIVIRAL EFFICACY OF UNANI HERBS (SAUSSUREA LAPPAPA AND ARTEMISIA ABSINTHIUM) IN CHRONIC HEPATITIS B

S. Ansari1, M. A. Siddiqui1, S. Mahotra2, M. Maza3

2Department Of Gastroenterology, Batra Hospital and Research Centre, New Delhi/India

Contact E-mail Address: drsahabmansari.md@gmail.com

Introduction: Chronic hepatitis B (CHB) is a serious health concern in terms of its high prevalence, as well as restricted and costly health care resources in India.1 Unani herbal drugs such as root of Saussurea lappa and whole plant of Artemisia absinthium have been used successfully in the treatment of hepatitis in Unani Medicine for centuries. These drugs have exhibited potential anti-hepatitis B, hepatoprotective, immunomodulatory, anti-inflammatory and anti-oxidant activities in various animal models.2 With this background, prospective clinical trial was tried to be designed according to the guidelines of American association for the study of liver diseases (AASLD) and implemented after Institutional ethical clearance.

Aims & Methods: Objective was to evaluate the antiviral effect of herbal drugs, Saussurea lappa and Artemisia absinthium against hepatitis B virus (HBV) in the management of CHB and to collect data to warrant further clinical trials. In an open prospective single-arm study, we assigned 30 patients with HBsAg-negative or HBsAg-positive CHB to receive decodination of root of Saussurea lappa, 15 mL (corresponding to 4.9 g of S. lappa) or Artemisia absinthium against hepatitis B virus (HBV) in the evening once daily empty stomach for 12 weeks. Physicochemical standardization and TLC and HPTLC fingerprinting of decoctions were also done. Test drug was provided for its efficacy testing (15 mL/Saussurea lappa (CLIA tech.), a plasma HBV DNA level (RT PCR) of less than 200 IU/mL at week 12 after treatment). Normalization of alanine aminotransferase levels [ALT (enzymatic assay) without any significant adverse effects (clinical parameters, hemogram, kidney and liver function tests, and blood also lasting and post prandial) at week 6 (mid-treatment) and 12 (after treatment) would be suggestive of resolution of inflammation of liver.

Results: 1. HBsAg loss was observed in 5 (35.71%) patients in HBsAg-positive group (n = 14) (p < 0.05) and 4 (25%) patients in HBsAg-negative group (n = 16) at week 12 after treatment (p = 0.10). These 9 HBsAg negative patients were further assessed on 26th week of treatment, all 9 maintained their negative HBsAg status. 2. HBsAg loss was observed in 74.27% patients at week 12
Aims & Methods: Serum HBsAg loss is the recommended stopping rule in nucleo(t)" University, Napoli, Napoli/Italy therapy from 3471 UI/ml at the baseline to 1758 IU/ml at the last determination months. There was a significant decrease of the HBsAg levels during NUC Lamivudine. The median treatment duration was 111 months, range 25–183 enrolled. Precisely 56 patients underwent to Tenofovir, 22 Entecavir and 17 median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were Results: Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting ''Federico II''. Sequential serum samples from these patients were tested for hepatitis the kinetics of HBsAg levels during the NUC therapy to evaluate the before the seroconversion, and NUC therapy was successfully stopped, without patients, in which undetectable HBsAg value was evidenced at least two years multivariate analysis showed that the only predic- treatment would be a useful parameter to optimize antiviral treatment schedule. Disclosure of Interest: All authors have declared no conflicts of interest.

P1347 QUANTIFICATION OF SERUM HBsAG IS A HELPFUL MARKER TO OPTIMIZE THE MANAGEMENT OF ANTIVIRAL NUC THERAPY IN CHRONIC HBeAg-NEGATIVE HEPATITIS B M. Guarino1, M. Masarone2, G. Portella1, A. Sessa1, R. Bonavolta3, N. Caporaso1, F. Morisco3, 1Gastroenterology Unit, Department of Clinical Medicine and Surgery, ''Federico II’’ University, Napoli, Napoli,Italy 2Internal Medicine and Hepatology Unit, San Giovanni e RuggiAragona, University of Salerno, Salerno,Italy 3Department of Translational Medical Science, University of Naples ''Federico II'', Napoli,Italy

Introduction: Serum HBsAg loss is the recommended stopping rule in nucleo(t)-side-analogues (NUC) responders, even if this event occurs rarely. Aims & Methods: We aimed to investigate in patients with chronic HBcAg+ hepatitis the kinetics of HBsAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with CHB, receiving NUC antiviral therapy with stable viral suppression (HBV DNA < 2010/ml), were recruited at the Gastroenterology Unit of the University of Naples ‘‘Federico II’’. Serum samples from these patients were tested for HBsAg quantification with the Elecsys HBsAg II Quant immunoassay (Roche Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting NUC treatment and at treatment every 12 months. Results: A total of 95 HBsAg-positive, HBeAg-negative patients (M/F: 73/22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were enrolled. Precisely 56 patients went to Tenofovir, 22 Entecavir and 17 Lamivudine. The median treatment duration was 111 months, range 25–183 months. There was a significant decrease of the HBsAg levels during NUC therapy from 3471 UI/ml at the baseline to 1758 UI/ml at the last determination (p < 0.001). The statistically significant HBsAg decrease was also maintained when the patients were clustered according to antiviral therapy, severity of liver disease and previous interferon treatment. HBsAg seroclearance occurred in 18/95 patients (19%). The multivariate analysis showed that the only predictive parameter statistically significant of HBsAg seroclearance is the HBsAg level at baseline. Moreover, HBsAg serocconversion to HBsAb occurred in 4/18 patients, in which undetectable HBsAg value was evidenced at least two years before the seroconversion, and NUC therapy was successfully stopped, without relapse after a mean follow-up period of 24 months. Conclusion: The results of this study suggest a role of on-treatment HBsAg quantification in the management of NUC-treated patients. HBsAg measurement would be a useful parameter to optimize antiviral treatment schedule.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1348 IMPROVEMENTS IN CHRONIC HEPATITIS B PATIENTS AND THE ALTERATION IN GUT MICROBIOTA AFTER FECAL MICROBIOTA TRANSPLANTATION C. Xiao, B. Zhang, J. Ren Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen/China

Contact E-mail Address: xiaoxn@xmu.edu.cn

Introduction: Chronic hepatitis B (CHB) is a common liver disease worldwide, and can be progressed to liver cirrhosis and hepatocellular carcinoma. Unfortunately, only a minority of CHB patients could achieve the clearance or seroconversion of hepatitis B virus e-antigen (HBcAg), the end point of treatment, even after multiple years of antiviral therapy. Therefore, it is urgent to develop new and effective strategy for treatment of CHB and examine the mechanisms.

Aims & Methods: In this study, we performed 60 times of fecal microbiota transplantation (FMT) by nasointestinal tube for 20 CHB patients who continued previous antiviral treatment, and accordingly measured the HBsAg level four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.

Results: Results showed that HBcAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 0.35% dissimilarity, there were significant (PERMANOVA, P = 0.001) differences in overall gut bac-}
P1355 HEPATITIS C IN LEBANON: BURDEN OF THE DISEASE AND VALUE OF COMPREHENSIVE SCREENING AND TREATMENT

\(^4\)SERNANP, Liege/Belgium

Contact E-mail Address: abouarachid@bc.edu

Introduction: As few reliable data on the burden of hepatitis C virus (HCV) are available from the Middle East, we analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages.

Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response 12 years (LYs) following SVR12 compared to no treatment and screening, adopting the high to F4 reduction in SVR12. Compared to no treatment and screening, adopting the high screening variant and DAAs access to F0-F4 would cost an additional 1,957 LY gained in SVR12.

Results: Low, medium and high HCV screening scenarios showed that 3838, 5566 and 7669 individuals would be diagnosed with HCV infection from 2016 to 2036, 40% aged 18–39 and 60% aged 40–80. In the absence of treatment, the projected number of patients developing cirrhosis (CC), hepatocellular carcinoma (HCC) and liver-related death (LrD) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%/85%/99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR12 rates were extracted from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for different prevalence and screening rates.

Conclusion: In our sample of ESRD under HD patients, 3D therapy allowed the eradication of HCV with high efficacy, even in patients who did not meet the expected duration of treatment or dose of ribavirin. The safety of DAA in this group is demonstrated by the non-occurrence of severe adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1352 HEPATITIS C TREATMENT IN RELAPSED PATIENTS: THE EFFICACY AND SAFETY OF DIRECT-ACTING ANTI-VIRALS IN THE REAL LIFE

L. Carvalho, J. Rodrigues, M.A. Túlio, T. Bana, E. Costa, L. Lebre, C. Chagas

Gastroenterology, Centro Hospitalar e Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Hepatitis C virus (HCV) infection in renal transplant patients pre-disposes to graft failure and progression of renal disease, increasing mortality. Due to immunosuppression and oscillating glomerular filtration rate (eGFR) in transplant recipients, treatment efficacy comes into question. Direct-acting antivirals (DAAs) are well-established, effective and safe treatment regimen of the HCV infection, however evidences on renal transplantation are scarce. Additional studies are still necessary in order to evaluate the real impact of these agents in the daily clinical practice.

Aims & Methods: Our objective was to assess the efficacy and safety of DAA treatment for HCV-infected patients with renal transplantation, in the daily practice of a tertiary care centre, describing the HCV infection, treatment type, the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects). HCV-infected and renal transplant patients treated with DAA between April 2015 and February 2017 were analyzed.

Results: Including 19 patients, 10 males (53%) and 9 females (47%) with a mean age of 57 years (40–70 years). The majority of these patients (89%) were treatment-naive. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to liver stiffness (LS) measured by Transient Elastography (TE) was as follows: F0–14% (3/19), F1–31% (6/19), F2–63% (12/19), F3–21% (4/19) and F4–16% (3/19). The majority of these patients (89%) were treatment-naive. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to liver stiffness (LS) measurements by Transient Elastography (TE) was as follows: F0–14% (3/19), F1–31% (6/19), F2–63% (12/19), F3–21% (4/19) and F4–16% (3/19). The majority of these patients (89%) were treatment-naive. The global sustained virologic response (SVR) rate was 100% (19/19) of patients had End of Treatment Response (ETR). The overall economic burden of these liver complications would reach 150 000 USD per patient for the entire life span of the individual. The overall economic burden of these liver complications would reach 150 000 USD per patient for the entire life span of the individual. The overall economic burden of these liver complications would reach 150 000 USD per patient for the entire life span of the individual.

Conclusion: In our sample of HCV-infected with kidney transplant, DAA are effective and well tolerated, even in the more advanced stages of fibrosis, maintaining the integrity and viability of the graft, without interfering with the efficacy of immunosuppressant.

Disclosure of Interest: All authors have declared no conflicts of interest.

9. Introduction: Monocyte chemotractant protein-1 (MCP-1) is a chemokine mediating inflammation in chronic liver disease. It promotes monocyte recruitment to the liver, mononuclear phagocyte system (MPS) and hepatic stellate cells is key for active fibrogenesis. The extent to which metabolic and immune factors are implicated in fatty liver of patients with CHC is still not clear.

Aims & Methods: Therefore, the aim of the study was to investigate the associations between serum MCP-1, liver fibrosis, fatty liver and metabolic factors in CHC patients before, and after antiviral treatment. We included 21 patients in the study (11 men, 10 women, age 42 ±9.7) with chronic hepatitis C virus (HCV) infection –17 with genotype 1 and 4 with genotype 3. Liver biopsy was done in 19 and histology showed fatty liver in 8 patients. Fatty liver was present in 17 of all patients on ultrasound. In 3 cases, active fibrosis was scored as bridging fibrosis (F3) in 9, significant (F2) in 7 and advanced bridging fibrosis (F3) in 2 cases (METAIVIR). Compensated liver cirrhosis (F4) was diagnosed in 3 cases by liver biopsy or endoscopic screening for varices. Weight was normal in 10, overweight in 5 and obese in 6 patients. MCP-1 concentration was quantified by ELISA in serum. Serum probes were obtained before treatment and after response evaluation. Statistical analysis included Spearman’s rho, Mann-Whitney U test, Wilcoxon’s test and Student’s paired t-test. Results: MCP-1 in serum correlated with BMI (r = 0.522, p = 0.015). MCP-1 correlated inversely with overweight in CHC patients (r = 0.522, p = 0.015). Patients with BMI ≥45 had higher BMI (p = 0.010) and HOMA-IR (p = 0.042). An increase in serum MCP-1 was found in patients after treatment (r = 0.030, p = 0.001), while no significant variation from baseline values was found in HOMA-IR. The result remained significant in subgroup analysis of SVR patients with F1-F2 (p = 0.002) and in those with fatty liver (p = 0.017). MCP-1 in serum did not show any association with assessment of liver fibrosis, fatty liver, insulin resistance and serum lipid levels.
Conclusion: MCP-1 concentrations in serum depend on overweight in patients with CHC. Overweight and insulin resistance are associated with progression of CHC. Serum levels of MCP-1 increase after HCV clearance. Fluctuation of the MCP-1 concentration in serum could reflect an anti-inflamatory activation of M1 and a gradient dependent dynamic replacement of the profibrotic cell subsets in the liver with resolution ones after SVR. Fatty liver plays a role for inflammatory responses in CHC patients after SVR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: HCV interferes with the host lipid metabolism leading to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, mild to severe simple steatosis in genotype 4 is associated with the potential to progress to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for host genetic factors in development of hepatic steatosis in chronic HCV patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A-B alleles and presence of steatosis in chronic HCV genotype 4 infected patients. This study included two hundred unrelated non diabetic non obese chronic HCV patients with normal lipid profile, 98% of them had biopsy proven steatosis. Serological testing of HLA class I antigens (HLA-A, and HLA-B alleles) were performed with a standard complement-dependent microlymphocytotoxicity assay.

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic HCV patients with steatosis (OR = 1.77, 2.64, 4.44, 5.68) and 95% CI = 0.96–3.27, 1.02–7.04, 0.84–31.17, 1.12–38.65 with P = 0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR = 0.56, 0.41) and 95% CI were 0.30–1.05, 0.20–0.83 and P = 0.015 and 0.005. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2.2, 3.9 and 11.18 fold risk to have hepatic steatosis (B coefficient: 0.78; 1.37; 2.41) 95% CI = 1.09–4.42, 1.04–11.50, 2.15–58.13; P = 0.027, 0.009, 0.004 while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis (OR = 0.34, 95% CI = 0.16–0.72; P = 0.005) with constant 94.7 and overall accuracy of 69%. In addition, patients who have moderate activity index in liver histopathology have 5.9 risk to have hepatic steatosis (OR = 9.52, 95% CI = 2.92–11.99, P<0.001).

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk for presence of hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

Introduction: Chronic liver diseases are quite frequently encountered in daily practice and are due mainly to chronic viral infections (B or C viruses) and to other conditions such as alcoholic steatohepatitis - (ASH) and to non-alcoholic fatty liver disease (NAFLD). While liver biopsy remains the gold standard for fibrosis assessment, stage classification and also for necro-inflammation grading, in the last years, non-invasive assessment methods (biological tests and elastographic methods) were developed and they are being used more and more, to the detriment of liver biopsy.

Aims & Methods: The aim of this study was to evaluate the performance of the 2D shear wave elastography technique from General Electrics (2D-SWE.GE), for the evaluation of liver fibrosis in patients with HCV compensated chronic hepatopathies, using Transient Elastography (TE) as the reference method. The study included 145 consecutive subjects with HCV compensated chronic hepatopathies, in whom liver stiffness was evaluated in the same session by means of 2 elastographic measurements: TE (FibroScan, EchoSens) and 2D-SWE.GE (LOGIQ E9, GE Healthcare). Reliable LS measurements were defined as follows: for TE-the median value of 10 measurements with a success rate of ≥60% and an inter-quartile range <30% and for 2D-SWE.GE - the median value of 10 measurements acquired in a homogenous area and an interquartile range (IQR) <30%. To discriminate between various stages of fibrosis by TE we used the following cut-offs: F0: F ≤ 7 kPa, F0-F2: 9.5 kPa, F2: 12.5 kPa [1].

Results: Reliable LS measurements were obtained in 138/145 (95.1%) subjects by 2D-SWE.GE in 139/145 (95.3%) patients. When we divided our cohort into 4 groups: F0-F1: 36/134 (26.6%), F2: 23/134 (17.2%), F3: 23/134 (17.2%) and F4: 52/134 (38.8%). The areas under the receiver operating characteristic curve (AUROC) were 0.909 for significant fibrosis (F ≥ 2), 0.954 for severe fibrosis (F ≥ 3) and 0.942 for cirrhosis (F = 4). The best cut-off values for F ≥ 2 was 7 kPa (Sensitivity 85.7, Specificity 80.5), for F ≥ 3 it was 9.2 kPa (Sensitivity 85.3, Specificity 91.5) and for F = 4 it was 10.7 kPa (Sensitivity 84.6, Specificity 91.4).

Conclusion: 2D-SWE.GE seems a reliable method for liver fibrosis staging in patients with HCV compensated chronic hepatopathies. The best 2D-SWE.GE cut-off values for F ≥ 2, F ≥ 3 and F = 4 in HCV chronic hepatopathies were 7, 9.2 and 10.7 kPa.

Introduction: The risk of developing novo hepatocellular carcinoma (HCC) persists after achieving sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n = 197, median of follow-up of 17 months). We evaluated with chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test: age, no. of platelets pre-treatment, fibrosis or cirrhosis pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child- Pugh B stage vs. an A stage (p = 0.007), pre-treatment DM (p = 0.002) and presence of radiological portal hypertension (p = 0.001) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significantly with the development of novo HCC. The incidence (≥1.5%) of novo HCC justifies the screening of HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

were significantly different from those patients with ALF. Significant differences between ALF and AOCLF were found in the literature. Discrimination of AOCLF from ALF might be trivial for pre-existing alcoholic or viral hepatitis. However, non-alcoholic steatohepatitis (NASH) in obese or diabetic patients might lead to a critical situation. Patients admitted to liver transplantation centers with the diagnosis of ALF might be suffering from AOCLF instead. It is also unclear if the ALF and AOCLF have different impact on disease course, clinical management and transplant organ allocation. Thus, patients suffering from AOCLF instead of an acute liver failure might go unnoticed in the critical situation of an ALF/AOCLF. Therefore, patients admitted to liver transplantation centers with the initial diagnosis of ALF should be aware of the possibility of AOCLF.

Aims & Methods: The present study was conducted to compare differences among patients with ALF and AOCLF with regard to age and severity of the disease and to identify the etiology of liver failure in AOCLF patients. A total of 31 patients (Male: 29/Female: 2) were included in this study. All patients were admitted to the University Hospital of Essen with the initial diagnosis of ALF between 2008 and 2015. Patients included in this study were fulfilling the criteria of the acute liver failure study group Germany. The diagnosis of AOCLF was established prospectively by a liver biopsy. Clinical records, in particular demographic data, serum parameters and outcome were analyzed for differences between ALF and AOCLF.

Results: Patients with AOCLF significantly older (50.3 ± 15.1 vs. 39.8 ± 16.2), had a higher BMI (27.5 ± 5.1 vs. 24.5 ± 6.2, p = 0.0014) and were more often male (65% in AOCLF vs. 34% in ALF p = 0.0008). In addition, the results that caused the liver failure in AOCLF were significantly different from those patients with ALF. Significant differences were also found for liver enzymes, which were significantly lower in AOCLF patients (AST p = 0.01; ALT p = 0.001). Cell death markers and the MELD did not differ between ALF and AOCLF. Moreover, the outcome was not different between AOCLF and ALF and there was no significant difference in the length of hospital stay. There is no remarkable difference in the liver function recovery level between two groups (P = 0.495; P = 0.141). No statistical difference was found in the total operation time, blood loss and length of hospital stay between two groups, and the occurrence rate of vascular complications, biliary complications and postoperative infection also showed no difference. Although more patients above Clavien IIIa were in the observation group, there was no statistical significant difference in the periparative mortality between the two groups. Besides, preoperative TACE could effectively reduce complications caused by immune reaction (P = 0.048). In terms of postoperative index of liver function, TBIL, ALT, AST all had a transient rise during the first 3 days after transplantation, but recovered gradually over time. There’s no remarkable difference in the liver failure recovery level between two groups (P = 0.495; P = 0.141; P = 0.101).

Conclusion: Preoperative TACE won’t affect liver function recovery and periparative safety after liver transplantation. For some patients, it could also reduce complications caused by immune reaction.

2National Cancer Registry Ireland, Cork/Ireland
3National Liver Unit, St Vincent’s University Hospital, Dublin/Ireland
Contact E-mail Address: susannemoreilly@gmail.com
Introduction: Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.
Aims & Methods: To examine all recorded malignancies over 2 decades in OLT PSC pts and compare to our non-transplanted PSC cohort. To analyse factors associated with development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent’s University Hospital from 1/1/1994 to 31/12/2014. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analyzed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from diagnosis to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.
Results: 107 of 173 patients had undergone transplant for PSC. 27/107 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 BCC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Previous studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with PTLD representing 4.7% of cohort. Median time to diagnosis was 5.3 yrs [IQR 2.8–10.2]. Regarding CRC, 2 patients developed CRC post OLT. 4 patients were diagnosed with colonic dysplasia: 3/4 underwent colectomy. All those who developed colonic dysplasia/CRC post OLT had co-existing IBD. All 5 coloectomy specimens for dysplasia/CRC showed significant co-existing inflammation. One patient post OLT underwent a completion proctectomy for rectal cancer. As expected, cholangiocarcinoma as indication for OLT (p = 0.005, RR 2.573, 95%CI 1.3–4.95) and an older age at transplant (p = 0.05, RR 1.027, 95% CI 1.0–1.054) were associated with higher mortality.
Table 1

</table>

Conclusion: These findings represent national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than those reported in the normal population, and slightly higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colonic neoplasia after OLT and require intensive surveillance.

2Department Of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
3Transplant centre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
Contact E-mail Address: drastich@hotmail.com
Introduction: Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.
Aims & Methods: The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course of UC after OLT. After applying inclusion/exclusion criteria we retrospectively evaluated electronic records of 57 PSC patients transplanted at Institute for Clinical and Experimental Medicine (Prague, Czech Republic) between July 1994 and November 2011. Only patients with proper records ±5years from OLT were included. We evaluated likelihood for each variable (ACR, rPSC, course of UC) in patients with either single, double or double mismatch in HLA-DR. Recipient data were analysed with χ2 and Fisher’s exact test using MedCalc statistical software. A p < 0.05 was considered as statistically significant.
Results: Out of 57 patients, 27 (47.4%) had single mismatch (‘M1’ group) and 30 (52.6%) had double mismatches (‘M2’ group) in HLA-DR. No patient had full match. 33/57 (57.9%) patients had ACR: 15/27 (55.6%) of M1 and 18/30 (60%) of M2 (p = 0.94). 4/27 (14.8%) of M1 and 2/30 (6.3%) of M2 had corticoresistant ACR (p = 0.57). Multiple–episodes of ACR occurred in 11/57 (19.3%) patients: 6/27 (22.2%) of M1 and 5/25 (20%) of M2 (p = 0.74). 12/57 (21.1%) had de-novo UC after OLT: 7/27 (25.9%) of M1 and 5/30 (16.7%) of M2 (p = 0.60). In 37 (68.5%) patients, UC was diagnosed prior to OLT. 9/16 (56.3%) patients with M1 and 6/21 (28.6%) patients with M2 had more severe course of UC as compared to course prior to OLT (p = 0.17). 38 patients were evaluated for rPSC, which was diagnosed in 17 (44.7%) individuals. 6/19 patients with M1 and 11/19 with M2 had rPSC (p = 0.19).
Conclusion: Patients with single mismatch in HLA-DR have slightly tendency towards development of rPSC and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway. Contact E-mail Address: es18497@gmail.com
Introduction: Liver biopsy remains the gold standard in the diagnosis of graft dysfunction in post-liver transplantation (GDPLT). Liver transient elastography is a valid non-invasive method for liver fibrosis evaluation, with a good correlation in chronic liver diseases. The progression of fibrosis represents a major problem in the post-liver transplantation.
Aims & Methods: We aimed to evaluate the predictive role of liver transient elastography in the evaluation of GDPLT and to determine the predictive factors of liver transplantation fibrosis. This was a retrospective observational cohort study of total of 49 patients with post-liver transplantation status who underwent liver transient elastography by Fibroscan®. Selected patients who underwent percutaneous/transjugular liver biopsy, in case of more than one liver biopsy, it was selected the biopsy closer to Fibroscan®. The fibrosis and steatosis evaluated by Fibroscan® were compared with those obtained by liver biopsy. Significant fibrosis was considered if ≥2. Demographic, analytical and associated liver transplantation variables were evaluated.
Results: A total of 32 patients underwent Fibroscan® and liver biopsy. Mean age of 48.53 ± 11.20years and male gender in 68.8% (n = 22). The mean time between Fibroscan® and liver biopsy was 29.77 ± 36.90months. The mean elastography score was 13.45 ± 8.31KPa with IQR:med of 17.11 ± 8.66%. Mean CAP score was 207.12 ± 57.35 dB/m. Regarding liver biopsy, 34.4% (n = 11) had significant fibrosis and 25.0% (n = 8) presented steatosis. Comparing two methods, there was no concordance for steatosis (kappa = 0.273; p = 0.117) or inflammation (Kappa = 0.063; p = 0.710). On the contrary, a moderate agreement for significant fibrosis (kappa = 0.431; p = 0.003) was verified. The mean elastography score showed an accuracy of 79.7% in predicting histological fibrosis (AUROC = 0.797; p = 0.007) to a cut-off value of 11.6 KPa. The mean elastography score of patients with double mismatch was 11.6KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.
Conclusion: Liver transient elastography represents a non-invasive and valid alternative procedure to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation. Liver transient elastography scoring ≥11.6KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.
Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Orthotopic liver transplant has become the standard of care for end-stage liver disease and hepatocellular cancer. Better immunosuppressive paved way for improved survival rates post-transplant. But with this longevity comes a higher prevalence of chronic diseases such as New Onset Diabetes After Transplant (NODAT), Hypertension, metabolic syndrome etc. which have a negative impact on function and patient survival.

Aims & Methods: Primary: To determine the incidence of New Onset Diabetes After Transplant (NODAT), Impaired Fasting Glycaemia (IFG) and post-transplant hyperglycemia in living-donor liver transplant recipients. Secondary: To determine the risk factors associated with NODAT and IFG. To determine impact of NODAT on survival and mortality. It was a retrospective cohort study of 283 living donor liver transplant recipients from 29/4/2011 till 26/4/2016. Data was collected from records. Simple means and standard deviation was calculated for continuous variables while frequency statistics were calculated for categorical ones. Risk factors were assessed using binary logistic regression analysis.

Results: A total of 130 post liver transplant patients were analyzed after exclusion. NODAT was present in 41/130 (31.5%) patients, while 19/130 (14.6%) patients had impaired fasting glycaemia. Acute cellular rejection, Post-transplant Hyperglycemia and Pre-transplant prediabetes showed increased odds of acquiring NODAT post-transplant. NODAT had significant association with mortality and decreased survival (p = 0.05).

Conclusion: This cohort showed that NODAT is an important post-transplant entity with significant impact on mortality and survival. Early identification of at-risk patients is suggested.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims: To evaluate the impact of vB12 as a risk factor for NODAT.
Methods: Retrospective assessment of 58 patients admitted to an intensive care unit with ACLF in the context of infection (group 1) and 53 patients with compensated hepatitis cirrhosis followed as Hepatology outpatients (group 2). Evaluation of vB12 as a predictor of 30 days’ mortality.
Results: 111 patients, 68% male, age 58 ± 18 years. Group 1 had more prevalent liver disease (CPT 11.9 ± 0.3 vs. 6.5 ± 0.2 and MELD 27.0 ± 1.0 vs. 10. ± 0.5), higher vB12 (1413 ± 149 vs. 735 ± 56 pg/mL) and lower survival (1.6 ± 0.4 vs. 6.4 ± 2.7 years). VB12 positively correlated with hepatic function scores (CPT: R = 0.53; P = 0.05 and MELD: R = 0.56; P = 0.03). In group 1, survival was lower in patients with high vB12 (≥ 8 ± 3 vs. 37 ± 11 months), and 1 month' mortality was associated with vB12, CPT, MELD, number of organ failure, urea, lactates and fibrinogen, in univariate analysis (p < 0.001). In multivariate analysis only fibrinogen maintained statistical significance (p < 0.001).

Conclusion: There was a strong association between high levels of vB12 and clinical decompensation of liver cirrhosis. VB12 correlated with scores of liver failure and multiorgan failure, as well as early mortality in patients with ACLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1368 THE ASSESSMENT OF THE ADC PREDICTIVE VALUE IN SURVIVAL OUTCOMES OF PATIENTS UNDERGOING RADIOFREQUENCY ABLATION FOR METASTATIC COLORECTAL CANCER LIVER TUMORS

O. Kozak1, T. Nowicki2, J.M. Pienkowska2, E. Izrycka-Swiezewska2, D. Zadrozny3, E. Szurowska1
1Department Of Radiology, Medical University of Gdansk, Gdansk/Poland
2Department Of Pathology And Neuropathology, Medical University of Gdansk, Gdansk/Poland
3Clinical Of Oncologic And Liver Surgery, University Warmia and Mazury, Olsztyn/Poland

Introduction: Liver is one of the most common metastatic sites of colorectal cancer, nearly 50% patients develop hepatic metastases during the course of their disease. Metastatic spread influences survival rate of those patients. The diffusion weighted imaging (DWI) is MRI sequence designed to detect random movement of water protons in extracellular compartment. Biophysical parameter expressed as a second in the equation for their system is diffusion coefficient (ADC). ADC values for b parameter lower than 300 s/mm² are influenced by perfusion whereas ADC values for b greater than 300 s/mm² depend mainly on diffusion. Aggressive malignant process often develops necrotic areas within neoplastic lesion. Necrotic changes are characterized by high ADC values. We suppose that low ADC values correlate with presence of necrosis in highly malignant lesions influencing in lower survival rate.

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 4383) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated, 27 incompletely, what was assessed in follow-up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 300 s/mm², ADC maps were calculated for b values of 015 and 0500 s/mm². The mean ADC value was obtained by threefold measuring ROI covering the whole metastatic lesion. In cases of multiple foci only the lesion with the highest ADC value was included into analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 015 s/mm² and 1.43 mm²/s for b value of 0500 s/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included Kaplan-Meier estimator for 52 patients with 9 censored cases (17.3%). In ADC maps for b value of 0500 s/mm², the ADC value ≥1.43 mm²/s correlated with longer survival time, whereas ADC value <1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test (p = 0.0067). Such a correlation was not observed for ADC values in ADC maps for b value of 015 s/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Disclosure of Interest: All authors declared no conflicts of interest.

Introduction: Nowadays liver fibrosis can be assessed using non-invasive elastographic techniques. ElastPQ is a quite novel point share wave elastography integrated in an ultrasound system.

Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastPQ. LSM of a trainee were compared to LSM of an elastography expert (with an experience of more than 500 examinations). Our study group included 50 subjects (mean age: 52.7 years, 66.6% men, mean BMI = 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastPQ (EPQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median difference between measurements obtained by the trainee and the expert in a homogenous area avoiding vessels and with an IQR/median <30%. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert’s results as reference.

Results: The trainee’s performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557–0.913), p = 0.01). The trainee started to have similar results with the elastography expert after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6 to 2.1 kPa vs 6.5 to 4.2 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastPQ can be easily achieved after 30 LS examinations.

Aims & Methods: This study aimed to test the latest approved version of a contrast-enhanced ultrasound algorithm (ACR CEUS LI-RADSv 2016) for detecting hepatocellular carcinoma (HCC), in a real-life cohort of high-risk patients. This study included 60 patients with chronic liver disease and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. This study aimed to develop a simple and effective diagnostic tool for HCC. This study included 60 patients with chronic liver disease.

Results: According to reference method, the 298 lesions were classified as follows: 268 (90.4%) benign, 10 (3.3%) with small tumor size, early tumor stage, and less vascular invasion. The Flt-1 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.001) were independent prognostic factors for monitoring of treatment response. Serum DKK1 level significantly decreased after HCC treatment with either radiofrequency ablation or ethanol injection. Multivariate Cox proportional analysis revealed that the FGFR2/C genotypes were associated with small tumor size, early tumor stage, and less vascular invasion. The FGFR2/C genotypes were significantly associated with increased survival rates (P = 0.047).

Conclusion: In our study, the CEUS algorithm exhibited high sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for HCC detection.
Conclusion: These observations suggest that the SNPs of the FGFR2 and FGFR3 genes can be potential prognostic indicators in patients with HBV-associated HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Extrahepatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available.

Aims & Methods: The aim of this study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastases were present at the time of HCC diagnosis. In patients with subsequent metastasis, the median time until its development was 9 months (IQR: 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%). The MELD score at the time of metastasis was higher than the MELD score at the HCC diagnosis (p = 0.009). Metastasis detection implied changes in HCC therapy in all patients, 41% stopped sorafenib and 55% were referred for supportive therapy. Seven patients performed metastasis targeted treatment, namely 3 patients under went radiotherapy. The median overall survival (OS) after metastasis was 4.0 months (95%CI 2.1–5.8 months) and the mortality rate was 81% at 12 months. Patients who underwent metastasis targeted treatment presented a longer OS than those who did not (median 18.5 vs 3.1 months; p = 0.002). In multivariate analysis, MELD score at the time of metastasis (p = 0.004) and metastasis treatment (p = 0.005) were independently associated with OS estimation.

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigraphy, may provide an earlier metastasis detection and enable a targeted treatment with a consequent improvement in survival in this difficult-to-treat population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging system, intermediate stage contains very heterogeneous hepatocellular carcinoma (HCC) patients. Recently, subclassification of intermediate stage on the basis of Milano criteria and up to 7 criteria is proposed. In this study, the effectiveness of DEB-TACE is also effective in the patients with less than 7 tumors in B2 + B3 group.

Aims & Methods: The aim of this study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastases were present at the time of HCC diagnosis. In patients with subsequent metastasis, the median time until its development was 9 months (IQR: 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%). The MELD score at the time of metastasis was higher than the MELD score at the HCC diagnosis (p = 0.009). Metastasis detection implied changes in HCC therapy in all patients, 41% stopped sorafenib and 55% were referred for supportive therapy. Seven patients performed metastasis targeted treatment, namely 3 patients underwent radiotherapy. The median overall survival (OS) after metastasis was 4.0 months (95%CI 2.1–5.8 months) and the mortality rate was 81% at 12 months. Patients who underwent metastasis targeted treatment presented a longer OS than those who did not (median 18.5 vs 3.1 months; p = 0.002). In multivariate analysis, MELD score at the time of metastasis (p = 0.004) and metastasis treatment (p = 0.005) were independently associated with OS estimation.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE
Hepatology Unit, Cardarelli Hospital, Naples/Italy

Contact E-mail Address: raffeillacellotorta@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of hepatocellular carcinoma (HCC) have been treated with direct antiviral agents (DAAs) for HCV infection. However there are conflicting data on HCC recurrence rate after DAAs therapy.

Aims & Methods: Aim of this study was to prospectively evaluate the rate of HCC recurrence following sustained virological response (SVR) by DAAs. From April 2015 to September 2016 we consecutively enrolled HCV infected patients previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had a free-disease survival from HCC of at least 6 months before starting antiviral therapy. The efficacy of HCC therapy was evaluated according to mRaiCest criteria on CT or MRI. Radiological evaluation was carried out within 30 days from the start of therapy. All patients underwent DAAs therapy, selected on an individual basis according to the recommendation issued by the Italian association of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had available data on SVR status and were considered for the analysis. There were 21 males (58.3%) and 15 females. The median age of the patients was 73 years (range: 34–88). The median follow-up was 12 months after the beginning of therapy (range: 6–18 months). Genotype distribution was as follows: 36 patients infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype 3. SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in 11/38 patients with SVR (28.9%). The median time for recurrence was 9 months from the start of therapy with a range of 1–13 months; with 2 patients who showed recurrence during therapy. Among the patients who did not achieve SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% even in patients with advanced liver disease. Nonetheless, in patients with previous history of HCC, the eradication of HCV did not reduce the risk of short and medium-term recurrence.

Introduction: Primary liver cancer is the sixth most common cancer in the world, after cancers of the lung, breast, colorectal, prostate and gastric[1]. However, the extremely poor prognosis for primary liver cancer makes it the second leading cause of cancer-related death globally (745,000 deaths, 9.1% of the total death)[2]. Histologically, the majority of primary liver cancer is either
hepaticocellular carcinoma (HCC) or intrahepatic cholangiocarcinoma (ICC), while cirrhosis and hepaticocellular carcinoma and cholangiocarcinoma is less common[3]. Though these treatments have shown modest improvement in overall survival in early stage disease, the 5-year relative survival for distant metastasis patients is still low (3.1%). As we all know, primary liver cancer preferentially metastasize to the portal vein and extrahepatic metastasis with or without extrahepatic spread, and AFP > 200 as post-treatment factors and DC as post-treatment variable were associated with survival.

Aims & Methods: The objective of this study was to further evaluate extrahepatic metastatic patterns of different histological subtypes and assessed effects of extrahepatic metastasis on survival of advanced disease. Methods: Based on the Surveillance, Epidemiology and End Results (SEER) database, we identified eligible population diagnosed with primary liver cancer. We adopted Chi-squared test to compared metastasis distribution among different histological types. Overall survival (OS) and cancer-specific survival (CSS) were compared between subgroups with different extrahepatic metastasises.

Results: We finally identified 8677 patients who were diagnosed with primary liver cancer from 2010 to 2012 and 1836 patients were in distant metastasis stages. Intrahepatic cholangiocarcinoma was more invasive and had a higher percentage of metastasis compared with hepatocellular carcinoma. Lung was the most common metastatic site and brain was least common site for both hepatocellular carcinoma and intrahepatic cholangiocarcinoma. Extrahepatic metastasis was an independent prognostic factor for liver cancer patients. Patients with brain metastasis had the worst prognosis, compared with other metastasis in OS and CSS analysis.

Conclusion: Different histological subtypes of liver cancer had different metastasis patterns. There were profound differences in risk of mortality among distant extrahepatic metastatic sites. Results from our studies would provide some information for follow-up strategies and future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1382 CONSERVATIVE MANAGEMENT OF EXTERNAL BILIARY FISTULAS COMPLICATING SURGERY OF HYDATID CYST OF THE LIVER

O. Barakat, K. Ayed, W. Triki, M. A. Lahmidi, A. Itami, I. Abbassi, S. Bouchoucha

General Surgery, Hospital Habibi Bouqueta Bizeri, Faculty of Medicine of Tunis, University Tunis EIMANAR, Bizeri/Tunisia

Contact E-mail Address: oubarakat@gmail.com

Introduction: Surgical treatment is nowadays the only curative treatment of hydatid cyst of the liver. Surgical approach exposes to many complications especially biliary fistulas. Many modalities are described for the treatment of these complications.

Aims & Methods: A retrospective study including 250 patients who underwent a surgical treatment for a hydatid cyst of the liver between 2007 and 2015. The aim of this study is to evaluate the place of conservative management and his benefits in the management of biliary fistulas.

Results: Conservative surgical treatment of hydatid cyst was done in 180 cases and radical surgery in 70 cases. A complication occurs in 66 cases. An external biliary fistula occurred in 29 cases (87.9%). Various etiologies were identified: in 21.2% (7 cases), intrahepatic PH was due to liver tumors and in 11.7% (n = 4), the etiology was hepatic tuberculosis. Etiological investigations retained: 3 cases (9%) of primary biliary cirrhosis in cirrhotic stage, 6 cases (18.18%) of hepatic portal sclerosis, 4 cases (12.12%) of hepatic sarcoidosis, 2 cases (6%) with hematological malignancies, 2 cases (6%) of polycystic liver, one case (2.9%) hepatic angiomatisous liver, a case chronic hepatitis B, a case of Gaucher disease and one case secondary to hamartoma of the liver. Treatment was indicated according the etiology of the PH and its severity (beta blockers, ligament). Conclusion: Non-cirrhotic intractable portal hypertension is mostly asymptomatic, related to a heterogeneity of diseases with a good prognosis, excepted solid and hematological malignancies.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: External biliary fistulas are a common complication after surgical treatment of the liver. Complete management of this complication is safe and very useful when we respect the indications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1383 THE EVOLUTION OF ESOPHAGEAL VARICES IN NON CIRRHOTIC PORTAL HYPERTENSION CAUSED BY PORTAL VEIN THROMBOSIS
L. Benelbarhdadi1, K. Loubaris2, H. Boutallaka3, F.Z. Ajana1

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infraportal occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro-esophageal varices.

Aims & Methods: The aim of this study is to specify the evolution of esophageal varices and thus risk of rebleeding in patients with PHT by PVT unrelated to cirrhosis. It is a retrospective study from June 1st 2010 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the department of hepatogastroenterology (medicine C) at Ibn Sina University hospital of Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.

Results: The mean age of patients was 36 ± 15 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.64. Five percent of patients had a splenectomy for undetermined reasons before the diagnosis of PHT. Concerning the clinical examination, 10.9% (n=11) were hospitalized for melena, 60.4% (n=61) for hematemesis and melena and 28.7% (n=29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n=11), showed an anemia in 11.9% (n=12), and signs of PHT such as splenomegaly and collateral abdominal circulation in 95.1% (n=91). Complete blood count showed that 16.8% (n=17) had thrombocytopenia, 12.9% (n=13) had ictericia, and 42.6% (n=43) had pancyclopenia. In all patients, upper GI endoscopy was performed. Hypertensive gastropathy was found in 30.7% (n=31), grade I esophageal varices in 3.9% (n=4), grade II in 30.7% (n=31), grade III in 48.5% (n=49) and gastric varices were noted in 13.9% (n=14). These varices were with red spots in 18.8% (n=19). All patients had abdominal doppler ultrasoundography showing a PVT in 60.3% (n=61), was partial in 33.6% (n=34), complete in 11.9% (n=12). Associated to the splenomegaly, the hyperechoic spleen was found in 39.6% (n=40). All patients performed an etiologic assessment of thrombosis, myeloproliferative syndrome was found in 8.9% (n=9), deficiency in inhibitors of coagulation in 31.7% (n=32), celiac disease in 4.9% (n=5), no etiology was found in 51.4% (n=52). Endoscopic variceal Ligation (EVL) was performed in 70.3% (n=71), the mean number of ligation sessions was 3 and eradication of oesophageal varices was noted in 69.3% (n=70). All patients received anticoagulant therapy except those having portal cavernoma with no obvious cause and 11.9% of patients (n=43) received beta-blockers for secondary prophylaxis. During follow up, 5.9% (n=6) of patients have not been seen at consultation and no rebleeding was noted in 89.1% (n=90). Concerning portal thrombosis, it dissolved in 49.5% (n=50) and stabilized in 10.8% (n=11).

Conclusion: The evolution of esophageal varices in non-cirrhotic portal hyperten-

Introduction: Percutaneous cholecystostomy (PTCS) has been an alternative treat-

Aims & Methods: This study was a retrospective observational study of 171 consecutive patients who treated with PTCS for ACC in the period from 1 Jan 2005 to 31 Dec 2015. Outcome measures included the success rates, adverse events, resource use, and mortality. All data were collected from patients' medical records.

Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n=3, 1.8%), hemorrhage (n=2, 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n=1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removed GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4% 3/14; p < 0.05). The frequency of recurrence of gallstone disease in patients with contrast passage to the duodenum on cholangiography after PTCS was lower than that in patients without contrast passage.

Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1384 EVALUATION OF COMMON BILE DUCT CLEARANCE AFTER ENDOSCOPIC MANAGEMENT OF DIFFICULT BILIARY STONES BY DIRECT PERORAL CHOLANGIOSCOPY: PRELIMINARY RESULTS OF A PILOT STUDY

Introduction: Incomplete stones clearance after endoscopic management of dif-

Aims & Methods: We aimed to evaluate the feasibility and safety of POC to confirm CBD complete clearance after endoscopic treatment of difficult biliary stones. From 1st June 2016 to 30 March 2017 all consecutive patients treated with Diluted assisted stone extraction (DASE) for difficult biliary stones at our institution, underwent POC to verify CBD stones complete clearance. Ultraslim (5.9 mm diameter) or Slim (8.5 mm diameter) endoscopes (Fujifilm EG 530NW or EG 530FP) or standard gastroscope (9.9 mm diameter) (Olympus GIF-HQ190), under CO2 insufflation, were used by the peroral route for intubating all accessible bile ducts. Technical success rate, procedural time, outcome and side effects of POC were assessed. All endoscopic events were recorded.

Results: POC was performed in 26 patients (17F/9M mean age 74.6 years ± 11.9) under propofol sedation (25 patients) or deep sedation (5 patients). Mean CBD size was 15 mm ± 3.65; mean stone diameter (13.5 mm ± 1.70); mean balloon dilation (13.5 mm ± 2.12). Intubation of the papilla and distal biliary duct was successful in 26 (100%) cases (guide-wire assistance in 17 cases, 65.4%). Hepatic hilum was reached in 13/26 (50%) patients with a complete CBD evaluation. Mean investigation time was 6.3 ± 1.5 min (range of 5–9 minutes). POC showed persistent large amount of sludge in 27.7% cases, completely suctioned through the endoscope, and stones in 4 (15.4%) cases with subsequent endoscopic stones removal. In the remaining patients, POC confirmed complete duct clearance. No adverse events occurred.

Conclusion: POC complete clearance confirmation using POC is a feasible, quick and safe procedure that can help on clinical decision making (for example obviating the need for possible plastic stent or naso-biliary drainage placement) without substantial increase of time or costs. Our experience, however, is preliminary and therefore aimed to assess the feasibility of the procedure, which could represent the first step for the development of a possible new indication in the setting of difficult biliary stone management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1386 SINGLE DEVICE TECHNIQUE FOR ENDOCOSCOPIC TREATMENT OF BILE DUCT STONES
M. Sen-Yo, S. Kaino, S. Amano, S. Shinoda, I. Sakaida
Gastroenterology And Hepatology, Yamaguchi University Graduate School of Medicine, Ube/Japan

Contact E-mail Address: msn730@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy is a well-established standard method for treating bile duct stones (BDS). After cannulation of the common bile duct (CBD), a guidewire is placed into the CBD and a sphincterotomy is performed. Subsequently, stone extraction using a balloon or basket catheter is performed. Because of this multi-step process, endoscopic treatment for BDS always comes with a risk of losing CBD cannulation. A combination catheter that combines a sphincterotomy and a retrieval balloon in a single instrument can eliminate one step in the previous procedure. Endoscopic treatment using a single device may be able to accomplish CBD clearance by using only single device. Additionally, a newly developed 0.025 inch guidewire that is, at once, rigid and flexible enables us to inject contrast agent through the Y-connector, and to use a combination catheter with a Y-connector and a 0.025inch guidewire may become a single device that can facilitate complete BDS clearance. Despite its utility, the success rate of bile duct cannulation and cost benefit requires further analysis.

Aims & Methods: We aimed to evaluate the therapeutic efficacy of a combined catheter as a single device required for BDS clearance. From January 2016 to July 2016, 11 consecutive patients with BDS ≤ 10 mm in size were enrolled in this study (Stonome group). In all cases, the combined catheter (Stonome) was
used for initial bile duct cannulation. Subsequently, sphincterotomy and stone extraction were performed using the combined catheter. The success rate of performing the combined procedure, procedure-related time, adverse events, and the cost of devices were compared with those in 10 patients with BDSs ≤ 10 mm in size who had undergone endoscopic stone clearance from April 2015 to December 2015 as historical control. Results: The success rate of selective cannulation and stone clearance did not differ significantly (Stonetome group: 90.9% and 100% vs control group: 100% and 100%, respectively). The median time after bile duct cannulation to complete stone clearance and total procedure time in the Stonetome group were significantly shorter than those in the control group (401.5 s versus 982.5 s, 464.5 s versus 1300 s, respectively). In the Stonetome group, delayed bleeding occurred in 1 patient. In the control group, bile duct injury caused by the guidewire occurred in 1 patient. The costs of the used devices did not differ significantly (Stonetome group: $678 versus control group: $669).

Conclusion: The combined catheter has the same selective cannulation ability as a conventional catheter and a similar capacity to remove BDSs as common retrieval forceps. Therefore, the combined catheter can reduce the procedure time to remove BDSs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1387 ACCURACY OF ASGE CRITERIA IN THE IDENTIFICATION OF PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS

C. Macedo, N. Almeida, D. Gomes, E. Camacho, S. Mendes, L. Tomé, A. M. Ferreira
Gastroenterology, Centro hospitalar e Universitário de Coimbra, Coimbra, Portugal

Introduction: Society for Gastrointestinal Endoscopy (ASGE) emitted, in 2010, guidelines for the clinical orientation of patients with suspected cholecodolithiasis (CL), suggesting the direct referral to endoscopic retrograde cholangiography (ERC) in certain groups. However, the ERC is an invasive exam and some studies demonstrated that a significant amount of patients classified with very strong risk of CL did not have alterations in ERC. Aims & Methods: The aim of this work was to assess the accuracy of the ASGE guidelines in Portuguese population. This is a retrospective study that included 212 patients (52.8% female, 47.2% male sex; mean age 73.9 ± 14.6 years) admitted to the hospital from 2014 to 2016. Results: Of the 212 patients, 28 (13.2%) had intermediate risk of CL and 184 (86.8%) had high risk, according to the ASGE criteria. These patients were submitted to the following exams/interventions: ERC (154 patients); magnetic resonance cholangiography (50 patients) and endoscopic ultrasound (8 patients). In patients classified with high risk of CL, this was confirmed in 119 (64.7%). The same was seen in 10 (35.7%) of the patients with intermediate risk. The ASGE criteria, when applied to this population, demonstrated an accuracy of 64.3% (21.7% sensitivity; 92.3% specificity) in the high-risk group, and an accuracy of 35.5% (78.3% sensitivity; 7.8% specificity) in the intermediate-risk group. Of the patients with intermediate probability, 12 (42.8%) underwent ERC, and CL was found only in 4 of these patients. The presence of cholangitis, a common bile duct >6 mm, a common bile duct stone visualized on transabdominal US and a total bilirubin >4 mg/dL were strong predictors of CL. The overall ERC complication rate was 13% (20 patients) of whom 8 had no CL. Conclusion: The ASGE guidelines showed a limited diagnostic accuracy in the identification of patients who actually require ERC, conditioning a significant number of unnecessary procedures with subsequent complications associated with them. Thus, the orientation of these patients, with greater use of less invasive diagnostic techniques such as magnetic resonance cholangiography and endoscopic ultrasound. Disclosure of Interest: All authors have declared no conflicts of interest.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY AROUND THE T-tube. REDUCE THE RISK OF BILE LEAKAGE? A RANDOMIZED STUDY

B. Darkahi1, G. Sandblom1, T. Norden1
1Surgery Department, Enköping/Sweden
2Surgery Department, Uppsala/Sweden

Contact E-mail Address: bahan.darkahi@gmail.com

Introduction: Laparoscopic choledochotony as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile leakage along the T-tube. To some extent the leakage may be reduced if the incision is situated around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suturing.

Aims & Methods: Between 2012 and 2016 a total of 1347 cholecystectomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholangi-otomy around the T-tube. Postoperative cholangiography was performed after 7–10 days after surgery. The amount of flow in the abdominal drain and the level of bilirubin was measured daily. In case the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time

Conclusion: Discussion: Fibrin glue may be an option to seal cholangi-otomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and cholangitis (AC). However, the complex post-surgical anatomy limits the possibility of performing an ERC as part of AC treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality and resource utilization among patients with AC using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AC were included. There were no exclusion criteria. Patients with a past history of BS were identified using the appropriate ICD-9-SCM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization: use of ERC, cholecystectomy, length of hospital stay (LOS), total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 4,240 patients with AC were included in the study, of which 4,240 (1.7%) had undergone BS. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.37, 95% CI: 0.51–3.65, p = 0.52). As far as resource utilization, patients with bariatric surgery had lower adjusted odds of ERC (aOR: 0.28, 95% CI: 0.09–0.83, p = 0.02), but higher odds of cholecystectomy (aOR: 3.18, 95% CI: 1.00–10.05, p = 0.04). Both patient groups had similar adjusted length of stay (adjusted mean difference: 1.19 days, 95% CI: 0.09–0.83, p = 0.16) total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute cholangitis, despite its association gallstone acute pancreatitis and limited ERC performance. In addition, bariatric surgery does not affect resource utilization in this patient population as measured by length of stay and total hospitalization costs.

Contact E-mail Address: sarah.wennmacker@radboudumc.nl

Introduction: Prevalence of gallbladder polyps in the Netherlands is 943 per 100,000 cholecystectomies. Histopathologically these gallbladder polyps can be divided into neoplastic polyps (with malignant potential) and nonneoplastic polyps (without malignant potential). Although cholecystectomy is only indicated for neoplastic polyps, 47% of polyps after cholecystectomy are nonneoplastic. Further information on the pathological characteristics and subsequent clinical and radiological features could be useful to predict neoplastic or nonneoplastic nature of the gallbladder polyp before surgery.

Aims & Methods: To assess pathological characteristics of neoplastic and nonneoplastic gallbladder polyps and identify preoperative clinical and radiological predictors for neoplastic and nonneoplastic polyps. Data of the Dutch Pathology Registry was used. In this search 2081 histopathologically proven gallbladder polyps (or focal wall thickening > 5 mm) were identified in patients of ≥18 years undergoing primary cholecystectomy between 2003 and 2013. Of these
Disclosure of Interest: nonneoplastic polyps are confirmed, identification of these characteristics on this cohort. Although pathological characteristics of neoplastic and identified in this study. The following clinical and radiological predictors were considered: age, gender, ethnicity, BMI, medical history (PS: Hepatitis, metabolic syndrome, gallbladder disease, Salmonella typhi or Helicobacter pylori infection), family history of gallbladder disease, presentation (size, number, shape, and echogenicity of the polyp). Associations between possible predictors and gallbladder polyps were assessed using univariate and multivariate logistic regression analysis.

Results: Patients with neoplastic polyps were found to be significantly older than patients with nonneoplastic polyps (mean age 65.0 vs 54.2 years, p < 0.01). Neoplastic polyps were significantly larger (mean size 18.1 mm (SD 7.5 mm) vs 7.5 mm (SD 5.9), p < 0.001), more frequently presented as wall thickening (29.2% vs 15.6%, p < 0.001), and as a single polyp (88.3% vs 68.0%, p < 0.001). Gallstones were more frequently found in gallbladders with neoplastic polyps (40.1% vs 40.4%, p > 0.01). No preoperative clinical features were predictive for neoplastic or nonneoplastic polyps. Presence of a single polyp on ultrasound was a predictor for neoplastic polyps (OR 6.00 (95%CI 1.32-27.31)). Size and type of polyp were often not mentioned in ultrasound report, or different from histopathological confirmation.

Conclusion: Except for age, no clinical characteristics for neoplastic polyps were identified in this cohort. Although pathological characteristics of neoplastic and nonneoplastic polyps are confirmed, identification of these characteristics on preoperative radiological investigations is poor.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1392 METFORMIN INDUCES APOPTOSIS AND MODULATES PROLIFERATION IN THE BILE DUCT CANCER CELLS

Gastroenterology; Hallym University Dongsung Sacred Hospital, Goyang/Do- Korea. Republic of

Contact E-mail Address: jine@hallym.or.kr

Introduction: Metformin has evidence of antineoplastic activity in some cancer cells.

Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms involved in the inhibition of cancer cell growth. Human extrahepatic bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. Apoptosis was measured by a cell death detection enzyme-linked immunosorbent assay and caspase-3 activity assay. Various protein expressions with or without specific SiRNA transfection were measured by Western blot. The migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by inducing apoptosis. 2) Metformin inhibited mammalian target of rapamycin (mTOR) by activation of AMPKThr172 - tuberous sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKser485. 3) Metformin decreased effect of IGF-1R by inhibiting serine/threonine protein kinase 1 receptor (IGF-1R). 4) Metformin increased expression of hOGG1 and XRCC1. 5) Metformin modulated invasiveness of bile duct cancer cells, and the effect was impaired by hyperglycemia.

Conclusion: This study shows that metformin has antineoplastic effect in bile duct cancer, and the effect of metformin is attenuated in the hyperglycemic environment. In addition, AMPK and IGF-1R play a key role in the proliferation of bile duct cancer cells, and they are expected to be important targets for future development of chemotherapeutic agents.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Molecular pathology of gall bladder anomalies and progression to carcinoma is still obscure and understudied; but is critically relevant to India which harbors the highest number of cases globally, and to ethnically distinct NEI population, and was therefore studied by this study. The following pathological characteristics of gall bladder polyps were collected from clinically and histopathologically confirmed cases of GBC (adenocarcinomas, N = 49) along with non-neoplastic control sections, chronic cholecystitis (CL, N = 78) and cholecystosis (CS, N = 56), along with blood from voluntary controls (N = 122) with informed consent. The pathway included two of the key stages, the conversion of primary bile acids to secondary bile acids and the conversion of secondary bile acids to primary bile acids. This study shows that metformin has antineoplastic effect in bile duct cancer cells, thus they are expected to be important targets for future development of chemotherapeutic agents.

Aims & Methods: The study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affects molecular mechanisms involved in the inhibition of cancer cell growth. Human extrahepatic bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. treatment. As negative controls, 19 non-GBCa bile juice and 33 non-GBCa tissue samples were used for mutations of oncogenes in the same way.

Results: The median (range) age was 77 (44–90) years and the male/female ratio was 0.43 (9:21). Six, six, and twelve patients were diagnosed as stage I, II, III, and stage IV, respectively. We set cut-off value at 5% for rare mutation rate based on our results of healthy samples to avoid false positive. Eleven of 20 (55%) tumor tissue samples were positive for mutation. TP53, MET, SMAD4, CTNNB1 and AR were detected in 7/20 (35.0%), 1/20 (5.0%), 1/20 (5.0%), 1/20 (5.0%) and 1/20 (5.0%) respectively. In this study, 14 of 30 (46.7%) patients had both tumor tissue samples and bile juice samples. Eight of 14 (57.1%) tumor tissue samples were positive for mutation. In these eight patients, 7 (87.5%) bile juice samples had the same mutation (TP53, ERBB2/3 were detected in 6/8 (75%). 1/8 (12.5%), respectively). On the other hand, bile juice samples of only 1/6 patients with tumor tissue mutation had no mutation. With regard to only bile juice, 14 of 24 (58.3%) bile juice samples with GBCa were positive for mutations. TP53 mutation, ERBB2/3 Kras were detected in 11/24 (45.8%), 2/24 (8.3%), 1/24 (4.2%), respectively. Bile juice analysis for mutations indicated that sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 58.3%, 100%, 100% and 65.5%, respectively. None of negative control samples had any mutations.

Conclusion: Mutations in tumor could be detected in bile juice using NGS. Liquid biopsy with bile juice may help us to diagnose GBCa because of high PPV (100%). It may allow us to make new genetic diagnosis of GBCa.

Introduction: Intraductal radiofrequency ablation (RFA) is a new endoscopic ablative technique with direct effect to local tumor have been developed to improve the eradication of self-expanding metal stents (SEMS) in the unresectable malignant biliary obstruction. However, there is the concern for the complication such as bile duct perforation or bleeding because the ideal power setting of intraductal RFA has not been clearly revealed still.

Aims & Methods: We aimed to investigate the effects of ablative injury after in vivo intraductal RFA according to the time variation using a novel RFA catheter (ELRA®, STARmed, Goyang, Korea). This novel catheter is a bipolar device and has a temperature sensor within the distal tip, therefore it has a characteristic of target temperature controlled mode. Nine female pigs were divided into three groups according to RFA time variation (60, 90 and 120 seconds) with the same power setting (10 watts) and RFA target temperature (80°C). All pigs underwent endoscopic retrograde cholangiography (ERC) and intraductal RFA. Additional cholangiogram was taken immediately after RFA and then a plastic stent was inserted. All the pigs were humanely sacrificed 24 hours after the intraductal RFA. Necropsy was performed and the common bile duct was washed for histologic analysis.

Results: The ERC and application of the intraductal RFA was successful in 100%, and post-RFA cholangiogram did not show the contrast leakage. Median depth of microscopic ablation was significantly different between three groups with ablation time (60 vs. 90 vs. 120 seconds) (1.17 ± 2.23 vs. 2.44 ± 2.31 ± 0.60) 2.52 ± 2.74 – 2.64 mm, p = 0.018). There was also a linear relationship between ablation time and microscopic ablation depth (r² = 0.552, p = 0.002). However, there were no statistical differences in macroscopic ablation length and microscopic ablation length. In addition, focal ablation injuries of adjacent liver were found in five out of nine pigs (2 of 3 pigs in 60 seconds, 1 of 3 in 90 seconds, 2 of 3 in 120 seconds).

Conclusion: Intraductal RFA using a novel RFA catheter successfully ablated the normal bile duct wall without serious complications in vivo swine model. The optimal time of intraductal RFA was presumed between 90 and 120 seconds at the power setting 10 watts and target temperature of 80°C. However, focal ablation injury was found in even short ablation time in which microscopic ablation depth was superficial. Further studies are needed to validate the optimal power setting of RFA in a swine model and then human clinical studies are also warranted.

P1396 PREDICTIVE MODEL FOR THE NEOPLASTIC POTENTIAL OF GBILIAL BLADDER POLYPYS

J.K. Lee
Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: jongk.lee@samsung.com

Introduction: While many studies have attempted to define the risk factors for neoplastic potential of gallbladder polyp, precise adaption of the risk factors individually in a real treatment strategy of gallbladder polyp remains elusive. The probability for neoplastic potential of gallbladder polyp using a combination of several risk factors before surgical resection would be useful in patient consultation.

Aims & Methods: This study was designed to provide the statistical predictive model for neoplastic potential of gallbladder polyps. We collected data of patients confirmed as GBP through cholecystectomy at Samsung Medical Center between January 1997 and March 2015. Those with a definite evidence for malignancy, such as adjacent organ invasion, metastasis on preoperative imaging studies, polyp larger than 15 mm, and absence of proper preoperative ultrasonography imaging, were excluded. A total of 1976 patients were enrolled.

To make and validate the predictive model, we divided the cohort into the modeling group (n = 979) and validation group (n = 997). Clinical information, ultrasonographic findings, and blood tests were retrospectively analyzed. A prediction model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significance level for removal of P ≥ 0.15 for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

Results: Clinical factors of older age, single lesion, sessile shape, and polyp size showed statistical significance of neoplastic potential of GBP in the modeling group. A predictive model5 of neoplastic potential of GBP was constructed utilizing the statistical outcome of the modeling group. Statistical validation was performed with the validation group to determine the optimal clinical sensitivity and specificity of the predictive model. Optimal cut-off value for neoplastic potential was 7.49. * Probability of Neoplastic GB polyp = e(^0.6667 x [Age] + 0.5784 x [Sex] + 0.2189 x [Size]).

Conclusion: The predictive model for neoplastic potential of GBP may support clinical decision before cholecystectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1397 COMPARISONS OUTCOMES FOR CONTROLLED PHOTODYNAMIC THERAPY IN HIGH GRADE UNRESECTABLE HILAR CHOLANGIOCARCINOMA

E.T. Park, B.C. Yoon, S.U. Lee, B.H. Han
Internal Medicine, Konis University, Gospal Hospital, Busan/Korea, Republic of

Contact E-mail Address: euopark@s.hanmail.net

Introduction: Photodynamic therapy (PDT) provide clinical benefit for patients with unresectable biliary malignancy. In this study, we evaluate the efficacies of controlled PDT for unresectable primary and secondary high-grade hilar cholangiocarcinoma (CC).

Aims & Methods: In cases of high-grade unresectable hilar CC (Bismuth type III or IV) and gallbladder (GB) cancer (biliary invasion to hilar portion (Group A), we performed controlled PDT. Controlled PDT means malignant stricture dilatation by using straight angled cylindrical diffuser. Finally, gemcitabine-based chemotherapy was done for 6 cycles. We compared to transpapillary approach with non-straight cylindrical diffuser using with gemcitabine-based chemotheraphy in similar patients (Group B) in terms of clinical parameters and developing complications.

Results: Between July 2010 and June 2015, 26 cases(31) of high grade unresectable hilar CC (Bismuth type III or IV), 5 cases of GB cancer with hilar invasion were enrolled for Group A, 23 cases(26) of high-grade unresectable hiliar CC (Bismuth type III or IV), 3 cases of GB cancer with hilar invasion were enrolled for Group B. On three months later, serum bilirubin levels decreased from 7.3 ± 3.7 mg/dL in group A, 6.9 ± 5.5 to 5.2 ± 3.7 mg/dL in group B (p < 0.05). PDT-induced cholangitis is developed in Group A (3/31, 9.6%) and B (7/26, 26.9%) within seven days (p < 0.001). Progression free survival is superior Group A to Group B that of 14.8 months vs. 8.9 months (P < 0.05).

Conclusion: Controlled PDT with straight applying cylindrical diffuser promise efficacy for clinical parameters and progression free survival compared with transpapillary PDT in unresectable high grade hilar CC and GB cancer. Additionally, diminished post-PDT cholangitis within 7 days affect improving long term progression free survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aim & Methods: The aim of this retrospective analysis of prospective case series from the Czech Republic and Slovak (n = 166) was to describe the (1) diagnostic yield of d-SOC visual diagnosis and biopsy in patients with undetermined bile duct stenosis; (2) the efficacy of d-SOC directed treatment of difficult lithiasis and (3) to analyze relevant procedure-related adverse events (AEs). The diagnoses of malignancies were (1) sensitivity and specificity for malignancy, (2) achievement of a complete duct clearance in patients with difficult lithiasis (3) procedure-related AEs.

Results: A total of 150 patients underwent 166 d-SOC procedures (165 cholangioscopes and 1 pancreatoscope); 81 (48.8%) for diagnostic intents (with biopsy in 66/61 patients (81.5%), and 85 (51.2%) for therapeutic intents (1 patient had pancreaticolithiasis). The most frequent indication for diagnostic d-SOC was undetermined stenosis (n = 59). Reliable views of a target lesion were obtained in all patients. The sensitivity, specificity and diagnostic accuracy of d-SOC for visual diagnosis of malignant lesion was 88.9% (95%CI, 70.8–97.7), 81.2% (65.6–92.3) and 84.6% (73.5–92.4). The mean number of biopsies obtained per patient was 4 (range 1–13) and the specimen was adequate for histopathological analysis in 95.5% of patients. The sensitivity, specificity and diagnostic accuracy of d-SOC guided biopsies for malignancy were 78.3% (95%CI, 56.3–92.5), 96.4% (81.6–99.9) and 83.3% (70.7–92.1). The diagnostic accuracy of visual inspection was not statistically influenced by the presence of biliary stent (Yates’ p = 0.9). Of 63 patients attended for d-SOC-guided stone therapy, a complete intraductal clearance was achieved in one session in 37 and in two sessions in further 10 patients, respectively and the overall success rate was 77%. A total of 11 patients (n = 16; 6.6%) experienced an adverse event (choangiitis n = 6, pancreatitis n = 3, perforation n = 2), one patient with severe cholangitis died. The incidence of cholangitis was higher among patients who had received prophylactic antibiotics (n = 5) compared to those who had not received it (n = 1). d-SOC directed biopsies were performed in 48.8% of patients and 46% of adverse events may occur and prophylactic antibiotics may not be effective in preventing post-d-SOC cholangitis. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adenoma of the major duodenal papilla is clinically important because this lesion is premalignant and should be resected completely. Endoscopic papillotomy of ampullary adenomas is a promising alternative to surgical resection, however acute and delayed pancreatitis represent a major complication of this procedure.

Aims & Methods: We evaluated the clinical importance of pancreatic duct drainage after endoscopic papillotomy in order to prevent early (acute pancreatitis) and late (pancreatic duct orifice stenosis) complications of this procedure. Our single-centre study with a minimal follow-up of 1 year, includes 19 patients who underwent endoscopic ampullotomy between 2012 and 2016. Careful preoperative evaluation was performed by EUS (100% of patients) and CT/MRI (94%). After a collective evaluation between the surgeon and the endoscopist, patients were candidate for endoscopic ampullotomy. Outcome parameters included ampulla morphology characteristics, biotechnical accuracy as well as safety, efficacy, recurrence rate, and survival.

Results: Endoscopic resection was successful in 15 patients (79%). Histological review of resected specimens revealed non specific changes (10.5%), low or medium-grade dysplasia (52.6%), high-grade dysplasia (15.8%) and carcinoma (21%). Biopic accuracy was 68.4%. In 4 cases histologic specimen revealed an invasive carcinoma: 2 patients underwent pancreaticoduodenectomy and two were treated conservatively with placement of biliary and pancreatic stents due to the high preoperative risk. After complete endoscopic resection (15 patients), pancreatic stents were placed in 10 cases (66%). In five cases the positioning of pancreatic stents was not possible due to anatomical difficulties: 2 developed mild pancreatitis after papillotomy; 1 patient developed, as late complication, a stenosis of the pancreatic orifice: the patient died of severe necrotic pancreatitis two years later. Hemorrage was observed in 2 patients, all with pancreatic stents. Recurrence occurred in 2 patients (10.5%), both were re-treated by endoscopic pancreatic duct drainage aiming to improve the success rate of pancreatic stent placement after papillotomy.

Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

Disclosure of Interest: All authors have declared no conflicts of interest.

Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcome was rate of complications; overall surgical time, 30 days mortality, postoperative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: ThreeRCTs and five non-RCTs were selected including 909 patients. Of these, 300 patients (33%) were treated with SEMS and 609 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in the metal stent group as well (5.1% vs 11.8%, p = 0.04) (OR 0.23 95%CI 0.06–0.96). The rate of postoperative surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred for patients with resectable periampullary or pancreatic head tumors when early surgery without PBD is not feasible. However, more RCTS are needed before a firm conclusion could be made.

Introduction: Dietary fat consumption affects the human body fat composition. It has been described that unsaturated fatty acids, enriched in human pancreatic necrosis (AP) [1] and patients in other regions (group C). This was a retrospective analysis of a prospective multicenter (23), nation-wide cohort of patients with AP: the ATLANTIS database. Group M included patients from Spanish autonomous regions in contact with the Mediterranean Sea. Group C included all other autonomous regions. Necrotizing AP and POF were defined according to the revised Atlanta classification. Chi² was used for univariate analysis. Multivariate analysis was performed by means of binary logistic regression, including in the model: sex, body mass index > 30, alcohol etiology and Charlson score (it includes age and comorbidity) ≥ 3.

Results: We analyzed 1655 patients, 854 (52%) from group M (12 centers) and 801 (48%) from group C (11 centers), with biliary etiology, 891 (54%) males. The incidence of necrotizing AP was 281 (17%) patients, persistent organ failure: 113 (7%), mortality 70 (4%). The proportions of patients with necrotizing AP was higher in group M: 178 (21%) vs 103 (13%), p < 0.001. POF was also more frequent in group M: 49 (6%) vs 21 (3%), p < 0.002. Finally, mortality was higher in group M: 49 (6%) vs 21 (3%), p = 0.002. In multivariate analysis, group M was independently associated to necrotizing AP [adjusted OR (aOR) 1.7 (1.3–2.3), p < 0.001], to POF [aOR 2 (1.3–3.1), p = 0.001] and mortality [aOR 2.6 (1.6–4.4), p < 0.001].

Conclusion: Patients from the Mediterranean regions of Spain have a higher incidence of necrotizing AP, POF and mortality. We hypothesize that this disbalance is associated to a higher diet unsaturated fat intake.

Introduction: Splanchnic venous thrombosis (SVT) is a common vascular complication of acute pancreatitis (AP). There is paucity of data on its frequency, risk factors, outcome and natural history. Coagulation abnormality has been implicated but not proven as a cause of SVT in AP.
Aims & Methods: We aimed to prospectively study the frequency, risk factors and extent of SVT in patients with AP as well as role of thrombophilia in causation of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to detailed analysis of coagulation parameters. Outcome was assessed in terms of presence or absence of necrosis, severity, organ failure, need for interventional therapy and mortality. None of the patients with SVT were given anticoagulation. Follow-up ultrasound Doppler was performed to look for the status of SVT.
Results: Nineteen patients with AP (17 males, mean age 31.85 ±13.34 years) were evaluated of which 26 (27.1%) had SVT. Single vessel, two vessels and three vessels were involved in 19 (73.1%), 3 (11.5%) and 4 (15.4%) patients respectively. Splenic vein, portal vein and superior mesenteric vein involvement were seen in 22 (88.5%), 14 (53.8%) and 4 (15.3%) patients respectively. Necrotizing pancreatitis, CTSI ≥6 and Modified CTSI ≥6 were found in significantly higher number of patients with SVT than those without SVT (96.2% vs 78.6%, 76.9% vs 47.8%, and 67.1% vs 67.1%, respectively). Coagulation analysis was performed in 42 patients (18 with and 24 without SVT). Protein C, protein S and AT III deficiency were found in 10 (23.8%), 14 (33.3%) and 13 (31.0%) patients respectively. β2GPI and lupus anticoagulant were positive in 2 (4.8%) and 2 (4.8%) cases respectively. Anticardiolipin antibody was negative in all the patients. Factor V Leiden mutation analysis was done in 33 patients (18 with and 15 without SVT). In 5 (15.2%) patients, mutation was present. Resolution of SVT occurred in 5 patients (71.4%) within 1 year. None of the patients had varices on follow-up.
Conclusion: SVT in AP is more common in patient with necrotizing pancreatitis and higher CTSI and MCTSI indices suggesting that local inflammation plays a major role in its causation. Thrombophilia in some form is seen in one third of the patients with AP but does not increase the risk of AP.

P1409 EUS-GUIDED PANCREATIC FLUID COLLECTION DRAINAGE WITH LUMEN-APPOSING METAL STENTS OR PLASTIC DOUBLE PIGTAIL STENTS: A MULTI-FACTORIAL ANALYSIS
N. Ge, S. Sun
Dept. Of Endoscopy, Shengjing Hospital, Shenyang/China
Contact E-mail Address: ge_nan2013@163.com
Introduction: We aimed to compare the efficiency of plastic and metal stents for symptomatic pancreatic fluid collection drainage and analyze other main associated factors that affect the outcome of drainage therapy.
Aims & Methods: Rates of technical and clinical success, procedure-related side effects (hemorrhage, stent migration, and cyst rupture), re-interventions, and duration of hospital stay.
Results: There were 52 patients, 40 who underwent plastic stent placement and 12 who underwent lumen-apposing metal stent placement. The total rate of technical success was 100%. The total rate of clinical success was 100%. The total rate of adverse events was 7.7% (4/52). On multiple logistic regression analysis, the use of plastic stents (P < 0.05, Exp B = 12.168) and presence of a large cyst (P < 0.05, Exp B = 1.036) were shown to significantly increase the risk of re-intervention. On multivariate linear regression analysis, etiology of pseudocyst (P < 0.05, B = 8.427; −9.785; −5.514) was associated with prolonged hospital stay, while stent type was not shown to be a factor (P > 0.05).
Conclusion: Both plastic and lumen-apposing metal stents are proven to be highly efficient in pancreatic fluid collection drainage. The lumen-apposing metal stent is superior in preventing complications such as migration and cyst leakage and reducing the rate of re-intervention. Large cyst size is associated with an increased risk of re-intervention and prolonged hospital stay.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Infected pancreatic necrosis (IPN) is associated to significant morbidity and mortality. Current management of IPN is based on a step-up approach, based on minimally invasive procedures. Our group has recently published a protocol of local infuson of antibiotics for the treatment of IPN (Pancreatology, 2016;6:719–25).
Aims & Methods: We aim at analysing the efficacy of this step-up approach for the treatment of IPN in clinical practice. This was a retrospective single-centre study of patients admitted with acute pancreatitis (AP) between January 2015 and December 2016. The cases were the diagnosis of pancreatic necrosis (IPN) and IPN (defined by positive culture of necrosis and clinical, analytical, and/or radiological data of infection) were identified and evaluated. IPN was treated following a step-up approach defined by 1. intravenous antibiotic therapy, 2. Endoscopic ultrasound guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.
Results: 694 cases of AP were included (mean age 79.5 ± 18.3, 555 male). CT scan was performed only if clinically indicated. 67 patients (9.0%) had acute necrotizing pancreatitis (ANP), and 21 of them IPN (31% of ANP). IPN patients were treated with intravenous antibiotics (imipenem [n = 15] and meropenem [n = 6]), with good response in 8 (38% of IPN). The remaining 13 cases underwent a EUS guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Introduction: Acute pancreatitis (AP) is one of the most common diseases of the gastrointestinal tract associated with significant morbidity and mortality. The management of AP is crucial in the management of the disease. The pathomechanism of AP is not well understood, it has no specific therapy. Current methods of risk stratification in AP have a limited value, as they provide little additional information thus may delay appropriate management. Early recognition of severe disease may prevent serious adverse events and improve patient management as well as overall clinical outcome. The EASY trial is an observational, multicenter, prospective cohort study for establishing a simple, easy and accurate clinical scoring system for early prognostication of acute pancreatitis.

Aims & Methods: We aimed to create a new scoring system, which can predict the severity of AP in early phase of disease. Evaluation of simple attainable potential prognostic parameters obtained at admission (or not later than 6–12 hours after admission) from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity. Approximately 1200 (900 ± 300) patients from multiple centers will be enrolled into this trial using the Registry. This is an observational prospective cohort study (in which the care or services that patients receive will not be altered; therefore it has a relatively low risk. The study has an ethical approval by the National Hungarian Ethical Authority (ETT TÜKEB). Study management will strictly follow the Ethical Guidelines for Observational Studies.

Results: 600 patients were enrolled in the EASY study from different international centers so far. In early phase of AP vomiting, loss of weight, fever, abdominal tenderness, elevated serum creatinine and lactate dehydrogenase level were most frequent findings in severe AP, as opposed to the mild and moderate groups.

Conclusion: EASY score may be an easy and accurate system to evaluate the early severity of AP. Although some parameters have shown correlation with the severity of AP in early phase of the disease, we have to include more patients to have reliable results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim was to evaluate the efficacy of local instillation of antibiotics into walled-off pancreatic necrosis. Between 2012 and 2016 we evaluated all patients treated with endoscopic transmural drainage and necrosectomy (EDTN) and concomitant local instillation of antibiotics. We added antibiotics (either gentamycin, vancomycin, or amphotericin B) to the irrigation fluid according to the microbiological findings. The antimicrobial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

Results: Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolates were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, P = 0.01), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericin B and in 17 (85%) patients the fungus was eliminated at the third culture.

Conclusion: Our data suggest a better efficacy of local antibiotics in the treatment of infected WON compared to systemic antibiotics. The local instillation of antibiotics may be a promising alternative or supplement to systemic administration. Particularly the use of local instillation of amphotericin B appears to be effective in the treatment of fungal infections.

P1413 OUTCOMES IN ACUTE PANCREATITIS IN PATIENTS WITH TYPE-2 DIABETES MELLITUS

P. Santos, J.R. Carvalho, S. Fernandes, M. Moura, T. Antunes, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Lisboa Norte, Lisbon/Portugal

Contact E-mail Address: patricia.santos@hotmail.com

Introduction: Predicting severe pancreatitis is important for early aggressive management of patients with acute pancreatitis (AP). Despite the established role of type-2 diabetes mellitus (DM) in the risk of AP, the impact on the clinical outcome in AP has not been fully elucidated.

Aims & Methods: Retrospective study including hospital admissions between January 2003 and December 2016 in a single tertiary referral center. Clinical outcomes included organ failure (OF), persistent (≥48h) admission to intensive care unit (ICU) and mortality. Variables were analysed by logistical regression (SPSS v23.0). The objective of this study was to assess the risk of mortality and severity in AP among patients with type-2 DM.

Results: A total of 553 patients (58.4% male) with AP were included, median age 80 (16-98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.5%). Twenty three percent developed OF (in 43% persistent) and 5.6% (n = 57) died. There were 127 AP patients (23.0%) with type-2 DM. Type-2 DM were not associated with higher Ranson's score. There was an association between DM and development of OF (OR 3.17, CI95% 1.88-5.37, p < 0.001), persistent OF (OR 4.51, CI95% 18.7-108.9, p < 0.001), ICU admission (HR 12.3, CI95% 1.9-104.9, p = 0.001), mortality (HR 1.7, CI95% 6.58-42.84, p < 0.001). At multivariate analysis DM was an independent predictor of OF development and ICU admission.

Conclusion: In our population, Type-2 DM was associated with severity and increased mortality in patients with AP. Our findings provide evidence of the potential role of DM in the management of severe AP.

P1414 ACUTE PANCREATITIS IN LIVER TRANSPLANT RECIPIENTS: INCIDENCE AND OUTCOME

1Department Of Gastroenterology And Hepatology, Institute For Clinical And Experimental Medicine, Prague/Czech Republic
2First Faculty Of Medicine, Charles University, Prague/Czech Republic
3Transplantcentre, Institute For Clinical And Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: peter.macina@iikem.cz

Introduction: Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported incidence ranges from 1.5 to 8% in patients undergoing liver transplantation with significant mortality.

Aims & Methods: The aim of our study was to assess the incidence, potential risk factors and outcome of AP following liver transplantation in our center. We performed a retrospective analysis of medical records of all adult patients who underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylase and lipase.

Results: Nine hundred and sixty-seven orthotopic liver transplantations were performed in 578 males and 389 females (mean age 51 years, range 18-74). AP occurred in 18 patients (1.9%, 16 males, 2 females) and resulted in death in 5 patients (28%). According to timing of AP we recognized two clinical presentation—early AP (≤ 1 month after liver transplantation) and late (>1 month). Four patients (22%) developed early AP, which was severe necrotizing with MODS in all cases and resulted in death in 3 of them (75%). Two of them were transplanted for fulminant hepatic failure, one for end-stage liver disease due to alcoholic hepatitis B infection and one for polycystic liver disease. Two patients were treated by surgical necrosectomy and died, the third deceased patient was treated conservatively. In the only surviving patient, a successful EUS-guided drainage of walled of pancreatic necrosis and repeated endoscopic procedures were performed. The surgery was unable to identify the culprit cause responsible for development of AP. Late AP occurred in 14 patients (78%) with a median delay of 31 months after liver transplant (range 2-176). In 12 patients AP was mild with no mortality and the following etiologies were represented: post-ERCP, 2; alcohol, 1 biliary stones, 1 juvenile polyposis, 1, 1 obstructive (pancreatic cancer); in 3 patients the etiology was unknown. One patient developed a pseudocyst. Two patients with late acute pancreatitis had a severe necrotizing form and both died. One patient with cirrhosis of the liver greater than stage 4 with chronic rejection, late ERCP pancreatitis which was complicated by retroperitoneal hemorrhage and graft failure. The other patient with necrotizing pancreatitis of unknown etiology developed MODS and eventually died. Male patients (p = 0.01) and patients transplanted for liver cirrhosis resulting from chronic hepatitis B were at a significantly higher risk of AP development (p = 0.03).

Conclusion: The incidence of AP after liver transplant in our center is low. In it necrotizing form which is more frequent early after liver transplant, it carries a significant risk of mortality exceeding 60%. Male patients and those transplanted for end stage liver disease resulting from chronic hepatitis B are more likely to develop post-liver transplantation pancreatitis.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borborygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paradoenal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature there are no studies analysing the exocrine pancreatic function over time. The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function

Aims & Methods: The objective of the retrospective study was to re-evaluate a series of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and important exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/sequelae of necrotizing pancreatitis (15), autoimmune (69), paradoenal (15), genetic (17) and idiopathic (27).

Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the years. Autoimmune and paradoenal pancreatic patients are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/outcomes of necroizing pancreatitis and idiopathic pancreaticins in an intermediate (33% and 26%) while genetic in a low percentage (12%).

Conclusion: The exocrine pancreatic function in patients with autoimmune pancreateitis improved in the first five years of the disease, probably due to the efficacy of steroid/immunosuppressive therapy. Pancreatic endocrine function was less compromised at diagnosis, but showed a progressive deterioration in the first five years. Endocrine and exocrine insufficiency were strictly correlated.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1417 "PAINLESS" CHRONIC PANCREATITIS: EPIDEMIOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERIZATION

Introduction: "Painless" chronic pancreatitis (CP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.

Aims & Methods: The aim of the present study is to characterize "painless" CP from the epidemiological, clinical, radiological, functional, and follow-up standpoint, through a comparison with other forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of "pancreatic-specific pain" into "painless" and "pain-associated" CP. A retrospective case-control analysis was carried out.

Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had "painless" CP. "Painless" patients were older (median age of 58.5 ± 10.8 vs. 42.5 ± 15.3 y/o; p < 0.001), less frequently presenting with a history of alcohol consumption (35% vs. 55%; p < 0.001), more frequently diabetics (18% vs. 1%; p < 0.001), presenting with steatorrhea (16% vs. 2%; p < 0.001), and asymptomatic (63% vs. 2%; p < 0.001) compared to pain-associated controls. From the radiological standpoint, cases cases were more frequently presenting with calcifications than controls (90%; vs. 68%; p < 0.001). Moreover, in most of painless cases, the CP cause remained unknown (56%). After a median follow-up of 2.6 ± 2.3 years, the incidence of diabetes was higher in the painless than in controls (48% vs. 30%; p < 0.006).

Conclusion: The present study represents the first definition of "painless" CP so far reported in the literature. The "painless" CP is a distinct entity from the epidemiologic, clinical, and radiological standpoint when compared to other forms of CP characterized by the absence of pain.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recently, EUS-guided pancreatic duct drainage with transmural stenting (EUS-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde pancreaticography (ERP) has failed. Although the feasibility and safety of EUS-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EUS-PD with a fully covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EUS-PD with an FCSEMS compared with EUS-PD with a plastic stent.

Aims & Methods: The aim of this study is to evaluate the procedural and long-term outcomes of EUS-PD with an FCSEMS for patients with painful obstructive pancreatitis who failed ERP. Forty-one consecutive patients with painful obstructive pancreatitis underwent EUS-PD with an FCSEMS after failed ERP. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign structure.

Results: 15 patients had malignant MPD strictures or complete MPD obstruction in benign pancreatic structure. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign structure.

Disclosure of Interest: All authors have declared no conflicts of interest.
Overall mean stent parity duration was 412 days (range 14–1081) during mean follow-up of 1081 days). Median stent patency was 525 days (range 14–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange was successful in benign strictures with stent dysfunction. At the end of the follow-up, two patients (5.6%) showed resolution of stricture after definite stent removal.

Conclusion: EUS-PD with an FCSEMS showed excellent long-term outcomes for patients who failed conventional ERP in both malignant and benign painful obstruction. EUS-guided FCSEMS removal and exchange could be successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fundamental aspects in the treatment of pancreatic exocrine insufficiency (PEI) include pancreatic enzyme replacement therapy (PERT). Monitoring the symptoms of malabsorption as well as the nutritional markers is essential.

Aims & Methods: To follow-up patients with PEI receiving PERT and to provide normal nutritional status by optimizing the suboptimal PERT if necessary. Study enrolled 142 patients (88 males, mean age 52 years): 82 patients had chronic pancreatitis, 54 patients had pancreatic cancer (CP) and 16 patients had chronic pancreatitis with pancreatic cancer. 58 patients were re-monitored 6 months after adjusting suboptimal therapy. Alcohol abuse was most common aetiology. Nutritional status was evaluated by prealbumin and retinol binding protein (RBP) via immunonephelometry, fat-soluble vitamins A, D, E via HPLC and LC-MS/MS; magnesium (Mg) and hemoglobin (Hb). We evaluated in addition albumin; cRP; BMI.

Results: Protein malnutrition with prealbumin (mean: 0.208 (Mg) and hemoglobin (Hb). We evaluated in addition albumin; cRP; BMI. Monitoring the symptoms of maldigestion as well as the nutritional markers is essential.

Conclusion: The aims of our study was to assess the reliability and correlation of the IAP regulation by mRNA stabilizing protein HuR and HO-1 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreateodudendectomy (2011–2016) were analyzed. Patient's mRNA expression levels of HuR, COX-2, HO-1, IAP1, Survivin and XIAP in PDAC were compared with normal pancreatic tissue obtained from organ donors. Additionally, the correlations among HuR, COX-2, HO-1, IAP1, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Results: HO-1, COX-2, HuR, IAP1, IAP2 mRNA expression were accordingly 3-fold, 8.8-fold, 1.5-fold, 4.8-fold and 5-fold higher, while XIAP and Survivin mRNA expression were 3.8-fold and 3.4-fold lower when compared to normal pancreatic tissue. Expression of HuR was positively associated with COX-2, HO-1, IAP1, IAP2, XIAP, and IAP2, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Conclusion: Our results suggested that upregulation of HuR in PDAC patients were significantly related with poor outcome. Even though, significant correlation with IAP proteins in PDAC was noticed, more data is needed to analyze the mechanism underlying HuR and IAP interaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The mRNA binding protein HuR is involved in the post-transcriptional regulation of cytoprotective molecules, such as COX-2, HO-1 and inhibitors of apoptosis proteins (IAPs, IAP2, XIAP, SURVIVIN), and might be related to poor prognosis in numerous cancer types. However, the association of HuR, COX-2, HO-1 and IAPs family, and their impact on chemoresistance and carcinogenesis in PDAC still remain unclear.

Aims & Methods: The aim of our study was to assess the reliability and correlation of the IAP regulation by mRNA stabilizing protein HuR and HO-1 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreateodudendectomy (2011–2016) were analyzed. Patient's mRNA expression levels of HuR, COX-2, HO-1, IAP1, Survivin and XIAP in PDAC were compared with normal pancreatic tissue obtained from organ donors. Introduction: Pancreatic cancer (PDAC) is one of the most lethal diseases worldwide and is the fourth leading cause of cancer-related death in the world. The median survival after PDAC diagnosis is reversed using 5-FU (1) indicating the role of hypoxia in pancreatic cancer. A secretome survey of chemoresistant PDAC cells was performed using SILAC-based mass-spectrometric analyses. Relative differences in protein concentrations among samples were investigated and led to the identification of previously unknown proteins. The impact of RNAi-mediated knockdown of selected genes in proliferating PDAC cells were analyzed using MTT-viability and cell cycle protein-expression studies were performed using Real-Time-PCR and immunohistochemistry using patient-derived PDAC samples.

Results: SILAC-based identification of the Tryptophan degrading enzyme KYNU (KYN-3-monooxygenase and aminolevulinic acid synthase) in chemoresistant PDAC cells revealed an overexpressed and secreted form of the KYNU protein, compared to the chemosensitive counterpart. We further identified various stress-related extracellular stimuli (Gemcitabine, IFNγ, Hypoxia) as major inducers of KYNU expression/secretion. The use of KYNU as a novel secreted biomarker of chemoresistant PDAC cells resulted from amino-acid metabolism.

Aims & Methods: The aim of the study was the identification of new biomarkers for chemoresistant pancreatic cancer. A secretome survey of chemoresistant PDAC cells was performed using SILAC-based mass-spectrometric analyses. Relative differences in protein concentrations among samples were investigated and led to the identification of previously unknown proteins. The impact of RNAi-mediated knockdown of selected genes in proliferating PDAC cells were analyzed using MTT-viability and cell cycle protein-expression studies were performed using Real-Time-PCR and immunohistochemistry using patient-derived PDAC samples.

1. Schnittert, J., Ramsal, R., Storm, G., Ostman, A., Prakash, J., R. Activation of hPSCs with TGF-targets (such as ITGA11) resulted in the significant upregulation of CD45, Cyclin E1 and PDH1 proteins which were used as a control. We performed study of miR-195 in transfecting Panc-1 cells with miR-195 mimic. We used miRNA qRT-PCR to study the transfection efficiency of miR-195 mimic. The biology behaviors of Panc-1 cells transfected with miR-195 and negative control were analyzed by CCK-8 proliferation assay, cell cycle, cell migration and invasion assay. We performed Real-Time PCR and western blot to detect the expression of CD45, Cyclin E1 in Panc-1 cells which were transfected with miR-195 mimic and negative control.

Results: We found that miR-195 was decreased in three pancreatic cancer cells (PANC-1, SW-1990, PANC 03.27) by qRT-PCR, and PDH1 proteins were used as a control. We performed study of miR-195 in transfecting Panc-1 cells with miR-195 mimic. We used miRNA qRT-PCR to study the transfection efficiency of miR-195 mimic. The biology behaviors of Panc-1 cells transfected with miR-195 and negative control were analyzed by CCK-8 proliferation assay, cell cycle, cell migration and invasion assay. We performed Real-Time PCR and western blot to detect the expression of CD45, Cyclin E1 in Panc-1 cells which were transfected with miR-195 mimic and negative control.

Results: We found that miR-195 was decreased in three pancreatic cancer cells (PANC-1, SW-1990, PANC 03.27). We also found that over-expression of miR-195 could suppress the proliferation, migration, invasion and cell cycle of Panc-1 cells. That means the malignancy potential of Panc-1 cells is inhibited by miR-195. Over-expression of miR-195 could down regulate the expression of CD45, Cyclin E1 in Panc-1 cells.

Conclusion: The expression of miR-195 was down regulated in pancreatic cancer cells. Over expression of miR-195 suppressed cell proliferation, cell cycle, migration and invasion of Panc-1 cells by down regulated the expression of CD45 and Cyclin E1. Moreover, this finding suggests a potential novel strategy for therapeutic interventions of this disease.

P1428  HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) THERAPY FOR UNRESECTABLE PANCREATIC CANCER
Contact E-Mail Address: a-sofuni@amy.hi-ho.ne.jp

Introduction: High-intensity focused ultrasound (HIFU) is expected as new advanced therapy for unresectable pancreatic cancer (PC). HIFU therapy with chemoradiotherapy is being promoted as new method to control local advance by ablation tumor, and mainly achieve relief of pain caused by PC.

Aims & Methods: We have evaluated the therapeutic effect of HIFU therapy in locally advanced and metastatic PC. We treated PC patients by HIFU as optional local therapy as well as systemic chemo/chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study took approval of member of ethic society of our hospital. HIFU device used is FEP-BYO2 (Yuande Bio-Medical Engineering Co., Ltd., China). The subjects were 140 PC patients, i.e. 69 cases in stage III, 71 cases in stage IV. Performance status (PS) was PS0:79, PS1:38, and PS2:3 cases. Mean age was 74.9 yrs. The details of PC was: head in 38, uncus in 19, body in 59, body + tail in 6, tail in 2, and others (recurrence) in 16 cases. Treatment data was followed; mean tumor size before and after therapy was 33.5±10.7 and 33.7±11.5 mm, mean treatment sessions: 2.3±0.7 times, mean total treatment time: 103±66.6 min, mean total number of HIFU shots: 1069.7±1106 shots. The effects of HIFU therapy were as follows; the rate of complete tumor ablation was 89.7%, the rate of symptom relief effect was 69.4%, the effectiveness of primary lesion was CR, in 0.45%, PR, in 21.2%, SD, in 73.3%, and PD, in 5 cases, primary disease control rate (DCR) more than SD was 75.7%. The therapy and HIFU treatment was operation in 14, chemotherapy in 116, immunotherapies in 4, and best supportive care (BSC) in 14 cases. MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 1028.3 vs 366.6 days, respectively (p=0.001). MST after HIFU therapy was 666 days. The therapy of HIFU with chemotherapy was better result than common chemotherapy alone.

Conclusion: This study suggested that HIFU therapy has the potential of new method of combination therapy for PC.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis with an overall 5-year survival rate <6%. Surgically resected patients, although undergoing negative resection, have nevertheless a 5-year survival <25%. In fact, it has been recently suggested that patients with a tumor of more than 2 cm might harbor micrometastases at diagnosis. In this view, given the preliminary data of combination therapy for PC, the correct evaluation of the T stage is of high importance as it might shift the therapeutic decision mostly for the evaluation of the T, giving high importance to the diameter of the tumor.

Pancreatic Adenocarcinoma TNM (8th edition), in fact, differs from the 7th edition mostly for the evaluation of the T, giving high importance to the diameter of the tumor. The treatment of PDAC as defined by the new upcoming TNM 8th edition and to establish the sensitivity and specificity of the two imaging modalities in discriminating T1 stage from more advanced T stages. We conducted a retrospective study on a cohort of surgically-resected histologically-confirmed high pathological grade pancreatic adenocarcinoma referred center between 2015-2017, who were prospectively included in a dedicated database. Inclusion criteria: a) having both preoperative EUS and CT scan with pancreatic phase evaluation at the centre; b) CT and EUS were performed, at the latest, 30 days apart from each other and both from surgical resection; c) no neoadjuvant chemo or radiotherapy was performed. The evaluation of the T by both imaging modalities was compared to the final pathology T re-established based on the new TNM 8th edition, in order to calculate specificity and sensitivity. T-stage was used for comparison of categorical variables.

Results: Among the 184 PDAC patients surgically resected between 2015 and 2017 at our center, 30 met inclusion criteria. Of these, 19 (63.3%) were males, with mean age at resection being 67.8±9.5 yrs. The tumor was located in the head in 23 (30.7%) patients. Mean diameter of the tumor at pathology was 24.9±10.8 mm, mean diameter at EUS was 24.0±6.6 mm (p=0.74), and mean diameter at CT was 25.9±10.9 mm (p=0.73). In 46 (31.3%) cases CT scan was the first modality that detected the T2 lesion before EUS. EUS resulted having a lower sensitivity but higher specificity in discriminating T1 lesions from T2 lesions compared to CT scan; when considering detection of ≥T2 lesion in any of the two imaging modalities the accuracy increased to 80% (24/30). The sensitivity and specificity in discriminating T1 lesions from ≥T2 lesions was respectively 64.7% and 76.9% for EUS and 76.5% and 72.7% for CT.

Conclusion: This is the first study evaluating the accuracy of CT and EUS imaging modalities in establishing the T stage in the setting of the new TNM 8th edition. In our study, CT scan and EUS have both a relatively low accuracy in determining the correct T stage for pancreatic cancer when used alone, while the accuracy raises significantly when used in combination. CT scan was not able to detect up to 30% of the T2 lesions and EUS performed alone in approximately 13% of cases. The combination of the two imaging modalities showed 80% accuracy in determining the T stage, and that the pancreas parenchyma in combination to EUS could be used to better assess the proper therapeutic management as neoadjuvant chemo or upfront surgical resection.

Introduction: Pancreatic adenocarcinoma is associated with a 5–6% survival at 5 years and a poor quality of life. In Romania there are few information about the prognostic influence of known risk factors for pancreatic adenocarcinoma.

Aims & Methods: The aim of this study is to evaluate the association between risk factors and the occurrence of pancreatic adenocarcinoma and patients' survival, which may constitute a theoretical basis for screening. We performed a prospective multicentric study of patients with suspected pancreatic tumors detected in abdominal ultrasound or CT examination, during January 2015-December 2016, in which were analyzed risk factors and possible association with survival adjusted statistically according to tumor stage (Chi square test, ANOVA, log-rank test).

Results: There were 279 patients with pancreatic adenocarcinoma included in the study. Male patients were 58% from all patients, and the mean age was 63.5 years. Smoking, new-onset diabetes and history of chronic pancreatitis are risk factors for pancreatic adenocarcinoma (p <0.05). Among patients, almost one-third of patients with pancreatic adenocarcinoma died (median survival = 5 months). It was demonstrated a statistically significant association adjusted for tumor stage between the presence of new-onset diabetes and survival: 5 months vs 3 months with a HR = 3. Other risk factors (alcohol, obesity, sex, genetics, coffee intake, some infections and abdominal surgery, history of chronic pancreatitis) had no prognostic role.

Conclusion: In our study, the risk factors for pancreatic cancer were smoking, having history of chronic pancreatitis and new-onset diabetes, but the only prognostic factor was smoking.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the 2012 International guidelines on the management of intraductal papillary mucinous neoplasms (IPMN), main-duct IPMN patients with a main-duct IPMN diameter of ≥10 mm should have surgical resection, whereas surgery is not always mandatory in those with MDP diameter between 5 and 9 mm.

Aims & Methods: The aim of the study was to analyze the prevalence of malignancy (high grade dysplasia or invasive carcinoma) in 20 resected IPMN with MDP diameter between 5 and 9 mm and to identify predictive factors of malignancy.

Retrospective analysis of patients with surgically resected IPMN between 2001 and 2016. Demographics, clinical presentation, imaging and histological features were compared between patients with preoperative evidence of MDP diameter between 5-9 mm (Group A) and ≥10 mm (Group B). Malignancy was defined as high-grade dysplasia or invasive carcinoma.

Results: From 122 patients with IPMN submitted to surgery, 66 with MD- or mixed-IPMN entered the final analysis. Mean age was 66 ± 12 years and 48 (72.7%) patients were men. Group A comprised 47 patients and Group B 19. Abdominal pain was present in 23 (34.3%) patients, jaundice in 19 (28.8%), diabetes in 18 (27.3%), pancreatitis in 15 (22.7%) and weight loss in 12 (18.2%). No statistical differences between study groups. The most common location of the MD-IPMN was the head of pancreas (60.6%), and it was multifocal in 34.8% of the patients. The prevalence of no dysplasia, low-grade dysplasia, high-grade dysplasia and invasive carcinoma was 18.2%, 42.6%, 8.5% and 38.3% in group A and 10.5%, 10.5%, 21.1% and 57.9% in Group B. No significant difference was found between the two groups.

Conclusion: Almost half of resected IPMN with MDP diameter between 5-9 mm harbor histologically proven malignancy. In these patients, particularly in those with jaundice and weight loss, surgery rather than follow-up should be recommended.

P1432 CLINICAL SIGNIFICANCE OF CHEMOTHERAPY FOR ELDERLY UNRESECTABLE PANCREATIC CANCER PATIENTS

S. Kaino, M. Sen-Yo, S. Shinoda, S. Amano, I. Sakaida

Department Of Gastroenterology & Hepatology, Yamaguchi University Gastroenterology & Hepatology, Ube/Japan

Contact E-mail Address: kaino@yamaguchi-u.ac.jp

Introduction: Pancreatic cancer has poor prognosis despite of improvements in multimodal treatments. As aging of the population advances, it is expected that elderly pancreatic cancer patients increase.

Aims & Methods: The aim of this study was to investigate the clinical significance of chemotherapy for patients with unresectable pancreatic cancer. At our hospital, 96 patients were diagnosed as having unresectable pancreatic cancer between January 2010 and December 2016. In this study, we defined elderly patients as those older than 75 years. We retrospectively examined the safety and efficacy of chemotherapy in patients with unresectable pancreatic cancer. We analyzed and compared the overall survival periods and adverse events between patients who received chemotherapy and aged patients.

Results: Twenty-seven patients were older than 75 years (group A), and 59 were younger than 74 years (group B). We treated 6/10/2/5/4 patients in group A with GEM/S-1-modified FOLFIRINOX (mFOLFIRINOX)/GEM + nabPTX/ nabPTX/ nabPTX in group B, respectively. On the other hand, we treated 12/14/11/5/13 patients in group B with GEM/S-1/mFOLFIRINOX/ GEM + nabPTX/BSC/others, respectively. Severe adverse events (more severe than grade 3 according to CTCAE v4.0) occurred in 18.2% of the patients in group A and in 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1433 THE USE OF A NEW CORE NEEDLE IN THE ENDOSCOPIC ULTRASOUND ASSISTED TISSUE SAMPLING FOR PANCREATIC SOLID MASSES: A MULTICENTRE PROSPECTIVE STUDY

Introduction: Endoscopic ultrasound-guided biopsy (EUS-biopsy) is considered a reliable, safe, and effective technique for obtaining samples from pancreatic masses with a very high sensitivity and specificity (ranged to 85%-92% and 96%-98%, respectively) [1-3]. A new EUS needle (SharK Core FNB needle, Medtronic, Dublin, Ireland) was introduced in order to improve the tissue acquisition.

Aims & Methods: The aim of the present study was to evaluate the presence of a histological sample using SharK Core Needles. This study was an observational multicenter prospective non-randomized clinical trial (NCT02946840). All consecutive patients referred for EUS examination and sampling of solid pancreatic masses underwent EUS-guided biopsy with 25 G SharK Core needles. This needle has an innovative tip geometry with a cutting surface designed to acquire cohesive tissue fragments without excessive trauma. Three needle passes were performed in every mass. At each pass, a macroscopic on-site quality evaluation (MOSE) was done by endoscopist. If a “worm-like” material was observed at gross visual assessment, it was placed into formalin. If only liquid material was observed, the sample was smeared between 2 glass slides, fixed with ethanol, and stained with a Papanicolaou-stain for cytological analysis. Endoscopists recorded macroscopic features of the specimens. Pathologists described macroscopic, microscopic, immunohistochemical and molecular studies. The primary outcome was the procurement rates of histologic core. Pathologists defined core all histologic samples with architecturally intact histology, measuring at least 5 mm in greatest axis. All the other specimens (< 5mm) were defined as micro-fragments. The final diagnosis was based on surgical resection, and clinical/radiological follow up. The secondary outcomes were diagnostic accuracy and procedure-related adverse events.

Results: Study population included 82 patients, enrolled in three centres, between August 2016 and April 2017, with a mean age of 64.0 (SD 13.7, range 21–84) and 57.3% female gender. The mean size of the lesions was 27.6 mm (SD 12.2) and the location was the body and tail in 27 patients (32.9%), neck in 11 (13.4%), head and uncinated process in 44 (53.7%). Three needle passes were performed in all but 3 patients who experienced mild bleeding precluding more than one needle pass at MOSE. At MOSE, endoscopists described presence of “worm-like” material in 192 biopsy samples over 242 (79.3%). In 8 patients only cytological specimens were obtained after 5 needle passes (9.8%). Six cases of mild self-limited bleeding were observed (7.3%). The pathologists described the presence of a core in 80 samples (41.7%), in the other cases, after the specimen preparation, a micro-fragmentation was observed, that didn’t affect the histological evaluation. A final histological diagnosis was reached in 73 patients (90%): 50 pancreatic adenocarcinoma, 16 NET, 5 chronic pancreatitis, 2 pancreatic metastasis from other organs.

Conclusion: The new biopsy needle showed a good overall adequacy and a good rate of histological specimens (both core and micro-fragments) during EUS-guided tissue acquisition of pancreatic masses, with a minimum number of passes and no major complications. This ability could allow to avoid the use of rapid on-site evaluation and to perform immunohistochemical, molecular and genetic studies on histological samples.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We retrospectively assessed 700 consecutive EUS-FNA procedures from January 2011 to January 2016. 459 (65.5%) solid pancreatic lesions were included in the final analysis after excluding 230 for biliary strictures, hepatic lesions, lymph nodes, gastric, oesophageal lesions, pancreatic cysts and 11 for insufficient information.

Results: In 399 (86.9%) cases on-site cytopathology support was available, while the remaining was unsupported. There were 228 males (57.1%) in the supported and 29 (48.3%) in the unsupported group. Mean age was 64.6 (SD: 11.4) and 67.4 (SD: 11.9) respectively. The mean number of passes in the two groups were 2.8 (SD: 1.12) and 1.9 (SD: 1.0) (P < 0.0001). A conclusive diagnosis (malignant, benign, NET, GIST) was made in 84% (67%, 12%, 10%, 5%, 0%) of the supported group and in 38% (23%, 10%, 3%, 2%) of the unsupported (P < 0.0001). The mean follow up for the entire cohort was 14.2 months (SD:14.1) and mean survival of in patients diagnosed with malignancy was 10.9 months (SD: 8.7). Overall performance characteristics of EUS FNA were Sensitivity: 90.8% Specificity: 66.9% PPV: 91.8% NPV: 85.4%

Conclusion: This review confirms high performance characteristics of EUS FNA. The presence of on-site cytopathologist significantly increases the diagnostic yield.

Introduction: Pancreatic cystic lesions are a common finding in clinical practice. Classification of cysts as mucinous or non-mucinous cysts, using EUS-FNA with cystic fluid analysis for cytology and CEA became widely used in clinical workup of patients with suspicious pancreatic cysts. Molecular analysis (KRAS and GNAS mutation) is not yet recommended in clinical practice.

Aims & Methods: We aimed to determine if mutation in GNAS and KRAS in cystic fluid analysis for cytology and CEA level and 29 (48.3%) in the unsupported ret. Mean age was 64.6 (SD: 11.4) and 67.4 (SD: 11.9) respectively. The mean number of passes in the two groups were 2.8 (SD: 1.12) and 1.9 (SD: 1.0) (P < 0.0001). A conclusive diagnosis (malignant, benign, NET, GIST) was made in 84% (67%, 12%, 10%, 5%, 0%) of the supported group and in 38% (23%, 10%, 3%, 2%) of the unsupported (P < 0.0001). The mean follow up for the entire cohort was 14.2 months (SD:14.1) and mean survival of in patients diagnosed with malignancy was 10.9 months (SD: 8.7). Overall performance characteristics of EUS FNA were Sensitivity: 90.8% Specificity: 66.9% PPV: 91.8% NPV: 85.4%

Conclusion: This review confirms high performance characteristics of EUS FNA. The presence of on-site cytopathologist significantly increases the diagnostic yield.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1437 DO BILIARY STENTS REDUCE THE DIAGNOSTIC PERFORMANCE OF EUS-BIOPSY IN PATIENTS WITH A MASS IN THE HEAD OF THE PANCREAS?
L. B. Bekkali1, M. Nayar2, L. Thornton1, S. J. Johnson2, B. Haugk1, A. Darne1, J. S. Leed1, R. Charnley1, K. Oppong1

Introduction: Self-expanding metal stents (SEMS) are increasingly preferred to plastic stents (PS) for pre-operative drainage and palliation of biliary obstruction secondary to a sticture in the head of pancreas (HOP). Their use has increased over the last 5-6 years. Endoscopic ultrasound (EUS) with fine needle aspiration or biopsy (FNA or FNB) is commonly utilised to make a tissue diagnosis and to aid in staging in those with borderline resectable tumours. Stents may reduce diagnostic performance of FNA-FNB by reducing the visible mass to puncture. There have been 2 studies that assessed the impact of stenting on EUS-FNA performance, one2 found no difference in yield and sensitivity among patients with or without stents and between SEMS and plastic. Whilst a more recent study3 found accuracy was significantly reduced by the presence of a stent.

Aims & Methods: The aim was to assess whether stents (SEMS or PS) impair diagnostic performance of EUS tissue acquisition, in a retrospective study of all patients with HOP mass undergoing EUS biopsy between January 2010 and June 2016. Stenting information was obtained from the EUS report and images. Biopsies reported as malignant were considered as such, all other reports were considered benign. A definitive diagnosis of cancer was based on positive pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded.

Results: A total of 1861 patients had EUS-FNA/FNB of which 731 were for HOP lesions, mean age 65 yrs (410 F), with tissue sensitivity of 72% for all types of needles used. Tissue accuracy was significantly different between the 3 groups (p = 0.0001); SEMS 67%, PS 71% and 83% in the unstented group. The difference in accuracy was significant between the unstented group versus SEMS (p = 0.0082) and PS (p = 0.03) and not between PS and SEMS. Stepwise multi-variable analysis revealed significant difference for accurate tissue diagnosis favouring size needle 25G (OR 1.7 [95%CI 1.1-2.7] and tumour size (OR 1.9 [95%CI 1.2-3.0]) and reduced by presence of a stent SEMS (OR 0.3 [0.2-0.6]) or PS (OR 0.5 [0.3-0.9]). Other needle sizes (19G or 22G), number of passes or types of needle did not significantly affect tissue accuracy.

Conclusion: Our results show a significant adverse impact of both SEMS and PS on tissue accuracy via EUS FNA-FNB. The effect is greatest with SEMS. These results suggest that where possible EUS and biopsy if required should be performed before stent placement.

Introduction: Pancreatic neuroendocrine tumours (PNETs) are relatively rare, i.e., 21 per 100,000 individuals per annum, and account for only 1-2% of all pancreatic tumours. They are separated into 2 major categories: 1) well-differentiated (WD-NETs) which have round to oval nuclei, finely stippled chromatin and finely granular cytoplasm and 2) poorly-differentiated (PD- NETs) which have a diffuse architecture with an irregular nucleus and less cytoplasmic granularity. WD-NETs tend to have an indolent course (survival ~67% at 5 years) but ~50% have metastasised at the time of diagnosis. PD-NETs are high-grade cancers with an aggressive course resembling NETs arising in lung. WD-NETs contain neurosecretory granules which stain for synaptophysin and/or chromogranin. Endoscopic ultrasonography guided fine-needle aspiration biopsy (EUS-FNA) can provide a non-operative cytological diagnosis of PNETs when the pathologist is provided with a good specimen such as the pellet of cells obtained through SurePath (SP).

Aims & Methods: EUS-FNA samples of pancreatic tumours were collected into a SurePath vial and slides prepared from the cellular pellet. The slides were stained forsynaptophysin and Ki67 by immunohistochemistry (IHC) and examined by 2 independent senior cytopathologists.

Results: Sixteen (16) patients with a mean age 65 years (8 male) were identified by EUS with a suspected PNET. The mean tumour size was 16.2 mm +/- 4.2 mm. All had the morphology of a PNET and stained positive for synaptophysin.

Conclusion: SP prepared cytology slides from solid pancreatic tumours provides enough diagnostic material for IHC staining for synaptophysin and KI67 without the need for a formal excision biopsy. Morphology of SP slides is often diagnostic but a positive stain for synaptophysin makes the diagnosis irrefutable.
mitotic index derived from Ki67 staining helps identify WD-NETs which can be monitored and PD-NETs which need aggressive treatment.

P1440 EFFECTS OF IGF2BPS ON GROWTH AND PROLIFERATION OF PANCREATIC TUMOR CELL LINES
L. Niefeld1, F. Sperling3, K. Theuerkorn1, H. Griessmann1, S. Krug1, S. Hüttemann2, P. Michl1

Introduction: Pancreatic neuroendocrine neoplasms (PNEN) are highly angiogenic tumors which despite of various targeted options including mTOR and VEGF inhibition frequently develop secondary drug resistance. IGF2BPs (IGF2 mRNA-binding proteins) represent a family of canonical RNA-binding proteins (RBP) comprised of three members (IGF2BP-1–3) which have been described to promote stem and/or progenitor cell maintenance with reported expression and oncogenic roles in aggressive cancers. IGF2BPs show a differential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

Aims & Methods: We aimed to characterize the role of IGF2BPs in progression and resistance of pancreatic neuroendocrine neoplasms. We used three different siRNA-pools (IGF2BPs) to inhibit the different IGF2BPs in pancreatic neuroendocrine BON1 tumor cells. Cellular effects were investigated by Western blot analyses, flow cytometry, clonogenic survival, cell viability and migration assays.

Results: In the pancreatic neuroendocrine tumor cell line BON1, knock-down of IGF2BP1 resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase progression paralleled by a reduction in the proliferation marker PCNA and a markedly reduced MEK/ERK activation. In contrast, Akt signaling was unaffected. Moreover, knock-down of IGF2BP1 significantly reduced clonogenic growth as assessed by colony formation assays and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP and caspase-3 cleavage as well as annexin-V FACS. Rather, si-IGF2BP1 increased the expression of both the anti-apoptotic and pro-survival factor BCL-2 and the cell cycle inhibitor CDKN1B. In contrast to IGF2BP1, knock-down of IGF2BP3 rather induced cell viability, whereas IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects of the three IGF2BPs on PNEN progression. These in vitro findings were paralleled by distinct expression patterns of IGF2BPs in human and murine PNEN tissues. Elucidation of IGF2BP-modulated RNAs in PNEN cells is ongoing.

Conclusion: In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP2 and -3 exert no tumor-promoting role in PNEN.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The chemopreventive effect of aspirin (ASA) and other NSAIDs have been observed in the setting of colorectal cancer, showing a reduction in the incidence and mortality. However, the impact of aspirin use on clinical outcome of patients with gastro-entero-pancreatic neoplasms (GEP NEN) has not yet been evaluated.

Aims & Methods: Aim of the study was to retrospectively evaluate the clinical outcome of GEP NEN patients treated with ASA at three different European referral Centres for NENs. All the GEP NENs patients followed up in three European Centres (Fondazione IRCCS Ca' Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericordiae University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA and disease grading, staging, primary site, overall OS and PFS were evaluated. At the time of enrolment, clinical data and biochemical parameters were collected for every patient. Chromogranin A (CgA) and specific circulating peptides were evaluated. Morphological and functional imaging (computed tomodiagrapy, magnetic resonance and Gallium 68PET) were performed to follow up the patients at each Centre.

Results: In the 253 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (35%), pancreas (38%), small bowel (18%), appendix (37%), colon (49) or unknown (97%). Grading was G1 in 154 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was observed in patients taking ASA compared to those not taking it. Interestingly, in pNEN an inverse relation was observed between Ki67 and ASA assumption (r = 0.35, p = 0.008). In small bowel NEN an inverse relation was observed between positive lymphnodes at surgery and ASA assumptions (r = -0.3, p = 0.02). As expected, the intake of ASA was related with the older age of the patients.

Conclusion: According to present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki67 values and less node involvement. Further studies are needed to confirm this observation.

Introduction: Intraductal papillary mucinous neoplasms (IPMNs) and neuroendocrine tumors (NETs) of the pancreas are rare tumors. Up to now 15 patients with association of endocrine and exocrine neoplasms of the pancreas have been reported in the literature, but this association is not expected to be frequent. The aim of this study is to describe a series of nine patients with IPMN and concomitant NET of the pancreas followed in our center and to look for any common findings between them that could help early recognition and further comprehension of this association.

Aims & Methods: Among all the patients who were followed in our clinic for IPMN or NET, we identified 9 with both diseases, diagnosed on imaging or after biopsies requested for uncertain results of previous investigations. We collected data about the patients (age, sex, symptoms, past and current medical history, blood chemistry, type of imaging) and about the lesions (classification, dimension, localization, imaging features, fine-needle aspiration (FNA) biopsies results and histology).

Results: All patients (4 men and 5 women), except one were asymptomatic. Average age at diagnosis was 61 years. All IPMN were branch duct, localized in the head (n = 4) and in body-tail (n = 5), with a medium diameter of the cysts of 12 mm (range 8 mm-16mm). All NETs underwent endoscopic ultrasound examination with FNA; 8 were non functional G1 with a Ki67 of 1%, positive for Chromogranin A and Neuron-specific Enolase staining. One NET was a symptomatic insulinoma located at the tail (Ki67 of 2%, 20 mm diameter) and underwent distal spleno-pancreatectomy. Among NETs, 6 were in the head and 3 at body-tail, with a medium diameter of 11 mm (range 6-15 mm). In 4 patients, the first diagnosis was IPMN followed by identifications of NET with second level imaging. In 5 patients, who underwent magnetic resonance imaging for NET, a concomitant IPMN was found.

Conclusion: Our study describes 9 cases of endocrine-exocrine pancreatic neoplasms association. In the 15 cases reported by literature one out of the two lesions, had a malignant behavior. In our records, except in one patient, both IPMN and NET in all patients behave in an indolent fashion. All the IPMN were branch type and all the NET, except one, were G1; mainly patients are asymptomatic and the symptom of the disease was observed in only one case. We did not find neither sex or age predisposition, nor predominant localization or common pathologic background in the patients. No other concomitant neoplastic diseases were found. Although the frequency of association between NET and IPMN is not too large and no diagnostic hallmark were found, it is still to be proven that this association is fortuitous. Further studies in the future are required.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syndrome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature is the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Turin) for management and follow-up of VHL and whose health data were in the study were; among the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients (demographics and medical history), about the lesions (imaging features, histological and cytological analysis) and about the management.

Results: Out of 24 patients, 18 of which (75%) had a pancreatic involvement. Multiple simple pancreatic cysts were found in 13 patients, SCAs were found in 2 patients and NETs in 7 patients. The mean age of the patients with pancreatic lesions was 42 (min 25 - max 75), 11 were males and 7 females (1.6:1 M:F). Simultaneously, affected 13 patients, are always multiple (ranging from 12 to 80 mm) mostly in the head. 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, Ki67 <2%). 7 were located in the head and 2 in the tail (2 patients had multiple tumors). 5 out of the 7 pNET patients underwent surgery. The two SCAs were multiple (max 65 mm), mostly affecting the head in 1 case and the tail in the other. No surgery was performed.

Conclusion: 75% of our VHL patients showed pancreatic involvement, mostly in males compared to females. 72% of patients with pancreatic lesions suffered from simple cysts, 39% from NETs and 11% from SCAs. To note that all NETs were G1 and behaved in a benign fashion. Surgery was performed only in patients with NETs in the pancreatic head and in patients with symptomatic cystic disease. The mean age of incidence of VHL-related pancreatic lesions was lower than in previous studies, thus confirming our dataset. Although all lesions in our patients were benign or stable, constant monitoring is needed.

References
at 4 patients. The mean age of our MEN-1 patients was 51 and the age at diagnosis was 41.8. The mean plasma calcium level was 11.46 mg/dl and there was no history of renal calculi at any of them.

**Conclusion:** The family presented here is the one which had the largest number of affected individuals with genetic and clinical properties of MEN-1 at Turkey. Based on the presented here is the result of genetic mutation causing loss of function that is described for the first time. Also at MEN-1 families, counseling to prevent the neoplasia development and to prevent the new family members to be effected with PGD has a pivotal importance. We could point out that awareness is the most important caution for prevention.

**Introduction:** Several inflammatory response materials could be used for prediction of prognosis in cancer patients. The neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR), thrombocytosis (the platelets number >400*10^3/mm^3) have been introduced for prognostic scoring system in various cancers.

**Aims & Methods:** The objective of this study was to determine whether the NLR, the PLR or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumours with ki 67 below 20% diagnosed in Fandeni Clinical Institute between 2011-2017. Data about site of the primary tumor, presence of metastasis, NLR, PLR, thrombocytosis (platelet count > 400) and survival were collected and analysed.

**Results:** The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastro-intestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% patients. The overall 2-year survival rate was 77.42%. The Ki 67 index (p < 0.04), PLR (cut off >300) p < 0.01 have statistical significant impact on survival, only univariate analysis and on multivariate analysis (P < 0.05). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

**Conclusion:** This study demonstrates the prognostic role of different variables like Ki 67 index, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognosis that could guide clinicians for a better management in patients with neuroendocrine tumors.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Neuroendocrine pancreatic tumors represent the second prevalent entity of malignant tumors of the pancreas and show an overall mortality of about 60%. At the moment surgical resection is the only option of potentially curative therapy, as with the currently available chemo- and radiotherapeutic approaches an inhibition of tumor growth but no regression of the tumor can be achieved. Therefore for about 80% of pNET patients no curative therapy can be offered. To obtain the identification of novel potential target genes for the development of new therapeutic strategies, primary tissues from pNET patients were analyzed. Amongst others PLC8 (Placent-specific 8) was identified, which is a small protein of unknown function, showing different forms of cellular localization depending on the cell type analyzed, indicating at its ability to fulfill a variety of physiological functions.

**Aims & Methods:** In the course of this study, the function of Plac8 in neuroendocrine pancreatic tumors is to be unveiled to evaluate its value as a potential target for pNET therapy. Therefore primary tumor tissue of about 100 pNET patients were analyzed for Plac8 expression by quantitative real-time PCR and immuno-histochemistry. Furthermore established pNET cell lines from human origin where transfected with siRNAs against Plac8 and there proliferative activity and metastatic behavior where analyzed by wound-healing and MT assay. Changes in these important characteristics of tumor cells were further examined by westernblot analyzes of key regulators of apoptosis and cell growth.

**Results:** Plac8 is highly expressed in primary human pNET tissues on RNA- as well on protein level. Functional in vitro analyses show that the siRNA-mediated knockdown of Plac8 not only in human but also in rat cell lines leads to significantly reduced proliferative activity and reduced cell growth. These effects came along with indicative changes in the expression of central regulators of cell cycle while apoptotic pathways seem to be only moderately affected.

**Conclusion:** Overexpression of Plac8 in neuroendocrine tumors of the pancreas promote the proliferative phenotype of the tumor cells while the inhibition of Plac8 inhibits cell growth and metabolism. Therefore in the future Plac8 could represent a very interesting target molecule for the treatment of pNET.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Since the majority of laryngopharyngeal carcinomas are detected at an advanced stage, most cases are treated with concurrent chemoradiotherapy and radiation therapy. The key to improving the prognosis and quality of life is early detection of the primary cancer and treatment using minimally invasive surgery. We previously reported the good oncologic outcomes with ELPS (Endoscopic laryngopharyngeal surgery) for superficial laryngopharyngeal carcinomas. However there is no clinical evidence for an additional treatment nor prognosis about the cases conducted endoscopic resection which were diagnosed to be surgically carcinoma with lympho-vascular invasion histopathologically.

**Aims & Methods:** This study aimed to investigate the optimial additional treatment and clinical course for the surgialy laryngopharyngeal carcinoma with lympho-vascular invasion. We analyzed clinicopathologic data in 9 patients showed Lympho-vascular invasion receiving ELPS between 2007 and 2014.

**Results:** Positive lympho-vascular invasion was found in 9 cases. Detected the tumor depth was SEP in 7 lesions and MP in 2 lesions. Mean alcohol consumption is 9.9 abv units. Average smoking history is 38.9 pack years. 5 cases are low activity ALDH2 heterozygotes and have alcohol flushing reaction. In clinicopathologic findings the lympho-vascular invasion cases with the siRNA 2 cases with vascular invasion(y0, v1), and 2cases with lympho-vascular invasion,(y1, v1). Two patients underwent an additional chemoradiotherapy without recurrence. Four patients had a cervical lymph node or local recurrence, two of them were salvage ELPS cases after chemoradiotherapy. One other two surgeries cases also had distant metastasis and was given palliative treatment, and finally died. The other one underwent surgical salvage and remained alive. One case with lymphatic and vascular invasion cases had no adjuvant therapy and remained recurrence-free. And the other 2 cases had recurrence but did not die of other cause. Finally Conclusion: Lympho-vascular invasion is a risk factor for cervical lymph node metastasis, which has a possibility to a very aggressive disease. In those cases, chemoradiotherapy as an additional treatment is recommended as far as possible.If patients already had prior radiotherapy, close follow-up is essential to detect recurrence early. In those cases, chemoradiotherapy or additional surgical resection are also considerable if the general conditions are satisfactory.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Bleeding control is one of the most important factors to success endoscopic submucosal dissection (ESD) in safety. We have reported the endoscopic precoagulation technique using soft coagulation mode (S method) is effective for the prevention of bleeding when relatively large vessels penetrates between muscle layers are dissected. However we have thought that S method is insufficient especially for large vessels such as more than 2 mm, we have to use hemostatic forceps for preventing hemorrhage despite treated vessel was able to give larger electrical energy in soft coagulation mode with low-high frequency power setting (F1-10 method) can exhibit precoagulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel precoagulation.

Aims & Methods: We investigated the deference of hemostatic ability between S method and F1-10 method in clinical study and ex vivo study. In clinical study we analyzed retrospectively their hemostatic ability about consecutive six gastric ESD cases in each groups excluded some cases, which have the risk of affecting data. We compared the diameter of treated vessels, frequency and duration of the compressed vessel, and bleeding frequency after cutting vessels were noted by the recorded videos. In ex vivo study, to investigate the coagulation mechanism of those two different power settings was evaluated the peak voltage, current elapsed time, and electric energy by using the data recording program (VIO DOKU) and the width and depth of coagulation was measured on macro- and microscopic levels using porcine tissues.

Results: The total number of vessels processed by endoknife precoagulation were 49 and 61 vessels in the S and F1-10 methods. The median vessel diameter was 2 mm in the S method and 1.5 mm in the F1-10 method. The median frequency of the compressed vessel was twice in both methods, and the median coagulation time was 9s and 10s in the S and F1-10 methods, respectively. No significant difference was found between the S and F1-10 methods. The bleeding rate after vessel processing was 18.4% (8/49) and 4.8% (3/61) in the S and F1-10 methods, respectively. No significant difference was found between the S and F1-10 methods.

Conclusion: F1-10 method strongly showed a trend in preventing bleeding after precoagulation compared with the S method (P = 0.058). We further investigated the bleeding rates of the large vessels, defined as ≥2 mm in diameter. There were 26 and 29 large vessels in the S and F1-10 methods, respectively. The bleeding rates of the large vessels were 26.9% (7/26) and 3.4% (1/29) in the S and F1-10 methods, respectively, which were significantly different (P = 0.021, OR: 10.32, 95% CI: 1.17–90.78). In ex vivo study, the median peak voltage was 172 Vp and 540 Vp in the S and F1-10 methods. The median current elapsed time was 0.22s and 1.54s in the S and F1-10 methods. F1-10 method could keep the electric current longer than the S method. The mean total electrical energy was 6.34 W and 12.5 W in the S and F1-10 methods. F1-10 method was able to give larger electrical energy in the poutine block. And the width and depth of coagulation in F1-10 method spread wider and deeper in macro- and microscopic sections.

Conclusion: F1-10 method is suggested to achieve a stronger hemostatic effect than S method. Further clinical procedures are required to investigate the safety and efficacy of these models.

PI451 EXPOSURE TO ENDOTHERAPY FOR UPPER GASTROINTESTINAL BLEEDING AT THE POINT OF GASTROSCOPY CERTIFICATION-IS IT SUFFICIENT?

*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Introduction: Although certification in diagnostic gastroscopy has been established in the UK, there is no formal process for quality assurance (QA) in endotherapy for upper gastrointestinal bleeding (UGIB). Training opportunities are variable, with 11% of final year UK gastroenterology trainees citing inadequate exposure, despite an expectation to independently manage UGIB upon achieving specialist status. Data on endotherapy exposure during endoscopy training is limited. We aim to assess whether trainees are receiving adequate exposure to endotherapy at the time of gastroscopy certification.

Aims & Methods: Trainees awarded certification in gastroscopy between September 2009-2016 were identified from the national trainee electronic portfolio (JETS). Trainee inputs and formative assessments (direct observation of procedural skills - DOPS) for UGIB therapy, up to their certification date, were analysed. Only trainees with >200 procedures were included, which is the minimum procedural number to allow certification within the UK, thereby excluding those who had submitted baseline information which may have contained therapeutic data. Exposure rates from medical endoscopists (physician and surgical trainees) were compared with non-medical endoscopists (NME).

Results: 885 trainee portfolios were analysed (765 medical and 120 NMEs), with a median procedural count of 276 (IQR 124). The median number of therapeutic entries and DOPS were 4 (IQR 11), and 1 (IQR 3) respectively. Overall rates for endotherapy and DOPS were 2.9% and 0.8% per procedure. When stratified by therapy, the median exposure to each therapy was either 0 or 1, with means displayed in Table 1. 25.2% of trainees had no exposure to any type of endotherpay (67.5% of NME and 18.6% of medical endoscopists, p < 0.0001). Of medical endoscopists awarded certification, 37.1% had not performed band ligation. 50.7% had not placed a clip, and 54% had not used heater probe. NME had significantly less exposure to each modality of endotherapy considered (overall odds ratio 0.10, p < 0.0001).

Table 1: Mean procedural counts at the point of UGI certification.

Conclusion: Training on endotherapy prior to certification is limited. The current endotherapy certification process requires more emphasis on trainee training and competency in endotherapy for UGIB. In response, the JAG QA team have recently released new DOPS forms specific to endotherapy and are consulting on introducing formal certification in endotherapy for UGIB.

1. GMC National Training Survey Results 2016. Gastroenterology.
March and September of 2016. All patients underwent EC with iScan. The esophagus was inspected with a ECM capable endoscope (EG- 2990-Zi) and deliberate biopsies were taken from tissue identified by ECM that suggested BE. All biopsies were confirmed by a GI pathologist. Primary endpoint was the correlation between visual inspection diagnosis of dysplastic BE by ECM versus pathologic diagnosis of BE as the gold standard.

**Results:** In our cohort 41% were male, with mean age of 47.7 years. Endoscopic diagnoses by ECM were divided into nondysplastic BE (96/100) and suspected dysplastic BE (4/100). On pathology nondysplastic BE was found in 94/100 patients. BE with low-grade dysplasia was found in 4/100 patients. Benign gastric mucosa with no alterations (1/100), and ulcerated esophagitis (1/100). The overall accuracy of endoscopic diagnoses using ECM against pathologic diagnosis was of 98%, with sensitivity of 100% [95% CI (96%-100%)], and positive predictive value of 98% [95% CI (93%-99.7%)].

**Conclusion:** Endoscopic diagnosis of BE by directed biopsies of esophageal tissue with use of ECM is highly accurate. Future prospective studies are needed to validate our preliminary findings and assess inter-observer variability.

**Introduction:** Barrett’s oesophagus (BO) is the main risk factor for oesophageal adenocarcinoma (OAC). International guidelines recommend endoscopic surveillance for early detection of dysplasia (DYS) and/or OAC but current biopsy protocols can miss areas of endoscopically unapparent neoplasia. At present, advanced diagnostic imaging technologies and specific endoscopist and pathologist expertise in detecting the subtle phenotypic changes associated with DYS/OAC or visible lesions are available (i.e. deep sedation, HD magnification endoscopes + NBI + acetic acid chromoendoscopy, Target biopsies and/or EMR were obtained in case of endoscopically visible lesions; 4-quadrant biopsies were obtained otherwise. All the specimens were diagnosed by two expert GI pathologists, who reached a final diagnosis (FD). In Group 2 patients where FD was BO without DYS/OAC, previous history was reviewed by two expert pathologist.

**Results:** Results are summarized in Table 1. Group 1 (n = 82): FD of DYS/OAC with visible lesion was reached in 2 out of 82 patients (2.4%), both treated by EMR + RFA. No one had a FD of DYS/OAC without visible lesions. Group 2 (n = 33): FD of DYS/OAC with visible lesions was reached in 13 out of 33 patients (39.4%); 11 were treated by EMR + RFA. 1 by surgery and 1 chemoradiotherapy. In 20 patients the AD was downgraded to uncomplicated BO: in 19 patients (57.6%), a review of previously taken biopsies by expert pathologist excluded neoplasia. In only one patient no lesion was found but the review of original histology slides confirmed a low-grade DYS and the patient was treated by RFA. Group 3 (n = 4): DYS/OAC was confirmed in all the 4 patients (2 treated by EMR + RFA, and 2 by surgery).

**Conclusion:** When upper endoscopy is performed in a BO reference center where specific facilities and expertises are available (i.e. deep sedation, HD magnification endoscopes, chromoendoscopy, expert endoscopist and pathologist) “inivisible” DYS is a very rare diagnosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

EVL was performed as primary prophylaxis in 50.9% (n = 226) and secondary prophylaxis in 11.2% (n = 22). Mortality-nil. Follow up endoscopy at 4 weeks showed healing in all 17 patients. Median follow up months = 24.

Conclusion: EVL is safe and effective for resection of SETs. Pre EFTR EUS and CECT may be useful to select appropriate candidates. Secure closure of defect is necessary for intraperitoneal full-thickness defects. Further studies comparing EVL and surgery are recommended.

P1455 PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS: EFFICACY AND SAFETY OF ENDOSCOPIC VARICEAL LIGATION (EVL) IN PRIMARY PROPHYLAXIS.

E. Soares1, M. Gravito-Soares1, A. Henriques1, N. Almeida1, L. Tomé1, 1Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal

Contact E-mail Address: es18497@gmail.com

Introduction: In the natural history of chronic liver disease, variceal bleeding represents a life-threatening complication of portal hypertension, with high risk of mortality and recurrence. Current guidelines for endoscopic and medical therapy recommend early use of prophylaxis with endoscopic variceal ligation (EVL) in primary prophylaxis and the combination of both in secondary prophylaxis.

Aims & Methods: We aimed to evaluate the efficacy of EVL therapy in both prophylaxis of variceal bleeding in cirrhosis and to establish the patient’s clinical outcome. This was a retrospective observational cohort study of a total of 444 EVL procedures performed in 250 cirrhotic patients, who were admitted in a gastroenterology department of a tertiary centre, between 2004–2016, to receive EVL as prophylaxis of variceal bleeding. Sessions of ligation were repeated every two to three weeks in order to reach variceal eradication. The clinical outcome included the recurrence of bleeding (primary endpoint), the eradication success rate of oesophageal varices, EVL-related complications and overall and bleeding-related mortality.

Results: The mean follow-up period for all 250 cirrhotic patients enrolled in the study was 73.2 ± 40.0 months, with mean age of 63.9 ± 9.8 years and a predominance of male gender (80.4% ± n = 201). At initial endoscopy, 237 (53.2%) patients had active variceal bleeding (AVB) and 207 (46.8%) had chronic esophageal varices. EVL was performed as primary prophylaxis in 50.9% (n = 226) and secondary prophylaxis in 49.1% (n = 218). Varices were obliterated in 209 (83.6%) patients with mean number of EVL procedures necessary to eradicate varices of 1.8 ± 0.95 and a maximum of procedures of 6. Recurrent bleeding occurred in 11.2% (n = 28) of cases with a mean time to re-bleeding occurrence of 8.1 ± 14.2 months. Major and significant complications were verified in 8.1% (n = 36) of patients. The main complications were bleeding related to post-banding ulceration (7.5% ± n = 27) and infection (22.2% ± n = 9), with mean time between EVL and complication occurrence of 11.1 ± 11.8 days (minimum:0;maximum:43). Intra-procedure complications occurred in 11 (2.5%) patients with no death, despite of two cases of Sengstaken-Blakemore devices used necessary. The overall mortality was 3.4% (n = 24), being 0.4% (n = 2) related to varical bleeding.

Conclusion: EVL seems to be an efficient, safe and relatively simple therapeutic option for primary prophylaxis of variceal bleeding in cirrhotic patients. Since the main complications occurs over 1 week after EVL procedure, the majority of patients can be safely treated in an ambulatory setting.

P1456 THE VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER.

M. Xu1, C. Zhang1, Q. Li1, 1Endoscopy Center, Zhongshan Hospital, Shanghai/China

Contact E-mail Address: whitelily.chen@aliyun.com

Introduction: Given diminishment of quality of life caused by surgery in the stomach and duodenum, a minimally invasive treatment is desirable for gastric and duodenal submucosal tumors (SMTs).

Aims & Methods: We aimed to assess the value of endoscopic full-thickness resection (EFTR) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscular propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTR between January, 2010 and February, 2014. The light adhesion of the tumour to gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs oriented endoscopically were performed EFTR using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.

Results: A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30–81 years). Among all the 276 SMTs in our study, 165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in pylorus, 1 located in duodenal bulb and 1 located in duodenal ulcer–C6. Closure of the defect in distal extra peritoneal rectum left open intentionally for healing by secondary intention; techniques—through-the-scope (TTS) clips–7, over-the-scope clip–4, omental patch + clip–2 (TTS–1, OTS–1), endoscopic suturing–1, endoloop + clip–1. Mortality-nil. Follow up endoscopy at 4 weeks showed healing in all 17 patients. Median follow up months = 24.

Conclusion: EFTR is safe and effective for resection of SMTs. Pre EFTR EUS and CECT may be useful to select appropriate candidates. Secure closure of defect is necessary for intraperitoneal full-thickness defects. Further studies comparing EFTR and surgery are recommended.

P1457 BLUE LIGHT IMAGING AND LINKED COLOR IMAGING FOR DETECTION AND CHARACTERISATION OF CHRONIC GASTRITIS.

J. Weigt1, A. Link1, A. Canbay1, P. Malferttheiner1, 1Gastroenterology, Hepatology & Infectious Diseases, Medizin. Universität Muegdburg Gastroenterologie und Hepatologie, Muegdburg/Germany

Contact E-mail Address: jochenweigt@gmx.de

Introduction: Current standard in the characterization of gastric mucosal changes is the use of virtual chromoendoscopy with magnification to visualize the pit pattern and vascular changes. The most recent development in light imaging technology is the so called Multi Light Illumination, that composes light output of 4 coloured LED. Blue Light Imaging (BLI) is composed of a continuous spectrum with peaks at 410 and 430 nm to enhance surface and vascular structures. Linked Color Imaging (LCI) uses BLI light together with post processing that reallocates colour tones resulting in a high contrast of different red tones. Until now only few data exist about the use of LCI and BLI in chronic gastritis (CG).

Aims & Methods: We aimed to analyse the use of LCI and BLI in detecting and characterisation of chronic gastriatic and premalignant conditions of the stomach. All patients were consented. All patients received LCI and BLI. A prediction of histology was made by the endoscopist.

Results: We investigated 24 patients (15 female, 9 male, age 65 yrs (25–87yrs)). H. pylori was detected by histology or urease test in 7 patients. 3 patients showed normal gastric mucosa, 13 patients presented IM or AG either in the antrum or the corpus. According to MAPS criteria 7 patients had extensive disease with premalignant conditions in both, antrum and corpus. The concordance of endoscopic classification and histology was 79.1% (19/24) in the antrum and corpus each. Despite the inconcordance of histology and endoscopic diagnosis in 5 cases the intervals for surveillance according to MAPS guidelines would have been correctly respected with the use of endoscopic assessment in all cases.

Conclusion: LCI and BLI are accurate in detection and characterization of changes in gastric mucosa with an acceptable concordance to histology. These new imaging modalities are a step towards precise endoscopic diagnosis of gastric mucosal changes and have the potential to reduce the number of unnecessary histologic investigations and offer the possibility for more appropriate endoscopic diagnosis.

**P1458** LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION(ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGAL SQUAMOUS CARCINOMA (ESECC) IN AGED PATIENTS

Z. Qi1, Y. Zhong1, P. Zhou1
1Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poem001@qq.com

Introduction: According to the Japanese Esophageal Society Guidelines, Early Esophageal Squamous Cell Carcinoma (ESECC) involving the muscularis mucosa or <200μm invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed after ESD. But in aged RI patients, most will refuse AT due to higher rates of debilitating symptom in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Results: Between January 2008 and December 2013, a total of 158 aged ESECC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Results: 89 patients included in absolute indication (AI) group and 69 in RI group, the baseline characteristics were balanced between two groups. During the follow-up time (median 56 (1-108) months), short-term adverse events (4.3% vs. 1.1%, p = 0.319) and postoperative stricture rate (31.8% vs. 21.3%, p = 0.104) were higher in RI group than in AI group. 5-year recurrence-free survival rate (85.8% vs. 87.2%, p = 0.561), metastasis-free survival rate (100% vs. 96.8%, p = 0.437), overall survival rate(96.6% vs 90.0%, p = 0.613) and cause-specific survival rate(98.9% vs 98.5%, p = 0.264) for AI group and RI group were comparable.

Conclusion: Aged ESECC patients without AT( esophagectomy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1459 RETROSPECTIVE ANALYSIS ON SUSPICION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES**

J. T. Correia De Sousa1, D. Libanio1, P. Lago1, R. Marcos-Pinto1, I. Pedroto1
1Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations, predictive factors to presence, types of FB found, and therapeutic approach.

Aims & Methods: Unicentric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 288 endoscopies were performed on suspicion of FB/FI (22% of total endoscopies, n = 1309, of them 69.1% (n = 199) were performed during the night. Patients’ median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2% (n = 205); of them 61.5% (n = 126) were solitary FB. The most frequently found foreign bodies were meat bones (8% (n = 37) and fish bones (14.6% (n = 30). Most FB/FI were found on the proximal esophagus (56.1%, n = 115). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic removal wasn’t achieved (10, where referred of otolaryngology; 2 for surgery mobilization). In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened stricture).

Endoscopy under sedation was performed in 20 cases (9,7%). About ¼ had associated comorbidities, the most common were esophageal ring in 22 (10.7%) and benign stenosis in 178.3()% patients. Major complications were rare: 1 perforation (0.3%) and 3 deep esophageal lacerations (1.5%). Age (>55years), presence of comorbidities, and previous episodes were associated with presence of FB/FI on Endoscopy (Odds Ratio 2.01, 3.59 and 4.63 respectively).

Conclusion: Endoscopy is frequently preformed for suspicion of FB/FI in our emergency setting. Presence is confirmed in the majority of the cases. Predictive factors for presence were identified. Most FB/FI were removed with success with low complication rates. This data favor the endoscopic approach on suspicion of FB/FI.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1460** LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE

S.T. Kim, T.H. Kim, S. Na
Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 30 experience. However, there was no statistical difference from the first (63.5±54.0) to the second quarter (44.7±31.4, p = 0.19), to the third quarter (40.7±27.8, p = 0.08), and to the fourth quarter (40.8±23.1, p = 0.09). There was no procedure that exceeded 100 minutes from the third quarter. There were a total of seven perforations, four of which were in the first quarter, two in the second, and one in the third. In the procedure time according to the location of the lesions, upper third lesion (92.6±43.7) showed longer procedure time than middle (46.6±40.2, p < 0.01) and lower third (39.5±27.5, p < 0.01) with statistically significant difference. In addition, in the fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: It needs accumulate experience with the help of a professional expert up to 30 cases, and to the more advanced level, about 90 procedures are needed. And, the location of the lesion is the important factor in determining the difficulty of the procedure. Therefore, it is best to avoid the upper third lesion as far as possible until experience 90 cases or at least 30 procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Examination of major duodenal papilla (MDP) by standard forward-viewing endoscopy presents many limitations for the access the validity of Cambridge protocol with a high resolution endoscope in patients with proven pathological conditions–7 (36.8%) (gastric–3, duodenum–2, rectum–2); and closure of chronic fistulae–5 (26.3%) (esophagus–3, duodenum–1, rectum–1). Previous h/o spreading tumor–1); for closure of bowel perforation during endoscopic resection–the clip was loaded on the distal end of the endoscope and endoscope–3/7 of bleeding patients, primary therapy using OTS clip in remaining 16. Technical success was 100%. Two patients needed two clips each due to large size of defect. Chronic success–bleeding arrested in 7/7 (100%); bowel perforation sealed–7/7 (100%); fistula closure successful–4/5 (80%). In one patient of chronic duodenal fistula, fistula reopened 12 weeks after initial sealing of fistula and required surgery. Follow up at 4 weeks revealed no delayed adverse events in any patient.

Conclusion: The new OTS Clip (Padlock™) is safe and effective for treatment of severe bleeding and for closure of post ER full-thickness defects and chronic fistulae. Further studies with larger sample size are recommended.

Disclosure of Interest: All other authors have declared no conflicts of interest.

Aims & Methods: Prospective, randomized, blinded, controlled, non-inferiority crossover study. Subjects scheduled for elective EGD were randomized to undergo CA-EGD (group A) or SVE (group B) before undergoing second examination by the alternate method. Image of the MDP was evaluated, after image processing, by three blinded multicenter-experts. Our primary outcome measure was complete examination of the papilla. Secondary outcome measures were image quality of mucosal pattern, ability to obtain an overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (1=poor, 10=excellent).

Results: A total of 62 patients were randomized and completed the study. Complete examination of MDP was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%, p=0.001). CA-EGD had mean scores of 8.7 ± 1.3, 7.1 ± 0.86 and 7.9 ± 1 ± regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3 ± 1.6 (p <0.001), 8.3 ± 0.9 (p < 0.001) and 7.6 ± 0.6 with SVE (p = 0.01).

Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MDP and can replace the SVE for complete examination of the MDP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1463 INACCURACY OF CAMBRIDGE PROTOCOL FOR PATIENTS HARBOURING CHD1 MUTATION: A CONSECUTIVE SERIES
R. Castro, D. Libánio Monteiro, T. Pinto-Pais, M. Dinis-Ribeiro, C. Brandão
Department Of Gastroenterology, Instituto Português de Oncologia, Porto, Porto/Portugal

Contact E-mail Address: rut.arrais.castro@gmail.com

Introduction: Hereditary diffuse gastric cancer (HDGC) accounts for 1 to 3% of all gastric cancers. It can be caused by a germline mutation of the gene CDH1. Life time risk for gastric cancer is 80% with a mean age at diagnosis of 40 years. Affected individuals generally present multiple foci of signet ring cell carcinoma (SRCC) scattered throughout the gastric mucosa, difficulty detected by endoscopy.

Aims & Methods: The aim of this study was to access the validity of Cambridge protocol with a high-resolution endoscope in patients with proven pathological germline mutation of the gene CDH1. A prospective cohort study was performed between September 2016 and March 2017 in 11 patients with CDH1 mutation. They perform a base line high-resolution endoscopy (Olympus-GIF-HQ190) with random biopsies according Cambridge protocol and additional targeted biopsies of any visible lesion. The total number of biopsies and the total number and localization of SRCC foci was recorded. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To access the validity of Cambridge protocol with a high resolution endoscope in patients with proven pathological germline mutation of the gene CDH1.

Results: During the 11 endoscopies a total of 353 biopsies (329 random biopsies and 24 targeted biopsies; mean of 32.1 biopsies per patient) were performed. Two patients presented 1 SRCC foci in random biopsies, being that one of them presented 2 SRCC foci. The total number of biopsies and the total number and localization of SRCC foci was registered. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To access the validity of Cambridge protocol with a high resolution endoscope in patients with proven pathological germline mutation of the gene CDH1.

Conclusion: Despite the use of high-resolution endoscopes and the high number of random biopsies, endoscopic examination presents many limitations for the diagnosis of HDGC. According to literature, prophylactic total gastrectomy remains the only option to prevent cancer propagation.

Introduction: Endoscopic clips are used in a variety of clinical situations in GI endoscopy—for arrest of bleeding or for closure of bowel perforations or chronic fistulae. Conventional through-the-scope clips often cannot provide optimum results; and therefore full-thickness (FT) over-the-scope (OTS) clips have been devised.

Aims & Methods: Current study describes the clinical experience of use of a recently developed FT OTS clip (Padlock™, Aponos Medical, USA). Data from a prospectively maintained database of all patients undergoing the new procedure was abstracted, primary diagnosis, history of previous endotherapy, endoscopic procedure, indications for FT OTS clip usage, technical and clinical success and early and delayed adverse events were recorded. The clip–clip is available in two different sizes for use in upper and lower endoscopy. It is supplied preloaded on a cartridge that fits on the distal end of the endoscope. The trip-wire travels alongside the endoscope, enabling additional instruments to be passed through the endoscope channel, and special double-channel endoscope is not required for its application. Technique of clip application–the clip was loaded on the distal end of the endoscope and endoscope advanced to site of interest. Bowel wall defect or bleeding point was positioned within the clip and strong suction was applied. Clip was fired by closing the handle on the delivery system. Suction was slowly released and site was inspected. Results: Total 21 clips used in 19 patients. M: F–12:7, mean age–57.9 years (range –24–84 years). Indications for FT OTS clip use–severe GI bleeding–7 (36.8%) (duodenal ulcer bleed–5, rectal ulcer–1, bleed during ESD for rectal lateral spreading tumor–1); for closure of bowel perforation during endoscopic resections–7 (36.8%) (gastric–3, duodenum–2, rectum–2); and closure of chronic bowel fistulae–5 (26.3%) (esophagus–3, duodenum–1, rectum–1). Previous h/o endotherapy–3/7 of bleeding patients, primary therapy using OTS clip in remaining 16. Technical success was 100%. Two patients needed two clips each due to large size of defect. Chronic success–bleeding arrested in 7/7 (100%); bowel perforation sealed–7/7 (100%); fistula closure successful–4/5 (80%). In one patient of chronic duodenal fistula, fistula reopened 12 weeks after initial sealing of fistula and required surgery. Follow up at 4 weeks revealed no delayed adverse events in any patient.

Conclusion: The new OTS Clip (Padlock™) is safe and effective for treatment of severe bleeding and for closure of post ER full-thickness defects and chronic fistulae. Further studies with larger sample size are recommended.

Contact E-mail Address: bmiuteasca@yahoo.com

Introduction: Endoscopic resection of ampullary adenomas has increased in the last decade due to the high morbidity with a high mortality in patients undergoing surgical procedures.

Aims & Methods: This study aims to evaluate the outcome of endoscopic ampullectomy (EA) in a tertiary endoscopy department. We included in the study patients that underwent EA between January 2014 - April 2017 at the Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, Romania. All patients had a benign pathological result prior to the EA. Post-procedural complications such as bleeding, perforation, cholangitis, pancreatitis and mortality were analyzed. Data about resection type, post EA histology and 1 year follow-up was also processed.
Results: 19 patients underwent EA, with a mean age of 63.5±17.7 years and a male to female ratio of 0.7. "En bloc" resection was done in most cases 15/19 (78.9%). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy was 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment and 65.8% required conversion to a posterior approach. Our results are in line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

P1467 NEW CHALLENGE FOR SAFER ENDOSCOPIC SUBMUCOSAL DISSECTION USING CO2 LASER

Y. Morita, R. Aiyoshi
Gastroenterology, Kobe University, Kobe/Japan

Contact E-mail Address: ymorita@med.kobe-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is increasingly accepted as a minimally invasive treatment for the patients with early gastrointestinal cancers. However, ESD demands high maneuverability technique, and the success of the operation is dependent on each operator’s skill. We have developed a novel laser surgery system for ESD to overcome such difficulties of ESD, which is composed of a CO2 laser source and a disposable flexible hollow fiber probe. Compared to conventional ESD (C-ESD) using electric surgical knives, ESD using CO2 laser (L-ESD) method has an advantage of less risk of perforation and massive thermal damage, because the CO2 laser is strongly absorbed by water such as saline or sodium hyaluronate. Further more, the cutting point can be precisely recognized by another visible guide laser. Due to non-contact laser irradiation and adequate visualization of treatment area, the laser system facilitates more precise and safer treatment and provides high quality and stable dissection. We hypothesized that performing ESD using CO2 laser with a submucosal laser absorber could be a safer and simpler ESD technique.

Aims & Methods: The aim of this study was to evaluate the feasibility of L-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 14 hypothetical lesions in three porcine stomachs (L-ESD, 7 lesions; C-ESD 7 lesions) under general anesthesia. Endo-Laser displacement was encountered in n=2 and replaced endoscopically including readmission of 1 patient for delayed mucosal incision site healing (Clavien-Dindo Grade IIb). There were no cases of mortality, perforation, infection/major bleeding.

(continued)
Grade 2A) corrosive-induced injury of upper gastrointestinal tract. Patients in whom gastroscopy could not be done or who had been hospitalised were excluded from the study. The study was approved by the Institutional Ethics committee and was funded by a fluid research grant received from Institutional Review Board at Christian Medical College, Vellore, India. The data was analysed using SPSS version 17. **P**-value of <0.05 was considered as significant. All continuous variables were expressed as mean ± SD and the non parametric continuous variables were expressed as median. Comparison between groups was done using Fisher’s exact test.

**Results:** During the study period a total of 112 patients presented with ACI. In all 82 patients were included in the study. Amongst them, 53% of the patients were females and the mean age was 36.5 ± 15.5 years. The intent of corrosive ingestion was suicidal in 70% and accidental in 30%. In majority (50%) of patients the natural history of corrosive was not known. Nasogastric tube placement was done in 50%, nasojugal tube placement in 32% and 8% no tube was placed. Surgery as needed in 19% (tracheostomy or feeding jejunostomy or a definitive surgery). Amongst the 82 patients who were included in the study, 11 were lost to follow up. None of the 71 patients in whom the median follow up period was 31 months (range 2–72 m) during which 12 (16.9%) patients expired (73% related to ACI). Amongst the 59 patients, that were alive 16(27%) were symptomatic, 12(20%) had dysphagia, 5(6%) had regurgitation, 4(5%) had chest pain, 67% had weight loss and 11(18%) patients required endoscopy. In all, 43(73%) patients underwent barium study during follow up and strictures were noted in 21(36%). The site of stricture was esophageal in 11(53%), stomach in 8(38%) and combined esophageal and stomach in 20%(39%). Esophageal stricture was seen in all patients with Grade III B esophageal injury, 27%(6/22) with Grade III A injury and 19%(5/27) with Grade II B injury. None of the patients with Grade II A injury developed stricture. Stricture in stomach developed in 22% (5/27) with Grade III B injury and 14%(4/28) with Grade III A injury, 10%(1/10) with II B injury and 20%(1/5) with II A injury. **Conclusion:** Acute corrosive ingestion is associated with significant morbidity and mortality. There needs to be stringent control on sale, use and storage of such chemicals.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

A prospective, single-center, cross-over controlled trial of confocal laser endomicroscopy assessment of persistent or recurrent intestinal metaplasia and recurrence of neoplasia after endoscopic treatment of Barrett’s esophagus-related neoplasia (born). J. Krajciová1, M. Kolář2, J. Malušková2, M. Kment2, Z. Vacková1, J. Spicák1, J. Martiněk1; 1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic; 2Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: krajj@i-kem.cz

Introduction: Probe-based confocal laser endomicroscopy (pCLE) has been developed to overcome limitations of the current endoscopic sampling techniques. pCLE allows detailed examination of cellular structures and may examine larger areas compared to standard biopsy. Patients after endoscopic treatment of Barrett’s esophagus (BE)-related neoplasia (BORN) should undergo endoscopic surveillance with biopsies to detect persistence or recurrence of intestinal metaplasia (IM) or neoplasia (N). Aims & Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN. A single-center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance after endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (a few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present). BE was defined in pCLE as columnar-lined epithelium with dark mucin in goblet cells, a villiform pattern, and regular-shaped capillaries in the mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, high dark contrast to the surrounding tissue, and irregular leaking capillaries in the mucosa.

Results: We examined 29 patients, from these 14 patients (48%) had the initial diagnosis of intraepithelial neoplasia (LIN), 7 patients (24%) had high-grade intraepithelial neoplasia (HGIN) and 8 patients (28%) had an early adenocarcinoma (EAC). Persistent/recurrent IM was detected at the level of neo-Z-line in 10 patients (34.5%) by both standard biopsies and pCLE. pCLE but not biopsies detected persistent/recurrent IM in 2 patients (6.7%), another 2 patients had IM present in biopsies but not in pCLE. pCLE diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, which was not confirmed in biopsies. Sensitivity and specificity of pCLE detection of persistent/recurrent IM was 83.3% (95% CI 51.6–97.9) and 89.47% (95% CI 66.9–98.7), respectively, with positive predictive value 83.3% (95% CI 56.1–95.0) and negative predictive value 89.5% (95% CI 70.4–96.8). Agreement of pCLE and histopathological findings was 86%.

Conclusion: pCLE seems to be comparable to standard biopsies in detection of persistent/recurrent IM after endoscopic treatment of BORN. Nevertheless, these results need to be confirmed in a larger cohort of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
3. Friedrich K, Scholl SG, Beck S, et al. Respiratory Complications in older patients undergoing oesophagectomy with gastric transposition are limited. Although commonly seen in the elderly, pneumonia is not infrequent in younger patients receiving thoracic surgery. In a multi-institutional study of 1,167 patients, the incidence of pneumonia was 1.9%. Pneumonia was associated with an increased risk of postoperative complications, including wound infections, sepsis, and death. 

Introduction: Therapeutic options for gastroparesis or delayed gastric emptying vary and there are limited data on the efficacy of these therapies in a publically-funded Western healthcare setting. This study assessed the effectiveness of these therapies in a Western setting as well as the rate, timing and predictors of complications in this patient population.

Aims & Methods: Endoscopic submucosal dissection (ESD) is an established technique for the treatment of early gastric cancer. The aim of this study was to evaluate the feasibility, safety and efficacy of ESD for gastric and duodenal lesions in a Western setting. 

Results: A total of 410 ESD procedures were performed at these locations. The use of anticoagulants is a risk factor for bleeding and perforation. Patients with a history of anticoagulant use were more likely to experience complications compared to those without. The overall complication rate for ESD procedures in this study was 10.5%. The most common complications were bleeding (7.3%) and perforation (3.2%). The bleeding rate was significantly higher in the group of patients receiving anticoagulants (12.2%) compared to those not receiving anticoagulants (5.5%). 

Conclusion: ESD in this Western setting was more commonly performed for colonic and esophageal lesions rather than gastric as seen in Japan. The complication rate is modest and almost all were managed successfully with an endoscopic approach. The procedures occurred more commonly in gastric and duodenal sites. This may be related to the technical difficulties of resection or low volume of procedures performed at these locations. The use of anticoagulants is a risk factor for bleeding and perforation. 

Disclosure of Interest: All authors have declared no conflicts of interest.

11. No significant differences for the occurrence of pneumonia (1.6%, GIES group vs. 0.4%, control group, p=0.041) in the age of the older age group (2.6% vs. 0.0%, p=0.041, and 7.8% vs. 2.5%, p=0.034, respectively) were detected. Inflammatory parameters were significantly increased after GIES, particularly on day three. GIES patients received antibiotic treatment more frequently and pulmonary infiltration did not differ significantly.
12. Conclusion: This study confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration. 
13. Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: 33 patients (13 male; mean age 45, range 17–80) underwent a total of 225 consecutive endoscopic procedures over 2 years. Treatments were either 100IU units of Botox injected into 4 quadrants of the pylorus or pneumatic dilatation (PD) incrementally up to 16–20mm (Hercules; Cook Medical). Patients with gastric malignancy, previous pyloric surgery or no documented follow-up were excluded. Non-therapeutic responses were assessed at first follow up post-procedur-
factor for delayed bleeding. Given that the majority of delayed complications occurred due to post-procedure, a standardised 5 day inpatient stay would prove futile in our cohort.

P1478 PREDICTIVE FACTORS AND MANAGEMENT OF REFRACTORY BENIGN OESOPHAGEAL STRICTURES

M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa

Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EFE, Lisboa/Portugal

Contact E-mail Address: cmiguelmour@gmail.com

Introduction: The optimal management and the predictive factors of response to endoscopic dilation of refractory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign refractory oesophageal strictures with scheduled endoscopic dilatation. Retrospective analysis of 75 patients submitted to scheduled endoscopic dilation of benign oesophageal strictures between October 2010 and November 2016. Strictures were classified as refractory when ≥5 endoscopic dilations were needed with at least one dilation achieving ≥15 mm of diameter during the course of management of the oesophageal strictures.

Results: The study sample included 42 (56%) male patients and the mean age was 55 years (12–76). Dysphagia scale at baseline was solids (1)–17 (22%), semi-solids (2)–23 (30.7%), liquids (3)–23 (30.7%) and complete (4)–12 (16%). Body mass index (BMI) at baseline was 22 ± 5 Kg/m². The aetiology of the benign strictures was: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.5%), radiotherapy–10 (13.5%) and others–9 (12%). The location of the oesophageal stricture was as follows: proximal: third–34 (45.3%), middle–third–12 (16%), distal third–27 (36%) and multiple locations–2 (2.7%). Stricture type: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilation over a median period of 19 weeks (1–229). Dilations were done with Savary-Gilliard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean diameter of dilation achieved was 15.7 ± 2.2 and a dilation diameter of ≥15 mm was achieved in 36 (74.6%) patients. Local injection of corticosteroids (p = 0.001) and higher dilation diameter (p < 0.001) were significantly associated with the need for local corticoid injection. In this subgroup, there was a significant association with post-surgical aetiology (p = 0.042), location (p = 0.039), higher rate of local injection of corticosteroids (p < 0.001) and higher dilation diameter (p < 0.001). Refractory strictures were significantly associated with the presence of local cortical injection (OR 9.76, 95%CI 0.35–0.46, p = 0.02) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local lateral decompressions during subsequent procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1479 LOCAL CORTICOSTEROIDS IMPROVE EARLY CLINICAL OUTCOMES IN PATIENTS UNDERGOING ENDOSCOPIC DILATION OF BENIGN OESOPHAGEAL STRICTURES

M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa

Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EFE, Lisboa/Portugal

Contact E-mail Address: cmiguelmour@gmail.com

Introduction: Local corticosteroids have been shown to improve outcomes in patients undergoing endoscopic dilation of peptic strictures.

Aims & Methods: To evaluate factors predicting early clinical response to endoscopic dilation of benign oesophageal strictures. Retrospective analysis of 75 consecutive patients submitted to scheduled endoscopic dilatations between October 2010 and November 2016. Clinical improvement was defined as dysphagia improvement ≥95% (mean 89.4%, 95%CI 86.4–91.4) post-dilatation. Endoscopic improvement was achieved with curative resection for benign adenomas and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillotomy on duodenal papilla tumors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1480 TRENDS IN CERTIFICATION FOR GASTROINTESTINAL ENDOSCOPY AND VARIATIONS BETWEEN TRAINEE SPECIALTIES: RESULTS FROM THE UK TRAINEE ENDOSCOPY DATABASE

*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: In the UK, endoscopy certification is overseen by the Joint Advisory Group. Since 2011, certification has been awarded for upper and lower GI endoscopy online via the JAG Electronic Training System (JETS). We aimed to analyse trends in endoscopy e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical endoscopy trainees (NME).

Aims & Methods: We prospectively identified trainees awarded certification for gastroscopy, flexible sigmoidoscopy (FS) and colonoscopy from the JETS database. For each specialty, we collected data on lifetime procedural counts, forative assessments, and key performance indicators (KPIs) at the time of certification. Comparisons between specialties were analysed using a combination of chi², Mann-Whitney and median tests.

Results: Between June 2011-Dec 2016, 2857 applications were awarded certification. Most certifications were awarded to GI trainees (Figure 2). Median procedural numbers (p < 0.001) and formatives (p < 0.001) pre-certification varied for each modality in the order of NME > GI > GS. Caecal intubation rates (CIR) at full certification were similar between GI (95.6%) and GS (95.6%, p = 0.81), but lower in NME (93.6%, p = 0.02 vs. GS, p = 0.006 vs. GI), despite no differences at provisional certification (median CIR 95.6%, p = 0.32). Rates of D2 intubation (median 98.7%) varied across groups (GS > GI > NME, p = 0.002). Certification awarded at first attempt were similar across specialties (mean 89.4%, p = 0.19), but varied for gastroscopy (NME 95.5%, GS 80.1%, GI 89.7%, p = 0.01).

Conclusion: Despite variations amongst trainee specialties, endoscopy certification is a transparent and robust benchmark for assessing competency, as evidenced by GI trainees. Further studies are required to study the impact of recent changes to certification, and if variations in KPIs exist following certification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1481 EFFICIENCY AND SAFETY OF ENDOSCOPIC PAPILLOCTOMY FOR TREATMENT OF DUODENAL PAPILLA TUMORS

Y. Chu1, M. Xu1, P. Zhou1, C. Zhang1

1Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xu.meidong@zs-hospital.sh.cn

Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasionally found during gastroduodenoscopy examination. Endoscopic papillotomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillotomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillotomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis. Endoscopic papillotomy was performed in 40 cases (21.3%). The procedural success rate was 95% (38 cases). The mean diameter of the duodenal papilla tumor was 15.7 ± 2.2 and dilation of ≥15 mm was achieved in 56 (74%) of patients. Local corticosteroid injection (dexamethasone 5 mg) was performed at least once in 39 (52%) patients and in ≥52% of dilations also in 39 (52%) patients. The rate of complications was 13.3% (perforation (n = 9) and bleeding (n = 1)). Surgery was performed in 10 patients (13.3%) (refractory stricture and post dilation perforation (n = 3)). Improvement of dysphagia symptoms was only associated with the maximum dilation diameter (p = 0.026) and local injection of corticoids (p < 0.001) as was confirmed by binary logistic regression wherein both maximum dilation diameter (OR: 4.92, 95%CI 1.05–2.04, p = 0.027) and topical injection of corticosteroids (OR: 7.22, 95%CI 0.021–0.55, p = 0.007) were strongly associated with improved dysphagia scores.

Conclusion: In our study sample with multiple aetiologies of benign oesophageal strictures, only the maximum dilation diameter and local injection of corticosteroids were associated with improved clinical outcomes in patients undergoing endoscopic dilation of benign oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.
PROCEDURAL SKILLS (DOPS) FORMS IN ENDOSCOPY TRAINING

P1482 CHANGES IN SCORING OF DIRECT OBSERVATION OF DOPS scores for gastroscopy (n = 2296) and polypectomy (n = 370) in the 6-months before July 2016 (old DOPS) versus after (new DOPS) for trainees at early and late stages of training (p < 0.001). To allow analysis, the new DOPS rating scale was aligned to a 4-point scale, hence a score of 4 on new DOPS = Scores 3 or 4 on old DOPS, and scores on the new and old DOPS compared using the Mann-Whitney U-test. Results: P1717 DOPS (77.7% new and 22.3% old) were included for analysis. Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (0.6% vs. 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1 & 2) were similar for gastroscopy (p = 0.53) and sigmoidoscopy (p = 0.34), but not for colonoscopy (new 11.9% vs. old 13.9%, p < 0.001) and polypectomy (new 6.8% vs. 19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 55.8%, p < 0.001). On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

Conclusion: Endoscopy assessors are applying a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1484 PROTECTIVE VACUUM SPONGE IMPLANTATION AND CONTINUOUS EVACUATION OF BILE AND Pancreatic Juice FOR PREVENTION OF SECONDARY PERFORATION AFTER PRIMARY SUCCESSFUL ENDOscopic RESECTION OF WIDESPREAD D2/D3 DUODENAL AND PAPILLARY ADENOMATA

Introduction: Endoscopic resection of duodenal adenoma carries an increased risk of perforation compared to other locations in the upper or lower GI tract. Additionally in endoscopic resection of widespread adenomatia (Spiegelman III/IV) at the level of D2/D3 there is an increased risk of secondary perforation due to auto-digestion of the denuded duodenal wall by pancreatic enzymes and bile independent of the primary endoscopic resection method. We recently reported the successful implantation of a mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophageal vacuum sponge. Aims & Methods: From September 9th, 2015 to March 20th, 2017 endoscopic resection of widespread duodenal or papillary adenomatia of > 2 cm in D2/D3 was performed in five patients. There was a surgical indication for Whipple's resection as primary intervention or in case of failure in all patients. All patients agreed and gave their informed consent to the procedure. Results: Five patients with widespread duodenal adenomatia were included (2x papilla, 3x D2/D3 extrapancreal adenomatia; 3x tubular; 2x HGIN, 1x LGIN). The macroscopic mean maximum diameter and perpendicular diameter of the lesions were 4 x 2.8 cm (largest 7.5 x 3.7 cm; smallest 2.2 x 1.8 cm). In all cases the implantation of a mini-vacuum sponge EsoVac reduced in volume to 1.2 x 1.5 cm (diameter, length) and suction tube; Braun Corp., Melsungen). Continuous suction was applied over several days (~125 mm Hg; ActiVac, KCI Medical, Wiesbaden) depending on the size of the resection area and healing status (m = 10 days, 4–14 days). An endoscopic/radiologic vacuum sponge exchange was performed every 3–5 days. In 4 cases additional atrumatic over-the-scope-clips (OTSC, Ovesco Tuebingen) were placed during the procedure and in 5 cases additional hemoclip were applied to secure the wall and for hemostasis. In 5/5 cases (100%) an excellent healing could be observed during follow-up. No patient had to be operated during or following the intervention (FU 2–14 mo.). In all cases the resection was curative with ‘en bloc’ resection, though in one case the specimen ruptured during retrieval into three parts (4x HGIN, 1x LGD, 4x R0, 1x Rx). In one case 10 days after resection an acute bleeding occurred with the need of endoscopic clipping and prophylactic radiologic coiling of the gastroduodenal artery with uneventful course. In a second case a minor bleeding occurred without necessity of transfusion during ablation of an OTSC three mo after the primary intervention. All patients were asymptomatic during follow-up.

Conclusion: The endoscopic resection of large duodenal adenomata in D2/D3 is feasible and was safe in our collective using the application of a duodenal mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophageal vacuum sponge. All authors have declared no conflicts of interest.

Aims and Methods: We used the UK trainee endoscopy database (JETS) to collect DOPS scores for gastroscopy (n = 1934), sigmoidoscopy (n = 517), colonoscopy
P1405 ENDOSCOPIC CLOSURE OF ACUTE PERFORATIONS OF THE GASTROINTESTINAL TRACT IN ANIMAL MODELS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Chorochane library: EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 46 studies on animal models were identified. 15 studies, including 4 guidelines.

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations with a reasonable technical success. Further confirmation from prospective studies in human is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a technique with remarkably greater difficulty than upper gastrointestinal ESD because of unstable maneuvers and inherited anatomic variability in the colon. Thus, aiming at reducing these restrictions, we have used single balloon (SB) overtube to assist colorectal ESD in cases considered to have difficult operability. In this study, to evaluate the usefulness of a single balloon overtube to assist colorectal ESD.
Aims & Methods: The study included 35 patients with 39 colorectal lesions who underwent ESD (group SB) or ESD without SB (group NSB). The background of the patients in group NSB were corrected by using the propensity score matching method. The application of the combined use of SB was determined when the circumferential access to the lesion was difficult, and paradoxical movement was observed.

Results: The characteristics of the lesions in group SB were as follows: proximal, 28 (73.7%); distal, 11 (26.3%); mean size of tumors, 37.6 ± 9.8 mm; gross findings of laterally spreading tumor of granular type (LST-G), 11 lesions; non-granular type (NG) tumors, 28; adenomas, 11; mucosal cancers, 22; and submucosal cancers, 6. The mean procedure time was significantly shorter in group SB (51 ± 17 min vs 106 ± 35 min; p < 0.05). No significant differences were found in en bloc resection, complete resection, postoperative bleeding, and perforation rates. No accidental symptom associated with balloon endoscopy was observed.

Conclusion: Using a balloon overtube can be expected to improve not only access to the lesion but also facilitate scope manipulation for colorectal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1490 COMPUTER-AIDED POLYP MEASUREMENT OF 78 POLyps DURING LIVE COLONOSCOPY (CAPME): A PROspective STUDY

C. Alliman1, O. Rouquette1, S. Le Roux2, B. Pereira3, A. Abergel1, A. Bartoli1, C. Tilmant4, L. Poincloux1

Contact E-mail Address: calimon@chu-clermontferrand.fr

Introduction: Polyp size measurement is an important outcome in current endoscopic practice. Polyp size estimation is mandatory to determine the surveillance interval after polypectomy and useful to anticipate and prevent complications in therapeutic procedures, for it has been proven that polyp size is one of the most important factor of complications (mucosal bleeding, perforation). Nevertheless, a high degree of subjectivity exists (especially overestimation of polyp size) in polyp size estimation because of a lack of validated and reproducible measurement methods. The aim of this study was to compare a computer-aided polyp measurement (CAPME) to an unassisted visual estimation (UVE) and an endoscopic reference measurement (ERM).

Aims & Methods: This prospective monocentric study was led between November 2015 and July 2016 in the University-affiliated Hospital of Clermont-Ferrand, the Blaise P1260cmvm (BPI) and the Image Science For Interventional Techniques (ISIT) research unit of Clermont-Ferrand (France). Video-endoscopic procedures were recorded and secondly used for the CAPME method. The endoscopic acquisition protocol was standardized with a slow back-and-forth movement of the endoscope and photography of each polyp was taken with an open biopsy forceps placed on the base of the polyp. ERM was then measured thanks to a simple rule of three knowing the fixed size of the open biopsy forceps (8 millimetres, mm). UVE was determined on the same photography without any measurement devices by two different endoscopists. All the measurements were realized blinded of the other results. Accuracy of the CAPME and UVE methods were defined by a variation less than 1 mm with the ERM. We used the Lin concordance correlation coefficient (CCC) to measure the agreement between the variables.

Results: 33 patients and 78 polyps were included in this study. The mean polyp size was 5.3 mm, with 73.1% (n = 57) of polyp less than 5 mm. The Lin CCC with the ERM was 0.972 (95% CI, 0.960–0.981; p < 0.001). Inaccuracy of polyp size estimation proportionally to polyp size (40.9% of inaccurate polyp measurement for polyps greater than 10 mm) and we observed a systematic overestimation of supracentimetric polyps for UVE method. Unlike UVE, CAPME accuracy was not impacted by polyp size variation in our study (11.1%; 14.7% respectively). Accuracy of the CAPME method was higher than UVE method (0.972 vs 0.960; p < 0.001). Agreement analysis showed a higher agreement rate for CAPME than UVE method (82.1% vs 63.4% respectively).

Conclusion: To our knowledge, this is the first prospective study with significant data analysing a computer-aided polyp measurement in live colonoscopic procedures. In our study, this methods shows more accuracy than the visual estimation, which is the actual gold standard. The main limitation of this study is the endoscopic protocol (back-and-forth movement of the endoscope) that increases the degree of subjectivity exists (especially overestimation of polyp size) in polyp size estimation. The use of DualFocus might be a solution to overcome this problem.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic Non-Technical Skills (ENTS) are an essential component of high quality endoscopic practice. Giving information about performance of these skills in a fair and accurate way is a major challenge for assessment of ENTs. Against this background there are essentially 2 possible answers, which we explore in this paper. One possible solution is to obtain a consensus in the literature regarding the technique of anaesthesia/sedation method. The application of the combined use of SB was determined when the circumferential access to the lesion was difficult, and paradoxical movement was observed. There is no consensus in the literature regarding the technique of anaesthesia/sedation method for ESD. We aim to describe current sedation practices used in ESD in Western Hospitals.

Aims & Methods: A systematic literature search was performed to identify all articles describing colorectal ESD procedure performed in Europe, America and Australia. Electronic databases including PubMed, the Cochran library and Embase were searched. Original articles or abstracts for congress in English were included. The author was sent to the authors of the identified articles in order to obtain additional information regarding sedation practice, if this was not explicitly detailed in the original articles. All articles were examined independently for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.).

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were longitudinal studies. In (10/18) 55.6% of cases, general anaesthesia was used according to the cases and clinician decision. A total of (10/18) 55.6% of the institutions used sedation instead of general anaesthesia. In (8) 44.4% of the institutions propofol was used in (8) 44.4% of the institutions. In (3) 16.7% of institutions, conscious sedation was used for polyps of >10 mm; 5–10 mm and <5 mm respectively.

Conclusion: The sedation strategy used in colorectal ESD in Western world is heterogeneous. Most institutions opt for deep sedation administered by anaesthesiologists within the endoscopy room. By and large, patients are admitted post procedure for observation. Greater sharing of experience is required to better understand and the optimal method of sedation for this technique within the context of western practice.

Disclosure of Interest: All authors have declared no conflicts of interest.
domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) for Decision-making (D&M). Each MARS domain was represented by 10 items and is assessed on a 7-point scoring scale – endoscopists should score >90 in each domain (80–90 = need for improvement, <80 = suboptimal performance). CIR and PDR measures are routinely calculated for all colonoscopists using the HICCS Electronic Reporting System with manual validation of these data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners ENTS scores were measured using the Pearson test.

Results: 9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTS using the MARS tool. Their ENTS scores were correlated with existing KPIs for each colonoscopy (Oct 2016—May 2017), with an overall positive correlation between ENTS domains and CIR (COMM 0.58; SITA 0.66; LEAD 0.66; D&M 0.75) and PDR (COMM 0.49; SITA 0.55; LEAD 0.50; D&M 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTS domains (operators 5, 7, 9). Taking into account important KPI thresholds 2 out of 3 (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTS competent group) and one (33%) did not meet PDR targets (c.f. 0% in ENTS competent group).

Conclusion: The MARS tool is a practical way to measure of ENTS performance designed as a 360 degree feedback and identifies areas for development within independently practitioners that are not currently highlighted by standard colonoscopy KPI measures. There is some correlation with current KPI feedback panels but not as strong a representation of the MARS assessment panels. Both CIR and PDR primarily depend on the colonoscopists’ individual skills rather than the team elements required by polypectomy or EMR and these more complex tasks may show stronger correlation with MARS ENTS evaluation.

P1493 RANDOMIZED CLINICAL TRIAL EVALUATING THE EFFECT OF A VISUAL EDUCATIONAL BOOKLET ON THE PREPARATION OF COLONOSCOPY IN HOSPITALIZED PATIENTS

A. Guardiola Arévalo1, A. Granja Navarrecida, F.J. Garcia-Alonso2, P. Bernal Checa2, M. Hernández Tejero2, D. Bonillo1, E.M. Andrés Esteban4, A. Alagba5, F. Bermejo6, 1Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain 2Aparato Digestivo, Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain 3Hospital Universitario Río Hortega, Valladolid/Spain 4Universidad Autónoma de Madrid, Madrid/Spain

Contact E-mail Address: toniga2011@gmail.com

Introduction: Safety and diagnostic accuracy of colonoscopy depend on the quality of bowel cleansing. Several factors have been reported to affect the quality of bowel cleansing, one of them being hospitalization.

Aims & Methods: We performed a prospective, randomised endoscopy blinded clinical trial between February 2016 and January 2017 included. Our aim was to evaluate the impact of a visual educational booklet in the level of cleanliness achieved in hospitalized patients who are undergoing a colonoscopy. Hospitalized patients >18 years undergoing colonoscopy were included. Exclusion criteria were: previous colonoscopy in the last 3 years, previous colorectal, known inflammatory bowel disease, urgent colonoscopy, dementia or refusal to participate in the study. Both groups received 4L polyethylene glycol solution. The intervention consisted of a visual educational booklet (visual cohort). Demographic data, personal history, reason for admission and for colonoscopy, work shift in which it was performed, findings at endoscopy were collected. The Boston Bowel Preparation Scale (BBPS) was used to assess the bowel preparation. A BBPS score <6 or with at least one segment was considered a poor preparation.

Results: One hundred and thirty six patients were included, 51.5% were male, with a mean age of 64.3±17.6 years, and 95.9% of Spanish nationality. The mean body mass index was 27.3±5.2 kg/m². Educational attainment was below secondary education in 71.6%. Most patients had hypertension (51.0%), diabetes (17.2%), and the gastroenterology ward (21.32%). Anemia (31.62%), abdominal radiographic findings (16.91%), hematochezia/rectal bleeding (15.44%), diarrhea (11.03%), and abdominal pain (8.82%) were the most frequent indications. Patients characteristics, bowel cleansing and endoscopic findings are shown in table 1. The educational booklet did not suppose a difference in bowel cleansing. Attained factors that impacted on the level of well and properly prepared patients in the bivariable study were: age (62.1±18.7 vs 70.5±14.8; p = 0.019), diabetes mellitus (72.3±42.2% vs 0.024), hypertension (45.63% vs 69.70%; p = 0.016), cardiovascular disease 14.5% vs 36.3%; p = 0.006), and colorectal cancer on colonoscopy (99% vs 81.82%; p = 0.001). In the multivariable analysis the only factors associated with a poor bowel cleansing were age (OR 7.34; 4.60; p = 0.001), and colorectal cancer on colonoscopy (OR 3.82 (1.26–11.61); p = 0.018).

| Hypertension (136) | 8 (11.43%) | 6 (9.09%) | 0.27  
| Caesarean (136) | 1 (1.45%) | 4 (6.06%) | 0.15  
| Other surgical interventions (136) | 4 (5.71%) | 5 (7.58%) | 0.66  
| Other surgery (136) | 21 (30%) | 29 (42.86%) | 0.18  

**Conclusion:** The use of a visual educational booklet for the preparation of colonoscopies does not provide a significant improvement in hospitalized patients in our health area. Heart disease and/or colon cancer were predictors of poor preparation for colonoscopy. An optimized preparation should be considered for this type of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P149 STUDY OF ULCERATIVE COLITIS COMPlicated BY PRIMARY SCLEROSING CHOLANGITIS**

S. Murasugi, A. Ito, H. Kambayashi, M. Yonezawa, T. Ohmori, K. Tokushige

Institute of Gastroenterology, Tokyo Women’s Medical University, Tokyo/Japan

**Contact E-mail Address:** murashun0305@yahoo.co.jp

**Introduction:** Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). While the complication of PSC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC.

**Aims & Methods:** We investigated the clinical and colonoscopic features of patients with PSC and UC. We retrospectively examined the clinical features, including the clinical course and colonoscopic findings, of 25 colitis patients with PSC attending our hospital between 2000 and 2016.

**Results:** The male-to-female ratio was 12:13 and the age at diagnosis of PSC was 49 ± 15 years. PSC was the initial diagnosis in 12 patients (48%), while colitis was the first to be diagnosed in 4 patients (16%), and both diseases were found concurrently in 9 patients (36%). Among the 21 patients with the diagnosis of PSC concurrently, 12 patients (57%) had UC and the other 9 patients had nonspecific colitis (43%). Among the 24 patients in whom the disease extent was assessed, 22 had pancolitis, 1 had left-sided colitis, and 1 had proctitis. Inflammation predominantly affected the right colon in 20/22 patients with pancolitis and also involved the terminal ileum in 9 patients (45%). The Mayo score for colonoscopic evaluation of UC was 1 in 16 patients (64%), 2 in 8 patients (32%), and 3 in 1 patient (4%). There were no rectal lesions in 10 patients (40%). Liver biopsy was performed in 17 patients, and Ludwig’s stage was Stage I in 1 patient (6%), Stage II in 12 patients (71%), Stage III in 3 patients (18%), Stage IV in 1 patient (6%). Ludwig’s stage did not correlate with the Mayo score. All patients with PSC and enterocolitis received oral urso-deoxycholic acid (UDCA), including 13 patients with UDCA only (52%), 2 patients with combination of ursodiol and UDCA (8%), 5 patients in combination with 5-aminosalicylic acid (5-ASA) (20%), 2 patients in combination with prednisolone (PSL) (8%), 1 patient with the combination of PSL and UDCA (4%), and 2 patients with 5-ASA + PSL (8%). The UDCA dose was 100 mg in 2 patients (8%), 600 mg in 15 (60%), and 900 mg in 5 (20%).

**Conclusion:** In colitis patients with PSC, there was no clear association between colonoscopic disease activity and the severity of PSC. There was no sex difference and the age at diagnosis of PSC showed a bimodal distribution (30s and 60s). Pancolitis was very frequent and predominantly affected the right colon, but disease activity was low. Rectal lesions were mild or absent. About half of the patients had inflammation of the terminal ileum.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** The use of a visual educational booklet for the preparation of colonoscopies does not provide a significant improvement in hospitalized patients in our health area. Heart disease and/or colon cancer were predictors of poor preparation for colonoscopy. An optimized preparation should be considered for this type of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1496 MAKING COLONOSCOPISTS MORE AWARE OF THEIR ENDOSCOPIC NON-TECHNICAL SKILLS—IMPROVING FEEDBACK FORMATS DERIVED FROM THE MULTI-ASSISTANT RATING SCALE (MARS) TOOL
N. Hawkes, F. Kokwara, B. Davies, J. Cornish
Gastroenterology, Cwm Taf University Health Board, nr Cardiff/United Kingdom
Contact E-mail Address: nelhawkes@aol.com

Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with effective performance and high quality endoscopic outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS domains amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS provided over 9 periods of time. We have previously demonstrated that the ENTS questionnaire is a useful tool in identifying low performers and those requiring specific feedback. We also showed that feedback from endoscopy assistants is helpful in identifying actions to improve. The current study aimed to develop feedback formats which can be used in the ENTS domain feedback tool. To achieve this, we have designed a feedback table which caters for low, average, and high performance levels.

Example Feedback table - Situational Awareness Domain for Endoscopist 9

| SITA 1 | Pre-assessment of potential patient risks | GREEN |
| SITA 2 | Recognises problems in a timely fashion | GREEN |
| SITA 3 | Aware of working environment, minimises disruptions | GREEN |

Conclusion: The MARS tool is a practical way to measure ENTS performance allowing identification of an individual’s strengths and weaknesses and the provision of a robust quality assurance system. The benefits of providing overall comparative data has been established previously in sharing more established key performance indicators. The feedback format for data derived from the MARS tool has additionally provided detailed domain-specific ENTS performance ratings that brings to attention areas for improvement in a clear and understandable way that can be re-tested as part of an integrated audit cycle.

P1497 OUTCOMES OF ENDOSCOPIC RESECTION OF COMPLEX COLORECTAL LESIONS REFERRED TO A TERTIARY INSTITUTION AFTER FAILED ATTEMPTS AT RESECTION OR EXTENSIVE MANIPULATION
A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom
Contact E-mail Address: aemmanuel@nhs.net

Introduction: Substantial manipulation or sampling of large colorectal lesions prior to endoscopic resection can have significant effects on the feasibility and outcomes of endoscopic treatment. Failed attempts at resection and extensive sampling or tattooing into lesions prior to referral to a specialist centre are common in western practice. However, there are few data defining the scope of prior manoeuvres and the effects on outcomes following endoscopic resection. We examined the effect of significant prior manipulation on the feasibility and outcomes of endoscopic resection of complex colorectal neoplasms in a UK tertiary referral centre.

Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colorectal ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Patients were grouped according to whether they had underperformed (5%) at resection, heavy manipulation (≥6 biopsies or tattoo into the lesion), or minimal sampling only (<6 biopsies). Outcomes included initial successful endoscopic resection, complications, recurrence and the need for surgery.

Results: Of 437 lesions ≥2 cm, 252 (58%) had been subjected to failed attempts at resection or heavy manipulation prior to referral. In 97 lesions (22%), an average of 1.5 (range 1-5) previous attempts at resection had been made. During 45 attempts at transanal surgical resection in 25 patients. A further 128 lesions (29%) had been extensively sampled or tattooed. Mean lesion size was 55.6 mm (+/- 30.7 mm). Initial endoscopic resection was deemed successful in 98% of cases after previous failed attempts. 97% of cases with prior heavy manipulation and 97% of other cases (p = 0.86). En bloc resection was possible in fewer patients with previous attempts at resection (14%, 31% and 42% respectively, p < 0.001). Complications associated with heavy manipulation were more frequent (p = 0.022) with failed attempts at resection and minimal sampling (14% versus 5% and 3%, p < 0.001). Recurrence rates were 21.4%, 14.6% and 12.2% respectively (p = 0.07). 95% of patients without invasive cancer who had prior failed attempts at resection were salvaged by surgery.

Conclusion: Failed prior attempts at resection or heavy manipulation of lesions reduces the chance of achieving en bloc resection and increases the risk of complications and recurrence. Nevertheless, specialist management in a dedicated endoscopy centre is associated with good results in safe and successful organ preserving endoscopic treatment of these extremely challenging lesions in over 95% of cases with few significant complications.

P1498 NBI VERSUS BLI WHICH MODALITY IS BETTER FOR OBSERVATION OF MUCOSAL BLOOD FLOW IN THE SMALL AND LARGE BOWEL USING NBI (NARROW BAND IMAGING) OR BLI (BLUE LIGHT IMAGING)
M. Yasuda1, Y. Naito2, Y. Itoh2

Introduction: In recent years, significant advances and innovations have been made in gastrointestinal endoscopy technology. The special light observation using a narrow band light source different from conventional white light is one such innovation. The special light observation with a magnifying procedure has more contributed to improve the diagnosis of lesions in the stomach, the intestines, the colon, the large bowel; it is particularly useful for differentiating between benign and malignant lesions and evaluating the depth of invasion. The instruments for narrow band imaging (NBI) were developed by Olympus Co., Ltd, and the use of blue laser imaging (BLI) by Fujifilm Co., Ltd. These systems are applied to magnifying endoscopy in clinical practice. Studies have examined the usefulness of magnifying observation with NBI (m-NBI), BLI (m-BLI), and new and brighter BLI (m-BLI bright) for the diagnosis of neoplastic diseases, especially for the early detection of gastrointestinal cancers. However, there are relatively few reports describing the application of these techniques to benign diseases.

Aims & Methods: This basic study aimed to explore the potential of magnifying observation with a blue light by evaluating the visualization of mucosal blood flow in the small and large bowel. The subjects were selected from among patients who had undergone colonoscopy since April 2016. They were randomized into three groups: patients undergoing examination with EC-LI200ZP, a high-end instrument manufactured by Fujifilm Co., Ltd. (group F), CF-HQ290ZL, a high-end instrument manufactured by Olympus Co., Ltd. (group O1) or PCF-H290ZI manufactured by Olympus Co., Ltd (group O2). Each group consisted of 25 patients. The visualization of mucosal blood flow in the small and large bowel by magnifying endoscopic observation with a blue light was evaluated and scored as follows: good visualization 2; partial visualization 1, and no visualization 0. The method and tip attachment were used in all cases.

Results: The respective mean scores for visualization of the small and large bowel were 2 and 2 in group F, 1.32 and 1.24 in group O1, and 1.48 and 1.40 in group O2. The visualization scores for both the small and the large bowel were significantly higher in group F than in groups O1 and O2. Group O2 had higher scores than group O1, although the difference was not statistically significant. The endoscopy used in group F has a bright laser light source and maximum optical magnification levels up to 135 times and maximum electronic magnification levels up to 270 times. On the other hand, the endoscopes used in groups O1 and O2

Disclosure of Interest: All authors have declared no conflicts of interest.

Note: The above text contains numerous medical terms and technical specifications that may require specialized knowledge to fully understand. The content is presented as text, without any visual aids or diagrams.
and O2 have relatively dark xenon light sources and maximum optical magnifi-
cation of 110 times, respectively. Therefore, the differences in visualization of mucosal blood flow in the small and large bowel among the groups were considered to be attributable to differences in instrument efficiency.

Conclusion: Our results show that magnifying observation with BLI is superior to that with OFI regarding the observation of mucosal blood flow in the small and large bowel. We are planning to conduct a study on the clinical application of magnifying observation with BLI for visualization of mucosal blood flow in the small and large bowel.

P1499  MULTIPLE COLORECTAL ADENOMAS WITHOUT APC OR MUTYH GERMINE MUTATION: A HETEROGENEOUS SUBGROUP OF PATIENTS

I. Sanchez Mete, E. Mannisi, A. Martayan, M. Varanees, V. Sigliano
Gastroenterology And Digestive Endoscopy, Regina Elena National Cancer Institute, Rome/Italy

Contact E-mail Address: lupe.sanchez@ifo.gov.it

Introduction: Multiple colorectal adenomas (MCRA) can be defined as an endos-}

Aspects of colorectal adenomas in 10 colorectal adenomas (MCRA) patients), without deleterious mutations of APC or MUTYH genes, were recruited for the study. Clinical features at diagnosis and extracolonic manifestations were reported. Forty patients underwent annual colonoscopy at our division with a median number of biopsies (range 1 to 30) taken from colonoscopy gastrodu-
denoscopies were also recorded. Eight patients were lost at follow-up.

Results: The mean age at MCRA diagnosis was 50.1±14.6 years (range, 19 to 79 years) and 20 pts (41.6%) had at least a first degree relative affected with colorectal neoplasia. Clinical features at diagnosis: the number of polyps ranged between 10 and 20 in 43.7% of the cases; 21 and 50 in 27.1%; >50 in 29.2%; 22.9% of pts had one or more adenocarcinomas (ADC); 16.6% had a previously diagnosed extracolonic cancer (breast, endometrial, thyroid, lung, bladder, brain, larynx). Twenty-five pts (52%) needed surgery, ten underwent a subtotal coliec-
tomy and fifteen a total colectomy. During follow-up twenty-two (55%) pts developed recurrent adenomas and two (5%) had one or more ADC in the retained colorectum; 12.5% of pts developed duodenal adenomas, one had a duodenal adenocarcinoma; we recorded one case of abdominal wall desmoid.

Conclusion: MCRA patients in the present study had similar clinical character-
istics to MUTYH associated Polyposis (MAP) affected patients. They were
generally diagnosed at a mean age of >50 years, they had more than 20 polyps (56.3%) at diagnosis, associated with ADC in 22.9% of the cases and required surgery in the majority of cases (52%). During follow-up, pts also developed recurrent adenomas. Clinical characteristics and family history in these patients support the hypothesis that pathogenic alterations in yet unknown genes may be involved. Next-generation sequencing is a promising technology aimed at this purpose. However, these patients should undergo a closer surveillance than those with sporadic adenomas.

Conclusion: Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonoscopies were performed for other indications (non-adenomatous polyp > 1 cm), multiple distal HP polyps the yield in the proximal colon was significantly smaller. These “soft” indications for colonscopy accounted for a significant additional workload that appears unjustified.

P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS

R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O’Shea, B.P. Saunders
Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real-time endoscopic assessment of the histology of diminutive colorectal polyps. For adoption of optical diagnosis in clinical practice, colonscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

Aims & Methods: Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study. Four weeks before the commencement of the study they were given a training module on optical diagnosis (OD). OD was based on NICE and WASP classification. During the study period (January 2016–August 2016), each trainee documented the optical diagnosis of polyps less than 10 mm in size. Confidence levels of OD were noted at the same time. Patient demographics and polyp details (site, size, Paris classification and histology) were collected prospectively. OD of each polyp was compared against the polyp histology. Polyps without the histological confirmation were excluded from the analysis. Every trainee had on-going feedback on their performance.

Results: A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364,214 and 52 respectively. Trainees OD performance was plotted on an upward CUSUM plot.

All 4 trainees achieved sustained accuracy (90% threshold) in OD within 12–58 observations. The number of polyps required to reach the plateau varied between 12 to 58. Every trainee’s confidence level improved over time (from 69% to 89%) and the effect was augmented by in-vivo feedback and revision of training module. Table 1 summarises the optical diagnostic performance of all 4 trainees. Negative predictive value for adenomas were above 90% for all trainees.

Conclusion: The CUSUM scores of all 4 trainees in the study reached the PIVI standards plateau by the 58th polyp observation. In-vivo feedback and continued training appears important to maintain the performance. Our preliminary findings could be used as a guide to plan the certification process for implementation of optical diagnosis.

P1503 THE CLINICAL VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR THE TREATMENT OF COLORECTAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA: A PROSPECTIVE SINGLE-CENTER STUDY

M. Xu, C. Zhang, Q. Li
Endoscopy Center, Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xumeidong@aliyun.com

Introduction: Given diminishing quality of life caused by colectomy and rectectomy, a minimally invasive treatment is desirable for colorectal submucosal tumors (SMTs).

Aims & Methods: The aim of the current study was to evaluate the clinical efficacy, safety and feasibility of endoscopic full-thickness resection (EFTR) for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these patients, 21 lesions were located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFTR in all cases. EFTR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

Results: Successful EFTR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemicolectomy and EFTR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get en bloc resection endoscopically. The en-bloc resection rate and complete resection rate were both 96.4% (54/56). Among 54 cases, 52 of these lesions were performed with EFTR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTs), 8 fibrous tumors, 3 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 haematomata. Three patients had local peritonitis and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritonitis. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

Conclusion: EFTR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1504 COLONIC ESD BY UTILIZING SHORT DOUBLE BALLOON ENDOSCOPE – HOW TO TREAT DIFFICULT CASES IN COLONIC ESD

S. Katsuki, T. Fujita, K. Takamashi, E. Waga
Center Of Gastroenterology, Otaru Ekisaikai Hospital Center of Gastroenterology, Otaru/Japan

Contact E-mail Address: sinichi-katuki.otaruekisaikai.jp

Introduction: Colon ESD has been a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we find it difficult to detach the colorectal neoplasm in ESD, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

Aims & Methods: We evaluated the outcomes of colon ESD by using DBE (DBE-ESD). Short DBE we used were EC450B1, EN550Bi and EI80BT (Olympus Co., Tokyo, Japan). We’ve performed DBE-ESD on 213 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th year after the ESD.

Results: There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days, and recurrence rate in patients with more than 5 year follow-up 0%.

Conclusion: Because the balloons and the overtube retained the scope at stable horizontal and vertical position, we were able to get good working space. Therefore, DBE should be one option for difficult cases in ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adenoma detection rate (ADR) is a quality indicator of screening colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy (FUSE) have been suggested to increase the ADR since allow an accurate evaluation of the hidden areas of the colon.

Aims & Methods: We aimed to evaluate whether monitoring of WT alone or in combination with the use of FUSE would be able to increase the ADR. In a prospective non-randomized observational study, consecutive outpatients, aged 18-85 yr, undergoing colonoscopy with different indications were enrolled. In phase 1, endoscopists performed 660 colonoscopies either with standard forward-viewing endoscope (SFVE) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WTs were measured without the endoscopists’ knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).

Results: No differences were observed among the four arms in terms of demographic, clinical features, and indications to colonoscopy. WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscope we observed a higher ADR: phase 1 SFVE 27.3% (90) phase 1 FUSE 33.0% (109) phase 2 SFVE 33.6% (111) phase 2 FUSE 41.8% (138); p = 0.001 and adenoma per colonoscopy (APC) phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.5 ± 1.08 phase 2 SFVE 0.4 ± 1.24 phase 2 FUSE 0.71 ± 1.08; p = 0.004. The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%; p = 0.056; Phase 1 FUSE 12.7% vs. phase 2 FUSE 18.9%; p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the SFVE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).

Conclusion: Unmonitored endoscopists have a sub-optimal WT, which increases with them aware to be monitored. Use of full spectrum scopes combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenoma in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.

Introduction: Systemic diseases including several types of cancer have been associated with periodontitis, potentially owing to the constant systemic inflammatory state in those patients. Data on a potential association of periodontal disease and colorectal neoplasia is scarce and conflicting.

Aims & Methods: Data from 25,407 patients undergoing healthy check up assessing periodontal disease according to periodontosis-risk classes (PRC 0-healthy gingiva, PRC 1 - tatar or plaque, PRC 2 - redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.

Results: In multivariable adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.070; 95% CI: 0.981; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.010; 95% CI: 0.840; 1.213]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.055 (0.785; 1.418)].

In the table below the adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) divided into the periodontosis-risk classes.

P1508 OUTCOMES OF ENDOSCOPIC RESECTIONS OF LARGE NON-POLYPOID LESIONS IN INFLAMMATORY BOWEL DISEASE: A SINGLE UNITED KINGDOM CENTRE EXPERIENCE

S. Gulati, A. Emmanuel, M. Burt, P. Dubois, B. Hayee, A. Haji
Endoscopy, King’s Institute of Therapeutic Endoscopy, RS/United Kingdom

Contact E-mail Address: shrahdha.gulati@nhs.net

Introduction: Patients with colitis carry an increased risk for the development of dysplasia compared to those without 1. The SCENIC consensus statement recommends endoscopic resection of all visible dysplasia 2. Due to technical challenges and limited experience in the West of large colitis associated non-polypoid endoscopic resections, such patients are often subjected to colectomy. The King’s Institute of Therapeutic Endoscopy (KITE) is a tertiary centre for endoscopic assessment and resection of large/challenging colorectal polyps. Here we present the largest single-centre case series of large non-polypoid resections associated with colitis.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and crohn’s colitis affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirty lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are presented in table 1. Mean lesion size was 47.3 +/- 22.4 (20-90) mm. All lesions were non-polypoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramucosal lesions in 5 cases where pit/vascular pattern was distorted due to inflammation. En bloc resection was achieved in 6 cases. 69% lesions were deeply scarred microscopically in 100% of resected lesions. Complete excision was confirmed in all en bloc resections. A single case of small perforation and another with delayed minor bleeding were both managed endoscopically. Mortality/hospital admission within 30 days post resection was 0%. Median follow up was 28 months (12-35) with no recurrence. Alternative site dysplasia was detected in 2 patients. All lesions were sub 20 mm and resected endoscopically. Two patients were referred for colectomy due to a concomitant diagnosis of neuroendocrine tumour and the second with alternate site advanced dysplasia.

P1509 RESEARCH ON APPLICATION OF TRANSANAL TUBE DECOMPRESSION FOR PREVENTION OF COMPLICATIONS IN COLORECTAL MUCOSAL LESIONS AFTER ESD

L. Bing, Z. Qi, Y. Zhong
Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, Shanghai, China

Contact E-mail Address: 13564623481@126.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used in the minimally invasive treatment of early colorectal mucosa and submucosal lesions. This technique has made it possible to resect even large mucosal or submucosal lesions en bloc, and the recurrence rate is lower. However, due to the thinner colorectal wall and more abundant blood vessels, postoperative complications after ESD is higher in this site. As a result, how to prevent complications related to ESD for colorectal lesions has raised widespread concern. In recent years, more and more researchers placed transanal tube for patients with colorectal cancer resection or intestinal obstruction to promote the early discharge of the gas and liquid in the intestine. The efficacy of this method to reduce incidence of complications and to promote recovery of intestinal function have been verified by a number of studies. Based on this, we applied transanal tube to some patients with colorectal ESD, hoping to provide new ideas for the prevention and treatment of complications.

Aims & Methods: We aimed to evaluate transanal tube for prevention of complications in colorectal mucosal lesions after endoscopic submucosal dissection (ESD). Data of 61 patients with colorectal mucosal lesions undergoing ESD from January to December 2016 were reviewed. All patients were followed up and we analyzed the incidence rate of complications after ESD within one month.

Results: The median age of 61 patients was 61(32 ~ 83) years. 21 of all lesions were located at right-half colon, 9 at left-half colon and 31 at rectum. The mean diameter of the lesions was 3.26 ± 2.27 (0.8-12.0) cm. There were not intraoperative complications including serious bleeding and perforation. Delayed bleeding on the eighth post-ESD day was detected in 1 (1.6%) patient who was cured by transfusion. 3.4% patients suffered post-ESD electrocoagulation syndrome and perforation did not present in all cases. In this group with transanal tube for decompression, the rates of perforation, delayed bleeding and post-ESD electrocoagulation syndrome were all lower than others which was 1.4 ~ 8.2%, 0.5% ~ 9.5% and 12.1% ~ 40.2% respectively in literature reports.

Conclusion: The application of transanal tube in colorectal mucosal lesions after ESD could effectively reduce the incidences of complications. However, we should do more research to know whether transanal tube need to be placed routinely after ESD or not.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1510 OUTCOMES FOLLOWING UNDERWATER ENDOSCOPIC MUCOSAL RESECTION (UER) OF >10MM COLONIC POLYPS: A PROSPECTIVE DUAL-Centre STUDY
K. Siau1, A. Yusu2, N. Suzuki3, S. Ishaq4

Introduction: Underwater endoscopic mucosal resection (UERM) is an alternative to conventional EMR for the resection of colonic polyps. With this technique, water insufflation is used in place of air or CO2, and submucosal lifting is usually not required, as water-immersed submucosa cushions itself from the muscularis propria.1,2 Theoretically, this reduces the risk of diathermy-induced injury,1,3 and allows for more complete resection margins.1,2

Aims & Methods: In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UERM for clinically significant (>10 mm) colonic polyps. Studied outcomes included: 1) completeness of UERM, 2) intraprocedural and 30-day complication rates, 3) percentage requiring submucosal lift, and 4) rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St. Mark’s Hospital, London, and Russell’s Hall Hospital, Dudley, UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with histology. Univariate analyses were performed using Pearson’s chi2 to identify predictors of measured outcomes.

Results: Between June 2014 and March 2017, and A total of 85 patients (median age 69.5 years, interquartile range [IQR] 11, 50.6%) male underwent UERM of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.4%) morphology. 43.8% of polyps were removed en bloc, whilst argon plasma coagulation (APC) was used in 17.3%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (3.1%) and non-dysplastic sessile serrated polyp (4.2%). Overall, resection at index UERM was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size >30 mm (OR 3.58, 95% CI 1.13–9.38, p = 0.011), but not morphology (flat vs. sessile, p = 0.099). The 30-day complication rate was 4.1% (n = 4), comprising of: 3) intraprocedural bleeding (n = 2, average diameters: 35 mm) and delayed rebleeding (n = 2; average diameter: 57.5 mm), with haemostasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n = 59) who attended for repeat endoscopy post-UERM, the rate of recurrence or residual polyp was 14.8% (6/42) at 4 months and 11.59 (22.0%) within 1 year. Significant predictors of post-UERM recurrence included: piece-meal vs. en bloc resection (OR 5.59, 95% CI 1.10–27.6, p = 0.03) and previous polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.04), but not polyp size, site, morphology or dysplasia status, use of submucosal lift, APC, patient age, or study centre. Conclusion: UERM is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UERM recurrence rate of 22.0% appears higher than other studies,1,2 but may be skewed by the tertiary nature of referrals. Although randomised trials are awaited, we strongly suggest that those performing UERM should attempt en bloc resection where possible, and consider wider resection margins for recurrent polyps.

P1511 WATER-AIDED COLONOSCOPY - RESEARCH FOCUS IN THE PAST DECADE AND CURRENT CLINICAL PRACTICE
F. W. Leung
Medicine, Seguridada Ambulatory Care Center, VAGLAHS; David Geffen School of Medicine at UCLA, North Hills/United States of America/CA

Contact E-mail Address: felixleung@socal rr.com

Introduction: Water-aided techniques have forged a paradigm shift in endoscopic diagnosis and therapy. The inauguration (10/22/2014) of the International WATERS with memberships worldwide attested to participants’ commitment to advance clinical, educational and research missions. To aid a planning of future work in each of these areas, a descriptive study of water-aided colonoscopy was performed.

Aims & Methods: The aims of this study were two-folds. Study 1: To assess the feasibility of each water-aided colonoscopy in the past decade. Study 2: To obtain a cross-sectional snapshot of current clinical practice. Study 1: Studies registered at Clinicaltrial.gov were searched for using the search term "water colonoscopy". Study 2: Members of International WATERS voluntarily participated in a survey. Results: After calculating the proportion of patients with different modes of sedation, respondents selected yes (1) or no (0) responses to each of 16 questions related to their practice of water-aided colonoscopy.

Results: Study 1: In the past decade, 48 trials of water-aided colonoscopy were registered at Clinicaltrial.gov. They aimed at evaluation of insertion pain in unsedated, minimally sedated, or on demand sedation patients; assessment of efficacy in difficult colonoscopy; study of the impact on adenoma detection; and underwater mucosal resection or polypectomy. Study 2: Questionnaire responses are summarized in Table 1. Respondents: n = 23. Water-aided colonoscopy is used in patients sedated with propofol, minimal sedation on demand or sedation (3–16%) but more commonly in patients with moderate or no sedation (30–34%). During insertion 95.5% use infusion of water and only 36.4% leave the air/CO2 pump on. 42.9% and 33.3% record volumes infused and suctioned upon arrival to the cecum. 52.4% remove almost all infused water during insertion. 71.4% and 59.1% performed polypectomy (<20 mm and >20 mm, respectively) underwater during withdrawal.

Table 1A: % of respondent’s patients

<table>

</tr>
<tr>
<td>Leave air/CO2 pump on</td>
<td>36.4</td>
<td>90.0</td>
<td>36.4</td>
<td>95.5</td>
</tr>
</tbody>
</table>

Conclusion: The variable modes of application amongst respondents who profess to use water-aided colonoscopy reflect the versatility and strength of the paradigm-changing approach, which is easily adaptable to meet the diverse needs of individual colonoscopists. Standardization based on results of randomized controlled trials appears to be prudent to permit further assessment of water-aided colonoscopy in clinical, educational and research settings.

P1512 ENDOSCOPIC SUBMUCOSAL DISSECTION: RESULTS AND LEARNING CURVE OF A LARGE PROSPECTIVE SERIE OF 183 CASES IN THREE CENTERS
M. Lopez Gomez1, M. Hernández1, C.E. González1, J. Santiago3, C. Bernardo4, B. Conde3, C. González-Lois2, P. Matalíanos1, J.L. Calleja1, I.E. Abreu García2, A. Herreros De Tejada1

Contact E-mail Address: albertoherrereros@yahoo.com

Introduction: Endoscopic submucosal dissection (ESD) is a suitable technique used for the endoscopic management of selected early gastrointestinal neoplasms (EGN).

Aims & Methods: This is a prospective study of patients with EGN eligible for ESD in three tertiary hospitals. The main goal was to evaluate initial therapeutic results and learning curve of ESD. Initial Technical success rates, procedure speed, en-bloc & R0 resection, R0, speed and complications rates were prospectively evaluated. The results of the learning curve were analyzed by chronological order of bocols of 50 cases. Perforation was established as any disruption of the muscular layer, regardless of size or identification of peritoneal fat. Time of procedure was considered from initial submucosal injection to final detachment of the specimen.

Results: ESD was attempted in 183 lesions from January 2012 to April 2017. Majority of procedures were performed at Puerta de Hierro University Hospital (160/187%). Mean age was 67 (SD 10.6) years, with male proportion 55.2%. Most common location was colorectal (77.8%), followed by gastric (12.8%) and esophageal (9.4%). Success was observed in 96.2% of patients with en-bloc and R0 resection of 93.9% and 92.3% respectively. Mean lesion size was 46.5 mm (range 8–130) with a mean speed of 9.01 min/cm2 (range 1-209). Perforation was...
the main complication (48 (26.2%) events), requiring surgery in 5 (10.4%) cases. Perforation was statistically significant to location (p = 0.05) and LST morphotype (p = 0.05). Most frequent location of perforation was transverse colon (OR 88.3; SE 37.0), followed by descending colon (OR 13.5; SE 19.4) and splenic flexure (OR 6.3; SE 11.8). Perforation was more common in LST-NG lesions vs LST-G (OR 141.5; SE = 19.3 vs 11.6 SE 15.0). Perforation rates were not statistically associated with the presence of severe submucosal fibrosis compared to absence of fibrosis (0.8 SE 0.6 vs 1 SE 1 p = 0.9). Post-ESD complications were observed in 15 (8.2%) patients (delayed perforation(7), bleeding(4), electrocoagulation syndrome(1), severe esophageal strictures(1), haemopterontium(1) and splenic rupture(1)). Six cases (40%) were managed with surgery. Results from the learning curve progression according to consecutive chronological blocks of 50 cases (33 last block) are summarized in table 1. Initial success increased from 94% to 100%; speed of ESD decreased after the first 50 cases (15.5 cm²/min), up to 6.7 and 6.5 cm²/min in the last 2 blocks. A high perforation rate in the first period (32%) was reduced to 18–30.3% the following periods. Endoscopic treatment was successful in most cases of perforation (96.9%). Surgery was required for severe complications, incomplete ESD and/or perforation (n, %) (16 cases, 8.7%).

Conclusion: On clinical ESD, high rates of success and en-bloc and R0 resection can be achieved along the learning curve. Perforation is the most common complication and is still a challenge for Western countries. However, increasing experience reflects a high success in endoscopic management of perforation.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1513 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL LESIONS: THE EXPERIENCE OF A UK TERTIARY REFERRAL CENTRE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Despite the advantages of endoscopic submucosal ressection (ESD) demonstrated in large series from the far east, the procedure is not commonly practiced in the west and its role in standard practice is still debated. Although limited evidence regarding its efficacy in European practice is emerging, very few centres in the United Kingdom perform ESD regularly, if at all. We report the experience of a UK tertiary referral institution using ESD as part of a lesion specific, pragmatic approach to endoscopic resection in a complex patient cohort.

Methods: Consecutive patients who underwent endoscopic colorectal lesions were included. Lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique, which included assessment of morphology, pit pattern, risk of submucosal invasion, and presence of submucosal fibrosis or scarring. ESD was used where en bloc resection was deemed essential, and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1514 RISK OF STENOSIS AND OUTCOMES FOLLOWING ENDOSCOPIC RESECTION OF LARGE COLORECTAL LESIONS INVOLVING MORE THAN 75% OF THE LUMINAL CIRCUMFERENCE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects ≤75% of the circumference.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. Resection technique included EMR, ESD and hybrid techniques involving ESD. Patients were grouped according to circumferential extent of the mucosal defect after resection. Surveillance colonoscopy was performed at 3 and 12 months. Clinico pathological characteristics and outcomes were compared between groups.

Results: 435 colorectal lesions ≥2 cm were resected using EMR (n = 342), ESD (n = 45) or hybrid techniques (n = 48). Circumferential extent of the resulting mucosal defect was ≤75% in 41 patients. 8 lesions were fully circumferential: 1 caecal lesion and the rest in the recto-sigmoid and rectum. 3 of these circumferential lesions contained deep invasive adenocarcinoma and 1 benign lesion ultimately required surgery. The 41 lesions with a mucosal defect ≥75% of the circumference had a mean size of 100.5 mm vs 49.0 mm for other lesions (p < 0.001). These patients had significantly more complications (16.7% vs 4.7%, p < 0.001), including a higher rate of perforation (8.3% vs 2.3%, p = 0.02), although none required surgery, and a significantly higher rate of recurrence (44.8% vs 9.2%, p < 0.001). 79% of patients without cancer were free from recurrence and had avoided surgery at last follow-up compared to 97% of patients with mucosal defects < 75% (p < 0.001). Stenosis occurred in 7 patients: 4 lesions extensively involving the rectum and recto-sigmoid and 2 lesions involving the sigmoid colon extending to the rectosigmoid. 1 of these involved a mucosal defect of only 50% of the circumference and 3 were fully circumferential. 1 patient had a symptomatic anorectal stenosis requiring dilatation under anaesthesia, 1 patient was asymptomatic but underwent early dilatation after the first surveillance endoscopy. 1 patient developed a post-ESD haemorrhage, which was successfully managed expectantly.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Colorectal lesions ≥2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia and invasive adenocarcinoma in the different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1517 OUTCOMES OF ENDOSCOPIC RESECTION OF RECURRENT COLORECTAL LESIONS TREATED AT A UK TERTIARY REFERRAL CENTRE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Endoscopic resection of large colorectal lesions, especially by piecemeal EMR, carries a significant risk of recurrence. Although several series examine the outcomes and risk of recurrence following endoscopic resection, few focus on the outcomes of patients being treated for recurrence after initial expert resection, and these mostly focus on one technique to deal with recurrence. We evaluated the outcomes after recurrence of colorectal lesions after apparent successful endoscopic resection in a specialised UK tertiary institution employing a range of resection techniques.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Outcomes were evaluated for patients treated for recurrent lesions.

Results: Of 396 colorectal lesions ≥2 cm initially resected, recurrence occurred in 48 patients. 36% of these patients had already had a mean of 1.6 previous failed attempts at resection prior to referral to our institution, and 66% had had either a failed attempt at resection or extensive sampling involving ≥6 biopsies or tattoo placed under the lesion. 69% of patients were successfully treated with further endoscopic resection and avoided surgery. 27 recurrent lesions larger than 20 mm were treated with endoscopic resection, with a mean lesion size of 48.3 ±/̇19.0 mm. Techniques used were EMR (n = 16), ESD (n = 2), Hybrid ESD and EMR (n = 9). The remaining lesions <2 cm were resected using EMR. A mean of 1.4 ±/̇0.75 procedures were required to achieve successful endoscopic treatment of recurrence. Of 23 patients who were ultimately successfully treated with endoscopic resection, 15 required a single further endoscopic resection after recurrence, 8 patients required 2 or more further resections. 8 patients required surgery, 3 as a result of developing invasive adenocarcinoma with the recurrence. There were no perforations as a result of endoscopic resection of recurrent lesions, and only one patient was readmitted with post-procedural bleeding which was managed conservatively.

Conclusion: These data demonstrate the challenges of an advanced endoscopic resection service in much of western practice where patients with recurrent lesions represent a particularly complex cohort, most of whom have already had extensive prior manipulation or attempts at resection. Familiarity with a range of resection techniques and appropriate equipment is essential to successfully treat recurrent lesions in this group with endoscopic resection, which can be achieved in the majority of patients without significant morbidity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1518 THE EFFECTIVENESS OF NEW TECHNIQUE WITH SELF-EXPANDABLE METALLIC STENT INSERTION IN TREATING RIGHT-SIDED COLONIC OBSTRUCTION

C.B. Ryu1, M.S. Lee1, J.Y. Bae2
1Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of
2Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ryuchub@gmail.com

Introduction: Self-expandable metallic stent (SEMS) is widely used to treat malignant colonic obstruction. However, most reports about SEMS insertion have represented a particularly complex cohort, most of whom have already had extensive prior manipulation and technical and clinical success, complications, and technical difficulties were analyzed. We compared the results between SEMS insertion and decompression tube placement in right colons and the outcomes of SEMS insertion between right- and left-sided colonic obstructions.

Results: Cannulation time with a curved type guiding tube decreased of all cases (20 mm vs 8.5 mm). For ascending colons, the technical and clinical success rate of SEMS insertion with new technique significantly 100% (10/10). There was no...
compilation (0.10). Concerning SEMS insertion, the technical difficulty and safety of SEMS insertion were similar between right- and left-sided colonic obstructions.

**Conclusion:** A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

P1523 DIFFERENCES BETWEEN BOWEL PREPARATION QUALITY OF SURVEILLANCE AND SCREENING COLONOSCOPY

Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Austria, Vienna, Austria

Contact E-mail Address: anna.hinterberger@meduniwien.ac.at

Introduction: Clinical bowel preparation is necessary for a successful and complete colonoscopy. Minimum of adequate rate (excellent + good + fair) should be 90% according to the actual ESGE guidelines (Kaminski et al., Endoscopy 2017). The aim of study was, to verify if there is a difference at quality of preparation between screening and surveillance colonoscopy. It might be that there is an improvement at surveillance colonoscopy due to better knowledge.

Aims & Methods: 107,614 examinations from 288 endoscopists were analysed between 2012 and 2017 within the Austrian certificate of screening colonoscopy. For this analysis different categories were included: excellent, good, fair, unsatisfactory, poor only in the right colon. Data are shown as Mean and SD. Results: 8578 surveillance colonoscopies (43.88% female, mean age 66.67) and 99271 screening colonoscopies (51.94% female, mean age 62.31) were included. Within screening colonoscopy 37.59% (SD = 31.50) were excellent prepared vs. 34.60% (SD = 33.98) within surveillance colonoscopy, good 47.43% (SD = 27.28) vs. 45.61% (SD = 31.28), fair 11.39% (SD = 11.58) vs. 14.39% (SD = 21.69), poor 2.38% (SD = 3.06) vs. 3.68% (SD = 9.75), unsatisfactory 0.77% (SD = 1.20) vs. 0.89% (SD = 3.69), poor only in the right colon 0.69% (SD = 1.81) vs. 0.39% (SD = 1.22). Calculations revealed no significant differ-

Introduction: Laterally spreading tumors (LSTs) are important precursors of colorectal adenocarcinoma. They are usually removed by endoscopic mucosal resection (EMR). However, local residual neoplasia (LRN) may occur during follow-up. The aim of the study was to evaluate the occurrence of LRN and the risk factors for its presence.

Aims & Methods: This retrospective study in a high-volume tertiary-referral center examined patients who had undergone EMR between 2013 and 2015 and who had had at least 1 surveillance colonoscopy after the initial treatment. LRN was defined histologically as the presence of neoplastic tissue in the post-EMR site. Results: 160 laterally spreading tumors were diagnosed in 138 patients (62% men, mean age 67 years). Mean follow-up interval for surveillance colonoscopy was 6 months. Residual neoplasia at surveillance endoscopy was present following 21% of EMRs. Single variate analysis showed evidence of an increased risk of residual neoplasia for LST ≥ 20 mm (p = 0.006), villous adenomas (p = 0.001), pimecellar resection (p = 0.011) and G-type morphology (p = 0.003). In multivariate analysis, only size of the lesion (p = 0.080) and villous component (p = 0.045) were found to be a significant risk factor for LRN. Conclusion: This retrospective study shows that the occurrence of LRN is frequent. Careful colonoscopic surveillance after EMR and the use of new methods to further reduce residual neoplasia are needed.

P1527 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4,949 PATIENTS AT TWO UK HOSPITALS

A Youef, S Paranekhwa, A Jeevagan, P Mayhead
Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyus12@nhs.net

Introduction: Flexible sigmoidoscopy is increasingly used to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated.1-3

Aims & Methods: Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital’s electronic system. The aim of this study was to determine the impact of endoscopic surveillance on CRR prevention in FAP patients after surgery. We did a retrospective single center study on findings of follow up endoscopies and determination of the cumulative risk of adenomas and prevalence of high risk adenomas (HRA) (villous histology, high-grade dysplasia and ≥10mm) and CRR.

Results: 30 patients submitted to IRA were included (50% women), with a mean age of 43 years, 2 patients with attenuated phenotype. Nine patients had adenocarcinoma in the resected colon. Six patients started chemoprophylaxis after surgery (sulindac-4; celecoxib -1). The median time to adenoma appearance was 5 years (95% CI 3.4-6.6) and to HRA/CRR 12 years (95% CI 5.2-18.8), with a decreased median time to both adenomas and HRA/CRR in patients under chemoprophylaxis. The cumulative risk of adenomas was 20% at 1 year after surgery, 34.1% at 3 years and 57.4% at 5 years. During the follow up period CR were developed in 17 patients (56.7%) HRA–12 patients (40%); intramuscular carcinoma–2 patients (6.7%); invasive adenocarcinoma–3 patients (10%). None of the patients died with CR. The cumulative risk of HRA/CRR was 21.8% at 5 years, 46.1% at 10 years and 66.3% at 15 years. All the patients with HRA/CRR had colonic resection prior to surgery (p = 0.008) and a higher number of adenomas resect in the rectal remnant (p = 0.017).

Conclusion: The CAP endoscopic surveillance program allowed detection of HRA/CRR in a high percentage of patients. Based on these results, an intensive surveillance program should be suggested but endoscopic surveillance intervals widen in the first 5 years after surgery.

Introduction: Endoscopic resection of large colonic lesions (LCLs, >20 mm) is effective and it is associated with an acceptable incidence of incomplete resection and complications when performed by appropriately trained endoscopists in resource centers. An adequately performed endoscopic submucosal dissection (ESD) is now the only acceptable option for the management of these lesions outside referral centers are reported in the literature.

Aims & Methods: Aim of present study is to evaluate the management of endoscopic resection of LCLs and intra-procedural complications in a real-life setting. In a prospective, multicenter, observational study in 20 centers, data from consecutive endoscopic resections of LCLs performed over a 6-month period were collected by a web-database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

Results: 1453 LCLs (mean size 30.6 mm, SD 12.4; 41.4% lateral spreading tumor, 28.1% sessile, and 30.5% pedunculated) were removed 1329 patients (58% males, mean age 66±11.4 years) were analysed. An endoscopic mucosal resection (EMR) was performed in 57.9%, snare polypectomy in 34.7%, underwater EMR in 1.2% and endoscopic submucosal dissection in 6.2% of the lesions. Patients with LCLs, 19.4% were on ATT (62.5% aspirin, 12.2% thienopyridines), 4.8% dual antithrombotic, 15.4% vitamin K antagonists [VKAs], 5.1% direct oral anticoagulants [DOACs]. Aspirin and/or thienopyridines were withheld before resection in 53.6% and 91.7% of patients, respectively. Overall, intra-procedural bleeding requiring endoscopic therapy occurred in 8.1% of patients; 28% of them were on ATT, which had always been withheld, but in 48% of patients on aspirin. At multivariate analysis, intra-procedural bleeding was correlated with increasing poly size (Odds Ratio 1.02 95% Confidence Interval 1.01–1.04), and inversely with execution of pre- and post-resection prophylaxis maneuvers (Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 and Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 respectively). As concerns
complications, delayed bleeding occurred in 4.5% of the subjects, whereas per- formed colonoscopies in 1.5% (0.9% early and 0.6% delayed) of patients, 86.7% of whom were successfully managed endoscopically. At the moment, 6-months follow-up is available for 35% of the patients, with a positive endoscopic and/or histological recurrence documented in 22.8%.

Conclusion: The management of resection of LCLs varies widely. The incidence of intra-procedural bleeding correlates with polyp size and prophylactic maneuvers, and its endoscopic management is successful in most of cases. Overall, complication rate is marginal and efficacy is good, even in a real-life setting.

scopic mucosal resection (EMR): European Society of Gastrointestinal

Results: We included 1721 endoscopic procedures of polypectomy and EMR, corresponding to 1250 patients; 64.5% (n=910) of patients were aged 65 years and over; 1381 (80.2%) sessile polyps, 153 (8.9%) flat lesions and 187 (20.9%) pedunculated polyps were identified, with a mean size of 7.9 ± 7.0 mm. Regarding sessile and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n=270) of ≤3 mm polyps (75.7% in 2011 vs. 95.8% in 2016; p < 0.001); 22.2% (n=109) of 4–5 mm polyps (12.5% vs. 36.5%; p < 0.001); 13.4% (n=59) of 6–9 mm polyps (5.4% vs. 23.8%; p < 0.001); 100% (n=206) of 10–19 mm polyps; and 100% (n=88) of ≥20 mm lesions. For pedunculated polyps, the excision technique was adequate in: 99.3% (n=134) of polyps of size ≤20 mm (100% vs. 97.6%; p > 0.05) and in 84.6% (n=44) of those ≥20 mm (82.6% vs. 86.2%; p > 0.05). Overall, 52.3% (n=900) of endoscopic procedures of polypectomy or EMR were performed as recommended; 42.7% (n=410) in 2011 vs. 64.5% (n=490) in 2016; p < 0.001.

Conclusion: Even before publication of the European recommendations, there has already been an increase in the proportion of polypectomies performed ade-
quately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4–9 mm, in order to strictly comply with the recommendations.

P1532 SELF-EXPANDABLE METALLIC STENT IN THE OCCLUSIVE COLRECTAL CANCER AS PALLIATIVE TREATMENT

T. Gago, A. Antunes, A.M. Vaz, P. Queirós, J. Roseira, A. C. Cunha, A. Ramos, H. Guerreiro
Serviço De Gastrenterologia De Faro, Centro Hospitalar do Algarve, Faro
Portugal

Contact Email Address: taniagago@gmail.com

Introduction: Colorectal cancer (CRC) is one of the most common malignancies in Western countries, with associated occultive disease being relatively common. Endoscopic placement of self-expandable metallic stent (SEMS) is the first-line palliative treatment for malignant bowel obstruction.

Aims & Methods: Evaluate the outcome of endoscopic SEMS placement in CRC obstruction. Retrospective analysis of patients CRC submitted to endoscopic placement of SEMS from 2009 to 2016 in the Gastroenterology Department of Centro Hospitalar do Algarve. Statistical analysis was performed with SPSS version 23.

Results: The study included 23 patients with CRC obstruction, who were submitted to endoscopic SEMS placement, with a mean age of 75.2 ± 13.47 years. The stents were placed with a palliative purpose in 69.6% of cases (n = 16) and a transitory procedure before surgery in 30.4% of cases (n = 7). Technical and clinical success was found in 91.3% of the patients, without any recorded death during the procedure. In patients whose goal was palliative treatment (75% men and 25% women) they had a mean age of 81.6 ± 9.28 years. In 43.8% of the patients the tumor was located in the rectum, 31.6% in the sigmoid region and 25% in the recto-sigmoid transition. Being the majority (75%) well differentiated. There was a need for dilatation in 31.3%, most of the stents were uncovered (56.3%), 25% of the patients had complications. After stent placement, almost 25% of the patients died. There was a 75% mortality rate (37.5% died by 6 months and 37.5% died by 12 months of follow-up). The use of chemotherapy after SEMS placement influenced the complications associated with the procedure (p < 0.05) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: SEMS is an effective and safe palliative option for unresectable malignant lesions, although the use of chemotherapy after the placement of prostheses may have an influence on the appearance of complications. Malignant colon obstruction of the colon can be treated effectively with the use of endoscopic techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1533 RISK FACTORS FOR ADENOMA RECURRENT RECURRENT AFTER ENDOSCOPIC MUCOSAL RESECTION OF LARGE COLORECTAL POLYPS

J. Pinho, D. Martins, P. Sousa, R. Araújo, A. Castaneira, E. Cancela, R. Cardoso, P. Ministro, A. Silva
Gastroenterologia, Centro Hospitalar Tondela/Viseu, Viseu/Portugal

Contact Email Address: julianapinho18@gmail.com

Introduction: Endoscopic mucosal resection (EMR) has been shown to be a safe and effective technique for removal of large colorectal adenomas. However, local adenoma recurrence remains a significant limitation, with prior published data describing recurrence rates of 10% to 30% post EMR.

Aims & Methods: This study aimed to evaluate the outcomes of EMR for large colorectal adenomas and identify the risk factors for adenoma recurrence. We did a prospective study of the colorectal EMR performed between January and December 2016. Resected lesions larger than 20 mm in diameter with at least 3 months follow up were included. Patients referred for surgery were excluded.

Results: During the study period, 201 colorectal lesions ≥20 mm in size were removed by EMR with associated polyps (mean age 68 years). Mean lesion size was 35 mm and 137 (68.2%) were located in the rectum and left colon. 66 lesions (32.8%) were larger than 40 mm in diameter. Piecemeal resection was performed in 171 lesions (85.1%). Local adenoma recurrence occurred in 44 cases (21.9%) after a mean time of follow up of 7.6 months, and the majority was managed with polyectomy or new EMR. The cumulative risk of adenoma recurrence was 7.5% at 3 months, 15.5% at 6 months and 17.1% at 12 months. In the multivariate analysis, the variables associated with a high risk of recurrence were lesions ≥40 mm in size (p = 0.0001) and intra-procedural bleeding (p = 0.020). The recurrence rate was higher in the patients treated with argon plasma coagulation (p = 0.046).

Conclusion: After EMR of large colorectal adenomas, local recurrence rate was 21.9%. The risk factors for adenoma recurrence include lesions ≥40 mm and intra-procedural bleeding. Argon plasma coagulation was not associated with lower recurrence rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: European colorectal screening guidelines have modified the follow-up interval times based on baseline colonoscopy findings in recent years. In addition, the waiting list and individual conditions may modify the real follow up times and this could impact in advanced adenoma detection rate in follow up and patients outcome.

Aims & Methods: The aim of the present study was to comparatively analyse the risk of advanced lesions (advanced adenoma, invasive cancer) in high-risk patients included in a colorectal cancer screening program with different real follow up times. One-hundred one-hundred and sixty-six patients (mean age: 60.66 ± 5.86 years, 69.1% men) who underwent a baseline colonoscopy with ≥adenomas and/or ≥10 mm between 2007–2012 were included. A Kaplan-Meier regression and a comparative subgroup analysis by Long-Rank test were carried out to determine the impact of real times in adenoma detection rate.

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36–60 months after baseline colonoscopy, being more important in ≥3 adenomas subgroup. There were no differences for 1–3 years interval.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
1. Perez-Cuadrado-Martinez2, F. Perez-Riquelme4
2. Perez-Cuadrado-Robles1, B. Martinez-Andrés2
3. Torrella Cortes1, E.A. Conclusions: The real follow-up times in ≥3 adenomas (n = 853, 73.18%) and ≥10 adenomas ≥10 mm (n = 779, 66.81%) were 38.54 ± 11.57 and 38.66 ± 11.68 months. The risk of advanced lesions were 0.26%, 1.46%, 2.26%, 0.93% and 10.38% (n = 121 advanced lesions) in 12, 24, 36, 48 and ≥60 months respectively. The most important increase was at 3–4 years (10.52%). The proportion of advanced lesions within 1–2 adenomas and ≥3 adenomas subgroups at 48 months were 5.43% and 10.43% (p < 0.0001), with no differences in small adenomas < ≤10 mm (p = 0.478).

P1535 CLINICAL OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION OF MALIGNANT NON-PEDUNCULATED COLORECTAL LESIONS

C. Römw1, E. Toth2, H. Thorlacius1
1Dept. Of Gastrointestinal Surgery, Lund University Surgery, Malmö/Sweden
2Skåne University Hospital, Malmö/Sweden

Contact Email Address: cf_frimand@hotmail.com

Introduction: Conventional endoscopic resection, such as snare polypectomy and endoscopic mucosa resection (EMR) of benign polyps in colon and rectum reduces colorectal cancer (CRC) incidence and mortality but the role of endoscopic submucosal dissection (ESD) for advanced neoplasia (i.e. submucosal invasion) remain elusive. Large sessile and flat lesions are difficult to remove en bloc with ESMC, resulting in a higher level of tumor recurrence. Thus, endoscopic resection of large (>2 cm) sessile and flat malignant lesion with snare or EMR is not recommended in men and locoregional submucosal dissection (ESD) results in high mucosal resection rates of large (>2 cm) benign lesions resulting in low numbers of recurrences. However, there is limited data in the literature on the potential role of ESD in the treatment of patients with early CRC. In the present study, we present our results on performing ESD in patients with large sessile and flat malignant lesion in the colon and rectum in a large European center.

Aims & Methods: Our aim was to investigate the potential role of ESD in treatment of early colorectal cancer. We retrospectively reviewed medical records of
254 patients that underwent colorectal ESD at the endoscopy unit at Skane University Hospital, Sweden from January 2014 to December 2016. Indications for ESD were flat and sessile lesions larger than 20 mm in diameter with low or high graded dysplasia (251 cases). Moreover, three patients with known colorectal adenocarcinoma underwent ESD due to significant comorbidity excluding surgery. In this study, we included and included 29 cases of histologically verified submucosal invasive CRC in this study.

**Results:** This study included 29 patients with median age of 69 years (range 44–89 years). Median tumour size was 40 mm, ranging from 20–70 mm. Tumours were either flat (Paris classification Ia, 6 cases), sessile (Paris classification Ia, 19 cases) or a combination of flat and sessile (4 cases). Half of the lesions were located in the rectum and half in the colon. En bloc resection was achieved in 24 cases (83%), piecemeal resection in 4 cases (14%) and ESD was incomplete in one (4%). In order to complete the resection, R0 was achieved after an en bloc resection of 89 min (range 59–594 min). Macroscopic complete resection was obtained in 26 cases (90%). R0 resection was found in 20 specimen (69%), RX was found in 3 cases (10%) and R1 was found in 5 cases (17%). Lymphovascular invasion was seen in 6 cases (21%), R1 was found in 3 (10%) as follows; Sm1: 15, Sm2: 7, Sm 3: 7. In total four suspected immediate perforations occurred, three of these were managed conservatively (clips, fasting and antibiotics) and in one case, ESD was aborted and the patient was taken to emergency surgery. Pathological assessment of the resected sigmoid segment revealed T3N0. No acute significant bleeding occurred during the procedures. One patient sought emergency care 12 days after the procedure with rectal bleeding, no colonoscopy was performed to determine the site of bleeding. Five patients underwent additional surgery since the pathological report stated that the resection was R1. Tumour residue was only found in one of the five resected specimens. 18 patients have undergone endoscopic follow up, to this date without any sign of recurrence. Two patients await surgery and three patients with endoscopic follow up, to this date without any sign of recurrence.

**Conclusion:** We herein present our findings on performing ESD on 29 patients with early CRC. Our results indicate that colorectal ESD is a safe and effective treatment in meticulously chosen patients even with malignant lesions. Further studies with a longer follow up is needed.

P1537 **TRENDS IN STATISTICS REGARDING EFFECTIVE ELECTRIC ERCP PROCEDURES IN THE VENETO REGION: A RETROSPECTIVE STUDY BASED ON ADMINISTRATIVE DATABASES**

M. Saia1, E. Rosa-Rizzotto1, E. Guido1, D. Caroli1, A. Frasson1, B. Germana1, D. De Lazzer1, F. Prat2, S. Leblanc2, H. Soliman3, B. Brieau3, M. Barret3, R. Coriat3, F. Prat4, S. Chausade4

Gastroenterology, Cochin Hospital, Paris/France

**Contact E-mail Address:** d.caroli@libero.it

**Introduction:** Since its introduction in 1968, Endoscopic retrograde cholangiopancreatography (ERCP) has become a highly effective procedure used to diagnose and to treat conditions associated to the pancreatobiliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

**Aims & Methods:** Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bile duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients’ post-procedure status; the threshold value that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

**Results:** A total of 3,136 admissions out of total of 14,626 hospital days (SD:4.6±5.8 days) were identified in a total of 40 hospitals, 6 (15%) of which performed more than 100 ERCPs per year. The mean sex ratio was 1.3, the mean age was equal to 68.3±14.2 (range 6–98 yrs), was higher in the males (69±1.49 vs. 67.5±13.5); significant differences were present throughout the period examined. A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%, p<0.05), besides a greater average hospital stay in those subjects (110±13.9 vs. 4.2±1.8 days, p<0.05), the within hospital mortality was 4.1% (13 cases) and there was a 6.1% of deaths due to complications. As far as the post-procedure hospital stay was concerned, in 55% of the cases, the discharge of patients within a two day period was more frequent in those assisted in public hospitals (OR:1.55;IC95%:1.21–1.90 p<0.05) in which 90% of the activities were performed and came out differently related to their characteristics. The stratification of complications according to the type of hospital (range 2–17%) did not show any significant differences. In particular, the type of hospital and the type of complication of the hospital can be attributed to the effectiveness of the regional hospital organization characterized by a capillary network of specialists capable of performing complex endoscopic procedures throughout the region limiting the need to transfer patients from one hospital to another.

**Introduction:** Large colorectal lesions (> 20 mm) can be removed endoscopically by endoscopic mucosal resection (EMR), often in a piecemeal fashion resulting in low en bloc and radial (R0)-resection rates. In this context, submucosal dissection (ESD) allows en bloc resection whatever the size, but still remains technically difficult and time consuming. A hybrid endoscopic technique has been developed, called simplified or hybrid dissection. The aim of our study was to evaluate the effectiveness and the complications of endoscopic dissection by hybrid technique compared to classical endoscopic submucosal dissection.

**Aims & Methods:** Our study was carried out from January 2013 to June 2016 from a prospective database. The 40 lesions removed by hybrid technique were compared to 109 lesions removed by classical ESD technique. The procedures were performed as follow: submucosal injection around the lesion of macromolecules, circumferential mucosal incision and submucosal dissection using the tip of a single-strand snare by endoscopic mode, central submucosal injection of the lesion and final resection with the single-strand snare, if possible in en-bloc.

Patient characteristics, tumor location and size, dissection characteristics, "block" resection rate, R0 resection rate (healthy margins), procedure and hospitalization time, and complications were identified and compared with the so-called "classical" ESD technique.

**Results:** Lesions were more frequently located in the colon (vs rectum) in the hybrid dissection group compared to the ESD group (72.5% versus 28.6%, p<0.001). The mean lesion size was 13 mm in the hybrid dissection group vs 10.4 mm in the ESD group (p=0.6). The mean size of the lesions was lower in the hybrid dissection group than in the ESD group (32.4 mm±13 mm compared to 54.4 mm±26.7 mm, p<0.001). An en bloc resection was performed in 52.5% and 84.4% in the hybrid dissection and ESD group, respectively (p<0.001). The procedure time (including general anesthesia time) was lower in the hybrid dissection group compared to the ESD group (103 min±62 min vs 191 min±73 min, p<0.001, respectively). The hospitalization time was lower in the hybrid dissection group than in the ESD group (1.1 days±1.13 days vs 2.8 days±1.8 days, p<0.001). R0 resection rates were lower in the hybrid dissection group than in the ESD group (47.5% and 61% respectively, p<0.001). Hybrid dissection was performed for adenocarcinoma, adenoma with high grade dysplasia and adenoma with low grade dysplasia in 12.5%, 42.5% and 40%, respectively. The rate of adenocarcinoma was lower compared to the ESD group (12.5% versus 30.8%, p=0.009). In the hybrid dissection group, the rate of perforation was lower than the ESD group (5% versus 20%, p=0.001). There was no statistical difference between the R0 resection rates in the bleeding (1.8% in the hybrid dissection group and 2.5% in the ESD group).

In case of complication, there was no need of surgical treatment in the hybrid dissection group, but was needed in one patient in the ESD group.

**Conclusion:** Hybrid dissection is less effective in terms of en bloc resection of large colorectal tumors. Classical endoscopic submucosal resection should be preferred, especially in case of suspected adenocarcinoma despite longer procedure and hospitalisation time.

P1539 PLACE OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN THE MANAGEMENT OF HEPATIC HYDATID DISEASE

Gastroenterology, Habib Thameur Hospital, Tunis/Tunisia

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Hepatic hydatid disease (HHD) is a major endemic health problem in certain areas of the world such as Tunisia. Intrahepatic rupture of a hepatic hydatid cyst is a common complication ranging between 3 and 17%. Furthermore, biliary leakage is the most frequent postoperative complication following surgery for hydatid cysts of liver. Both conditions require endoscopic biliary drainage.

Aims & Methods: The aim of this study was to assess the results of ERCP in patients with HHD. We retrospectively analyzed the results and complications of all ERCP performed for HHD whether before or after surgical treatment over a 10 years period [January 2007 - December 2016] and carried out at the gastroenterology unit of our hospital.

Results: Sixty seven procedures were included (mean age 40.4 years [15-82] and sex ratio male/female [31:36]. Of the 67 procedures, 58 (86.6%) were performed in patients who had undergone previous surgery. The indications of the ERCP were persistent external biliary fistulae in 77.6%, overflow obstruction or cholangitis due to residual materials within bile duct in 20.7% and secondary biliary strictures in 1.7%. In patients who had not undergone previous surgery (13.4%), the indications of the ERCP were cholangitis due to intra-biliary rupture of hydatid cyst in 44.4% associated with acute pancreatitis in 55.6%. The cannulation of the papilla was impossible in 6 cases (8.9%) and the endoscopic sphincterotomy (ES) could not performed. When papilla cannulation was obtained, per endoscopic cholangiographic findings were: dilation of the biliary tract (21.3%) with filling defects of varying size and shapes (52.5%), leakage of contrast medium into the cyst cavity (41%) and distal strictures (3.3%). ES was then performed in all cases with satisfactory results. Thus, hydatid membranes (36%) or daughter cysts (1.6%) encountered in bile ducts have been emptied out in 93.4% by biliary occlusion balloon and/or Dormia basket. Nevertheless, two patients required biliary stenting due to the bile leakage and two others required nasobiliary drainage. One patient presented post ERCP pancreatitis (1.5%).

Conclusion: ERCP is a safe and effective way to manage biliary complications of HHD. In most patients, ES is the most efficient treatment of postoperative external biliary fistulae, jaundice and accompanying cholangitis. In some cases, biliary stenting or nasobiliary drainage may be required.

Introduction: Biliary tract complications (BTC) are the leading problem in patients after orthotopic liver transplantation (LT). The present study analysed the results and predictors of treatment outcomes in patients with biliary stenoses undergoing endoscopic retrograde cholangiopancreatography (ERCP) and/or percutaneous trans-hepatic cholangiodrainage (PTCD) at the University Medical Centre Hamburg-Eppendorf.

Aims & Methods: All adult patients who received ERCP or PTCD for BTC after LT between 2009 and 2015 were retrospectively analysed. Remission of BTC was defined as no need of intervention for at least 12 months. To identify predictors of endoscopic treatment outcome in patients with biliary stenoses, a multivariate logistic regression analysis was performed after univariate variable selection. Laboratory parameters that were significant in the multivariate analysis, were dichotomised stepwise according to the most informative cut-off predicting outcome. Furthermore, endoscopic techniques were analysed in both the ERCP- and PTCD-subgroup.

Results: Of 144 patients with BTC after LT, 116 were diagnosed with biliary stenoses. Among these, 86 received ERCP, 17 PTCD and 13 both techniques. Long-term remission was achieved in 55 patients (47% overall; 53% in ERCP alone and 30% when PTCD was applied). Patients with non-anastomotic strictures (NAS; odds ratio [OR] 0.25; 95% confidence interval [CI] 0.10-0.57; p = 0.001), requirement of PTCD (OR 0.30; 95% CI 0.10-0.97; p = 0.018) and higher pre-interventional serum-bilirubin levels (OR 0.88; 95% CI 0.76-0.98; p = 0.037) were less likely to achieve remission. The most informative bilirubin cut-off to predict the outcome was 5 mg/dl. This cut-off maintained a significant association with outcome in the multivariate model (OR 0.30, 95% CI 0.08-0.95; p = 0.049). In the ERCP-subgroup, dilatation with a higher maximal balloon-diameter was associated with a favourable outcome (p = 0.043).

Conclusion: Both ERCP and PTCD can provide long-term benefit in patients with BTC after LT. However, patients with NAS and requirement of PTCD had less favourable outcomes. The pre-interventional bilirubin level was a valuable parameter to identify patients at risk of treatment failure. Larger ERCP balloon diameters may benefit remission.

Introduction: Confoal endomicroscopy is an endoscopic imaging technique permitting the microscopic analysis of the digestive mucosa in real time (esophagus, stomach, duodenum, colon, biliary tract and pancreas) due to injection of fluorescein which is a intravascular contrast. The aim of this national observational study under the guidance of SFED is to evaluate the practice of confocal endomicroscopy in France, specifically its indication, histologic correlation, therapeutic benefits depending on the operator and complications.

Aims & Methods: We executed a multicentric observational prospective study from September 2013 to February 2015. Collection of data was based on a standardized collection sheet. All patients were treated on performing confocal endomicroscopy. The intravenous injection of fluorescein was given either in bolus or in a perfusion method at a dilution of 1 or 10%. Demographic, clinical, endoscopic and endomicroscopic data were collected. For each act the correlation of the confocal endomicroscopy and histology and the outcome of the ECM depending on the operator was reported.

Results: In total 399 procedures of confocal endomicroscopy were done on 399 patients (median age was 39 +/- 14.5, males were 52%) and these were performed in 12 centers. The main indications were: diagnosis and monitoring of Barrett esophagus 28% (111/399), surveillance of gastritis 4% (16/399), characterization of colorectal polyp and searching for dysplasia in IBD patients 17% (68/399), undetermined biliary stenosis 11% (42/399), pancreatic cysts 30% (123/399) and other rare cases (lymph nodes characterization, lymphoma, GIST, celiac disease, control post mucosectomy of gastric and duodenal polyp) 10% (39/399). The quality of imaging was good in 83% of cases (331/399), average in 16% (64/399) and poor in 1% (6/399). The correlation with histology was measured by using Cohen’s kappa coefficient. The results were respectively k = 0.9, 0.78, 0.82, 0.7, 0.94, 0.93 for Barrett’s esophagus, gastritis, IBD, colorectal polyps, undetermined biliary stenosis and pancreatic cysts. The outcome of the procedure according to the operator was favorable for three main indications: Barrett’s esophagus (especially for targeting biopsy), serious pancreatic cysts (100% of cases), and undetermined biliary stenosis (90% of cases and especially for real time therapeutic decision). One major side effect was seen during the study, which was an anaphylactic shock after a bolus injection of 2.5cc of fluorescein in a 69y old patient who didn’t have any previous history of allergies. This patient was hospitalized for surveillance for three days.

Conclusion: In conclusion, confocal endomicroscopy is an in vivo microscopic technique that is easily performed throughout the digestive tube with a good histologic correlation especially for Barrett’s esophagus, undetermined biliary stenosis and pancreatic cysts. Its importance in the management of patients remains to be clarified with the advent of new endoscopic magnification techniques.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) represents a crucial procedure in the management of biliopancreatic pathology. However, its performance in patients with surgically modified gastro-enteric-biliary anatomy (SMGA) is a challenging issue.

Aims & Methods: We aimed to evaluate the efficacy of this advanced endoscopic technique in patients with SMGA. This was a retrospective observational cohort study of all patients with surgical modification of biliary/pancreatic access undergone ERCP, between 01/2002 and 02/2017. Demographic variables, indications, the breakdown of surgical procedures and technical success rate were evaluated as well as potential predictive factors of therapeutic efficacy rate. Compared patients with successful technique(G1) and therapeutic failure by ERCP
P1546 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION DURATION OF ERCP: COMPARISON BETWEEN CONVENTIONAL AND DOUBLE-BALLOON ENTEROSCOPY-ASSISTED ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

S. Dong
Korea, Republic of

Introduction: The technical and therapeutic success rates of ERCP in patients with altered GI anatomy who underwent DBE-ERCP at our institution between February 2011 and March 2017. The primary endpoint was the global success rate defined as successful cannulation of the native papilla or successful biliary access at the same procedure. Immediate complications were observed in 8 cases (8%), 6 of them (6%) were bleeding. All were successfully controlled, and none of the patients required blood transfusion or repeated endoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n = 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.32 mins); and peripapillary stenosis (n = 189, 5.32 mins).

Discussion: The ERCP registry is an essential tool for measuring quality indicators. The universal usage will allow benchmarking at individual, institutional and national level and will help in quality improvement. Efficacy, safety and impact on different pancreaticobiliary disorders will be also measurable.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: To obtain representative information about invasive endoscopic procedures is a principal goal to monitor efficacy and safety. A web-based, online central registry can serve this aim allowing structured data collection and universal acceptance of quality parameters. The prospective observational research project was approved by the Scientific and Research Ethics Committee (Budapest, Hungary). A web-based case report form was developed after finalisation and tested from January 2017 at our department. ERCP related data of consecutive patients were collected prospectively after the specific procedure. The endoscopists should be aware of the increased dose of radiation required when performing ERCP in patients with increased BMI, old age, and who need two more ERCP procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1548 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION DURATION DURING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

S. Dong, C. Oh, H.J. Moon
Kyuung Hee University College of Medicine Dept. of Internal Medicine, Seoul, Korea, Republic of

Contact E-mail Address: gidrondong@hanmail.net

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) relies on the use of ionizing radiation in the form of fluoroscopy. Because use of fluoroscopy has positive relationship with radiation exposure, it makes a risk of the development of cancer and other radiation toxicity. The increasing exposure of patients and endoscopists to radiation is concerning.

Aims & Methods: The aim of our study was to evaluate of predictive factors of radiation exposure to the patients and endoscopists during procedure as determined by radiation dose in dose area product (DAP), absorbed dose (AD) and fluoroscopy time. And we correlated them with age, sex, body mass index, diagnosis, duration of procedure, procedure name and procedure complexity.

Results: A total of 153 ERCP procedures were carried out in 103 patients with SMGA (mean age: 75.4 ±11.3 years, men:80.6%). The breakdown of surgical procedures were: Billroth I-17.7% (n = 80), Billroth II-11.0% (n = 51), Roux-en-Y-8.7% (n = 9); post-duodenopancreatectomy-2; gastric sleeve-1. We decided to develop a web-based registry which is easy to use and captures relevant procedure related information. The primary aim of the registry is to monitor relevant outcome data of ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1549 DOUBLE-BALLOON ENTEROSCOPY FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED UPPER GASTROINTESTINAL ANATOMY

C. Ghaoui1, A. Celenghi2
1Hepato-gastro-enterologie Et Endoscopie Digestive, Hôpital Européen Georges Pompidou, Paris, France
2celineghaoui@hotmail.com

Introduction: Double-balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography or DBE-ERCP allows access to the biliary ducts of patients with surgically altered upper gastrointestinal anatomy. We studied the feasibility and efficacy of DBE-ERCP at our institution.

Aims & Methods: This is a retrospective study of all patients with surgically altered GI anatomy who underwent DBE-ERCP at our institution between February 2011 and March 2017. The primary endpoint was the global success rate of DBE-ERCP. The secondary endpoints were: (1) the success rate of enteroscopy defined as reaching the desired postsurgical anatomical target, (2) the diagnostic success rate defined as successful cannulation of the native papilla or...
anastomosis, and (3) the therapeutic success rate. We used a 2.2 m DBE with a 2.7 cm 2.0 mm of operating channel (EN-450 T5, or EN580F Fujinon inc Saitama Japan).

Results: A total of 12 patients (sex ratio1/1) with a mean age of 65 [47–82] underwent 14 DBE-ERCP. 7 patients had Roux-en-Y gastro-jejunostomy with a bilio-jejunostomy had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/ 14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n = 4), biliary stone extraction (n = 4) and biliary dilation (n = 2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE- ERCP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERCP in patients with surgically altered GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of the technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1549 NEEDLE-KNIFE SPHINCTEROTOMY (NKS) VERSUS TRANSPANCERIC SPHINCTEROTOMY (TPS) FOR DIFFICULT BILIARY CANNULATION: A SYSTEMATIC REVIEW AND META- ANALYSIS
A. Tringali1, M. Cintolo1, L. Cristofani1, E. Forti2, E. Pugliesi1, L. Diodorici1, M. Mutignani1
1Endoscopy Unit, Niguarda Hospital, Milano/Italy

Introduction: Biliary cannulation may be difficult in 10–15% of patients (1) and needle-knife sphincterotomy is more often used as a rescue treatment. A more recent technique for difficult cases is transpancreatic sphincterotomy. Both situations are well known as Post-ERCP pancreatitis risk factor (2). To best of our knowledge only few studies compared success rate and adverse events in these techniques (3–7).

Aims & Methods: We aimed to compare the efficacy and safety of NKS comparing to TPS in difficult biliary cannulation We conducted a bibliographic search using PUBMED, EMBASE including 2 RCTs and 4 non randomized trials from January 2000 to December 2016. OR using the Manthel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity. A previous study had suggested that TPS might be as effective as double guidewire cannulation (DGW) technique in achieving biliary cannulation in difficult cases and has a lower pancreatitis rate. [1].

Aims & Methods: The aim of this study was to review the practice, complications and outcomes of TPS in University Hospital of North Tees (district general hospital in the north-east of UK). All ERCP procedures between January 2014 and October 2016 were reviewed. Endoscopy reports, blood results and discharge letters were used for data collection.

Results: 1365 ERCP procedures were performed in the study period. Overall CBD cannulation rate was 91.3%, 105/1365 (7.7%) were guided TPS procedures were performed. Mean age 67.7 years (range 20–99). 67 patients (50%) were male and 64 (47.4%) were female. Mean CBD diameter was 10 mm (range 5–16 mm). Indications for TPS were: (1) Therapeutic success rate regarding complete clearance of the bile duct. Statistical analysis revealed that success rate was 100%. The global success rate of DBE-ERCP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERCP in patients with surgically altered GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of the technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
CBD stones any diameter
Guidelines on the prevention, diagnosis and treatment of gallstones. European Association for the Study of the Liver (EASL). EASL Clinical Practice Reference stones 7–15 mm can be successfully removed by using retrieval balloon or lithotriptor combined with balloon dilator. Most intermediate CBD stones 7–15 mm was balloon dilator combined with retrieval balloon. In most patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator (Group 5). The success rate in this group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 12.4 mm. In Group 6 we included cases which required combined techniques (≥ 7.8). We observed a mean stone diameter of 9.4 mm with a mean CBD diameter of 13.8 mm in patients solved endoscopically, compared to those referred to surgery who had a mean stone diameter of 14.2 mm with a mean CBD diameter of 14.3 mm (P < 0.001). In this group the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm (P < 0.001).

Conclusion: The most successful endoscopic method to remove large stones ≥15 mm was balloon dilator combined with retrieval balloon. Intermediate stones ≤15 mm can be successfully removed by using retrieval balloon or lithotriptor or a combination of basket with retrieval balloon ≥ balloon dilator. Most CBD stones <7 mm were successfully removed by using basket. In conclusion, any diameter >7 mm will most probably require more elaborate techniques.

Introduction: Diclofenac and indomethacin are the most studied drugs for preventing ERCP pancreatitis (PEP), but their use is controversial.

Aims & Methods: Our aim was to evaluate all trials published in full text and studied efficacy of diclofenac or indomethacin prophylaxis with placebo or non-treatment for the prevention of PEP in adult patients undergoing ERCP. Systematic search of databases (PubMed, Scopus, Web of Science, Cochrane) for relevant articles was published from inception to 30 June 2016.

Results: Our meta-analysis of 4741 patients from 17 trials showed that diclofenac or indomethacin significantly decreased the risk ratio (RR) of PEP to 0.60 (95% confidence interval/CIs):0.46–0.78, P = 0.0001), number needed to treat (NNT) was 20, and the reduction of RR of moderate to severe PEP was 0.64 (95% CI 0.43–0.97, P = 0.0339). The efficacy of indomethacin compared to diclofenac was similar (P = 0.98). The efficacy of indomethacin or diclofenac did not differ according to timing (P = 0.99) nor between patients with average-risk and higher risk of PEP (P = 0.6231). The effect of the rectal administration of indomethacin or diclofenac was not significant (P = 0.1507), but rectal route was effective (P = 0.0005) with a NNT of 19. The administration of indomethacin or diclofenac was avoided in patients with renal failure. Substantial adverse events were not detected.

Conclusion: The use of rectally administered inexpensive and safe diclofenac or indomethacin before or closely after ERCP is recommended in every patient (without renal failure) undergoing ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rectal diclofenac or indomethacin reduces the risk of pancreatitis after endoscopic retrograde choledangiopancreatography (ERCP). Most studies of its efficacy included high-risk cohorts and excluded low-risk patients. We investigated the potential of rectal diclofenac to prevent post-ERCP pancreatitis (PEP) in a variety of patients.

Aims & Methods: A cohort of 1534 ERCPs performed at the Hospital Clínico Universitario between 2009 and July 2016 was collected. The median age of the patients was 75 years old (between 12 and 102 years). 54% were male and 45.9% were female. There were 93 procedures in which cannulation of the desired pathway was not achieved but the papilla had been manipulated so they were patients who had been included in the study. In May 2012, with a few exceptions, patients received diclofenac before their procedure. 730 patients did not receive Diclofenac. PEP was defined by consensus criteria.

Results: The data were similar in age, sex, suspicion of Oddi sphincter dysfunction, recurrent acute pancreatitis, chronic pancreatitis, cannulation time, use of pre-cut, previous PEP, dilation without sphincterotomy. There were differences in the number of sphincterotomies in which it was greater in the Diclofenac group (p=0.004). There was also a greater number of Wirsung cannulations in the group treated with Diclofenac (p=0.004). There were a total of 47 PEP (3.1%), being 7.8% in the patients who did sphincterotomy in the Diclofenac group (p=0.004). Taken as a whole the patients had no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%.

There was no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%.

When taking only patients with de novo sphincterotomy, there was no difference between the number of PEP between the two groups being 4.4% in those treated with Diclofenac versus 4% in the untreated patients. In those patients who were cannulated Wirsung, an incidence of PEP of 8.2% was observed in the group treated with Diclofenac, compared to 6% in the control group (p=0.006). There were not differences between those treated with Wirsung’s prosthesis and those not treated in both groups. There was no PEP in patients treated with pancreatic prosthesis.

There was a higher incidence of PEP in women in both groups and a trend towards greater number of PEP among those treated with Diclofenac, although without statistical significance. There was also a greater number of PEP in patients under 40 years of age treated with Diclofenac compared to those not treated with 14.3% versus 7.1% (p=0.024).

No differences were found between the groups treated and not treated with Diclofenac when crossing with sphincter dysfunction of Oddi, previous PEP, number and sizes of choledocholithiasis and sizes with the appearance of PEP.
Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

Introduction: The confocal laser endomicroscopy (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangioscopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucus secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of histologic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvisio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, MA, U.S.A). Learning sets were constructed by using 49 images of normal area and 25 images of cancer lesion. The test sets of the pCLE images were constructed using 6 images of normal area and 14 images of cancer lesion separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 69.8%, 50%, 100%, and 90%, respectively. Although the negative-diagnostic value was good, the pCLE image was thought to have a characteristic suitable for CAD by using deep learning technology. However, many false-negative diagnose with a probability 1.0 may have occurred owing to deflection and the lack of learning sets. To improve this situation, a set of images was added to the learning set.

Conclusion: Automated diagnosis of bile duct cancer can be achieved by using the deep learning technology of pCLE imaging. Our CAD system will be improved with the appropriate learning sets.

Introduction: Acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, controversy still remains that which EUS-TS techniques would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions with the use of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). Patients who referred to EUS-TS for pancreatic mass were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n = 5), cystic lesion (n = 5) and loss of follow up after EUS-TS (n = 2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without technical failure and procedure-related adverse events. The median size of the lesion was 15 mm (range, 11 to 31 mm). There were 31 pancreatic cysts and 14 benign lesions. Overall core tissue acquisition and diagnostic accuracy was 84.8% (139/164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p = 1.000) and diagnostic accuracy (72.0% vs. 74.4%, p = 0.860).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including variable lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unfit for surgery. Sixteen consecutive patients (9 males; mean age: 84 years) with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were conservatively treated and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopic centers by 4 experienced endoscopists (≥50 EUS-FNB performed yearly), by using the NAGI-stent. Each attempt to access the gallbladder was firstly performed from the transduodenal position and resulted successful in 13 (81%) patients, whilst a transgastric approach was preferred in the remaining 3 patients. Two different approaches were performed for the EUS-guided gallbladder puncture: a) a 0.035-inch wire was advanced through a 19G-needle into the gallbladder and dilation of the access was achieved with a 10 Fr cystoenteroscope; b) a 0.035-mch wire was advanced through a 10 Fr cystoenteroscope directly, a 26G-needle, and a 10 Fr cystoenteroscope were advanced into the stent but it resolved with a new stent positioning. Symptoms relief occurred in all patients, 1 day after the procedure in 12 (75%) cases and 2 days later in remaining 4 (25%) patients. A bleeding episode occurred in 2 (12.5%) patients, in one case such complication was intra-procedural and it was successfully stopped during the same endoscopic session, in the other case it was a delayed adverse events requiring arterial embolization but the patient died 10 days later. At follow-up, two patients died due to myocardial infarction at 2 and 6 months, one for acute renal failure after 6 months, two for pancreatic cancer, 7 months and one for chronic cholangiocarcinoma after 5 months. In the remaining patients no cholecystitis recurrence or biliary obstruction were observed at median follow-up of 112 days (range 49–180 days).

Conclusion: Our data showed that EUS-guided gallbladder drainage with NAGI-stent is safe and successful in patients with acute cholecystitis unfit for surgery. Since this type of stent is cheaper compared to others, the use of such device may result more attractive as a further endoscopic option for these selected patients.

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is considered the gold standard method for assessment solid pancreatic masses. The needles for aspiration currently available are 19G, 22G and 25G and there is no concrete evidence to prove the benefit of one against another.

Aims & Methods: Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided gallbladder drainage (EGBD) in cadaveric specimens. Using a linear EUS scope, the interface between the head of the pancreas and the duodenal wall to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no reports on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall to increase the peri-pancreatic space for the course of radiotherapy.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall in a cadaveric model. Baseline CT was performed on three unfixed cadaveric specimens. Using a linear EUS scope, the interface between the head of the pancreas and the duodenal wall was identified in a cadaveric model. A 19-gauge FNA needle was used to inject the hydrogel into the peri-pancreatic space with creation of a visible separation between the duodenal wall and the pancreatic parenchyma. The procedure was repeated along the length of the head and uncinate of the pancreas. CT was performed post procedure to confirm location and to measure the distance created between the duodenum and pancreas. Gross dissection of the pancreas and duodenum was performed to evaluate localization of the hydrogel.

Results: All three cadavers underwent successful EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall. Recurrent cholecystitis occurred in 1 patient (2%) during follow-up. When comparing the first 25 procedures to the subsequent 25 procedures, significant differences were observed in the procedural time [29.21 (10.65) vs 15.6 (1.66) minutes, P < 0.001], the need of an additional stent [24% vs 0%, P = 0.022] and hospital stay [7.76 (5.13) vs 5.75 (5.50) days, P = 0.090]. While there were no differences in the technical and clinical success rates and adverse events.

Conclusion: EGBD is a safe and effective method for achieving gallbladder drainage in patients that are at high-risk for cholecystectomy. Performance of 25 procedures are required to gain competency in the procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Results: 50 patients were recruited during the study period. The mean (S.D.) age was 64.3 years old and 42% were male. Acute cholecystitis that are at high-risk for cholecystectomy. However, the long-term outcomes and the learning curves of the procedure are uncertain.

Aims & Methods: This was a retrospective review of all patients that received EGBD in the Prince of Wales Hospital between June 2012 to March 2017. All procedures were performed or supervised by a single operator. EGBD was performed in patients that are at high-risk for cholecystectomy and suffering from acute cholecystitis or on long-term cholecystostomy tube drainage. Outcome parameters included demographics, technical and clinical success, procedural characteristics, adverse events and follow-up duration.

Introduction: EUS-guided gallbladder drainage (EGBD) is gaining popularity as an alternative method for drainage of the gallbladder in patients suffering from acute cholecystitis that are at high-risk for cholecystectomy. However, the long-term outcomes and the learning curves of the procedure are uncertain.

Contact Email Address: rossi.gemma@hsr.it

Introduction: There are few published studies about the use of a novel radiofrequency (RF) system (EUSRA RF needle; VIVA RF generator; STARmed Co., Ltd.) in pigs. With poor standardization of the procedure in terms of ablation powers and ablation times, resulting in great heterogeneity of the results.

Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure using this new system performing ex-vivo tests on porcine liver in order to find the best ablation power and ablation time to produce the maximum size of coagulative necrosis at histological examination. The system consists in a radiofrequency generator delivering electric energy, a 19 Gauge needle (150 cm in length with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the needle with chilled saline solution, maximizing the ablation volume without tissue charring), an isolating plate and a pedal to deliver RFA. Liver samples were treated at different powers: 10, 20, 30 and 40 Watts (W); each ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to Forniacci excisional dose scheme, used in phase I studies. We registered macroscopically: the size (millimeters) of the global treated area and the size of the coagulative necrosis, coagulating the insertion point of the needle deflection (A zone) with a maximum diameter of 4 millimeters and a surrounded larger area of "diaphanization" (B zone), showing mild signs of cellular alterations (cytoplasmic hypochromia) without cellular necrosis. A zone sizes didn’t change among different ablation times (mean size: 3.25 mm) while B zone diameter increased with the increase RF application at the fixed power of 10 W. At the microscopic analysis the pathologist didn’t see any difference in size of coagulative necrosis among the different ablation powers (R = 0.24).

Conclusion: With this new system is feasible and effective to produce very small areas of coagulative necrosis (millimeters) well-demarcated in respect to the surrounding parenchyma and could be useful, in the future, to treat, with multiple passes and higher precision, target lesions with a flexible needle. Moreover, the system can produce larger zones of mild cellular alterations at lower ablation powers (10 W), increasing with the increase of ablation times, but it needs future in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis? necrosis? recovering?).

Introduction: Malignant associated thromboembolic disease (TED) has a complex multifactorial pathogenesis. Tumor cells activate platelets and express procoagulant factors including tissue factor and thrombin; in addition, normal host tissues express procoagulant activity in response to the tumor. Thrombotic risk varies substantially according to cancer location and pancreatic cancer is one of the leading causes. The clinical spectrum includes migratory superficial thrombophlebitis, arterial thrombosis, deep venous thrombosis, portal vein thrombosis and disseminated intravascular coagulation. We report here to assess the role of endoscopic ultrasound (EUS) diagnosing TED in pancreatic cancer patients.

Aims & Methods: We perform a retrospective review of all EUS cases for pancreatic cancer in two centers and assess all TED events diagnosed.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms were performed in two centers. TED was present in 5 patients (9%): 3 were male and the mean age was 70 (range, 46-81). In 1 patient the EUS indication was a large abdominal mass whose origin was not clear, in the remaining 4 the indication was the pancreatic neoplasm. In all of them was performed EUS with fine-needle aspiration (EUS identified a superficial bulbar lesion (PE) and 1 inferior vena cava thrombosis (IVCT) with right atrial extension: 2 (3.6%) had recently been diagnosed by computed tomography (CT) but 3 (5.4%) were not previously known. In all these, CT confirmed diagnosis.

Conclusion: To the best of our knowledge, this is the first case series of EUS-based TED diagnosis in pancreatic cancer patients. This series underlines importance of a systematic, station approach EUS technique, namely in the mediastinum regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Introduction: Cholecodolithiasis is the most common cause of biliary pain, leading to hospital admission. Patients affected by cholecodolithiasis presents an incidence of cholecodolithiasis ranging from 8% to 20%. When the suspicion of choledocholithiasis is confirmed, stones should be removed by ERCP, but this operative measurement is associated with high rates of adverse events as post-ERCP pancreatitis, bleeding or perforation. A correct diagnosis of cholecodolithiasis, before ERCP, is mandatory to decrease the operative risk and health care costs. Endoscopic ultrasound (EUS) has a high sensitivity and specificity in the diagnosis of CBD stones and could substitute other imaging modalities as CT-scan or MRCP, when indicated.

Aims & Methods: The aim of our study was to assess the role of early EUS (<48 hours), in patients undergo ERCP in emergency room for suspected biliary colic.

We retrospectively evaluated all the patients admitted at first aid for suspected biliary colic (i.e. right upper quadrant pain and/or epigastric region, associated with an elevation in serum ALT, AST, GGT, ALP, or total bilirubin, but in absence of amylase or lipase elevation). All patients, irrespective of the finding at the US, performed an EUS within 48 hours since admission. Data are presented as proportions with 95%-CI and mean±standard deviation (SD). Correlation between categorical variables was evaluated by computing the “phi” coefficient. We computed the number needed to misdiagnose, i.e. the number of patients who need to be tested in order for one to be misdiagnosed by the test, as 1/(1-diagnostic accuracy).

Results: Overall, from January 2016 to December 2016, 88 patients (56% female; mean age 64 ± 17 years) were admitted to our hospital for suspected biliary colic. All the analyses were run with RStudio (version 1.2.5042). Further, US documented common bile duct (CBD) stones in 58 (65%) patients, CBD sludge in 4 (5%) patients, whereas no cholecodolithiasis was found in 26 (30%) patients. At EUS examination CBD stones were found in 70 (80%) patients. Comparing US to EUS, US gave false negative results in 16 (18%) cases and false positive findings (i.e. identifying CBD stones not documented by EUS) in 8 (9%) patients. The two diagnostic procedures showed little correlation (phi = 0.289). The number of
patients needed to be tested by US in order to provide an incorrect diagnosis was 3.7 (95%CI: 2.6–5.5).

Introduction: The preoperative differentiation of the solid pancreatic neoplasms by endoscopic ultrasound fine needle aspiration (EUS-FNA) remains around 90% and different needles or techniques of sampling has been used for improving the results. Data about the progress in diagnosis when the contrast harmonic enhanced EUS-FNA (CH-EUS-FNA) is used are scarce.

Aims & Methods: We aimed to assess the role of contrast-enhanced EUS-FNA compared to standard EUS-FNA in diagnosing the solid pancreatic neoplasms. Methods: Patients from one tertiary medical center with visible solid pancreatic mass on CT scan were included. EUS-FNA(one pass) and CH-EUS-FNA (one pass) were performed randomly in each patient by using a standard 22G needles, an Olympus-Aloka equipment and Sonovue as contrast agent. Core histology was assessed separately for each pass by the same pathologist blinded from the randomization process. The final diagnosis was based on the results of EUS-FNA and surgery, or the findings after 9 months’ follow-up.

Results: The final diagnosis of 40 patients included was adenocarcinoma (n = 36), chronic pancreatitis (n = 2) and other pancreatic mass (n = 1). The lesions were located in the head of the pancreas (60%), body (32%) and tail (8%). The diagnostic sensitivity and specificity based on core histology was 89% and 94% in the CH-EUS-FNA passes and 86% and 91% in the EUS-FNA passes and the diagnostic value was significantly better in the CH-EUS-FNA group (p = 0.0046, t-test). The visual core size was not significant for the true-positive diagnosis of malignancy.

Conclusion: In a randomized control trial, CH-EUS-FNA improved significantly the diagnosis of solid pancreatic neoplasms over standard EUS-FNA. These techniques are complementary, not competitive, and they can be performed in the same session, resulting the increasing of the diagnostic rate with a minimum of passes.

Introduction: Traditionally, clinical symptoms such as melena were used as strong predictors for an upper GI bleeding source with primary evaluation with an EGD (esophagogastroduodenoscopy). Little consideration was given to the small bowel. It has been known for decades that melena can originate from the nose to the right colon and hematochezia can originate from the proximal gut to the rectum. Thus, current endoscopic approaches have limited localization value and diagnostic yields. We hypothesize capsule endoscopy (VCE) provides better localization of bleeding when compared to clinical symptoms alone.

Methods: We recruited patients with inflammatory bowel disease (IBD) from a tertiary center. CDAI was taken to be significant.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study. Disease severity was assessed by the capsule endoscopy Crohn’s Disease activity index (Cedcadi) score. MH was defined as Cedcadi score < 3.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study. Disease severity was assessed by the capsule endoscopy Crohn’s Disease activity index (Cedcadi) score. MH was defined as Cedcadi score < 3.

unknown whether fatigue affects the accuracy of SBCE reporting and how many SBCE readers can be used in one session.

Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 6 pre-selected SBCE studies consecutively. These studies were presented in a random order. All readings took place using the single view mode, where readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine the influence of fatigue on the accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-reader variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. As progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was assessed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 5% when using the 22–28 speed. There was no significant change in accuracy with progressive capsule read when the group was analyzed as a whole. The accuracy of experienced readers decreased after just one study read, from 38% to 27% and plateaued thereafter. Novice readers demonstrated no significant change in accuracy at the time points with trend towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

P1574 FEASIBILITY OF SAME-DAY COLON CAPSULE ENDOSCOPY (CCE) IN PATIENTS WITH INCOMPLETE COLONOSCOPY

M. Hussey1, G. Holleran2, C. Tersaruolo2, D. McNamara1
1Gastroenterology, Tallaght Hospital, Dublin/Ireland
2Trinity Academic Gastroenterology Group, Trinity College, Dublin/Ireland

Contact E-mail Address: husseyma@tcd.ie

Introduction: Rates of incomplete colonoscopies (IC) range from 2–19%, requiring repeat procedures or radiological imaging which can often lead to diagnostic delays as well as increased inconvenience for the patient. Same-day CCE may offer a more convenient and cost-effective mode of colonoscopic examination post IC.

Aims & Methods: We aimed to determine the feasibility of same-day CCE post incomplete colonoscopy (IC) in consecutive patients. Patients were selected without a contraindication to CCE with an IC for reasons other than poor bowel preparation. Of 84% (n = 34) of patients deemed to be excellent in 16% (n = 15), inflammation 22% (n = 12) and severe diverticular disease 30% (n = 12). The mean colonic passage time was 222 minutes and overall image quality was deemed to be excellent in 16% (n = 6), good in 31% (n = 12), adequate in 44% (n = 18) and poor in 9% (n = 4) of participants. Overall findings were normal 25% (n = 10), polyps 38% (n = 15), inflammation 22% (n = 9), diverticular disease 25% (n = 10), intussusception 30% (n = 12) and severe diverticular disease 30% (n = 12). The mean sedation used during OC was 5 mg midazolam (range 3–10 mg) and 75 mcg of fentanyl (range 50–100 mcg). In all 84% (n = 34) of CCE were complete, however full colonic views were obtained in 94% (n = 33). Mean colonic passage time was 222 minutes and overall image quality was deemed to be excellent in 16% (n = 6), good in 31% (n = 12), adequate in 44% (n = 18) and poor in 9% (n = 4) of patients. Overall findings were normal 25% (n = 10), polyps 38% (n = 15), inflammation 22% (n = 9), diverticular disease 25% (n = 10), intussusception 30% (n = 12). Amongst the patients who had polyps, 8 required polypectomy and the remaining 7 were put on a surveillance programme. Based on the CCE findings, 4 of the IBD patients required treatment escalation. In terms of adverse events one patient reported abdominal pain during the procedure and one patient retained the capsule due to an inflammatory stricture.

Conclusion: CCE would appear to be feasible in the majority of patients and significantly detects colonic pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: M.Lahaye@nki.nl

Introduction: Peritoneal carcinomatosis (PC) is a well-known mechanism of spread in cancer; it is the second most frequent cause of death in colorectal cancer patients. However, the prognosis of PC patients has dramatically improved due to the development of severe complications and the availability of adjuvant chemotherapy. Cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC), 5-year survival rates of up to 50% are reported after CRS-HIPEC. Despite this survival gain, CRS-HIPEC has a considerable morbidity rate of 12%–23% and a mortality rate of 21%2. Obviously, CRS-HIPEC is only an option for patients with a limited life expectancy to avoid pointless and costly aggressive surgical procedures. Hence, recognizing patients with a maximum risk-to-benefit ratio for the procedure is imperative. To select patients who could benefit from CRS-HIPEC the Peritoneal Cancer Index (PCI) is used. The PCI combines the location/size of peritoneal tumours found at surgery in 13 abdominal regions. Each of the 13 regions is scored for implant size on a scale of 0–3 (= no visible tumour implants; 1 = implants < 0.5 cm; 2 = 0.5–5.0 cm; 3 = 5.0 cm). The PCI is the sum of the lesion scores from all 13 areas, and thus can vary between 0–39. The PCI is widely validated and is a quantitative prognostic indicator for long-term outcome. However, with this surgical staging procedure it is not always feasible to inspect all relevant abdominal regions. In this study we evaluate whether the PCI could be used to identify patients who are candidates for undergoing CRS-HIPEC. However, currently there is no validated imaging tool that can accurately predict PCI.

Aims & Methods: Therefore, the aim of this study was to estimate the PCI preoperatively with diffusion weighted MRI (DW-MRI) and compare this with the PCI found at surgery to assess whether DW-MRI can be used to select CRS- HIPEC candidates. In this ongoing study twenty-four consecutively included patients (April 2016–April 2017) with histologically proven peritoneal carcinomatosis from colorectal origin were included. Patients were scheduled for exploratory laparoscopy and/or CRS/HIPEC and underwent preoperative dedicated DW-MRI (scanning time: 30 min).

Two independent readers prospectively determined the PCI on DW-MRI. Patients were categorized as low-risk (PCI 0–21) versus high-risk (PCI 22–39); in our center considered operable versus non-operable. Reference standard was PCI on open surgery. Furthermore, the correlation of PCI with the number of adhesions and/or tumour. So, there is a desperate need for a non-invasive imaging tool that could select those patients who will benefit from CRS-HIPEC. However, currently there is no validated imaging tool that can accurately predict PCI.

Results: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

P1576 HISTOLOGICAL PREDICTION OF COLONIC POLYS BY COMPUTER VISION, PRELIMINARY RESULTS

Introduction: During colonoscopy, clinicians perform visual inspection of the polyps to predict histology. Kudo’s pit pattern classification is one of the most commonly used for optical diagnosis. These surface patterns present a contrast with respect to their neighboring regions and they can be considered as bright regions in the image that can attract the attention of computational methods.

Aims & Methods: We aimed to assess the accuracy of a new computational system based on the segmentation and characterization of bright regions as...
cases to obtain an automatic histological classification of colonic polyps. Our automatic classification system is based on the segmentation of textural elements from polyp surface and their correlation with Kudo’s pit pattern classification. Textural elements are identified as bright regions on polyp surface and there are characterized according to their shape into tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous.

Taking this into account, we characterized segmented bright regions using a tubularity metric (Tub) designed to obtain low values for circular shapes and high values for tubular shapes of the same area. We tested our method in high definition (HD) white light polyp images which were obtained with a colonoscope Olympus CIF-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoendoscopy were used. These images were selected to show as much variability in polyp appearance as possible. We used the mean of all Tub values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of Tub. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

Results: 51 polyp images were analyzed: 38 (74.5%) adenoma and 13 (25.5%) non-adenoma. Mean size of polyps was 14 ± 13 (range 1–40) and had the following morphology based on Paris classification: 5 (9.8%) 0-Ip, 27 (52.9%) 0-IIa and 19 (37.3%) 0-IIa. Mean Tub values were different for adenoma compared to Non-adenoma (19.5 ± 6.5 vs 14.1 ± 6.3; p = 0.013). An optimal threshold value of Tub = 13.14 to separate adenoma vs. non-adenoma was selected from the operating point of the ROC curve. With this value, our method was able to provide an accurate histological diagnosis in 44 out of 51 images (86%) (table) with a Sensitivity, Specificity, PPV and NPV for the diagnosis of adenoma of 95%, 61%, 88% and 80%, respectively. On the other hand, processing of a single HD image took 2.7 seconds making feasible its use in the endoscopy room.

Conclusion: A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyp histology during colonoscopy. Though the use of shape characterization is promising, the inclusion of other polyp characteristics (i.e. shape, color, vessels…) as well as enlarging the validation database could improve the robustness of our methodology.

P1577 COLORECTAL LATERALLY SPREADING TUMORS DETECTED AT CT COLONOGRAPHY

M. Iwabuchi, M. Sugimura, S. Toda, K. Ukai
Gastroenterology, Sendai Medical Center, Sendai/Japan

Contact E-mail Address: s7856@snh.go.jp

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified into the following two subtypes according to their morphology: granular type (LST-G), and non-granular type (LST-NG). Meanwhile, CT colonography (CTC) can effectively detect LST-Gs, while the detection of LST-NGs is limited. The detection of LST-Gs has been shown to be correlated with lesion size, location and presence of prominent tubular structures associated to non-adenomatous. CTC showed a sensitivity of 85.7% for detecting LST-Gs and that for detecting LST-NGs was 50%.

Results: Thirty-five pathologically proven LSTs were identified and matched by CTC (85.7%). 23 out of 24 (95.8%) LST-Gs were detected by CTC, while 12 out of 11 (109.1%) LST-NGs were missed by CTC. Of the 24 LST-Gs detected by CTC, 23 (95.8%) were detected at the optimal threshold for Tub = 13.14.

Conclusion: CTC can effectively detect LST-Gs, while the detection of LST-NGs is still challenging.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1578 ANALYSIS OF CT COLONOGRAPHY MISS RATE OF LARGE NEOPLASTIC LESIONS DETERMINED BY COLONOSCOPY ON JAPANESE NATIONAL CT COLONOGRAPHY TRIAL (JANCT)

M. Hirayama1, T. Takayama2, R. Fuji1, T. Minagawa1, S. Ohiwa1, K. Sakata1, M. Yoshida1, Y. Okagawa1, H. Ihar1, T. Sumiyoshi1, Y. Tsuji1, N. Yoshizaki1, H. Kondo1, K. Nagata2
1Gastroenterology, Tonan Hospital, Sapporo/Japan
2Oncology, Tonan Hospital, Sapporo/Japan

Contact E-mail Address: otarugi@gmail.com

Introduction: CT colonography (CTC) may be readily used for imaging of the colon in elderly or poor risk patients with colon polyps and cancer because of its noninvasive nature and relatively high sensitivity in recognition of polyps. However, it may have drawbacks to make a misdiagnosis may be inevitable. Therefore, analysis of misdiagnosis case is crucial on the new modality for the colon cancer screening examination.

Aims & Methods: We evaluated the misdiagnosed case of large neoplastic lesions (PNL) reported by colonoscopy follow-up after CTC in JANCT by radiologist and gastroenterologist interpretations1,2. Out of 1257 cases enrolled in JANCT, 1181 cases were actually studied, omitting 76 cases according to the exclusion criteria. More than 16 DAS CT were used for CTC, respectively. Images were retrospectively reconstructed by using a 0.5 mm section index. The CTC examination was prepared by PEG-C solution before scanning. CO2 gas as an efferent agent was then administrated just before scanning. This was used for the contrast medium. CTC images were analyzed by AVE Virtual Place software. The CTC and CS were independently analyzed by endoscopist and radiologist in blind fashion. We investigated misdiagnosed lesions with CTC more than 10 mm detected by CS. We considered the pseudo-negative lesions misdiagnosed with CTC interpretation (PNL) by radiologist or gastroenterologist and also considered the true pseudo-negative lesions misdiagnosed with CTC interpretation (true PNL) by radiologists and gastroenterologists. Because we conceived true PNL showed the limitation of CTC interpretation instead of PNL involved a human error.

Results: PNL was diagnosed by CS at 0-Ip (8 cases, 8 lesions) and 0-IIa (17 cases, 19 lesions), respectively according to the criteria of the Paris classification. True PNL was also diagnosed at 0-Ip (case, 1 lesion), 0-IIa (5 cases, 6 lesions) and 0-IIa (11 cases, 13 lesions), respectively. True PNL: PNL ratio was 0-Ip 12.5%, 0-IIa 50% and 0-IIa 68.5%, respectively. There was no PNL at 0-Iic. Type I, II and III on this study. Most of all true PNL were so called flat lesion not only 0-IIa lesion.

Conclusion: CTC was proven to be a reasonably useful approach to obtain the image of colon diseases without any invasiveness to the patient. On CTC interpretation, lower protruded lesion was considered less detectivity than highly protruded lesion like 0-Ip.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The formation of fibrotic tissue in intestinal wall of Crohn’s Disease (CD) patients is transmural and mucosal biopsies are unrepresentative of real intestinal damage. Magnetic Resonance Enterography (MRE) allows a transmural study of the bowel loops. Recently the percentage of gain of contrast medium has been proved useful to study fibrosis in CD patients. Diffusion Weighted Imaging (DWI) through the restriction of the apparent diffusion coefficient (ADC) allows an accurate evaluation of disease activity in CD patients avoiding contrast agents.

Aims & Methods: The aim of this study is to investigate if DWI sequence of MRE was able to identify intestinal fibrosis in CD patients candidate to surgery, using the histopathology specimens and percentage of gain as gold-standard. Thirty ileocolonic CD patients candidates to surgery for structuring disease were consecutively enrolled from October 2010 to November 2015. All patients underwent MRE before the surgery. The histopathological examination was performed using an histological score for inflammation (AIS) and fibrosis in the stenotic segment and in the ileum before the stenosis.

All population had an active disease at MRE. ADC value had a significant correlation with fibrosis score (r = 0.648; p < 0.0001), AIS (r = 0.763; p < 0.0001) and percentage of gain (r = 0.687; p < 0.0001). A strong correlation emerged between wall thickness and fibrosis score (r = 0.671; p < 0.0001). The
Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal segment of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air insufflation, the external fixation was removed. Otherwise, the fixation was kept for another 2–4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15–30–60 days after stent placement. In cases of migration of the entire length of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fixed with dental floss strands as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1582 CLINICAL OUTCOME WHEN USING SELF EXPANDING METAL STENT IN OBSTRUCTIVE COLRECTAL CANCER IN 248 PATIENTS AT 7 YEARS EXPERIENCE IN TERTIARY CENTER

M. Shafazand, T. Radomski, L. Alkelin, N. Papachrysos
Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden

Contact E-mail Address: mortenza.shafazand@vgregion.se

Introduction: The reported incidence of colorectal cancer in Sweden in 2014 was 60–65/100,000 inhabitants and caused 25–30 deaths/100,0001. Of all colorectal cancer, approximately 15–20% debates with acute obstructive symptoms. Conventional acute surgical procedures in these conditions (open surgery) have been shown to lead to mortality risk up to 20% and morbidity risk of 45–50%, followed by increased need for intensive care and more infections and stoma complications2. Self-expanding Metal Stent (SEMS) for relieving malignant colorectal obstruction is a treatment option for non-curative cases or for bridging the patient for later surgery. Studies have shown 3clinical success3 of SEMS at 90%. An article from 2007 concludes that SEMS in acute colonic obstruction has better results regarding sickness and side effects compared with acute open surgery.

Aims & Methods: Our compilation covers the years 2010–16, when 248 SEMS interventions(53% men, 47% women, age 28–97) were performed at SU/Ostra Hospital. In 78% of cases, the obstruction was located below the left flexure. In 80%, SEMS was made for palliative purposes.

Results: Technically, SEMS succeeded in 98% of cases and had clinical success in 90% of cases(abscence in need of emergency surgery). Complications (colony perforation) occurred in 6% of the cases. Mortality within 30 days was 11% and within 90 days 22%. In our experience, the incidence with regard to 90-day mortality for the indication was palliative vs. bridging, 29 resp. 3%. Based on the clinical outcomes "success" vs "failure", the 90-day mortality rate was 19 resp. 55%.

Conclusion: Our interpretation is that SEMS is an effective method of acceptable safety regarding complications in acute malignant colonic obstruction. The method is suitable for both intended intestinal relief for palliative purposes, as well as awaiting later curative measure (bridge to surgery).

P1581 HOMEMADE FIXATION OF FULLY-COVERED SELF-EXPANDING METAL STENT

Endoscopy, ICESSP Sao Paulo Dept. of Endoscopy, Sao Paulo/Brazil

Contact E-mail Address: kpennacchi@yahoo.com.br

Introduction: Esophageal self-expandable metal stents are currently used as an alternative for surgical treatment in esophageal neoplasia, benign strictures, fistulas and anastomotic leaks. Migration is a common complication after stent placement and have higher rates when fully covered stents are employed. Covered stents prevent tumor ingrowth and can be removed easily, they can be used in the closure of fistulas and leaks. External fixation of the stent with Shim’s technique seems to be efficient in preventing stent migration, but has a high cost and variable availability. Fixation by clipping or sutures has similar limitations. We developed a homemade technique for external fixation of the stent using dental floss to prevent stent migration. We present the results of this technique in a small cohort.

Aims & Methods: The present study enrolled sixteen patients with esophageal malignancies, anastomotic leaks, esophageal fistulas and extrinsic compression. The stents used in these patients were five partially covered and ten fully covered. We developed a homemade technique using dental floss for external fixation of the stent which prevent stent migration. We pull stripes of dental floss into the stent mesh and using a method similar to exchange of a nasobiliary drainage catheter, the dental floss is drawn out through the nose, tied a knot into it and its loose end is fixed to the patient’s carbole.

Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal segment of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air insufflation, the external fixation was removed. Otherwise, the fixation was kept for another 2–4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15–30–60 days after stent placement. In cases of migration of the entire length of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fixed with dental floss strands as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

P1580 MOLECULAR IMAGING OF c-MET IN THE CLINICAL MANAGEMENT OF GASTROINTESTINAL CANCERS

N. Mcdonald, C. Portal, I. Wilson
Edinburgh Molecular Imaging, Edinburgh/United Kingdom

Contact E-mail Address: i.wilson@edinimage.com

Introduction: The primary indication for c-Met targeted optical imaging agents is the potential for earlier detection of lesions during colorectal cancer screening, including flat lesions that are difficult to detect by normal white light endoscopy. We have evaluated the potential benefit of EM-137 and analogues beyond colorectal cancer screening since c-Met is up-regulated in many other cancers.

Aims & Methods: We have synthesised analogues of EM-137 where the fluoroscent reporter was replaced by a radiouclide chelating moiety for PET imaging. The use of this agent alongside EM-137 could enable the PET localization of the lesions prior to surgery guided by fluoroscent signals. Through a systematic analysis of scientific literature databases, and the Human Protein Atlas, we have identified more than 13 different types of solid cancer that are amenable to PET imaging for which there is evidence for c-Met as a target. We believe that imaging of c-Met with EM-137 in these indications has the potential to positively impact critical problems in the existing patient care path and reduce morbidity, mortality, and healthcare costs. We have assessed: 1) the healthcare problem, the impact on patient care path, and the likelihood of adoption by clinicians 2) the hardware landscape; whether imaging hardware required is commercially available or is being developed, and feedback from clinicians in the US and EU 3) our confidence in c-Met as a valid imaging target to address the healthcare problem.

Results: We have identified a number of promising applications within Digestive Oncology; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by utilising imaging of c-Met with EM-137. Compatible imaging systems are commercially available for these indications. There is also strong evidence for c-Met as a biomarker in stratification in Barrett’s oesophagus (BO), a potentially precancerous lesion with the risk of progression to oesophageal cancer. Progression rates are low and overall survival rates in BO patients are similar to the general population. However, due to the poor prognosis of oesophageal cancer, patients with BO lesions are managed by regular endoscopic surveillance and biopsy. This means that there is arguably a disproportionate healthcare burden relative to the level of risk.

Conclusion: Gastric cancer, locally advanced rectal cancer, and bile duct cancer surgery all have strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EM-137 having the potential to have high impact and improve curative procedures in serious, life-threatening conditions. An imaging agent that enabled more accurate risk stratification of BO patients would lead to a change in patient management, with the potential to affect the type of surgery all have strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EM-137 having the potential to have high impact and improve curative procedures in serious, life-threatening conditions. An imaging agent that enabled more accurate risk stratification of BO patients would lead to a change in patient management, with the potential to affect the type of surgery.
P1584 LONG-TERM OUTCOME OF ENDOSCOPIC TREATMENT OF SYMPTOMATIC ENTERIC STRICTURES IN CROHN’S DISEASE

Department Of Gastroenterology, Hepatology And Endocrinology, Robert Bosch Hospital, Stuttgart/Germany

Introduction: Endoscopic treatment of enteric strictures in patients with Crohn’s disease (CD) is well established; however, long-term outcome is unknown.

Aims & Methods: All patients with CD, who had undergone endoscopic therapy of symptomatic strictures at Robert-Bosch-Hospital Stuttgart from 2008 – 2017, were included in this retrospective cohort study. A follow-up was available for 131/135 (97%) patients with a mean of 30.1 months (0 to 103).

Results: A total of 452 endoscopic interventions (mean 3.4 per patient, median 2 per patient, range 1–69 treatments) were performed in 135 patients (female n = 67/male n = 68, mean age 47.5 years, BMI: 22.8 ± 4.98 kg/m², duration of illness: median 25.1 months). In 165 cases, the dominant structure was located in the ileocecum, in 105 in the colon, esophagus (90), duodenum (54), upper intestine (26), lower intestine (11) or stomach (1). In 166 and 286 cases, there was an anastomotic and non-anastomotic structure present, respectively. Treatment consisted of hydrostatic balloon dilatation (n = 447); bougienage (4), and iSEMS (1). Dilatation was performed to a mean of 14 mm (SD: 2.4, range 7 to 24 mm). In seven cases complications occurred after endoscopic treatment (bleeding: n = 5; infection: n = 1; perforation: n = 1) which resulted in an extension of the hospital stay (n = 5), antibiotic therapy (1) and surgery (1). Immediate clinical success was observed in 438 of 452 of cases (96.9%). A single intervention was performed in 61/135 patients (45.2%), two interventions in 36 (26.7%), and three or more in 38 (28.1%). In 41 of 135 patients (30.4%), surgical treatment of the structure was required in the course of disease.

Conclusion: Endoscopy of symptomatic structure in CD is safe and effective. Repetitive dilation is feasible with a significant reduction of clinical symptoms, and surgery was required in about 30% of patients at long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic dilation is an effective treatment in oesophageal strictures, but recurrences may require frequent and repeated dilations in the long term. Several trials have been conducted to determine the efficacy of intralesional steroid injection in the treatment of benign oesophageal reflux oesophageal strictures, since the first pediatric case series was published in 1969. However, a meta-analysis has not been carried out yet.

Aims & Methods: The aim of the analysis is to summarise the results and establish evidence in support or against the complementary treatment. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). Two reviewers conducted a comprehensive search on databases from inception to February 2016, to identify trials, comparing the efficacy of dilation with injection combined with intralesional steroid injection. A meta-analysis was conducted on the data using the random-effects method by DerSimonian and Laird, because of the high level of the heterogeneity. There were 45 articles found in Embase, 55 in PubMed, and 6 in the Cochrane database. Altogether 11 articles were suitable for analyses, after exclusion of duplicate articles, case reports, results from non-human and pediatric studies. These studies involved 373 patients in total. The periodical dilation intervention was combined with dilation and injection. The combined treatment was compared with dilation alone group (95% CI: 0.777; 0.482, p-value: 0.004). The dysphagia score was comparable in 5 studies, but in this case no significant difference could observed between the two groups (standardized mean difference: 0.274, 95% CI: 0.822; 1.165, p-value: 0.510).

Conclusion: Our meta-analysis showed a significant improvement in the periodical dilation index and total number of repeated dilations in the patients treated by intralesional steroid injection as well. We recommend the use of intralesional steroid injection for benign reflux oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to the role of esophageal SEMS in patients with advanced esophageal cancer and expected survival longer than 6 months. Disease control was defined as successful deployment of the stent in the correct position. Clinical success was defined as relief of dysphagia 1 week after placement.

This was a retrospective study of patients with clinical dysphagia and advanced esophageal cancer who underwent SEMS placement with a stent dwell time of greater than 6 months. In all patients the indication for stent placement was dysphagia due to esophageal malignancy.

Results: Forty-to-five patients were followed for 298 days (183–861 days). At the end of follow-up the mortality was 93%. The majority of lesions were located at the proximal/middle esophagus (55%), and were traversable using an ultrathin gastroscope in 79% of patients; in no patient could a standard upper endoscope be passed. In nine patients (15 migrations, 8 overgrowth/ingrowths and 2 stent-induced fistulae). The median stent patency was 236 days (19–513). Two AEs occurred within 30 days of stenting, 7 occurred between 30–90 days, 7 occurred between 90–180 days, and 9 occurred after 180 days. Endoscopic management was attempted in every SEMS-related AE (20 patients required a second SEMS, 2 had successful SEMS repositioning and 1 was treated with argon plasma; 2 SEMS were removed without the need for further therapy), with a clinical success of 100%, however, in 7 patients the previously treated AE recurred (in overgrowths and 3 migrations). Multivariate analysis showed that strictures traversable with an ultrathin gastroscope were associated with a higher risk of AEs (OR 11.7, 95% CI [1.2–114.6], p = 0.035).

Conclusion: Long-term esophageal stenting in patients with advanced esophageal malignancies is associated with a high prevalence of AEs without an impact on mor-tality, and most could be managed endoscopically. Strictures traversable only using an ultrathin gastroscope are a risk factor for AEs.

Disclosure of Interest: All authors have declared no conflicts of interest.

available in many centers and have revolutionized the management of iatrogenic bile duct injuries and vascular injuries.

Aims & Methods: Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focusing on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients post-cholecystectomy complications were referred to intervention radiology unit in our university hospital. We had 9 males and 21 females (age range: 18-66 years). Patients presented with biliary leaks (n=12), benign biliary strictures with intrahepatic biliary dilations (n=21), postoperative hemorrhage (n=2), biliary bleeding related to hepatic artery pseudo-aneurysm (n=1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n=16), sequential dilatation of benign stricture with increasing catheter calibers over 6 months followed by manometric studies before catheter withdrawal (n=6), biliary stenting with plastic stent (n=2), Insertion of pigtail catheter (n=15), preoperative progressive pneumo-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n=1), and selective embolization of bleeding hepatic pseudo-aneurysm (n=1) using tissue adhesives (n=Butyl 2 Cynoacrylate).

Results: All percutaneous procedures were technically successful. No recorded bleeding related hepatic artery pseudo-aneurysm (n=1). Angiography was done for: bleeding recurrence (36.2%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%). Multidisciplinary meetings were convened in 45% patients undergoing endovascular procedures for the management of biliary leaks. The reasons for deciding not to embolize were: absence of active bleeding (80%), suboptimal embolization result (10%) or post embolization complication (n=4).

Disclosure of Interest: All authors have declared no conflicts of interest.

PI590 WHAT IS THE ROLE OF ANGIOGRAPHY IN ACUTE COLONIC AND SMALL BOWEL BLEEDING?

R. Vale Rodrigues1, P. Amaro1, M. Ferreira1, M. Barros1, P. Donato1, L. Tomi1

Introduction: Angiography is a diagnostic and therapeutic modality that is widely available for upper gastrointestinal bleeding but is used less frequently when the source of bleeding is placed distally to the Treitz angle.

Aims & Methods: To assess the usefulness of angiography in the diagnosis of colonic and small bowel bleeding and to determine the efficacy and complications of therapeutic procedures. Retrospective study; we included all patients with colonic and small bowel bleeding that were submitted to arteriography with or without embolization, admitted to the gastroenterology department of a tertiary hospital between February 2006 and November 2016. Statistics: Chi-square/Fisher exact test, T-student.

Results: Fifty patients (n=50) were evaluated, 63.6% male, mean age = 75 years (29–95). Angiography was done for: bleeding recurrence (36.2%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%). The aetiology after angiographic study was: presumed diverticular (n=28), angietasis (n=8), confirmed diverticular (n=6), tumor (n=5), post-mucosectomy/polyectomy (n=4), unclarified (n=12), others (n=3): Deulafoy, ileum ulcers, radiation proctitis. Angiography showed additional clinical information in 58% of patients (n=17). Twenty-three patients (34.8%) underwent arterial embolization, all with technical success, with bleeding recurrence in 3, of which only one was submitted to surgery; there were 2 cases of bowel ischemia. The reasons for deciding not to embolize were: absence of active bleeding (90.7%) and end-vealus bleeding (9.3%). There were no differences between the groups in demographic data, comorbidities, mortality, source of bleeding, haemoglobin at admission/diagnosis and discharge and creatinine (p > 0.05). Arterial embolization was more frequent if hemodynamic instability (p = 0.029); The average time of hospital stay the was lower in the group submitted to embolization (8.8 vs 11.5 days, p = 0.014). Overall, 11 patients died, due to: re-bleeding/hypovolemic shock (n = 5), exacerbation of comorbidities (n = 3), hospital acquired infection (n = 2) or post embolization complication (n = 1).

Conclusion: Arteriography was a valid option for the diagnosis of colonic and small bowel bleeding; allowed therapeutic intervention in more than one third of patients, with 87% of clinical success and reduction of hospitalization time.

Introduction: Surgery for radical treatment of oesophageal cancer carries significant inherent risk. Objectively Identifying patients that are high risk of complications is of importance. The aim of this study was to assess the prognostic value of physical fitness variables determined objectively by cardiopulmonary exercise testing (CPET) in patients undergoing potentially curative surgery for oesophageal cancer (OC) within an integrated recovery programme.

Aims & Methods: Consecutive 180 OC patients (106 ACA, 11 SCC, 3HGD) underwent preoperative CPET with prospective recording of morbidity and survival. Non-parametric receiver operating characteristic (ROC) curves and logistic regression were used to assess the relationship between CPET variables and postoperative morbidity severity score (MSS).

Results: Of 180 patients, 120 were included for analysis (median age 65 yr., 100 male, 75 neoadjuvant therapy); 60 did not proceed to surgery and were excluded. Postoperative morbidity and mortality occurred in 83 (69%, CD4 ≥ 27, 22.5%) and 4 (3.3%) patients respectively. ROC curve analysis showed oxygen uptake (peak VO2) gave an area under the ROC of 0.66 (95% CI 0.55 to 0.77, p = 0.006) and optimum cut-off of 25 ml/kg/min (sensitivity 80%, specificity 84%). Anaerobic Threshold (AT) gave an area under the ROC of 0.62 (95% CI 0.51–0.74, p = 0.048) and optimum cut-off of 10.5 ml/kg/min (sensitivity 60%, specificity 44%). Multivariable analysis revealed peak VO2 to be the only independent factor to predict morbidity severity CD3 ≥ 3 (OR 0.85, 95% CI 0.75–0.97, p = 0.018). Cumulative survival was associated with operative MSS (Chi2 4.892, DF 1, p = 0.027) but not with CPET variables.

Conclusion: CPET is a significant predictor of morbidity after oesophagectomy with peak VO2 the most important factor.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI592 PROPENSITY SCORE ANALYSIS OF 18-FDG PET/CT ENHANCED STAGING IN PATIENTS UNDERGOING SURGERY FOR OESOPHAGEAL CANCER

N. Patel1, K. Fok2, D. Chan3, C. Brown1, A. Powell1, T. Abdelrahman1, P. Fielding2, A. Roberts2, W. Lewis1
1General Surgery, University Hospital Wales, Cardiff/United Kingdom
2Radiology, University Hospital Wales, Cardiff/United Kingdom

Introduction: PET/CT has become an integral part of the staging pathway for malignant disease. PET/CT is conducted for patients with metastatic cancer (OC), primarily used to identify occult distant metastases unseen by conventional radiological modalities. The aim of this study was to analyze the effect of PET/CT introduction on overall survival and assess patterns of recurrence after oesophagectomy.

Aims & Methods: Consecutive 496 patients undergoing oesophagectomy for cancer [median age 63 (31–80) yr., 395 male, 425 ACA, 71 SCC, 325 neoadjuvant therapy] were studied. Two hundred and twenty-three patients underwent PET/CT enhanced staging protocols and the primary outcome measure was overall survival based on intention to treat.

Results: Overall 3-year survival pre-PET/CT was 42.5% compared with 57.8% post-PET/CT (Chi2 6.571, df 1, p = 0.010). On multivariable analysis, t stage (HR 1.486 [95% CI 1.27–1.74, p = 0.001], p stage (HR 1.116 [95% CI 1.05–1.20, p = 0.001) and PET-CT (HR 0.689 [95% CI 0.53–0.89, p = 0.004) were independently associated with duration of overall survival. Recurrent cancer was observed in 125 patients (51.4%) pre-PET/CT; compared with 74 patients post-PET/CT (37.8%, p = 0.015), and was less likely to be distant in location after PET/CT inception (39.5 vs. 27.0%, p = 0.006).

Conclusion: PET/CT enhanced staging is a significant and independent factor associated with improved survival in patients undergoing oesophagectomy for cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI593 PREDICTION OF LYMPH NODE METASTASIS FOR SUPERFICIAL ESOPHAGEAL CANCER WITH USING RANDOM FOREST ANALYSIS

M. Takeuchi1, H. Kawakubo1, K. Fukuda1, R. Nakamura1, K. Suda1, N. Wada1, Y. Kitagawa1
1Department Of Surgery, Keio University School of Medicine, Tokyo/Japan

Contact E-mail Address: masaty71222@gmail.com

Introduction: Although surgical techniques and perioperative management for esophageal cancer has been developed, it cannot be still safe to be performed esophagectomy. Therefore, endoscopic submucosal dissection (ESD) for the superficial cancer has been increased. We also need to consider the risk of lymph node metastasis before treatment in each patient and the aim of this study is to predict lymph node metastasis for superficial esophageal cancer.
Aims & Methods: Seventy patients who were diagnosed as clinical T1a-MM, T1b-SM1 or T1b-SM2 and underwent esophagectomy at the Keio University, Tokyo, Japan between July 2000 and June 2016 were enrolled in this study. Patients who underwent esophagectomy as additional resections after ESD were included. We used random forest analysis to predict lymph node metastasis. Results: There were 62 men and 8 women in this study. The mean age of all patients was 62.8±8.2 years. The major location of the tumor was in the middle thoracic esophagus (Upper: Middle, Lower: 13: 39: 18, respectively). 14 patients had lymph node metastasis in pathological findings; 2 patients (25%) were diagnosed as clinical T1a-MM, 2 patients (6%) were pT1b-SM1 and 10 patients (31.3%) were T1b-SM2. Random forest technique (2000 trees) resulted in an estimate of error rate of 25.7%. Lymph node metastasis was most associated with the factor of pathological T (relative importance 100%) followed by lymph nodes (89.7%) and N (72.3%).

Conclusion: Random forest analysis confirmed the predictors for lymph node metastasis such as pathological T and lymphatic invasion. Disclosure of Interest: All authors have declared no conflicts of interest.

P1594 PROGNOSTIC SIGNIFICANCE OF CARDIORESPIRATORY FITNESS, BODY COMPOSITION ANALYSIS, AND SYSTEMIC INFLAMMATORY RESPONSE IN UPPER GASTROINTESTINAL CANCER

N. Patel1, P. Blake1, J. Wheat1, C. Brown1, A. Powell2, T. Abdelrahman3, W. Lewis1
1General Surgery, University Hospital Wales, Cardiff/United Kingdom

Contact E-mail Address: neilrama@hotmail.com

Introduction: Malnutrition is associated with higher rates of operative morbidity and therefore represent potentially reversible prognostic risk factors. Bioelectrical Impedance Analysis (BIA) is a non-invasive, reproducible and simple means of accurately measuring body composition.

Aims & Methods: The aim of this study was to assess the prognostic value of body composition variables determined objectively by bioelectrical impedance analysis (BIA) and subjectively by analysis potentially undergoing surgery studies in the gastric and cancer (GC) with an enhanced recovery programme (ERP). Consecutive 168 OG patients [median age 65 (24–86) yr., 131 male, 105 OC, 64 GC, 157 ACA, 8 SCC, 3 Neuroendocrine] underwent preoperative measurement of systemic inflammatory response [NIR, including FBC, CRP, Albumin, and modified Glasgow Prognostic Score (mGPS)]. Patients underwent multi-frequency (0.5 kHz, 50 kHz and 100 kHz) BIA assessment using a Maltron Bioscan 920 (Maltron International Ltd, Essex, UK), and Cardiac Pulmonary Exercise (CPX) assessment was performed selectively (70 OC, 27 GC). Primary outcome measure was Clavien Dindo (CD) morbidity severity score (MSS) of ≥3.

Results: Oesophagectomy was performed in 106, gastoecomy in 64, and laparotomy only in 23 patients. Postoperative morbidity and mortality occurred in 75 (45%, CD ≥ 3 in 35, 21%) and 4 (2%) patients respectively. On univariable analysis, MSS ≥3 was associated with anastomotic leakage (p = 0.011), CRP (p = 0.001), mGPS (p = 0.011), intra-cellular water (ICW, p = 0.041), and extracellular water content (p = 0.015). Multivariable logistic regression revealed ICW content [OR: ICW < 3.7 compared to ≥ 3, 3.7 < DR ≤ 3.9, DR ≥ 3.9] correlated significantly with improved DFS in HCC (p = 0.006). OR: ICW 3.7 to 3.9 vs. > 3.9 was (95% CI: 1.06–1.41) p = 0.006 and CRP [OR: ICW < 3, DR ≤ 3.7 vs. > 3.7, OR 1.03 (99–106) p = 0.076] to be independently associated with MSS.

Conclusion: Seven-fold variation in morbidity severity was observed after OG cancer surgery. Multicenter and NIR were the most important prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1595 COPING AND QUALITY OF LIFE AFTER ESOPHAGECTOMY FOR CANCER

Introduction: Coping is one the most challenging and burdening operation for its length and the variety of anatomical districts involved. Nowadays, as consequence of the improved postoperative mortality, effects of esophagectomy are chronic and quality of life (QoL) has become one of the main outcome measures to evaluate treatment. Coping is the ability of managing stressful situations such as postoperative conditions. At present, there are no studies focusing on coping after esophagectomy for esophageal cancer.

Aims & Methods: The aim of this study is to describe coping styles and QoL after esophagectomy. EORTC QLQ-C30 was used to assess QoL while the modified Glasgow Prognostic Score (mGPS) was used to evaluate treatment. Coping is the ability of managing stressful situations such as postoperative conditions. At present, there are no studies focusing on coping after esophagectomy for esophageal cancer.

Results: There were 62 men and 8 women in this study. The mean age of all patients was 62.8±8.2 years. The major location of the tumor was in the middle thoracic esophagus (Upper: Middle, Lower: 13: 39: 18, respectively). 14 patients had lymph node metastasis in pathological findings; 2 patients (25%) were diagnosed as clinical T1a-MM, 2 patients (6%) were pT1b-SM1 and 10 patients (31.3%) were T1b-SM2. Random forest technique (2000 trees) resulted in an estimate of error rate of 25.7%. Lymph node metastasis was most associated with the factor of pathological T (relative importance 100%) followed by lymph nodes (89.7%) and N (72.3%).

Conclusion: Random forest analysis confirmed the predictors for lymph node metastasis such as pathological T and lymphatic invasion. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The tumor micro environment plays a vital role in the growth of malignancies. Through for example tumor-infiltrating lymphocytes (TILs) it influences overall and disease free survival of patients in various cancer entities. Therefore, the ability to identify these features is critical. However, there is great heterogeneity about how to quantify these cells in the tumor tissue. Therefore, we present a novel Quantification of the Tumor Stroma (QTS) Algorithm to reliably and accurately quantify cells of the tumor stroma and to perform a correlation with survival after resection of patients with hepatocellular carcinoma and pancreatic cancer.

Aims & Methods: Immunohistochemical staining of CD3 and CD8 antigens in frozen sections of metastatic colorectal cancer (mCRC) and ovarian cancer (mOC) as well as in paraffin sections of hepatocellular carcinoma (HCC) and pancreatic cancer (PCa) was performed. For each entity 10 slides per antigen were examined (n = 80). In these different entities reliability and accuracy of computed quantification was tested in order to develop a general algorithm (Figure: First, reliability of identification of hot spots was investigated using two blinded observers. Hot spots were defined as regions with the highest density of TILs. The absolute amounts of cells were compared with the intra-class-correlation coefficient (ICC). Second, accuracy was tested. To examine whether quantification of 1 vs 3 hot spots yields accurate results CD3+, CD8+ ratio as well as the absolute cell numbers were compared with the ICC respectively. Third, computed counting methods (1) ZEN 2 software counting (ZC), (2) ImageJ software with subjective threshold (ISC) and (3) ImageJ with colour deconvolution (IAC) was used. All methods were compared to a manual (gold standard) using a linear regression analysis. Finally, 60 resected tumor tissues of HCC and 30 of PCa were retrieved. 3 hot spots have been selected for every slide and groups of low/high infiltration of CD3+ and CD8+ lymphocytes have been created according to the median value. Then, statistical correlation with overall survival (OS) and disease free survival (DFS) was performed.

Results: Quantification results from 2 blinded observers for reliable detection of hot spots were 0.949 in mCRC, 0.843 in mOCa, 0.805 in HCC and 0.957 in PCa. The ICC for the ratio of CD3/CD8 in 1 hot spot compared to the average from 3 hot spots was consistent in all groups. The absolute cell count in 1 vs 3 hot spots of CD8+ was statistically not significant. Nineteen patients completed the questionnaire twice, with 3–6 months between the two fillings. The mean differences of the COPE-NVI scales were not statistically significant.

Conclusion: In our series, patients used Positive Attitude to manage everyday life for their daily activities (i.e. emotions, physical functioning, social and family functioning) were used, social abilities were compromised. Moreover, after surgical intervention coping seemed to be a stable feature. Therefore, in the early follow-up after surgery multidisciplinary team can identify and the coping features of patients in order to improve them to get a good social support.

P1598 LIVER RESECTION IN OBESE PATIENTS WITH HEPATOCELLULAR CARCINOMA
Hepato-biliary-pancreatic Surgery, Hyogo College of Medicine, Hyogo/Japan
Contact E-mail Address: iwama3307@yahoo.com
Introduction: Hepatocellular carcinoma has been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.
Aims & Methods: We performed curative LR in 471 patients with HCC between 2001 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the safety and the benefit of laparoscopic partial hepatectomy and left lateral segmentectomy in the obese patients.
Results: Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatic steatosis were significantly more frequent in the obese patient group than in the non-obese patients group (p = 0.05). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 1.4%). No significant difference was found in relapse-free survival rate, or overall survival rate between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However the operation time (265 min vs. 397.5 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group (p = 0.05).
Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

Introduction: We developed a CT-based patient-specific holographic surgical simulation navigation system of immersive mixed reality (MR).
Aims & Methods: The aim of this study is to identify its benefit of simulating, analyzing and evaluating operative surgical treatment options in gastrointestinal and hepato-pancreato-biliary surgery.
Methods: We used our original immersive MR application using HoloLens, that is a pair of MR smartglasses built-in head-mounted display. By reconstructing the patient-specific 3D surface polygons of each organ out of the patient’s MDCT images, MR anatomy was displayed on the glasses three-dimensionally during actual surgery. We performed pre- and intra-operative imaging with better visualisation of the surgical anatomy and spatial awareness using visualisation of surgical instruments in relation to anatomical landmarks.
Conclusion: We report illustrative benefits of the immersive MR in surgical planing, simulation, education, and image-guided navigation. These could overcome the limitations of the conventional image-guided surgery.

P1599 TIMING OF ELECTIVE CHOLECYSTECTOMY AFTER ACUTE CHOLECYSTITIS - A POPULATION-BASED STUDY
A. Popowicz, G. Sandblom
Department Of Clinical Science, Intervention And Technology, Karolinska Institute, Stockholm/Sweden
Contact E-mail Address: agnieszka.popowicz@ki.se
Introduction: Acute cholecystitis as treatment of acute cholecystitis is standard of care. However, many patients are still treated conservatively and undergo elective cholecystectomy 2–12 weeks following the primary admittance is postulated as a good timing for an elective surgery but there are no studies on the optimal timing for delayed cholecystectomy.
Aims & Methods: The aim of our study was to determine when it is most advantageous to operate when less is less in the obese patients group in the non-obese patients group. All patients treated for acute cholecystitis in Sweden during the years of 2006 and 2013 were identified through the Swedish Inpatient Register. This cohort was cross-linked with the Swedish register for gallstone surgery. Only patients with surgical outcome was retrieved. The impact of time from admission to surgery with regards to operative time, percentage of procedures completed with minimally invasive technique, peri and postoperative complications and bile duct injury or bile leakage was analysed with logarithmic transformation of time and multivariate logistic regression adjusting for gender and age.
Results: During the years 2006 to 2013, 31091 patients were treated for acute cholecystitis in Sweden. After exclusion of patients that did not perform surgery, were not registered in GalRx and patients that were treated with acute cholecystectomy 8532 patients were identified that underwent planned surgery. In multivariate linear regression analysis with adjustment for gender and age the risk for peri- and postoperative complications, bile duct injuries and bile leakage and amount procedures not completed with minimally invasive technique decreases with time from the last hospitalization to surgery. All p-values < 0.05.
Conclusion: For those patients undergoing elective cholecystectomy after an acute cholecystitis the safety increases if surgery is performed later than 30 days after discharge.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1600 MIXED REALITY SURGERY USING CT-BASED PATIENT-SPECIFIC IMMERSIVE 3D Holograms ENHANCED SPATIAL AWARENESS IN HEPATO-PANCREATO-BILIARY AND GASTROINTESTINAL SURGERY

tertiary centers has been performed. DPTS are traced by the pharmacies of our two hospitals and all cases of DPTS were ana lysed thanks to the database of the pharmacies of our two hospitals since May 2014 (first DPTS used for non bariatric upper digestive tract fistula) or 10 french DPTS have been used according to the size of the fistula and the choice of the physician. Technical success was defined as the possibility to place the DPTS within the fistula. Clinical success was a composite endpoint combining clinical amelioration of the patient and healing of the fistula allowing the removal of the DPTS.

Results: 17 patients have been treated by DPTS from May 2014 to March 2017 for an upper digestive tract leaks non linked to bariatric surgery. Fistulas were linked to a lewis-santy surgery in 8 patients (47%), total gastrectomy in 4 (23.5%), Boerhaave syndrome in 2 (11.8%) and endoscopic perforation in 2 (11.8%) and aortic surgery in 1 (5.9%). An infected collection was present in 16 patients (94%) and 11 (64.7%) suffer from a clinical sepsis. The mean delay between surgery and the diagnostic of fistula was 10 days and the delay of the diagnosis of fistula and the endoscopic drainage by DPTS was 16.4 days. DPTS were used alone in first intention in 11 cases (64.7%), in first intention in combination with a SEMS in 11.7% and in second intention after failure of a SEMS in 3 (11.7%). All patients had a technical success and 15 patients (88.8%) had a clinical success. The mean delay for refeeding after DPTS was 17 days. The mean ablation time of the DPTS was 73 days. 3 patients presented a complication (1 stenosis, 1 bleeding and 1 migration).

Conclusion: Endoscopic internal drainage using DPTS seems to be an interesting therapeutic option for upper digestive tract leaks non-linked to bariatric surgery. DPTS are effective, safe, cheap and could replace SEMS not always well tolerated and with a high rate of migration. Prospective multicenter studies are needed to confirm these preliminary results.

Introduction: Peritoneal collections and abscesses after Bariatric Surgery (BS) leaks are dreaded complications. Laparoscopic or open surgery and percutaneous CT drainage are the current indications. Endoscopic management of pancreatic collections is a rationale for Endoscopic Peroral Drainage (EPOD) approach in cases of BS leaks with abdominal collections.

Aims & Methods: The aim of this study is to evaluate utility and safety of EPOD to treat peritoneal collections and abscesses secondary to BS leaks. Methods: This retrospective study included 65 consecutive patients from 2007 to 2015 at a single center (40 Sleeve gastrectomy, 25 gastric bypass) after 5 to 21 days from...
surgery. Patients presented heart rate over 120 bpm. Images from CT showed left side diverting subcutaneous small free abdominal ileostomy. An Upper GI endoscopy was performed to localize the leak opening and enter to peritoneal cavity. Either 9.8 or 5.8 mm diameter gastroscopy were used. In 10 patients with orifices smaller than 5.8 mm balloon dilatation of the leak opening allowed peritoneal access. The time interval from AK to reversal procedure (100 to 700 ml). Sample was taken for bacterial cultures. The cavity was flushed and suctioned out with sterile saline solution (200 ml to 1000 ml). In cases of inadequate location surgical drains catheters were repositioned or replaced using endoscopic forceps and snare. Fibrinolytic (assemblies to facilitate peritoneal navigation. In 5 patients without surgical drainage systems one laparoscopic port was localized inside peritoneum and re-opened under endoscopic vision to allow drainage catheters placement. In 8 patients peritoneal adhesions were endoscopically lib- erated using endoscopic forceps or knives to facilitate peritoneal navigation.

Results: Heart rate returned to normal within 24 hours and leukocytosis improved after 72 hours. In 50% of patients heart rate returned to normal immediately. Average time for the whole procedure was 45 minutes. Abdominal catheters were removed between 7 and 18 days once full resolution of the drainage was achieved. Twenty patients were discharged within the first 24 hours. The rest were discharged between 3 and 8 days. Partially covered SEMS were placed for 6 to 8 weeks leading to complete closure of leaks. There were no adverse events related.

Introduction: A diverting loop ileostomy with procedure of intestinal resections and adhesions decreases morbidity logistic regression indexes and may even reduce the risk of anastomotic leak as shown in recent studies. Reversal of a temporary ileostomy is considered a simple surgical procedure presenting with a low morbidity and mortality rates. However, ileostomy reversal may be asso- ciated with number of complications requiring reoperation, with anastomotic leak (AL) being most critical often leading to failure in restoration of digestive tract continuity.

Aims & Methods: The study aimed at evaluating the results of restoration of intestinal continuity in patients primarily operated on for colorectal cancer and inflammatory conditions. We assessed the frequency of failure following the surgical procedure of diverting loop ileostomy closure. The study was conducted at a tertiary referral center. 147 adult patients (89 men, mean age 50.5y ± 16.71 and 58 women, mean age 49.9y ± 16.99y) were enrolled to this study. All included patients underwent surgical closure of a temporary loop ileostomy at the Department of General and Colorectal Surgery, Lodz, Poland, between 2004 and 2016. The data was collected in a retrospective manner basing on hospital records. The analyzed parameters included length of hospitalization, gender, age, BMI, comorbid conditions, American Society of Anesthesiologists classification score (ASA) and the character of postoperative complications. Statistical analysis was used to evaluate the correlation between the variables and postoperative complications.

Results: AL as a postoperative complication with the need to create a new ostomy occurred in 15 patients (10.2%). Higher values of BMI and older age have been noted compared to noncomplicated surgeries (27.54 vs. 23.36 and 23.02 ± 3.98; p < 0.001; 54.53 ± 12.3 vs. 50.25 ± 15.95; p = 0.029 respectively). There was significant correlation between patients’ gender and the incidence of AL (p = 0.087). The number of prior surgical procedures and ASA scale positively correlated with the prevalence of AL (p = 0.038; p = 0.003 respectively). There were no significance difference between patient with colorectal cancer and inflammatory conditions (p = 0.534). The average time interval from prior surgery to reversal of the stoma and AL occurrence were not related and did not reveal statistical significance (8.5 ± 4.11 vs. 7.24 ± 4.47; p = 0.25). Univariate logistic regression demonstrated that a BMI levels, patients’ age and average time inter- val from prior surgery to reversal procedure were significantly associated with failure of restoration of intestinal continuity. Multivariate logistic regression analysis showed that patients undergoing loop ileostomy clouser. Patients with elevated BMI, older age and shorter aver- age time interval from prior surgery to reversal procedure presented higher risk of failure of intestinal continuity restoration. The incidence rate of AL was similar in patients operated primarily on for inflammatory conditions and color- ecial cancer.

Introduction: The impact of body composition on the outcomes following pan- creaticoduodenectomy is still unclear.

Aims & Methods: The aim of this study was to analyze the association between body composition the postoperative complications and 90-day mortality in patients undergoing biliopancreatic cancer surgery. Retrospective study of patients with pancreatic, ampullary or bile duct carcinoma that underwent sur- gery between March 2012 and October 2016. Body composition (skeletal muscle mass, total body fat area, subcutaneous fat area and muscle radiation attenuation) was assessed in diagnostic or staging computed tomography (CT), in axial images at the level of the 3rd lumbar vertebra. Postoperative complications were recorded according to Clavien-Dindo classification and categorized as minor (grade I–II) or major (grade III+). Patient mortality was calculated.

Results: Fifty-nine patients were analyzed and 11 were excluded due to unavailable CT scan at our institution. Forty-eight were included, 28 were men, with a mean age of 70.9 ± 8.5 years. The incidence of major complications was 25% and 90-day mortality was 8.3%. On simple logistic regression of factors associated with major complications skeletal muscle area (OR 0.97, 95% CI 0.94–1.00, P = 0.09) and index (OR 0.91, 95% CI 0.81–1.00, P = 0.09) showed a trend for protective effect. On multivariate logistic regression, skeletal muscle mass index was a protective factor (OR 0.89, 95% CI 0.79–0.99, P = 0.05) and longer surgery (1.01, 95% CI 0.99–1.03, P = 0.07) was associated with higher incidence of major complications. The receiver-operator characteristic (ROC) curve showed an acceptable power of discrimination on major complications using a model with skeletal muscle index and surgery duration as independent variables (area under the curve of 0.736). On simple logistic regression surgery duration (OR 1.02, 95% CI 1.00–1.06, P = 0.05), visceral fat area (OR 1.02, 95% CI 1.00–1.04, P = 0.02) and ASA grade (OR 1.05, 95% CI 1.00–1.09, P = 0.04) were associated with higher 90- day mortality whereas muscle radiation attenuation had a protective effect (OR 0.88, 95% CI 0.76–0.99, P = 0.05).

Conclusion: These results suggest that low values of skeletal muscle and muscle radiation attenuation as well as high values of visceral fat and low muscle mass that are associated with worse clinical outcomes following biliopancreatic cancer surgery.

3Emergency Surgery, Emergency Children’s Clinical Hospital “G. Alexandrescu” Bucharest, Bucharest/Romania

Contact E-mail Address: anamariabrad@yahoo.com

Introduction: Gastroschisis is a ventral body wall defect through which protrude mainly large and small intestines. The disease’s clinical course and prognosis can often depend on both surgical techniques, severity of the defect, accompanying anom- alies and complications.

Aims & Methods: We performed a retrospective study based on the analysis of patients records admitted to our hospital Neonatal Intensive Care Unit between January 2000 and December 2016. The aims of this study were to evaluate defect’s incidence, management and outcome of patients with gastroschisis in our institution.

Results: During the period 2000–2016 the overall incidence of gastroschisis in our NICU was 1.3% (107/8026). The diagnosis occurred in 125 cases (43.9%). The surgical procedure was performed in 111 cases (88.6%). The postoperative mortality was 33% (37 cases). Since 2011, 84% of cases were born during the period of normal birth. The variables associated with worse clinical outcomes were found in 5 cases (free abdominal fluid, pneumothorax, peritonitis, infection of the abdominal cavity, septic shock).

Conclusion: The management of neonates with gastroschisis depends on several factors including the status of herniated organs, the size of abdominal cavity, the presence of other associated congenital anomalies and last but not least on the resources and experience of the neonatal interdiscipinary team. Significant changes occurred in the management of gastroschisis in our Unit and as conse- quence, the outcome of patients with gastroschisis has dramatically improved during the studied period.

P1608 ASSESSING THE EFFECT OF ETHNICITY ON URINARY METABOLIC PROFILES IN INFLAMMATORY BOWEL DISEASE
1Gastroenterology, Imperial College Healthcare NHS Trust, London/United Kingdom
2Division Of Digestive Diseases, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom
3Division Of Computational And Systems Medicine, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: l.hicks@imperial.ac.uk

Introduction: Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also separate ulcerative colitis (UC) from Crohn's disease (CD) in Caucasian (Cau) cohorts (1). Diet and lifestyle also have an effect on metabolic profiles (2), and variations in fermentable fiber intake. A randomized, double-blind, crossover trial was performed. Patients with quiescent UC (Partial Mayo Score 0) were randomised to two periods of 14 days, one with a high fiber diet (CD) and one with a low fiber (HC) diet. Clinical and dietary data were collected. Samples from 405 IBD patients (283 Caucasian and 122 South Asian) and 137 healthy controls (98 Caucasian and 48 South Asian) were analysed by HNMR spectroscopy. Clinical and dietary data were collected. Orthogonal partial least squares discriminant analysis (OPLSDA) was performed to examine whether there were differences in metabolic data between Cau and SA. R2 (variance), Q2 (quality assessment) and p values (validity) for each model were described.

Bacteroides was negatively correlated with the calculated Crohn’s disease activity indices. Our findings showed the specific characteristics and dysbiosis of fecal microbiota within Chinese IBD patients. In addition, the abundance of the Bacteroides was significant lower in active CD group than in inactive CD group. Furthermore, it was negatively correlated with the CDAI, indicating that the Bacteroides could be related with the disease activity.

P1611 HYPOXIA-MEDIATED IRON UPTAKE PREVENTS INFLAMMATORY GENE EXPRESSION IN THE INTESTINAL EPITHELIUM THROUGH THE REGULATION OF NF-κB BINDING ACTIVITY

Gastroenterology And Hepatology, University Hospital Zurich, University of Zurich, Zurich/Switzerland

Contact E-mail Address: PedroAntonio.Ruiz-Castro@usz.ch

Introduction: We sought to elucidate the effects of iron supplementation on hypoxia-mediated responses in the intestinal epithelium. For this purpose, serum starved Caco-2 monolayers were subjected to normoxia (21% O2) or hypoxia (0.2% O2) in the presence and absence of ferric ammonium iron citrate (FAc) and the iron chelator deferoxamine (DFO). Total RNA was isolated and changes in the expression of tumor necrosis factor (TNF), interleukin (IL)-1β, DMT-1, FPN and ferritin was assessed by real-time quantitative PCR. Western blot analysis was performed with antibodies against ferritin, p-NF-kB, HIF-1α, p-STAT6, p-STAT3 and LC3. mRNA synthesis in Caco-2 cells under hypoxia was blocked using actinomycin D. Chromatin immunoprecipitation experiments were carried using antibodies against NF-κB and primers for promoter binding regions of TNF and IL-1β. Healthy volunteers (n = 10) were subjected to hypoxic conditions resembling an altitude of 4,000 m above sea level for 3 h using a hypobaric chamber. Serum samples were collected the day prior to hypoxia, and one day, one week and one month after hypoxia.

Conclusion: Environmental hypoxia has been stabilised to influence the development of inflammatory bowel disease (IBD). Adaptive responses to low oxygen tension are mediated through hypoxia inducible factor (HIFs), which are tightly regulated by oxygen and iron levels through the action of hydroxylases. Dietary iron is mainly absorbed by duodenal enterocytes through the divalent metal transporter (DMT)-1. Once iron is inside the enterocytes, it is either sequestered into ferritin or transported out of the enterocyte into the circulation by ferroportin (FPN). Regulation of uptake, storage and export of iron is mediated by signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic iron requirements. Central to systemic iron regulation is the liver hormone hepcidin, which regulates and is regulated by systemic iron levels. Hepcidin expression is induced by cytokines and results in anemia of inflammation.

Results: Hypoxia induced the mRNA expression of TNF and IL-1β concomitantly with the iron transporters ferritin (Ftn) and Tfrc and the iron transport inhibitor hepcidin (Hamp). All mRNA expression levels were decreased under hypoxic conditions, thereby promoting iron uptake. The iron chelator deferoxamine (DFO) induced HIF-1α stabilization and TNF mRNA expression under both normoxic and hypoxic conditions. Conversely, iron supplementation induced ferritin protein accumulation under normoxic and hypoxic conditions, and reduced TNF and IL-1β mRNA expression. Interestingly, neither iron chelation nor iron supplementation reduced hypoxia-mediated p-NF-kB. Iron induced p-MTOR and blocked autophagy. Iron overload enhanced decay of TNF, but not IL-1β mRNA. Iron also prevented binding of NF-κB to the promoter of TNF and IL-1β. Healthy volunteers presented reduced serum levels of iron, as well as transferrin saturation. Ferritin levels were unchanged indicating absence of inflammation and suggesting enhanced intracellular iron accumulation in enterocytes following hypoxia.

Conclusion: Our results suggest that hypoxia-mediated iron uptake is crucial to counteract hypoxia-induced pro-inflammatory gene expression, and identify iron intracellular uptake and storage as a hypoxia protective mechanism to reduce mucosal inflammation.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: In both forms of inflammatory bowel disease (IBD), Crohn’s disease (CD) and ulcerative colitis (UC), inflammation of the gut wall is associated with extracellular tissue acidification. Low extracellular pH stimulates the family of proton-sensing G-protein coupled receptors (GPCRs). Ovarian cancer G-protein coupled receptor 1 (OGR1), T-cell death-associated gene 8 (TDAG8) and G-protein coupled receptor 4 (GPR4), which activate sepsis and infl ammatory signaling cascades. Recent studies reported a link between IBD and this family of pH-sensing receptors; in genome-wide association studies (GWAS), TDAG8 has been identified as an IBD-risk gene. The mechanism behind the interaction between treatment groups (5-ASA, Azathioprine and Steroids) and OGR1 and TDAG8 is alleged to act in opposition by regulation of the inflammatory response; enhancing or inhibiting infl ammatory pathways respectively, however the interplay between OGR1 and TDAG8 is unclear.

Aims & Methods: In this study we aimed to investigate the role of OGR1 in IBD patients. Expression of OGR1 in surgical specimens from non-IBD (n = 5), CD (n = 10) and UC (n = 10) patients was determined by immunohistochemistry, RT-qPCR and Western blotting. Clinical disease activity was assessed by the Harvey–Bradshaw Index (HBI) and the Modified Truelove and Witts activity index (MTWAI) for CD and UC patients, respectively. Nonparametric Spearman’s rank correlation analysis was performed.

Results: OGR1 immunostaining of human surgical samples from non-IBD patients revealed OGR1 expression mainly in lamina propria cells, with weaker staining in epithelial cells. OGR1 staining in IBD patients was stronger compared to controls; however, in IBD patients OGR1 is highly expressed in both epithelial cells and the lamina propria. Further, paired samples taken at the same time, from non-infamed and inflamed intestinal tissue from IBD patients showed stronger OGR1 staining in the inflamed mucosa compared to the non-inflamed mucosa. Accordingly, mRNA and protein expression of OGR1 was significantly increased in inflamed IBD compared to non-IBD patients. Furthermore, a significant positive correlation was observed between OGR1 expression and the clinical score in both the non-infamed (rs 0.7311, p = 0.0069) and the inflamed mucosa (rs 0.7698, p = 0.0034).

Conclusion: The expression of OGR1 is significantly increased in patients with IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role of OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target among the pH-sensing receptors involved in IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: IBD is a chronic inflammatory disease of the gastrointestinal tract that affects the mucosal lining of the colon and rectum. It is characterized by chronic inflammation, ulceration, and regeneration of the mucosa. The disease can affect either the large intestine (distal colon and rectum) or both the small intestine and the large intestine. The prevalence of IBD is increasing worldwide, and it is estimated that there are currently over 3 million people with IBD in the United States alone. The exact cause of IBD is unknown, but it is believed to be a combination of genetic, environmental, and immunological factors.

Aims & Methods: This study aimed to assess the effect of vitamin D replacement in patients with IBD, with and without ultrasound changes. The study was conducted over a period of 6 months, during which patients were given vitamin D supplementation in addition to their regular treatment for IBD. The effects of vitamin D supplementation were evaluated through changes in disease activity, markers of inflammation, and quality of life.

Results: Eight patients with active IBD and non-IBD controls received 40,000 units of vitamin D weekly for 12 weeks. No demographic differences were noted among the groups. Mean baseline 25(OH) vitamin D levels were 22 ± 9 nmol/L, and vitamin D supplementation increased mean 25(OH) vitamin D to 111 (range 71–158) nmol/L (P < 0.001), and increased para-thyroid hormone levels from mean 4.3 to 3.3 pmol/L (p = 0.017). No change in baseline medications for UC took place in patients with UC, except for one patient with active UC who ceased his 5-aminosalicylic acid. Faecal calprotectin levels reduced from median 275 to 91 μg/g (p = 0.023) in patients with active ulcerative colitis, but did not change in patients with inactive colitis or non-IBD controls. Similar improvements in albumin, platelet count and symptomatic disease activity indices were noted. There were no changes in overall bacterial diversity. There was a trend towards an increase in abundance of Ruminococcus gravis post vitamin D supplementation in active UC patients, but this did not reach statistical significance.

Conclusion: Vitamin D supplementation was associated with reduced intestinal inflammation in patients with active UC. A randomised controlled trial evaluating vitamin D in IBD is recommended, along with further investigation of potential mechanisms by which vitamin D may alter specific microbial composition.

Introduction: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Aims & Methods: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Results: Luminal UDCA-LPE reduced the PLA2 activity in stool by 36.4%.

P1616 THE IMPACT OF THE RS8005161 POLYMORPHISM ON G PROTEIN-COUPLED RECEPTOR GPR65 (TDAG8) PH-ASSOCIATED SIGNALING IN INTESTINAL INFLAMMATION
Abt. für Innere Medizin IV, Universität Heidelberg, Heidelberg/Germany
Contact E-mail Address: wolfgang.stremmel@med.uni-heidelberg.de

Introduction: Inflammatory bowel diseases (IBDs), Crohn’s disease (CD) and ulcerative colitis (UC) are typically associated with a decrease in local pH. Inflammatory mediators and the pattern of secretion may vary according to their phenotype. We have previously reported that STAT6-dependent macrophages mediate mucosal repair after TNBS-induced acute colitis and that, in a chronic model, STAT6-deficient animals accumulate macrophages expressing the CD6 marker that promote intestinal fibrosis.

Aims & Methods: We aim to analyse whether the expression of pro-fibrotic mediator TGFβ is related with this macrophage phenotype and the relevance of these cells in murine intestinal fibrosis. Murine peritoneal macrophages obtained from both WT or STAT6 (-/-) mice were treated with IL-4 (20 ng/ml), IL-10 (10ng/ml) or vehicle and the mRNA expression of CD16, TGFβ and the collagen synthesis markers (TIMP1, TIMP2) was evaluated in all groups and a positive and significant correlation between CD16 mRNA and TGFβ expression was found (r = 0.5729, P < 0.01; MMP2: r = 0.3958, P < 0.0071).

Results: A positive and significant correlation between CD16 mRNA and TGFβ expression was found (r = 0.5729, P < 0.01; MMP2: r = 0.3958, P < 0.0071).

Introduction: The intestinal inflammation is reduced by electrical stimulation of the different vagus nerve. Cholinerig output may be a target to minimize tissue damage in autoimmune disease. Cholinerig neural output can modulate innate immune responses through stimulation of α7 nicotinic acetylcholine receptors (α7nAChR). GTS-21, a selective α7nAChR agonist, has previously demonstrated to inhibit the inflammation associated with rheumatoid arthritis (RA). In this study we investigate whether GTS-21 protects against DSS-induced colitis and its potential mechanism.

Aims & Methods: Male BABL/c mice (8–10 weeks old, n = 32) were randomly divided into 4 groups: normal control group, DSS-induced group, GTS-21 treatment control group (DSS-induced mice treated with GTS-21), a-BGT group (DSS-induced mice treated with a-BGT and GTS-21) (n = 8, each group). DSS group was given final concentration of 3.5% DSS drinking water, the treatment group was treated with GTS-21 (30 μg/ml intraperitoneal injection per day, a-BGT group was pre-treated with a-BGT (0.1 mg/kg/day, intraperitoneal injection) for 30 min prior to GTS-21 injection, and the control group received saline. Caco2 cells were randomly divided into 4 groups; normal control group, TNF-α induced group, GTS-21 treatment control group, a-BGT group. TNF-α group of Caco2 cells were exposed by 25 ng/ml TNF-α, GTS-21 group were given 100 ng/ml GTS-21 for 30 min prior to TNF-α; a-BGT group pre-treated with a-BGT (50 μg/ml) for 30 min prior to GTS-21 injection. BAY 11-2085 (NF-κB inhibitor) group was given 50 μg/ml BAY 11-2085 for 30 min prior to TNF-α. Disease activity index, macroscopic scores, and colonic damage were determined. The intestinal permeability of mice was measured by fluorescein-isothiocyanate-dextran (FITC-Dextran) method. Western blot was used to detect the tight junction protein and NF-κB associated protein expression.

Results: Compared with DSS-induced mice, DAI score decreased and colon length improved after administration of GTS-21 (9.1 ± 0.74 cm vs 6.85 ± 0.53 cm, P < 0.01). The α7nAChR antagonist a-BGT can eliminate those protective effects (Figure 1). The intestinal permeability improved after administration of GTS-21 compared with DSS-induced mice (49.52 ± 28.59 μg/ml vs 157.4 ± 32.40 μg/ml P < 0.05), whereas a-BGT can block the decrease (115.5 ± 10 μg/ml vs 49.52 ± 28.59 μg/ml P < 0.05) (Figure 2, 3). The expressions and distribution of tight junction protein in DSS-induced mice were enhanced after treatment with GTS-21 (p < 0.05) (Figure 4, 5). 4. GTS-21 attenuated the NF-κB activation (p < 0.05) and β-catenin translocation reversed the inflammatory effect of GTS-21 (p < 0.05) (Figure 6). 5. GTS-21 improves the distribution of tight junction protein. The mucosa of CD patients accumulate pro-inflammatory macrophages and the expression of Wnt10b in human macrophages are enhanced after treatment with GTS-21 in both, control (83.3 ± 4.8%) and CD (89.6 ± 3.9%). In these GTS-21+cells, an increased expression of CD16 in CD mucosa was observed (Control: 34.5 ± 6.8%; CD: 59.7 ± 6.4%) while that of CD163 was similar in both groups (control: 72.8 ± 8.4%; CD: 85.2 ± 7.3%). The analysis of Wnt10b in CD206+ showed a significantly higher expression in CD patients (56.6 ± 4.2%) than in control samples (30.1 ± 10.4%). Additionally, CD68+ macrophages were more abundant in the CD206+ marker (Control: 29.3 ± 10.2%).

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as CD68+ cells while those macrophages expressing the M2 marker CD206 after their phenotype increasing the expression of both, CD16 and CD163. This may represent the profibrotic mediator Wnt10b.

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequently observed extra intestinal finding, prevalence of which varies from 6% to 74%. It’s of great importance to determine and treat anaemia as it lowers patients’ life quality and leads to labour loss. The main causes of anaemia in IBD are iron deficiency anaemia (IDA) and anaemia of chronic disease (ACD).

In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD). We conducted a retrospective study on 465 patients, who were diagnosed with IBD and followed up at our hospital from June 2015 to June 2016 (male: 254, female: 211, average age: 47 ± 14.4, Crohn disease (CD): 257, Ulcerative Colitis (UC): 108).

Aims & Methods: In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD). We conducted a retrospective study on 465 patients, who were diagnosed with IBD and followed up at our hospital from June 2015 to June 2016 (male: 254, female: 211, average age: 47 ± 14.4, Crohn disease (CD): 257, Ulcerative Colitis (UC): 108).

According to WHO criteria, anaemia stages are below 13 g/dL in men and 12 g/dL in women.

Results: In our study, we determined that 50.3% of total 465 patients had anaemia, which was more frequent in women then men (64% vs. 39%, p < 0.001).

Anaemia frequency was higher in CH cases (57%) then in UC cases (41%) (p = 0.001). CD involvement were as follows: 54.5% in ileal involvement, 60.4% in colonic involvement and 58.5% in ileocolonic involvement. Furthermore, 27.5% of UC patients had proctitis (EI) involvement while 41% of them had proctitis in left colitis (E2) and 31.5% had pancolitis involvement. There was no significant relation between anaemia frequency and duration of disease (p = 0.216). We specified the following types of anaemia: IDA only 32.9% (77), ACD only 5.5% (13), IDA and ACD combination 6.8% (16), anaemia from B12/folic acid deficiency 6.4% (15), anaemia with other causes 17.5% (41) and anaemia with no etiology 30.7% (72). 50% of patients with anaemia received treatment; 23% of IDA patients had oral iron intake and 41% of them had parenteral iron treatment while 53% of patients who were suffering from megaloblastic anaemia got B12/folic acid treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: We found that almost half of all IBD patients (50.3%), whom we followed up, had anaemia, the most frequent reason of which was IDA. Almost half of these patients received anaemia treatment. We should increase the treat- ment rate in our IBD patients that have anaemia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1622 SUCINATE RECEPTOR (SUCNR1) MEDIATES INFLAMMATION IN A MURINE MODEL OF COLITIS

D.C. Macias Ceja1, D. Ortiz-Masía2, P. Salvador1, L. Gisbert-Ferrández2, S. Coll-Puig2, C. Hernández1, J.V. Esplugues1, S. Calatayud1, M.D. Barrachina3

Introduction: IBD is a chronic disorder of the gastrointestinal tract characterized by disruption of epithelial barrier function and gut inflammation. Evidence supports a relevant role of succinate, an intermediate of the tricarboxylic acid cycle, in inflammation and the succinate receptor, SUCNR1, has been recently linked with rheumatoid arthritis3.

Aims & Methods: To analyze the role of SUCNR1 in a murine model of colitis induced by TNBS. WT or SUCNR1+/− mice received TNBS (3.5 mg/20g mice, intrarrectally) or vehicle (EtOH 40%) and were weighed daily (results are expressed as percentage vs the weight at day 0) and mice were sacrificed 2 and 4 days after TNBS administration. Colon length and mucosal histology were evaluated. The colon mucosa gene expression levels of iNOS, Arginase I, COX-2, T NF-α, IL-1β, IL-6 and IL-10 were analyzed by qPCR.

Results: Treatment of mice with TNBS induced a loss of body weight that peaked 2 days after treatment. Subsequently, mice began to recover and, four days after treatment, body weight reached similar values to those of control animals. In TNBS-treated SUCNR1+/−/ mice compared with TNBS-treated WT mice: a) the loss of body weight was significantly (P < 0.05) attenuated (96.99 ± 0.7% vs 91.78 ± 1.1%); b) the reduction in colon length was prevented (6.6 ± 0.2 vs 5.2 ± 0.1 cm); c) the score was significantly reduced (3.5 ± 0.2 vs 4.8 ± 0.5) two days after TNBS treatment. d) The expression in the pro-inflammatory molecules was significantly prevented (P < 0.05) (table 1) while no significant differences were detected in the expression of COX-2 (Table 1).

Table1: mRNA expression of different molecules detected in the colon of TNBS-treated mice. Results are expressed as fold induction vs the value obtained in WT mice.

P1623 ZIP7 INDUCES DISRUPTION OF THE INTESTINAL BARRIER THROUGH ACTIVATION OF ENDOPAS-
MIC RETICULUM STRESS IN INFLAMMATORY BOWEL DISEASE

J. Sun, Q. Zhan, F. An

Wuxi People's Hospital, Nanjing Medical University, wuxi/China

Contact E-mail Address: jingdianjing99@126.com

Introduction: Inflammatory bowel disease (IBD) is a chronic intestinal inflammation disease with a tendency to recurrence, and intestinal barrier disorders play a key role in its development. The deficiency of zinc is a clinical manifestation and could worsen the development of IBD. Zinc Transporter Member 7 (ZIP7) is a gatekeeper protein in the intracellular release of zinc in cells. Recent studies revealed that ZIP7 helps to maintain the intestinal mucosal integrity. In addition, ZIP7 can regulate endoplasmic reticulum stress.

Aims & Methods: Our aim was to investigate the role of ZIP7 in IBD initiation and progression. We investigated the expression of ZIP7 in the intestinal mucosa of IBD patients and in interleukin-10 gene-deficient (Il10−/−) mice, and assessed the relation between ZIP7 and disease activity. ZIP7 upregulated/downregulated lenvus was used to infect IEC6 and HIEC cells, then we evaluated the expres-
sion of inflammatory factors, mucosal tight junction proteins (Occludin and ZO-
1), and proteins related with endoplasmic reticulum stress (IRE1, XBP1, TRAF2, ASK1 and p-JNK). In addition, we used siRNA to silence IRE1 and SP600125 to inhibit the JNK pathway respectively, then evaluated the effect of endoplasmic reticulum stress on mucosal tight junction proteins.

Results: We found that ZIP7 was downregulated both in the intestinal mucosa of IBD patients and in Il10−/− mice, which was associated with disease activity. In IEC6 and HIEC cells, the expression of mucosal tight junction proteins was consistent with the level of ZIP7, but the expression of inflammatory factors and endoplasmic reticulum stress associated proteins were on the contrary. After the silence of IRE1 and the inhibition of JNK pathway, the expression of mucosal tight junction proteins was partly resumed in ZIP7 downregulated cells.

Conclusion: ZIP7 induces disruption of the intestinal barrier, which was asso-
ciated with activation of endoplasmic reticulum stress in IBD. It is expected to provide a novel mechanism of IBD and provide a new target for the treatment of IBD.

P1624 EFFECT OF T CELL ACTIVATION AND INFLAMMATION ON THE INTERACTION BETWEEN T CELLS AND ENTERIC GLIAL CELLS

Introduction: In contact with immune cells, astrocytes participate in the enteric nervous system. These interactions have been implicated in the development of IBD and in the regulation of immune responses. The aim of this study was to evaluate how T cell activation and inflammation influence the interactions between enteric glial cells (EGC) and T cells.

Aims & Methods: To analyse the interactions between immune and enteric neural cells, EGC isolated from the myenteric plexus of the rat digestive tract were co-cultured with CFSE-labeled T cells. Impact of T cell activation on neuro-immune interactions was investigated by treating cells with anti-CD3/anti-CD28 antibodies. To determine whether inflammatory conditions favored the contacts between glial and immune cells, EGC were treated with LPS or TNF/IL-1 prior their exposition to T cells. After 2 hours, non-adherent cells were removed and the T cells interacting with EGC (S100+) were counted. Immunocytochemistry were also used to characterize the subpopulations of T cells (CD4+, CD8+) that contact glial cells.

Results: Analyses reveal that non-activated T lymphocytes are capable of interacting with EGC. They also show that activation of T cells with anti-CD3/anti-
CD28 antibodies increases the number of T lymphocytes interacting with EGC. Interestingly, an increased number of EGC-T cell interactions was observed after pretreatment of EGC with inflammatory stimuli. This phenomenon was also noted with activated T cells. Characterization of T cells show that both CD4 and CD8 cells are capable of contact with EGC.

Conclusion: Our present data reveal that EGC interact with T cells. These con-
tacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experimental conditions are required to characterize these neuro-
immune interactions but they suggest that EGC-T cell contact may play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association François Aupetit.

Introduction: Enteric glial cells (EGC) are essential to intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC impact on IEB permeability was altered in an inflammatory environment and in CD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytokines TNF (lL18+HL1beta) at 1 to 100 ng/ ml) or LPS for 2 or 4 days. Reactive EGC phenotype where characterized and reactive EGC functional impact on IEB permeability was studied (i) in vitro using human intestinal epithelial cells (IEC) in a non-contact co-culture model, or (ii) in vivo by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB permeability after T treatment with untreated or LPS treated EGC. LPS or T treatment had no significant effects on IEC alone. In vivo colon wall grafting with control EGC did not modified the permeability whereas colon wall grafting with EGC preconditioned by T significantly reduced
Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In enteric inflammation, liquid chromatography tandem mass spectrometry was performed using high sensitivity liquid chromatography tandem mass spectrometry. Consequences of flolan PGII analogue supplementation were evaluated in a DSS-induced mice model of colitis, measuring disease activity index (DAI), inflammation (pro-inflammatory cytokine mRNA) and IEB permeability (sulfonic acid flux). Molecular mechanisms involved were assessed by quantification of junctional and pro-proliferative or pro-apoptotic protein expression (western blot and immunostaining). Eventually PGII impact on reversing IEB breakdown was assessed in vivo measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IEB biopsies both treated or not with flolan.

Results: Biopsies from IBD patients had lower PGII production compared to control patients, and addition of flolan reduced their permeability. In vivo PGII supplementation significantly reduced DAI, and inflammation (Interferon mRNA) as well as reduced IEB permeability. DSS-induced clivage of Caspase 3 is normalized by flolan. Ex vivo measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IEB biopsies both treated or not with flolan.

Conclusion: This study not only presents a role of PGI2 in controlling IEB permeability but also shows that EGC patients have lost these reactivity. This could define EGC as active players in CD pathogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims: To analyze the serum levels of following cytokines: interleukin (IL)-17A and IL-21, and 22 in UC patients both in the acute stage of disease and remission. Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay for TH17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

Results: Statistically significant increase of IL-17A level (15 pg/ml [12.11;23.38]) and IL-22 (14.68 pg/ml [11.29;17.19] respectively) was observed in patients with UC both in acute stage and remission compared to controls (7.36 pg/ml [5.18;8.06], p = 0.0007, p = 0.00029 respectively). The same trend was observed regarding IL-21, which median values were higher both in acute stage (156.51 pg/ml [133.44;233.53]) and remission (144.02 pg/ml [133.44;154.43]) compared to control group (98.31 pg/ml [89.14;124.86], p = 0.065). IL-21 was revealed that IL-23 which stimulates Th17 functional overactivity was a sign of autoimmune type of inflammation. Statistically significant increase of IL-10 in remission (21.93 pg/ml [17.3;35.3]) compared to controls, however differences were not statistically significant (p = 0.06; p = 0.172). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. Statistically significant increase of IL-10 in remission (27.99 pg/ml [17.53;33.55]) compared to controls (4.36 pg/ml [3.26;15.25], p = 0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;35.35] compared to controls, however differences were not statistically significant (p = 0.06; p = 0.172). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. Statistically significant increase of IL-10 in remission (27.99 pg/ml [17.53;33.55]) compared to controls (4.36 pg/ml [3.26;15.25], p = 0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;35.35] compared to controls, however differences were not statistically significant (p = 0.06; p = 0.172). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation.

Disclosure of Interest: All authors have declared no conflicts of interest.
The steroid-refractoriness is a common complication of ulcerative colitis (UC). Different responses to glucocorticoids have been implicated in corticosteroid failure. However, there are no conclusive mathematical models generated by means of Systems Biology.

**Results:**

Evaluation of 18 proteins. ANP32e is a secreted protein, mainly detected in the plasma (e.g. RelA), glucocorticoid receptor transcription (e.g. NR3C1 and NCOA3) and angiogenesis (e.g. VEGF), mainly. But among these 18 proteins, the ANP32e has never been related to either steroid-refractoriness or ulcerative colitis. ANP32e is associated with high C-reactive protein (CRP) levels and increased CRP reactivity. In addition, the association of ANP32e with CRP levels does not change over time but increases in the levels of CRP reactivity.

**Conclusion:** In conclusion, this study has identified a potential new MoA related to UC steroid-refractoriness involving chromatin remodeling modifications.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Results: (before vaccination, 4 weeks after the first vaccination, 4 weeks after the second vaccination group and booster group were randomly assigned to adult patients with Crohn’s disease or ulcerative colitis, and quadrivalent influenza vaccine. Serum samples were assigned to adult patients receiving immunosuppressant therapy, especially infliximab, even with a serological response rate to influenza vaccination was low in IBD (0.06–0.91); H3N2: 0.19 (0.06–0.56)).

Aims & Methods: Single vaccination group and booster group were randomly assigned to adult patients with crohn’s disease or ulcerative colitis, and quadrivalent influenza vaccine was administered subcutaneously. Serum samples were collected at 3 points (before vaccination, 4 weeks after vaccination and after the end of influenza season) in the single group and 4 points in the booster group (before vaccination, 4 weeks after the first vaccination, 4 weeks after the second vaccination and after the end of the influenza season). Antibody titer against each influenza strain was measured by inhibition of hemagglutination.

Results: A total of 132 patients with IB were randomly assigned to single vaccination and booster groups. Eighteen patients received immunomodulatory monotherapy and 20 received anti-TNF-a agents. Nineteen patients received combination therapy of immunosuppressant and anti-TNF-a agents. No significant difference between the single vaccination group and booster group was observed (geometric mean titer: H1N1: p = 0.81; H3N2: p = 0.79; B/Phuket: p = 0.82; B/Texas: p = 0.84). In patients treated with infliximab, serum protein level (SP%) and serum conversion rate (SC%) tended to be lower in influenza. A strain in patients who maintained blood concentrations of H1N1: OR 0.37 (0.11–1.21); H3N2: OR 0.22 (0.07–0.68), SC%; H1 N1: 0.23 (0.06–0.91); H3N2: 0.19 (0.06–0.56).

Conclusion: Serological response rate to influenza vaccination was low in IB patients receiving immunosuppressant therapy, especially infliximab, even with a quadrivalent influenza vaccine.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The global incidence of inflammatory bowel disease (IBD) is increasing. Migration may influence disease epidemiology. The UK demographics are affected by sustained migration from South Asia. The incidence of UC in South Asians (SA) was previously reported as higher than the Caucasian population.1,2 These single centre studies were done over 20 years ago. The current epidemiology of IBD in the multiethnic UK is unknown.

Aims & Methods: We aimed to describe the UK incidence of IBD and distribution within ethnic groups. Census data (2011) was used for background population size, ethnic groups and to identify areas with high SA populations where Leicester and Pakistan were the predominant groups. The incidence was calculated by using the number of subjects in each ethnic group in the background population as the denominator. Adult patients (>16 years) with newly diagnosed IBD (fulfilling Copenhagen diagnostic criteria) were prospective recruited over one year in 7 catchment areas with high SA population. Data including demographics ethnic codes and disease phenotype (Montreal classification) was collected onto the Epicomp database. Chi-squared test was used to detect differences in IBD incidence between ethnic groups. A p < 0.05 was considered significant.

Results: Over 1 year IBD was diagnosed in 351 cases; 219 ulcerative colitis (UC), 107 Crohn’s disease (CD) and 26 inflammatory bowel disease unclassified (IBDU). Collective crude incidence rates were 15.54/100,000 for IB, 9.69/ 100,000 for UC, 4.80/100,000 for CD and 1.01/100,000 IBDU. (Table 1) Crude IBD incidence rates varied between populations: lowest was 6.81/100,000 in Peninsula, North Manchester and highest 26.11/100,000 in Leicester. Overall incidence of UC was higher than CD (9.69/100,000 vs. 4.80/100,000) and was consistent for all populations except Penny (3.31/100,000 for CD and 2.76/100,000 UC). Of the total number of IBD cases recruited 298/351 were coded as Caucasian, Indian or Pakistani. IBD, UC and CD incidence was similar between Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucasians and Pakistanis (p < 0.001). Data for disease phenotype was available for 160/219 patients with UC (24% E1, 42% E2 and 34% E3). There was no significant difference in disease extent between ethnic groups.

Conclusion: The incidence rates for IBD in seven urban populations in England is similar to recent data from Western Europe (IBD 18.5/100,000, UC 9.8/100,000 CD 6.3/100,000 and IBDU 2.4/100,000). Ethnic-adjusted incidence rates showed that Indians have higher incidence of UC than Caucasians and Pakistanis with highest observed incidence in Northwest London. These findings are consistent with previous data suggesting that Indians have a higher predisposition for UC. Genetic, environmental and dietary factors may be responsible for differences and further analyses are underway. Better understanding of the susceptibility of Indians to UC may lead to the underlying cause of UC.

Introduction: Inflammatory bowel diseases (IBD)-Crohn's disease (CD); ulcerative colitis (UC) are lifelong inflammatory conditions of the gastrointestinal tract. IBD-associated colorectal cancer (CRC) accounts for approximately 1–2% of all cases of CRC. Although data on mortality rates in IBD patients are controversial, CRC has been shown to account for approximately 10–15% of all deaths among IBD patients. The aim of our nationwide registry was to prospectively collect IBD-related mortalities and all types of malignancies diagnosed in the Hungarian IBD population.

Aims & Methods: Data on all death and malignancies developed between 2015 and 2016 in IBD patients were recorded. Each member of the Hungarian Society of Gastroenterology were prospectively interviewed 3 monthly by personal emails to report both death and malignancies observed in their patient population. Demographic and clinical data including previous immunosuppressive and biological therapy were also collected.

Results: Fifty-five newly diagnosed malignancies were reported (mean age: 49.3 years old, mean disease duration was 16.9 years; male:female ratio was 34:21). 30 Crohn’s disease (CD) patients and 25 ulcerative colitis (UC) patients were recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under general anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Disclosure of Interest: Aims & Methods: The aim of the study was to assess AC HPV infection prevalence and its risk factors in an IBD population. The ‘Human Papillomavirus Anal infection’ - PAPILLAN- study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under general anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) colonization may increase risk of malignancy in infected colonic tumours.

Aims & Methods: The aim of the study was to analyze whether gut colonization with ESBL-E producing Enterobacteria may influence the risk of clinically relevant disease activity increase in ulcerative colitis (UC) and in Crohn’s disease (CD). All consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016) were included in the study, interviewed, rectal swabs were collected, Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines. To clinically evaluate disease activity UC patients were evaluated according to Mayo score, 2016 classification, adapted Truelove and Witts criteria and CD patients according to Crohn’s disease activity index (CDAI), suggested by ECCO IBD guidelines (2016).

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1635** ANAL CANAL HUMAN PAPILLOMAVIRUS (HPV) INFECTION IN MEN AND WOMEN UNDERGOING COLONOSCOPY: PREVALENCE AND RISK FACTORS, HIGH INFECTION RISK IN MEN AND WOMEN UNDERGOING COLONOSCOPY.

Introduction: The increasing incidence of anal canal (AC) carcinomas in men and women requires better knowledge on Human papillomavirus (HPV) infection at this site and its risk factors. Higher incidence of AC cancers in Crohn’s disease (CD) patients is strongly suggested in the literature, without knowledge on HPV involvement. A gastroenterology population offers the opportunity to study a mixed and non-sexually at-risk population and to study anal HPV infection in CD patients.

Aims & Methods: The aim of the study was to assess AC HPV infection prevalence and its risk factors in an IBD gastroenterology population. The ‘Human Papillomavirus Anal infection’ - PAPILLAN- study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under general anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Results: A total of 469 consecutive patients (median age 54 years, 52% women) had suitable anal swabs for HPV DNA detection. Among them 101 had inflammatory bowel diseases (IBD); 70 had CD. 112 patients had at least one immunosuppressive treatment for IBD or another condition. Overall 34% of the population had a detection of any HPV type in AC smears. HR HPV prevalence was 18%, LR HPV prevalence was 9% and HPV16 prevalence was 7%. Most prevalent HR HPV types were, by decreasing order: HPV16, HPV51, HPV52 and HPV39. Among all patients with HPV positive or HR HPV positive samples, 65.6% and 65.9% were women, respectively (p = 0.0001; p = 0.0035, compared to men). Regarding medical history, HR, HPV and HPV16 prevalence were significantly higher in Crohn’s disease patients (30%, p = 0.0051; 14%, p = 0.0072, compared to the rest of the study population). Eleven/12 patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated female gender and history of sexually transmitted disease with the presence of any HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV.

Conclusion: We demonstrated that CD patients harbor more frequent AC infection with HR HPV and that immunosuppressive treatment is an independent risk factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

50% had mild to moderate to severe disease activity, according to Montreal classification disease activity section (p = 0.037). Most of the UC patients with out ESBL-E colonization (n = 81; 91%) had mild disease activity, whereas half of the patients with ESBL-E colonization (n = 6; 50%) had moderate disease activity, according to modified Truelove and Witt's criteria (p < 0.001). Most of the CD patients without ESBL-E colonization (n = 38; 90%) had moderate disease activity, whereas most of the patients with ESBL-E colonization (n = 3; 60%) had severe disease activity, according to CDAI (p = 0.05).

Conclusion: Gut colonization with ESBL-E might increase disease activity in out-patients with IBD. Such finding could be clinically relevant and help to improve diagnostic and treatment protocols for IBD patients, because eradication of ESBL producing bacteria might reduce IBD disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1636 IS SMOKELESS CESSATION LINKED TO NEW ULTERCATIVE COLITIS CASES? A RESTROSPECTIVE COHORT-BASED HYPOTHESIS

Disclosure of Interest:

Results: The study population was characterized by a high DMFT index with mean value 19.35. There was a significantly higher number of filled (F) and lower number of lost teeth (M) among patients who underwent respective surgery. No significant incidence of IBD in the family was similar in both groups of patients. Type of treatment has no significant impact on DMFT index values. There were no statistically significant differences between UC and CD group in DMFT index, M and F values. However, it has been found that these groups differ in D values which averaged 4.5 and 3.2 for CD and UC groups (p < 0.05). The analysis of both patients' groups with regard to gender showed statistically significant differences in D and F values. The lowest mean D value was noticed in UC females group (2.8) and the highest in CD males (5.2); average F values were opposite-11.4 for UC females and 7.8 for CD males. Statistical analysis of DMFT index among patient from CD and UC groups according to disease phenotype showed no significant differences in DMFT, D and M in both groups. Average DMFT varied from 18.14 for L1 to 20.59 for L4 patients in CD group and from 17.30 for E1 to 20.55 for E2 in UC group. However, significant difference in F values was observed in CD patients: L1 and L2 have lower average F than those with L3 and L4 (6.66; 7.46, 10.25 and 14.00 respectively; p = 0.0215). D values were significantly higher for patients with none or one extraintestinal symptoms (p < 0.05). Results of D values obtained in our study were higher than for healthy population aged 35-44 in Poland (mean D~2).

Conclusion: The results of preliminary POLIBD study among two groups of IBD patients showed similar values in DMFT index and higher average number of carious teeth in CD patients, especially in men.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: maude.grueber@gmail.com

Introduction: Smoking has a differential effect on inflammatory bowel diseases (IBD); deleterious for Crohn's disease (CD) and protective for ulcerative colitis (UC). Thickness of the mucus layer, immune system (cytokines production), microvasculature and intestinal microbiome are potential mechanistic factors influenced by the nicotine and numerous other substances. It has been hypothesized that smoking cessation is associated with the second peak of diagnosis in UC patients after 50 years old. Our aim was to confirm this hypothesis using data on smoking status at IBD diagnosis.

Aims & Methods: Adult IBD patients included in the Swiss IBD cohort from November 2006 to November 2015 were asked about their smoking status at diagnosis. We compared the proportion of former smokers in 10-year groups of UC and CD patients.

Results: 2361 IBD patients (1366 CD, 995 UC) were included in the analysis. Among them 52% of CD ans 24% of UC patients were smokers at diagnosis (proportion of smokers in Switzerland (2014): 29%). Among UC patients we found 52% of UC patients showed similar values in DMFT index and higher average number of carious teeth in CD patients, especially in men.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn's disease (CD) is a chronic inflammatory disease that can affect any section of the gastrointestinal tract. Malnutrition is a common sequela in these patients and many pathogenic mechanisms could be involved such as poor dietary intake, altered energy expenditure, nutrient malabsorption and/or losses.

Aims & Methods: This cross-sectional study aimed to evaluate the resting energy expenditure (REE) in CD patients, in accordance with clinical status of disease, compared to a control group.

Methods: All consecutive adult women were prospectively enrolled, while a group of healthy women, matched for age and weight, served as control group (C). Patients were classified in clinically active disease (CD-A) and clinical remission (CD-R) according to Crohn's Disease Activity Index (CDAI) (> 150 and < 150, respectively). All subjects underwent REE measure by indirect calorimetry with a canopy system, while body composition variables, such as fat-free mass (FFM) and fat mass (FM), were assessed by bio-impedance analysis (BIA).

Results: Finally, forty-two women with CD, 23 with clinically active disease (CD- A: CDAI = 219 ± 53) and 19 in clinical remission (CD-R: CDAI = 83 ± 41) were recruited for the study, while 40 matched-healthy women were enrolled as control group (C). We found that body weight, FFM and phase angle (PA) differed among groups; but age, height and FM did not. Post-hoc analysis revealed that body weight was significantly lower for CD-A in comparison with C (CD-A: 65.7 ± 9.73 kg vs C: 65.4 ± 6.3 kg; p = 0.02). FFM was reduced in women with CD than with C (CD-A: 39.6 ± 4.43 kg and CD-R: 39.5 ± 6.68 kg vs C: 44.4 ± 6.8kg; p < 0.01) while PA was lower for CD-A compared to both CD-R and C (CDAI > 150 and < 150, respectively). All subjects underwent REE measure by indirect calorimetry with a canopy system, while body composition variables, such as fat-free mass (FFM) and fat mass (FM), were assessed by bio-impedance analysis (BIA).

Introduction: In aetiology of inflammatory bowel disease (IBD) role of microbial organisms including those from the oral cavity is taken into account. Oral bacteria are known for biofilm formation and enamel demineralisation leading to the formation of caries cavities.

Aims & Methods: The aim of the study was to determine the state of hard teeth tissues measured by DMFT index in adult patients with ulcerative colitis (UC) and Crohn's disease (CD). The study involved 119 UC and CD patients aged from 18 to 72 (mean 34.45). Disease phenotype at diagnosis was classified according to the Montreal classification and only the patients who had confirmed diagnosis of the entire UC or CD tract were included. Following, the data on the occurrence of extraintestinal symptoms, the incidence of IBD in the family, type of treatment, including surgery, were also collected. The complete assessment of the hard teeth tissues based on the DMFT index (decayed, missing, filled teeth) was performed.

Results: DMFT index was performed. Following, the data on the occurrence of extraintestinal symptoms, the incidence of IBD in the family, type of treatment, including surgery, were also collected. The complete assessment of the hard teeth tissues based on the DMFT index (decayed, missing, filled teeth) was performed.

Magnetic Resonance Cholangiography in Patients with Inflammatory Bowel Disease

A. Belle1, A. Lopez2, V. Laurenç2, C. Baumann3, H. Rousseau4, X. Ory², J. Bronwiczki1, L. Peyrin-Biroulet1
1Gastroenterology And Hepatology, CHU de Nancy, Vandœuvre-Les-Nancy/France
2Service De Radiologie, CHRU de Nancy, Vandœuvre-Les-Nancy/France
3Plateforme D’aide à la Recherche Clinique, CHRU de Nancy, Vandœuvre-Les-Nancy/France

Contact E-mail Address: arthurbelle@hotmail.fr

Introduction: Primary sclerosing cholangitis (PSC) is a rare and devastating complication of inflammatory bowel disease (IBD). There is no standard for the screening of primary sclerosing cholangitis (PSC) in patients with IBD. Magnetic resonance cholangiography (MRC) may replace liver biopsy in this clinical situation. The main objective of this prospective observational study was to assess the frequency of MRC-detected liver abnormalities, including PSC, in adult IBD patients with liver function abnormalities and to identify clinical and biological characteristics associated with these findings.

Aims & Methods: From June 1, 2009 to January 31, 2017, 421 patients were included and screened with MRC: cohort 1 included 206 IBD patients with liver abnormalities; cohort 2 included 28 IBD patients without liver abnormalities; and cohort 3 included 187 non-IBD patients with liver abnormalities. Two senior radiologists independently evaluated MRC findings.

Results: MRC abnormalities were observed in 18% of patients in the cohort 1; 3.6% in the cohort 2; and 31% in the cohort 3 (Table 1). Based on MRC, we found respectively 11.2%, 0%, and 7% of PSC in cohorts 1, 2, and 3. 29.2% of IBD patients with liver abnormalities had infra-clinical PSC. A history of intestinal resection (P = 0.0064), and abnormal alkaline phosphatase values (P = 0.021) were significantly associated to suspected PSC.

Table 1: MRC abnormalities in cohorts 1, 2 and 3

Conclusion: Using MRC in patients with IBD, we found a higher prevalence of PSC than based on clinical symptoms. Systematic screening for PSC using MRC could be recommended in routine practice for IBD patients.

4Mathematical Institute, University of Oxford, Oxford/United Kingdom
5Botnar Research Centre, Centre for Statistics in Medicine, Oxford/United Kingdom
6Wellcome Institute of Molecular Medicine, Oxford/United Kingdom

Introduction: TCUC is a comprehensive real-time web-based programme for patients with UC. It monitors multiple parameters via electronic questionnaires: symptoms, quality of life (QoL), outcomes (eg emergency department visits) and medication adherence. Patients are entered and personalised treatment guidance is formulated. This information, graphically displayed on a traffic light system, is available to the patient and clinical team via the TCUC website, which is housed on a secure National Health Service server. Patients then received email prompts linked to scheduled questionnaires. Monthly home Fecal Calprotectin (FCaI) measurements were incorporated, monthly blood tests collected and flexible sigmoidoscopy performed at entry and after 6 months. Adherence to all questionnaires and samples incorporated, monthly blood tests collected and flexible sigmoidoscopy performed, and once only (outcomes). Patients then received email prompts linked to scheduled questionnaires. Monthly home Fecal Calprotectin (FCaI) measurements were incorporated, monthly blood tests collected and flexible sigmoidoscopy performed at entry and after 6 months. Adherence to all questionnaires and samples calculated. Usage was assessed via the System Usability Scale (SUS) (n = 59) and qualitative interviews (n = 28). SUS broadly classifies usability of a system from poor (<70) to superior (>90). A deductive approach was used for the qualitative coding and analysis.

Results: Sixty-six patients were recruited (recruitment rate 66/240 invitations delivered, 28%). Of 66 patients, 29 (44%) were male, median age 40.7 yrs.

Table 1: Adherence to Questionnaires

Conclusion: Patients with UC will collect digital data in real-time, with good adherence to symptom, QoL, outcome questionnaires and FCaI home testing. Usage was classified as ‘superior’ but further improvements are possible. Larger studies are required to determine cost effectiveness.

Introduction: The majority of Crohn’s disease (CD) develop structuring complications of the disease at some point. The proper selection of patients with potential benefit of therapy escalation is crucial in order to avoid unnecessary bowel damage. The rapid uptake in the affected bowel segment at intravenous contrast-enhanced ultrasound (CEUS) has been shown to correlate with disease activity but there are no data available on the benefit of CEUS for the therapeutic decision making in this clinical setting.

Aims & Methods: The aim of the study was to evaluate the clinical outcomes of CD patients with structuring disease managed based on the CEUS findings. CD patients with structuring disease were recruited from two IBD centres between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS was performed using a power Doppler (SonoVue, Bracco Imaging). Patients having rapid uptake (within 20 second after injection) were indicated for therapy escalation, patients without uptake with obstructive symptoms were referred for surgery; patients without uptake and no obstructive symptoms remained at the stable medication. In patients with the minimal follow-up of one year clinical and endoscopic remission was evaluated.

Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch of biologicals, 1 pts had therapy step-up to antiTNF or thiopurine suppression). Remaining three pts improved subsequently on stable therapy with antiTNF and one patient with longstanding symptomatic colonic stricture was referred for surgery. Ten patients (37%) had no rapid uptake at the CEUS; seven out of these patients had symptomatic structuring disease referred for surgery. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13–23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with no rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in this group continued in therapy after the surgery and none of these patients had recurrence at the surveillance colonoscopy at 12 months.

Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with structuring Crohn’s disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1645 DIAGNOSTIC DELAY AND PREDICTIVE FACTORS FOR CROHN’S DISEASE IN AN ALGERIAN POPULATION
Y. Chelbi, R. Bounloup
Constantine, Ben Badis Hospital, Constantine/Algeria

Contact E-mail Address: Yacinechelbi4@yahoo.fr
Introduction: Crohn’s disease (CD) is a chronic inflammatory bowel disease whose diagnostic delay (DD) is highly variable. A delay in diagnosis of MC (≥6 months) is strongly associated with inappropriate use of Therapeutic Interventions. Factors Influencing SD may be a function of the country’s health system, but also linked to the particular clinical and evolutionary profile of the disease. The objective of this study was to measure the DD of CD, to describe its distribution and evolution over time and to The factors associated with a long DD (≥Q3).

Aims & Methods: All patients with certain or probable CD between 2004 and 2016 identified by The department’s inflammatory disease hospital registry was included. The socio-demographic characteristics collected included: the patient’s residential area at the time of diagnosis in urban, rural or semi-urban, distance from the nearest hospital (CH). Clinical symptoms and phenotype of CD to diagnosis according to the Montreal classification were collected

Results: Among 247 patients with CD; 90 had a median SD of 03 months. A DD ≥ 7 months was considered a diagnostic delay observed in most patients is 157. In univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of enemas (27%), absence of extra-diagnostic manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (32.67%) were associated with a shorter DD. The univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of enemas (27%), absence of extra-diagnostic manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (32.67%) were associated with a shorter DD. Diagnostic delay. Socio-demographic characteristics were not associated with delayed diagnosis.

Conclusion: This study shows that most of the patients, 63.56% have a diagnostic delay significantly associated with the female sex, The young age, the absence of weight loss and a localization of the disease limited to the bowel the penetrating phenotype of disease. No socioeconomic variables or reflective of access to care were found to influence.

Reference
Aims & Method: We intend to know the incidence of tuberculosis in IBD patients under anti-TNF therapy in a single tertiary referral centre, analyzing the tuberculosis screening methods and demographic characteristics. IBD patients treated with anti-TNF therapy before January 2000 and December 2016 were retrospectively analyzed.

Results: During this period 166 patients received anti-TNF therapy. Before anti-TNF treatment, screening for LT was performed through medical history, chest X-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had positive screening and received tuberculosis prophylaxis prior to anti-TNF therapy. Fourteen patients (4.2%) developed tuberculosis while under anti-TNF therapy (four women, mean age 44 ± 7 years and mean IBD duration 10 ± 8 years). Six of them had a negative LT screening (methods: 4 TST and 2 IGRA) and one patient had positive TST screening, been treated with isoniazid before starting anti-TNF therapy. During screening three patients were under immune suppressive and one under corticosteroid therapy. In the IGRA negative screening patients, the diagnosis of tuberculosis occurred within the first 10 weeks after starting anti-TNF therapy. There were five cases of miliary tuberculosis and two of pulmonary disease. Despite difficult diagnosis, all patients were treated successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under anti-TNF therapy was 4.2% and most of them presenting with a severe disease pattern. The therapeutic regime of tuberculosis was effective and no mortality was recorded. This patient had a previously negative screening, two of them with IGRA, been considered a high sensitivity and specificity screening method. Therefore, a surveillance strategy for IBD patients with anti-TNF therapy is needed.

Introduction: The MediCrohn study was designed to evaluate the level of agreement between the Harvey Bradshaw Index (HBI) translated into a patient-based questionnaire completed through a mobile app, and the original HBI questionnaire assessed by the clinician (considered as reference).

Aims & Methods: Patients completed the HBI score through a mobile app designed for both Android and iPhone devices and thereafter (<48 h later), the questionnaire was completed onsite by the gastroenterologist who was blinded for the patients’ responses. We assessed agreement between HBI scores of the clinician and patient on the total sum score and per item. HBI score <5 was considered as inactive disease.

Results: 135 patients participated in the study and completed the HBI trough a mobile app (mean age: 36.8 ± 8 years, 58% women). The proportion of agreement between clinician and patient assessment, both evaluating CD as active or in remission was 91.1%. Only in 12 cases (11%), the patient classified CD as active whereas the physician evaluated it as inactive. No active cases remained undetected by the patient evaluation. Sensitivity, specificity, positive and negative predictive values are shown in Table. The highest agreement was seen for the questions: “abdominal mass” and “general well-being” whereas “number of liquid stools per day” was the item with the lowest agreement.

Conclusion: The HBI score self-administered by the patient through a mobile app resulted in a high percentage of agreement with the gastroenterologist evaluation, and high negative predictive value for disease activity. Results of the MediciCrohn study encourage the use of this mobile app and gives some hints on its conditions of use as a support for the involvement of patients in the management of their disease. Future studies will help to define its precise role in clinical practice.

Introduction: Histological remission (HR) has become an important treatment target in ulcerative colitis (UC). However, limited data exist on reliability of histological scoring in daily practice, when it comes to assess minor histological abnormalities. We investigated the reproducibility and reliability of UC histological scores in colonic biopsies assessed by HR by a general pathologist in daily practice. Next, we investigated correlations between the initial histological assessment and the expert review by expert gastrointestinal (GI)-pathologists.

Aims & Method: We performed a retrospective single-centre study in a tertiary IBD referral centre. Colonic biopsies of UC patients with mucosal healing (MH) throughout the examined colon were included. All biopsies were re-assessed by three blinded GI-pathologists using three histological scoring indexes (Geboes score (GS), Riley score (RS), Harpaz-Tarpea Index (HGI)) and a global visual scale (GVS). We evaluated intra- and interobserver variation and correlations between scores and initial histological assessment using Cronbach’s alpha and Spearman’s rho analysis.

Results: We included 270 biopsies from 39 UC patients. The interobserver concordance for all histological indexes was substantial to almost perfect (GS 0.84; RS 0.91, HGI 0.61; GVS 0.74). The correlation between the RS and GS was almost perfect (R = 0.94) as scored by expert GI-pathologists.

Conclusion: Available histological scores for UC are reliable with strong mutual correlations in case of limited histological abnormalities. However, limited data exist on reliability of histological scoring in daily practice, when it comes to assess minor histological abnormalities. We investigated the reproducibility and reliability of UC histological scores in colonic biopsies assessed by HR by a general pathologist in daily practice. Next, we investigated correlations between the initial histological assessment and the expert review by expert gastrointestinal (GI)-pathologists.

P1649 EVALUATION OF MODIFIED MAYO ENDOSCOPIC SCORE AND MODIFIED JACOBS ENDOSCOPIC SCORE IN THE PREDICTION OF RELAPSE
1Gastroenterology, CHVNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimeperereiraroque@gmail.com

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES)1 and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN)5. We aimed to evaluate the relation of the scores with disease activity and as predictive factors of clinical relapse. Patients with UC in clinical remission (partial Mayo score [pMS] ≤1.0) who underwent colonoscopy between January/2010 and December/2013 were included. MMES and DUBLIN scores were calculated. Analytical and histological activity (defined by Geboes scores ≥3.1 and Nancy score ≥2.4) as well as predictive factors of relapse and relapse-free time were evaluated. Relapse was defined as pMS ≥2.0, therapy to induce remission, hospitalization and/or colectomy.

Results: 82 patients were selected. 51.2% (n=42) female, mean age 49.4±13.7 years. MMES ranged between 0–13.8 and DUBLIN between 0–9. MMES and DUBLIN scores presented good correlation (r=0.55, p<0.001). MMES was higher in patients with histological activity defined by Nancy (3.7±4.0 vs. 0.8±1.5; p<0.001) and Geboes (4.0±4.2 vs. 1.3±2.4; p=0.005). DUBLIN was also higher in patients with histological activity defined by Nancy (1.9±2.1 vs. 0.5±0.8; p=0.001) and Geboes (2.0±2.3 vs. 0.7±1.2; p=0.005). There was no significant correlation between both scores and analytically.

Relapse occurred in 36.6% (n=30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, 31.5 and 40.0% at 12, 24, 36, 48 and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p=0.001), MMES (p=0.001), DUBLIN (p<0.001) and Nancy score (p=0.001) presented a significant association with relapse. In multivariate analysis, MES (OR=2.32; p=0.001), MMES (OR=1.19; p<0.001) and DUBLIN (OR=1.36; p<0.001) were predictive of relapse independently from histology. Areas under the ROC curve were 0.71 (MES, p<0.0001) and 0.74 (DUBLIN, p=0.001) for prediction of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002–0.072); p=0.03.

Conclusion: MMES and DUBLIN scores correlate with each other and with histological activity, acting as independent predictors of relapse. MMES was superior to MES in the prediction of relapse.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1650 USEFULNESS OF MAGNETIC RESONANCE ENTEROGRAPHY ON MEDICAL DECISION-MAKING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD) AFTER A 1-YEAR FOLLOW-UP: A MULTICENTER STUDY

Contact E-mail Address: farre.clementine@gmail.com

Introduction: Crohn’s disease (CD) is a chronic progressive destructive disease, resulting in cumulative structural bowel damage, which may predict long-term disability. The Lémann Index (LI) has been developed to measure CD-related bowel damage, including bowel surgery, presence of strictureing and penetrating lesions (Pariente and al, Gastroenterology 2015). The first Inflammatory Bowel Disease - Disability Index (IBD-DI) has recently been validated (Gower-Rousseau, Gut 2015).

Aims & Methods: The aim of the present study was (1) to identify factors associated with bowel damage and with disability in CD and (2) to evaluate the correlation between the LI and the IBD-DI. We performed a prospective study in the tertiary referral center of the Clínica Huérez Hospital in Lille from September 2016 to November 2016, including all consecutive CD outpatients. Bowel damage was assessed by the LI calculated according to the published LI protocol. Abdominal and pelvic Magnetic resonance imaging (MRI) were reviewed and red by the same couple of one gastroenterologist and one radiologist. The IBD-DI was also calculated for all patients. Factors associated with LI and IBD-DI levels were identified by means of bivariate analyses of variance.

Results: 230 patients were prospectively and equally included. Mean age was 34.0 (interquartile range [IQR]: 26.0–46.0) and median disease duration was 10.0 (IQR: 5.0–17.0) years. 65 patients (50%) underwent at least one resection surgery. The median LI was 10.8 (IQR: 0.6–17.5). Disease duration (p<0.0001), cumulative anal location (p<0.0001) and CD activity (p<0.0001) were associated with higher LI scores. Median IBD-DI was 25.0 (IQR: 14.7–41.1). Female gender (p=0.02), CD activity (p<0.0001) and current anoperinal lesions assessed by clinical examination and pelvic MRIs (p=0.001) were associated with higher IBD-DI scores. The correlation coefficient between the LI and the IBD-DI was 0.12 (±0.05, 0.29; p=0.154).

Conclusion: In a large cohort of CD patients from a tertiary referral CD center, disease duration, anal location and CD activity are associated with bowel damage assessed by the LI, while female gender, disease activity and current anoperinal lesions are associated with disability assessed by the IBD-DI. Correlation between the LI and the IBD-DI was low.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The aetiology of Crohn’s disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest a different cytokine profile between CD and UC. Aims & Methods: The aim of this study was to analyse the expression of mRNA of proinflammatory, regulatory anti-inflammatory cytokines, chemokines and their ligands (IL-6, IL-10, 12, IL-23, TNFa, CCR1, CCR2, 2-59, IL-10,TLR2, 4, CD80), and transcription factor FoxP3 in the inflamed and non-inflammatory intestinal biopsy samples of mucosa in IBD patients. We performed a cross-sectional study. The cohort consisted of 87 consecutive IBD patients (47 CD and 40 UC) who underwent colonoscopy at the IB Centre of University Hospital Bratislava. We performed biopsy and immunohistochemistry from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD). mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer and reverse transcribed. We normalized the expression of the target genes to the expression of the house-keeping gene (GAPDH). Finally, we compared the expression of cytokines in inflamed and non-inflamed mucosa separately for CD and UC patients.

Results: In UC patients, we observed higher expression of IL-8 (p < 0.04), IL-23 (p < 0.018) TLR2 (p < 0.002), CCR1 (p < 0.007), CCR2 (p < 0.037), CCR5 (p < 0.01), CD206 (p < 0.011), TNFa (p < 0.002) and IL-6 (p < 0.006) in the inflamed mucosa from sigma. In CD patients, we observed increased expression of IL-8 (p < 0.005) and IL-12 (p < 0.001) in the inflamed mucosa of a terminal ileum and decreased expression of CCL5. Also, in group of patients with CD we did not observe the difference of the expression of mRNA cytokines between the inflamed and non-inflamed mucosa of sigma.

Conclusion: There was a significant difference in the mRNA cytokine profiles between CD and UC patients. Disclosure of Interest: All authors have declared no conflicts of interest.

P1654 THE RELATIONSHIP OF NEUTROPHILIC AND ENDOTHELIAL ACTIVITY MARKERS WITH THE DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASE

S. Boga1, A.R. Koksal2, H. Alkim1, A. A. Ozragari1, I. Sen1, M. Sahin1, C. Alkim1

Introduction: The disease activity in inflammatory bowel disease (IBD) is not searched yet. The increase in endoglin expression with the inflammation in the colonic mucosa of mice was shown before, its relationship with the disease activity in inflammatory bowel disease (IBD) is not searched yet. The relation of serum NGAL and endoclin levels in ulcerative colitis (UC) and Crohn’s disease (CD) patients was investigated in this study.

Aims & Methods: Eighty-six UC, 63 CD, 36 non-IBD (screening, irritable bowel syndrome) and 52 healthy controls who were followed up in Gastroenterology Department of Sisli Hamidiye Etfal Education and Research Hospital between years 2015-2016 were enrolled. Patients were evaluated by endoscopic (Rachmilewitz index for UC, simple endoscopic score for CD (SES-CD)) for CD clinical (colitis activity index (CCI)) for UC and CD activity index (CDAI) for CD, and pathologic activity scores and immunohistochemical staining.

Results: There were no differences between UC and CD patients in terms of serum endoglin and NGAL levels. NGAL and endoglin levels were significantly higher in endoscopically active UC group (n = 59) (142.8 ± 67.8 ng/mL and 28.0 ± 15.0 pg/mL) compared to inactive UC (n = 27) (119.7 ± 26.3 pg/mL and 46.5 ± 134.2 pg/mL), to non-IBD (115.8 ± 27.2 pg/mL and 460.6 ± 103.2 pg/mL) and to controls (116.7 ± 31.7 ng/mL and 457.2 ± 114.1 pg/mL). Although there were limited number of inactive CD patients (n = 11), serum NGAL and endoglin levels were significantly higher in endoscopically active CD groups (n = 52) (135.0 ± 28.9 ng/mL and 555.6 ± 133.6 pg/mL) compared to inactive CD (115.2 ± 35.9 ng/mL and 458.7 ± 132.8 pg/mL), to non-IBD and to controls (Figure). Structuring and fistulizing CD groups had significantly higher endoglin levels compared to inflammatory CD (p < 0.001 and p = 0.001). NGAL levels were significantly increasing with the increasing disease extension in UC and CD (p = 0.012 and p < 0.001). While the clinical activity subgroups were evaluated, there were significant difference in UC and CD patients in terms of endoglin levels but not NGAL levels (Endoglin: p = 0.002 p = 0.574, NGAL: p = 0.020 p = 0.171). Endoglin levels were more strongly correlated with the pathologic activity scores in both UC and CD groups compared to NGAL levels. (Endoglin: r = 0.443, p < 0.001; r = 0.453, p < 0.001; NGAL: r = 0.274, p = 0.011; r = 0.409, p = 0.001). The immunohistochemical staining index of endoglin showed positive correlation with the immunohistochemical staining of vessel endothelial growth factor (VEGF) (UC r = 0.486, p < 0.001; CD r = 0.383, p = 0.004). The immunohistochemical staining index of endoglin in the colonic mucosa was correlated with the serum levels of endoglin in both UC and CD patients (UC r = 0.641, p < 0.001; CD r = 0.437, p < 0.001).

Conclusion: The present study highlights significant associations between endoglin and NGAL and IBD presence and activity, and demonstrates elevated serum and colonic endoglin levels in patients with active IBD as a novel finding.

Introduction: Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regime in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

Aims & Methods: In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count <4.0 10^9/l, platelet count <150 10^9/l) and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (γ-GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)). The secondary outcomes were prevalence of myelotoxicity and hepatotoxicity and additional diagnostic procedures due to this toxicity.

Results: This study included 223 IBD patients (55% female, 64% with Crohn’s disease, mean age at diagnosis 27.2 years (SD 11.5)). Median follow-up was 3.2 years (IQR 1.9–4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 445/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukopenia (leukocyte count <4.0 10^9/l), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukopenia (leukocyte count <3.0) than with mild leukopenia (p < 0.01). In total, 2 complications were recorded, 1 patient was hospitalized because of pancytopenia and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

Conclusion: Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regime to monitor thiopurine-induced toxicity should be considered.

Introduction: Intestinal fibrosis represents one of the main sources of morbidity for patients with Crohn’s disease (CD), as its onset is associated with the development of CD-related complications which increase the likelihood of hospitalization and surgery. Ultrasound elasticity imaging (UEI) is a non-invasive ultrasonographic technique developed to evaluate tissue fibrosis by measuring tissue strain after application of a force. We have recently demonstrated that UEI can reliably detect severe ileal fibrosis in patients with Crohn’s disease. We therefore hypothesized that a more severe range of fibrosis might influence the therapeutic response to anti-tumor necrosis factor (TNF) treatment.

Aims & Methods: The aim of this explorative study was to assess the ability of UEI to predict therapeutic outcome in active CD patients treated with anti-TNF antibodies. 30 patients with ileal or ileocolonic CD (20 males, age 38.8 ± 14.5 years) initiating anti-TNF treatment were enrolled in the study. All patients completed the induction phase and underwent scheduled maintenance therapy with anti-TNF for 16.1 ± 8.5 months. Patients underwent bowel ultrasound and UEI at baseline and 14 weeks after initiation of anti-TNF. Bowel wall stiffness at UEI was quantified by calculating the strain ratio (SR) between the bowel wall and the surrounding mesenteric tissue. Receiver operating characteristic curve analysis was used to identify the best SR cut off able to predict surgery/bowel obstruction.

Results: Five patients (16.7%) underwent surgery or hospitalization for bowel obstruction during the follow up. Frequency of CD-related surgeries or hospitalizations was significantly greater in patients with SR ≥ 2 at baseline than in patients with SR < 2 (p = 0.02). A significant reduction in bowel thickness was observed after 14 weeks of anti-TNF treatment (from 5.8 ± 1.5 mm to 5.1 ± 1.7 mm, p < 0.005), while SR values remained unaltered (1.5 vs 1.3, p = 0.5). A significant inverse correlation was observed between values of strain ratio at baseline and thickness variations following anti-TNF therapy (p = 0.007). Eight out of 30 patients (27%) achieved transmural healing at 14 weeks. Baseline SR was significantly lower in patients with transmural healing than in patients not achieving this endpoint (1.06 ± 0.16 vs 1.67 ± 0.17, p < 0.05).

Conclusion: This explorative study shows that UEI is be able to predict therapeutic outcomes, including CD-related surgeries and transmural healing, in patients with Crohn’s disease treated with anti-TNF therapy.

P1657 CLINICAL CHARACTERISTICS OF RECTAL-SPARING ULCERATIVE COLITIS

A. Itc, O. Tepei, T. Katutoshi
Dept. Medicine, Inst. Gastroenterology, Tokyo Women's Medical University, Tokyo,Japan

Contact E-mail Address: itoayumi@ige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) generally involves the entire large intestine extending from the rectum to the ileocecal junction. However, some patients with moderate or severe UC lack any obvious rectal involvement (known as rectal-sparing (RS)-UC).

Aims & Methods: In this study, we evaluated the differences in the clinical characteristics of patients with UC who had rectal sparing compared with patients with UC who did not. The patients were classified into 3 groups: RS (n=70), UC without RS (n=320), and UC with RS (n=1000).

Results: Significant differences were observed in age at onset (10 years older in the RS group), sex ratio (58% male in the RS group vs. 67% male in the UC group), and disease activity (CRP: RS-UC: 2.4, S-UC: 0.05). Other significant differences included greater endoscopic score and relapse rate in the RS group than the standard UC group. We recommend aggressive treatment for patients with UC who exhibit high CRP, endoscopic score, and relapse rate.

Conclusion: There were no significant superiority of FICE, in dysplasia screening. Consistent with the literature, if FICE is to be used in clinical practice, this study showed that FICE could detect diminutive polyps, and evaluating surface patterns without magnification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1658 EVALUATION OF COLONIC MUCOSA WITH FLEXIBLE SPECTRAL IMAGING COLOR ENDOSCOPY (FICE) IN PATIENTS WITH LONG TERM ULCERATIVE COLITIS DURING DYSPLASIA SCREENING

G. Bengil, S. Kaya Ozdinç, H. Akpınar
1Gastroenterology, Dokuz Eylül University Hospital, Izmir/Turkey

Contact E-mail Address: sedozinc@yahoo.com

Introduction: UC associated colorectal cancer risk is related to the age of onset and duration and anatomic extent of the disease. The rate of malignancy increases with the duration of the disease (1). Current guidelines recommend beginning the surveillance colonoscopy after eight to ten years of disease; random biopsies should be obtained from 4 quadrants of every 10 cm of the colon. However, some patients should undergo colonoscopy before the end of the first decade of onset (2). Recent endoscopic imaging techniques provide a more detailed visualization of the superficial microstructure of the mucosa and vascularity. Thus it is possible to get targeted biopsies. The purpose of this study is to evaluate the image patterns of dysplasia in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Aims & Methods: The purpose of this study is to evaluate the image patterns of dysplastic changes in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Results: In a total of 18 patients, by evaluating 123 colonic segments, 1831 images were acquired by FICE. Random biopsies were taken 129 (48.2%) random and 22 (15.7%) targeted biopsies. While there were no dysplasia in random biopsies, low-grade dysplasia was detected in 22 (15.7%) targeted biopsies. When all the images are analyzed, channels 2 and 9, were found to be significantly different from other channels. When the most rated channels, 2 and 9, were compared to the WLE, the FICE image is better for evaluation of the mucosal and vascular structure. However, there were no significant difference between channels 2 and 9.

Conclusion: There were no significant superiority of FICE, in dysplasia screening. Consistent with the literature, if FICE is to be used in clinical practice, this study showed that FICE could detect diminutive polyps, and evaluating surface patterns without magnification.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The gut microbiome is thought to be relevant to the pathogenesis of inflammatory bowel disease (IBD). We aimed to explore associations between microbial dysbiosis and clinical as well as inflammatory disease activity in an inception cohort of treatment-naïve IBD patients as well as with inflammatory activity in symptomatic non-IBD patients and healthy controls. The term ‘dysbiosis’ expresses alterations in the gut microbial community.

Aims & Methods: Patients were grouped according to international criteria, including endoscopic and histopathological assessment. Clinical disease activity in Crohn’s Disease (CD) patients was measured by the Harvey-Bradshaw index (HBI), and in ulcerative colitis (UC) patients by the Simple Clinical Colitis Activity Index (SCCAI). Inflammatory activity was assessed by CRP and faecal calprotectin (FCaI). (FCaI® ELISA, Bühlmann laboratories AG). Stool samples were collected within 60 days prior to and 14 days after the diagnosis, and stored at –80°C. Antibiotic treatment within the last two months was an exclusion criterion. 17 fecal microbial profiles were generated by 16S rRNA analyses, using the GA-map™ Dysbiosis Test. Dysbiosis was defined as non, mild or severe (1). Differences in disease activity between levels of dysbiosis severity were analysed using ANOVA at a significance level of P = 0.05. Significant associations between dysbiosis severity and disease activity and log-transformed microbiota profiles were analysed using ANCOVA. P-values corrected for multiple testing, using Benjamini-Hochberg correction, are presented. For enterotypes, we used the reference database of the Human Microbiome Project.

Results: Data on dysbiosis, bacteria profiles, and FCal were available in 57 CD, 80 UC, 12 IBD-U patients and 100 symptomatic non-IBD patients, and 45 healthy controls. CRP was available for 52 CD, 74 UC, 10 IBD-U patients, and 88 symptomatic non-IBD patients. HBI was available for 50 CD patients, while SCCAI was available for 77 UC patients. Disease activity: No association was found between FCal and dysbiosis in UC patients (P = 0.08), CD patients (P = 0.22), and healthy controls (P = 0.57). However, an association was found between FCal and dysbiosis in symptomatic non-IBD patients (P = 0.04) and in IBD-U patients (P = 0.005). An association was found between CRP and dysbiosis in CD patients (P = 0.02), while not for UC and symptomatic non-IBD patients. No association was found between HBI and dysbiosis in CD patients (P = 0.23), and between SCCAI and dysbiosis in UC patients (P = 0.32). Microbiota: Increasing dysbiosis severity in UC and non-IBD patients yielded lower abundance of Faecalibacterium prausnitzii, and higher abundance of Proteobacteria, a profile typically observed in gut inflammatory conditions. In addition, the commensal bacteria Bifidobacterium yielded lower abundance with increased dysbiosis severity in UC and non-IBD patients, and in combination with elevated levels of FCal and/or CRP in UC patients. In the healthy controls, increasing dysbiosis severity yielded higher abundance of Proteobacteria.

Conclusion: In conclusion, a relationship between faecal dysbiosis in subgroups of IBD patients and some bacterial profiles was evident. Accordingly, gut bacteria profiles and abundance may potentially be used to differentiate between severity in UC and CD patients, as a non-invasive tool to monitor disease activity in IBD.

Contact Email Address: tfujii.gast@tmd.ac.jp

Introduction: Crohns disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn's disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions. To date, several studies have shown clinical utility of the 3-point MR enterocolonography (MREC) classification for assessing CD activity based on endoscopic findings.

Aims & Methods: A total of 120 patients (70 for derivation cohort and 50 for validation cohort) with CD was enrolled and undergone MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment; rectum, sigmoid, descending, transverse, ascending colon, terminal, proximal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 3-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcer. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohorts. The AUCs of MREC classification were 90.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA (p < 0.001). The cross-validation accuracy was 81.9% in the derivation and 81.3% in the validation phase. The MREC classification showed good agreement.

Conclusion: For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 3-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large and small bowel segments.

P1661 RISK FACTORS FOR METABOLIC SYNDROME AND ITS COMPONENTS IN INFLAMMATORY BOWEL DISEASE
Department Of Medicine And Ageing Sciences And Center For Excellence On Ageing And Translational Medicine (cesi-met), "G. D'Annunzio" University and Foundation, Chieti/Italy
Contact E-mail Address: effk78@gmail.com

Introduction: Metabolic syndrome (MetS) is a combination of biochemical and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

Aims & Methods: The aim of this study was to assess the effect of individual disease activity-related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included during a 1-year period. MetS was diagnosed according to the “harmonized” criteria as the presence of >3 criteria among elevated waist circumference, blood pressure, blood glucose, serum triglycerides, or reduced HDL cholesterol. All subjects underwent colonoscopy; endoscopic disease activity was assessed according to SES-CD and Mayo endoscopic scores. CRP, falciprotein (FC), hemoglobin and ferritin levels were also measured.

Results: We enrolled 145 consecutive IBD patients (53 Crohn's disease and 92 ulcerative colitis; 58 M:87 F; mean age 51 ± 18 years) and 250 age- and sex-matched controls. Overall MetS prevalence was 37% in IBD and 21.6% in controls (OR = 2.1, 95% CI: 1.32–3.39). Prevalence according to sex or disease type did not show significant differences. At multivariate analysis, age and BMI ≥ 25 were associated to an increased probability for a positive MetS status both in IBDD (OR = 3.41, and OR = 6.01) and controls (respectively OR = 3.47 and OR = 3.74). In patients under 50 ages, OR (1.24, CRP (OR = 1.9) and FC (OR = 1.35) positivity were associated to MetS status, while a BMI ≥ 25 increased risk at any age (<50ys OR = 3.8, >50ys OR = 1.56). Depression was not associated to MetS status at any age. Interestingly, anti-TNFα treatment was protective in both groups, but reached statistical significance only in older subjects (>50ys OR = 0.08). Regarding individual MetS components, in the <50ys subgroup, age and CRP positivity associated with an impaired glycemic (respectively, OR = 1.15 and OR = 2.28) and lipidemic status (respectively, OR = 1.23 and OR = 2.3). In older patients, CRP positivity only associated to impaired HDL status (OR = 5.41). Importantly, anti-TNFα treatment favourably associated to HDL status (OR = 0.2).

Conclusion: MetS prevalence is increased in IBD compared to healthy controls at any age, and patients with increased BMI and/or inflammatory markers are at higher risk for MetS, while anti-TNFα agents appear to be protective. The components associated to MetS are differently distributed according to age, with the inflammatory ones prevailing in subjects <50 years and metabolic disturbances in older patients. These results indicate that inflammatory markers in the short-term assessment may reduce MetS occurrence and associated risks in subjects >50 years, in younger patients more effective inflammation control measures may prevent MetS and its related long-term neoplastic and cardiovascular complications.

P1662 C-REA TIVE PROTEIN/ALBUMIN RATIO IS A GOOD PREDICTOR OF RESPONSE TO INTRA VENOUS CORTICOSTEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS
S. Monteiro1, T. Cândia Gonçalves1, F. Dias De Castro2, S. Leite1, M.J. Moreira1, J. Cotter2
1Gastroenterology, Hospital Senthora do Oliveira-Guimaraes, Guimaraes/Portugal
2Ivs/38’s, PT Government Associate Laboratory, Guimaraes/Bragu Portugal
Contact Email Address: sara.s.monteiro@gmail.com

Introduction: Patients with acute severe ulcerative colitis (ASUC) have a high risk of rescue medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio at the 3rd day of treatment, with intravenous corticosteroids, has been shown to be a predictor of early colectomy in patients with ASUC.

Aims & Methods: To evaluate the accuracy of CRP/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids in 123 was based on endoscopic remission or non-response, rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids, p < 0.001 and p = 0.008, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 ± 3.5 (g/dL), p = 0.005, respectively. The CRP/albumin ratio was higher in unresponsive patients 40.06 vs 22.14, p = 0.022, showing a good accuracy for predicting non-response to intravenous corticosteroids with an AUC of 0.746, p = 0.01.

Conclusion: A high value of CRP/albumin ratio was significantly associated with the probability of response to intravenous corticosteroids, at the 3rd day of treatment. This index may allow a better risk stratification on admission, of patients with acute severe ulcerative colitis.

P1663 INSUFFICIENT VARIATION OF MEDIUM CORPOREAL VOLUME (ΔMCV) IN INFLAMMATORY BOWEL DISEASE UNDER THYOPURINES PREDICTS DIFFICULTY IN ACHIEVING CONTINUOUS DEEP REMISSION COMBINATION WITH ANTI-TNF - THE OTHER SIDE OF THE MCV FLOW STUDY

2Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal
Contact Email Address: jsr_roseira@hotmail.com

Introduction: The MCV flow study confirmed the association ΔMCV ≥7fl at week 26-28 of Azathioprine monotherapy (mAZa) with favourable outcomes in a Portuguese IBD population.

Aims & Methods: For this work, our aims were to evaluate the need for step-up therapy in those under mAZa with ΔMCV <7 and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzaExposed+ Anti-TNF). Evaluation of patients under mAZa with ΔVGM <7 at key timepoint week 26-28 treatment, included for The MCV flow study. Demographic characterization and severity of pre-treatment disease was evaluated [Montreal classification, previous surgery status, Mayo score and Crohn’s disease activity index (CDAI)]. ΔMCV’s association with DeepRem [Steroid-free clinical remission (CDAI ≤150, Mayo ≤2) + mucosal healing (MH)+C-reactive protein (CRP) <10] and need for biological therapy at the week 26-28 of DeepRem was verified. The fourth independent predictor in patients who subsequently started combination therapy. Statistical: Chi-square test; Binary logistic regression.

Results: A total of 106 IBD patients were evaluated [56.6% men, mean age 39 ± 12.5 years; 58 ad, 14% operated] at week 26-28 of mAZa. Identified strong association between a average ΔVGM ≥7 (n=70; 66%) with DeepRem (p <0.05), while a ΔVGM ≤7 was associated with biological therapy need (p <0.05). 45 patients were later started with Anti-TNF therapy
(Aza + Infliximab 46.7%; Aza + Adalimumab 53.3%) and only 44% achieved DeepRem at the key-timepoint. A Crohn’s A3LB3 p+ phenotype (p = 0.045), steroid therapy in the last year (p = 0.009) and ΔVGM < 7 (p = 0.036) were identified as the variables that best explained the difficulty reaching DeepRem.

**Conclusion:** This study confirms the prognostic value of ΔVGM in our population. ΔVGM ≥ 7 was associated with DeepRem and ΔVGM < 7 was found to be associated with biological therapy need. However, even after starting Anti-TNF, ΔVGM < 7 was identified as a predictor of the difficulty reaching DeepRem.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1664 FCAL PROTECTIN PREDICTS SHORT-TERM RELAPSE IN INFLAMMATORY BOWEL DISEASE PATIENTS IN DEEP REMISION**

2Department Of Social Medicine And Health Management, Section Of Biostatistics, Medical University, Sofia, Sofia/Bulgaria

**Contact E-mail Address:** radislav.nakov@gmail.com

**Introduction:** Most inflammatory bowel disease (IBD) patients with clinically successful treatment seem to have some degree of residual mucosal inflammation. Elevated fecal calprotectin (FC) concentrations can be found despite clinical remission and may indicate relapse risk in asymptomatic IBD.

**Aims & Methods:** The aim of this prospective study was to evaluate whether elevated FC values can predict short-term clinical and/or endoscopic relapse. We enrolled 60 IBD patients (30 ulcerative colitis - UC, 30 Crohn’s disease - CD) who were in clinical and endoscopic remission. FC was measured using quantitative immunochromatographic point-of-care test (Quantum Blue® Calprotectin, Bühlmann Laboratories AG, Switzerland). Patients were followed-up by FC examination and clinical activity assessment every second month until relapse or up to 24 months. Heocolonoscopy was performed at inclusion and at the time of clinical remission.

**Results:** During the follow-up 36 (60%) relapsed and 24 (40%) remained in remission. The mean time to relapse in all patients was 13.9 (range 2-20) months. The mean FC levels before relapse were 2.1 mg/L (p = 0.001) lower than before endoscopic relapse. ROC analysis indicated that a cut-off of ≥ 90 μg/g (OR 24, 95% CI = 5.1-117, p < 0.001) in mean FC values 2 months before relapse could predict relapse in UC patients with 83.3% sensitivity and 82.9% specificity. All CD patients with a cut-off of ≥ 155 μg/g (OR 193, 95% CI = 23.1682, p = 0.001) could predict relapse within two months with 91.7% sensitivity and 94.6% specificity. Constantly normal FC values during the follow-up were predictive for deep remission.

**Conclusion:** It is seen that FC elevates two months before clinical and/or endoscopic relapse. FC is a suitable marker for predicting relapse and building a follow-up strategy for IBD patients in clinical practice.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jazternbisa@gmail.com

**Introduction:** Hyperglycemia associated with critical illness - also called stress hyperglycemia - has been linked to the highest prevalence of severe ill patients. It is connected with many factors, including increased cortisol level, catecholamines uptake, glucagon production, glucoseogenesis, insulin resistance and inflammatory markers. It is not considered as an adaptive response anymore. However, hyperglycemia is associated with poor outcomes and significantly increases mortality rates. That is why stress hyperglycemia and insulin resistance may be a marker of severe illness.

**Aims & Methods:** We analysed the data (glycemia, insulin level, HOMA IR level, C-reactive protein level, Hba1c) of 62 patients aged 18 and older (92 women and 40 men, 32.26 +/-13.8 years of age) with IBD hospitalized in our clinic from 2016 to 2017. 16 patient were with Ulcerative Colitis (UC) and 48 patients with Crohn’s Disease.

**Results:** The analysis of the patients with Ulcerative Colitis showed that only one of the patients had hyperglycemia within the range of 140-200 mg (the patient had type 2 DM) but interestingly 37.5% of the patients had fasting hyperglycemia over 100 mg. Over 85% of these patient were admitted to our clinic with the exacerbation of the disease and had abnormal level of C-reactive protein, calprotectin (> 1800) and fasting insulin level over 10 IU/ml. The analysis of the group of patients with Crohn’s Disease showed different results which may be connected with different metabolic profile of these patients. Most of the patients with fasting hyperglycemia (only 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 101 U/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

**Conclusion:** In our opinion there is a strong connection between fasting glucose, CRP level and exacerbation of the disease in CA patients but not in case of the Crohn’s Disease. In this group the elevated fasting insulin may be a marker of severe illness.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1666 THE ROLE OF MR IMAGING IN ASSESSMENT OF LEMANN INDEX IN THE COURSE OF CROHN’S DISEASE**

J.M. Plenkowska, O. Kozak, T. Nowicki, E. Szurzewska
Radiology, Medical University of Gdansk, Gdansk/Poland

**Contact E-mail Address:** oliviak@gumed.edu.pl

**Introduction:** Crohn’s disease (CD) is a progressive, chronic and destructive inflammatory bowel process which, during its course, can lead to complications such as strictures and penetrating lesions (fistulas and abscesses), which may consequently require operative treatment. In some patients, bowel damage is present at the moment of diagnosis. The aim of the study is to assess the initial Lemann Index (LI), which comprehensively evaluates the entire gastrointestinal tract damage in patients with newly diagnosed Crohn’s disease.

**Aims & Methods:** In 209 patients with clinical suspicions of Crohn’s disease MR imaging was performed. Endoscopic examinations and histopathology were performed. In 151 patients with confirmed active/chronic CD the Lemann Index has been calculated on the basis of radiological and clinical information for initial assessment of cumulative digestive tissue damage. To create the Lemann Index the gastrointestinal tract was divided into 4 organs: upper digestive tract, small bowel, colon rectum and anus. Each organ was divided into segments (5 for the upper digestive tract, 6 for the colon/rectum and 1 for anus). Strictures and penetrating lesions were assessed at each segment on 4-degree scale (0–3) according to the severity of lesions.

**Results:** Based on the findings of the initial radiological examination, active inflammation process was found in 76 patients and chronic process in 75 patients. The baseline study demonstrated such complications as strictures in 14 patients, fistulas in 15 and abscesses in 4 patients. For all patients the LI was calculated. The obtained values were within the range from 0 to 22.

**Conclusion:** Over the years, the progression of Crohn’s disease leads to an increase in the value of Lemann Index, therefore, it seems that the evaluation of the first baseline stage and the follow-up control MR examinations will allow for a more complete assessment of patients in terms of progressive bowel damage and modification of the therapeutic process.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Optical imaging is being increasingly advocated for characterization of polyps during colonoscopy. The accuracy of these techniques during surveillance colonoscopy in colon inflammatory bowel disease (IBD-C) is unclear and with variable results reported. We aimed to perform a systematic review and meta-analysis of the diagnostic accuracy of optical imaging techniques including narrow band imaging and virtual chromoendoscopy, magnification endoscopy and confocal laser endomicroscopy.

**Aims & Methods:** We searched Medline and Embase for relevant papers. Full articles or abstracts were eligible when characterization performance of dye-based chromoendoscopy (DCE), virtual chromoendoscopy (VCE) (narrowband imaging [NBI], i-scan, Fujinon intelligent chromoendoscopy [FICE]), magnification endoscopy and confocal laser endomicroscopy (CLE) had been compared with histopathology, as the reference standard. Enough information had to

with fasting hyperglycemia (only 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 101 U/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

**Conclusion:** In our opinion there is a strong connection between fasting glucose, CRP level and exacerbation of the disease in CA patients but not in case of the Crohn’s Disease. In this group the elevated fasting insulin may be a marker of severe illness.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhoea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) colonoscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units.

**Aims & Methods:** Publications on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search terms/descriptors were used: collagenous colitis(CC) OR lymphocytic colitis(LC) AND endoscopy, colonoscopy, findings, HD colonoscopies. An additional search for MC AND perforation was made.

**Results:** Eighty (n=80) articles, predominantly single case reports (n=45), were retrieved. Overall, 1,582 (1,159 female; 61.6±14.1 years) patients(pts) with MC and endoscopic findings were reported. The majority of articles (n=62) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhoea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic findings. The most common colonic findings were non-ulcerous lesions i.e. pseudomembranes, a variable degree of vasculature pruning & dwindling, mucosal lacerations & abnormalities such as erythema/edema/nodularity, or surface textural alteration (n=537; 87.2% pts). Isolated linear ulcerations were identified in 5 pts(0.8%) and in conjunction with non-ulcer lesions in 74 pts(12.8%).

**Conclusion:** Endoscopic findings are recognized with increased frequency in pts with MC. This could improve MC diagnosis by prompting a more extensive biopsy protocol in such cases and an earlier initiation of treatment. Procedure-related perforation has been reported in this group; therefore, cautious air insufflation is advisable when endoscopic findings are recognised.

P1670 PREVALENCE AND QUANTITATIVE ASSESSMENT OF LIVER STEATOSIS IN INFLAMMATORY BOWEL DISEASE PATIENTS

Contact E-mail Address: juliaenache.89@gmail.com

Introduction: It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients by using the controlled attenuation parameter (CAP).

Aims & Methods: We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients with alcohol intake >20 g/day and those with existing viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HSI) and transient elastography with CAP (Fibroscan, Echosens, Paris). Significant steatosis (S ≥ 1) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

Results: Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn's disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare:48.5/31.4% in the UC group, 55.6/44.4% in the CD group), BMI (24.1 and 24.3 kg/m²), HSI (61.1 and 59.9) and CAP even 2 more (23/62, 37.1%), yielding an extra 8% detection rate. NAFLD-IBD patients were more likely to have CD phenotype, history of smoking, steatosis and lower disease duration.

Conclusion: In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

P1671 INTESTINAL MICROBIOTA BIOMARKERS AS A NEW TOOL TO SUPPORT IRRETTIBLE BOWEL SYNDROME SYNDROMICS

Contact E-mail Address: joan.amoedo@goodug.eu

Introduction: Irritable Bowel Syndrome (IBS) is a common gastrointestinal disorder that affects around 11% of global population. Despite the high prevalence of IBS, the cause of this disorder remains unknown and the criteria used to diagnose IBS are still unclear. In recent years, disturbances in the intestinal microbiota have been associated to the pathophysiology of IBS. Recently, two accurately measured biomarkers, FprA (Fpra) and Escherichia coli (Eco) have been shown to discriminate between Inflammatory Bowel disease (IBD) and Healthy subjects (H). Therefore, the purpose of this study was to verify the capability of FprA and Eco abundances to distinguish among healthy subjects, IBS, and IBD patients, in order to create a non-invasive system of diagnostic support for IBS patients.

Aims & Methods: A cohort consisting of 33 H and 14 IBS was enrolled. IBS patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS) and alternating IBS (A-IBS). Rome IV criteria were used to diagnose IBS patients. Moreover, 29 ulcerative colitis (UC) and 15 Crohn’s disease (CD) patients were also included. All subjects were recruited by the Gastroenterology Services of the Hospital Universitari Dr. Josep Trueta, Girona, Spain.

Results: We found lower abundance value of FprA in IBS patients when compared with H (P = 0.005). In contrast, Eco abundance was higher in IBS patients, although the differences observed were not significant (P = 0.221). When comparing among subtypes of IBS (C-IBS, D-IBS, and A-IBS) no significant differences were observed, although FprA abundance was lower in C-IBS. We also used FprA in combination with Eco as a complementary indicator of dysbiosis (Ratio FprA/Eco). This ratio allows a good discrimination between H and IBS (FPR = 0.04). When it comes to discrimination between IBS and IBD patients, significant differences were observed in FprA/Eco ratio between UC and IBS patients (P = 0.008), but not between IBS and CD patients (P = 0.775).

Conclusion: FprA abundance is a good biomarker to discriminate between healthy subjects and IBS patients. The use of FprA/Eco ratio allows to distinguish IBS from H and UC patients. In contrast, none of the used biomarkers was able to differentiate HS and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to stablish any eventual pathogenic link.

P1672 DISTINGUISH BETWEEN ULERATIVE COLITIS AND CROHN DISEASE USING AN ELECTRONIC NOISE AND DATA MINING: PRELIMINARY STUDY

Contact E-mail Address: Belenbeltrannicolos@gmail.com

Introduction: Inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS) may present in a similar manner [1] [2]. Measuring faecal calprotectin concentration is often recommended to rule out inflammatory bowel disease, however, there are no tests to positively diagnose irritable bowel syndrome and investigative tests are still used to rule out other pathologies [3, 4]. There is a chance, therefore, for novel, non-invasive despecific biomarkers. Volatile organic compounds (VOCs), originating from physiological metabolic processes in the human body, are excreted as waste products through stool samples. For this reason, several biological, non-invasive, simple and low-cost biological markers of inflammation that are useful in clinical practice for both diagnostic screening and therapeutic or course response monitoring are being evaluated in recent years Evolution of the disease. In this sense, stool markers, and especially calprotectin, have become of great importance in recent years as screening to select patients requiring more diagnostic studies and as a marker of activity for therapeutic follow-up [5]. Can the VOCs from stool samples show differences between ulcerative colitis and Crohn’s disease?

Aims & Methods: Five healthy individuals (control group- CON) and nineteen patients diagnosed with IBD were selected for the analysis of their stool VOCs. Healthy participants Healthy control samples (Control) (n = 5) were collected from healthy volunteers workers in the Digestive Diseases Area and they revealed no illnesses related to the gastrointestinal tract and had not undergone antibiotic treatment in the 3 months before sampling. Active patients were defined as a Mayo Clinical score of 3 or more for ulcerative colitis (UC) and a Harvey Bradshaw clinical index of 4 or more for Crohn’s disease (CD). In both cases, calprotectin > 300 mg/mg or relevant endoscopic lesions. Patients were classified according to Montreal and ECCO criteria. This preliminary study is based in a group of CD-UC-CON where was analyzed 10 CD patients, 9 UC patients and 5 controls with 455 samples. Data from stool samples was obtained using eNose MOOSY32 [6].

Results: Figure 1 shows the scatter 3D plot with three voltage parameters for the group CD-UC-CON. These parameters mean the voltage from the eNose’s signals on saturation slice (vB) and late saturation (vE) and the number of sensor from the MOOSY32. Table 1 shows the comparative between relative error absolute and classification.

Conclusion: In this preliminary research to distinguish between Ulcerative Colitis and Crohn’s disease, the best algorithm for patient’s classification was the MLP with 30% to train and 70% to test. Although the high classifications result it is hopeful is necessary continue working to understanding how the eNose’s signals affect to the relative absolute error and improving the algorithms to decrease the error.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: In patients with inflammatory bowel diseases (IBDs), comprising Crohn’s disease (CD) and Ulcerative colitis (UC), a patient-tailored therapy is an unmet need that requires accurate monitoring of the intestinal disease activity. We demonstrated recently, that the expression of microRNA (miR)-320a follows the clinical and endoscopic disease activity and may distinguish between CD patients with low (pMayo 3–4), moderate (pMayo 5–6) and severe disease activity (pMayo > 6) as compared to UC patients in remission (p < 0.001). Furthermore, we detected a significantly enhanced miR-320a expression with increasing endoscopic disease activity (eMayo 1: 9.4 ± 1.4 vs. eMayo 2: 210 ± 31, p = 0.0006; vs. eMayo 3: 775 ± 245; p = 0.002). Most importantly, miR-320a expression in CD and UC patients with acute flare of disease was significantly increased as compared to patients with infectious colitis (53 ± 12, p < 0.001).

Conclusion: The miR-320a expression in peripheral blood from IBD patients follows the clinical and endoscopic disease activity and may distinguish between ID patients and infectious colitis. Therefore, miR-320a might serve as biomarker for non-invasively assessing the disease activity in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
The intraclass correlation coefficients were 0.81 (p < 0.001) and 0.89 (p < 0.001) for the Quantum Blue® assay and the cut-off levels used in practice, are based on a high time consuming ELISA procedure, processed in a batch-like method (technical delay) and requiring high expertise. An easy to use, rapid point-of-care test would dramatically reduce the turnaround time for results, allowing a faster decision. The aim of this work is to compare a newly developed point-of-care diagnostic test (Quantum Blue® assay) with the standard ELISA method (Promonitor® assay) determining a correlation factor that permits therapeutic management in a similar way.

Aims & Methods: A total of 135 serum sample from patients with CD and UC. IFX concentration in serum samples were determined using a well established IFX-specific ELISA assay (Promonitor®) and the tested assay Quantum Blue®. According to the manufacturer, the lower and upper limits of quantification are: In the Quantum Blue assay 0.035 μg/ml and 14.4 μg/ml respectively. In the Promonitor assay 0.035 μg/ml and 14.4 μg/ml respectively. All statistics were carried out using the statistical programs IBM SPSS statistics 21 and Epidat version 4.2.

Results: The IFX levels measured by the point-of-care method were higher than those measured by established ELISA (Promonitor level: mean 4.67, median 3.2 s.d. e. 4.39 (0.035–14.4)); Quantum Blue level mean 6.31; median 3.7 s.d. 6.27 (0.4–20). The intra- and inter-assay correlation coefficients were 0.81 (p < 0.001). The standard ELISA had a high (r = 0.89) and significant (p < 0.001) correlation with the Quantum Blue® assay. A Bland-Altman analysis showed a bias of 1.88% confirming the overall excellent correlation of the two methods. The results for each method are shown stratified according to the patient's clinical history. In this study, 7 tracts had a lower and 3 higher than 7) with a high agreement. We estimated a simplified score to convert the “point-of-care” level into “Promonitor” level and facilitate dose management: "Nivel de Promonitor = 0,793 + 0,615*Nivel QB". Consistent with previous studies, this assay is a really useful technique enabling the fast and friendly quantitative determination of IFX levels to ensure correct dosing in IBD.

**Conclusion:** In patients with IBD the addition of an immunosuppressant is an effective and safe optimization strategy after loss of response to anti-TNF alpha monotherapy. Low doses of IM are sufficient to achieve a clinical response in this setting.

Contact E-mail Address: claire.painchar1@laposte.net

Introduction: Ustekinumab (UST) has been shown to be effective in refractory Crohn's disease (CD) in phase III trials. The aim of the present study was to prospectively evaluate the association between UST trough levels and anti-ustekinumab antibodies, with the response to induction and maintenance UST treatment in CD patients.

Aims & Methods: We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous UST from September 2015 to April 2016. All the patients received replacement therapy with ferric carboxymaltose, intravenous or subcutaneous. The study analyzed the effect of iron supplementation with and without anti-TNF: group 1 and 2 respectively. Active disease was defined as C-reactive protein (CRP) ≥0.5 mg/dl, faecal calprotectin (FC) ≥50ng/ml or presence of ulcers in colonoscopy. Anaemia was defined according to ECCO criteria (iron deficiency anaemia (IDA), anaemia of chronic disease (ACD) and mixed anaemia (MA)). Multifactorial anaemia (MFA) was diagnosed when there was also vitamin B12 or folate deficiency.

Results: 169 patients were included: 111 with Crohn’s Disease (CD), 54 with Ulcerative Colitis (UC) and 4 with unclassified IBD. The median age was 32.2 years (range 7-82). 98.2% had anaemia and 1.8% had only iron deficiency; 3.5% and 18.3% had a deficit of vitamin B12 and folate. The most common forms of anemia found in CD and UC were IDA (54.1% and 46.3%), followed by MFA (19.8% and 24.1%), ACD (15.3% and 24.1%) and MA (8.1% and 5.6%). Female gender (OR 3.743 95% CI 1.554–9.018, p = 0.003), previous surgery (OR 2.845 95% CI 1.111–7.284, p = 0.02) and pene-trating CRC in CD (OR 8.252 95%, CI 1.289–52.919, p = 0.026) were predictors of normal hemoglobin (Hb). CRP was associated with highest ferritin values (294.85 ± 302.00 vs 102.10 ± 127.75, p = 0.001). Hb and CRP had a negative correlation (p = 0.167, p = 0.022). In UC, CRP and FC normalization was associated with ferritin and transferrin saturations (13.63 ± 1.66 vs 12.47 ± 1.38, p = 0.005 and 51.33 ± 25.60 vs 27.63 ± 9.96, p = 0.048). There was no difference in the parameters evaluated comparing groups 1 and 2. There was also no significant difference in the variation of Hb and iron values after treatment with ferric carboxymaltose or intravenous iron.

Conclusion: It is necessary to differentiate anemia from the two forms of iron replacement were significant difference in the variation of Hb and iron values after treatment with ferric carboxymaltose or intravenous iron.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel diseases (IBD) are chronic conditions characterized by elevated costs (both direct and indirect). Over the last years also a significative healthcare burden associated with IBD has emerged, due to an increasing use of biological therapies and hospitalization costs. Despite the creation of local or regional databases in Italy data regarding healthcare expenditure are lacking.

Aims & Methods: The aim of this study was to evaluate costs comprehensive of biological treatments and hospitalizations in a series of patients with ulcerative colitis (UC) and Crohn’s disease (CD) and their correlation with demographic and clinical variables. Disease severity was evaluated by clinical scores (partial Mayo score for UC, Harvey Bradshaw Index for CD). We analyzed retrospectively patients treated by biologics referred to our IBD Unit between May 2015 and April 2016 who underwent at least six months follow-up (last visit October 2016). As regards biological therapies costs burdened by our Centre pharmacy for each drug (Infliximab, Adalimumab, Golimumab, Vedolizumab) and for single patient were evaluated. About hospitalizations the average costs of hospital care specific for a department through fares for homogeneous groups of patients i.e. Diagnosis-Related Group (DRG) were collected. The mean overall monthly expenditure for each case was then evaluated.

Results: We collected clinical-economical data of 142 patients in biological treatment in the selected period (52 UC, mean age 44.3 years and male 40.4%; 90 CD, mean age 38.8 years and male 56.7%). About half of CD patients (48.9%) underwent previous intestinal surgery. The disease severity was higher in UC group vs CD one. In UC group Infliximab was the most prescribed biologic (51.9%), followed by Adalimumab (29.9%) and Golimumab (21.2%). While CD patients were treated with Adalimumab in 54.4% and Infliximab in 45.6%. The average cost for month of treatment was 1235.41€/month for CD (no statistical differences between the groups) and 358.38€/month for UC and 1148.92€ ± 337.36€/month for UC (no statistical differences between the groups). In both groups expenditure due to biologics amounts for more than 80%. We analyzed costs in groups different for sex, age and disease activity (only the last one was associated with increased costs with R² = 0.84 for UC and 0.95 for CD). The cost increases in patients with more lines of therapy in UC (not in CD) but the difference wasn’t significative.

Conclusion: In our study the main cost is due to biological therapy but the subjects enrolled were the most severe in comparison to the whole IBD population under conventional therapy. No differences were found between the type of biologic administered and the way of administration (intravenous or subcutaneous) so the therapeutical choice could be driven by clinical reasons and not only economic ones.

Disclosure of Interest: All authors have declared no conflicts of interest.
RESULTS: From January 2013 to January 2017, 1578 patients were included. Incident cases were 1151 (808 Cronh’s disease [CD], 333 ulcerative colitis [UC]). In the analyzed cohort, 865 patients were included. It was shown that 22.2% of patients experienced more than one type of therapy during the twelve weeks and one year of treatment. As clinical endpoint, we set remission (corresponding to a Mayo Partial Score ≤ 2 for UC, and to a Harvey-Bradshaw Index ≤ 5 for CD) and response (reduction of Harvey Bradshaw Index ≥ 3 for CD and Mayo Partial Score ≥ 2 for UC compared with baseline).

CONCLUSION: In one of the largest “real-life” series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and ADA in UC. Being naïve to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

P1687  BENEFICIAL EFFECT OF A LOW FODMAPS DIET IN DIFFERENT INTESTINAL DISORDERS

A. Testa, N. Imperatore, A. Rispò, M. Rea, R. Tortora, O.M. Nardone, L. Lucci, G. Accarrino, N. Caporaso, F. Castiglione 1Gastroenterology, Department of Clinical Medicine and Surgery, School of Medicine Federico II of Naples, Naples/Italy 2Hepatology Unit, Cardarelli Hospital, Naples/Italy 3Nutrition, Department of Clinical Medicine and Surgery, School of Medicine Federico II of Naples, Naples/Italy

Contact E-mail Address: annatesta82@virgilio.it

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and celiac disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPS diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPS diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPS diet on patients affected by IBS, CD following at least a 1-year GFD, and IBD who had been experiencing abdominal symptoms without signs of active inflammation. Each subject was put on a low FODMAPS diet after being evaluated by filling out questionnaires concerning on quality of life and symptoms experienced (IBS-SSS and SF-36), and was re-evaluated twice, first after 1 month and second after 3 months.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month of low FODMAPS diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293 ± 137 SD, average score in IBD: 206 ± 86 SD, average score in CD: 222 ± 65 SD, p < 0.001). Furthermore, by analysing the SF-36 questionnaire, while we did not observe any significant difference between the three groups in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPS diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1688  EFFICACY OF VEDOLIZUMAB ON INTESTINAL AND ARTICULAR SYMPTOMS: REAL-LIFE DATA FROM THE SICILIAN NETWORK FOR INTESTINAL BOWEL DISEASE (SN-IBD)

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is a network composed by all Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real-life data about pre-scriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal after 10 and 24 weeks, clinical symptoms at initiation of VDZ, and arthritis.

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients reaching 24 weeks of follow-up, 29 (40.8%) were in steroid-free remission, and 10 (14.1%) had a clinical response. No significant difference in terms of clinical benefit (rate of remission plus clinical response) among patients with UC and CD was reported at week 10 (68.4% vs. 64.3%, respectively; p = 0.58) and at week 24 (54.3% vs. 55.6%, respectively; p = 0.91), and no difference was observed comparing naive and non naive patients, neither at week 10 (61.5% vs. 67.7%, respectively; p = 0.48) nor at week 24 (30.0% vs. 59.0%, respectively; p = 0.11).

At multiple logistic regression analysis, a longer duration of disease (OR 0.961, p = 0.047) and presence of steroid-dependence (OR 0.189, p = 0.033) were predictors of reduced rates of clinical benefit at week 10, while a lower serum level of C-reactive protein at baseline (OR 0.950, p = 0.031) was predictor of clinical benefit at week 24. An improvement of articular symptoms was reported in 39.5% of patients with active spondyloarthritides at baseline at week 10, and in 45.4% of patients at week 24. The only factor associated with articular response was the coexistence of clinical benefit on intestinal symptoms, both at week 10 (OR 3.471, p = 0.05) and week 24 (OR 5.600, p = 0.08). Three inductions or flares of spondyloarthritides during treatment with VDZ were reported.

</table>

Conclusion: In this large cohort of Sicilian IBD patients, VDZ showed good efficacy after 10 and 24 weeks of treatment, particularly in those with a shorter duration of disease and a limited inflammatory burden. A subset of patients reported improvement also on articular symptoms, probably as a consequence of the concomitant control of gut inflammation.

Introduction: Combined immune suppression of antitumour necrosis factor (antiTNF) biologicals and thiopurines is superior to restorative monotherapies in remission induction and maintenance of response in inflammatory bowel disease (IBD). Recent mechanistic studies of this clinical benefit is mutually positive pharmacokinetic effect of thiopurines on antiTNF levels and vice versa. It has been suggested that for this synergistic effect, reduced dose of thiopurines might be sufficient but the data supporting this hypothesis are still limited.

Aims & Methods: The aim of the study was to assess the differences of infliximab trough levels according to the dose of concomitantly used thiopurines. All IBD patients treated with infliximab (Remicade®) in two IBD centres between November 2015 and April 2017 were eligible. Infliximab trough levels were routinely measured in all patients with maintenance infliximab therapy using commercially available ELISA kit (Ridascreen®, R-Biopharm). All patients were in remission with stable dose regimen of 5mg/kg every 8 weeks at the time of the first infliximab administration. Infliximab trough levels were identified retrospectively from the medical records. The differences in the proportion of patients with adequate trough levels (3-12 μg/mL) between patients on infliximab monotherapy, reduced (below 2 mg/kg) azathioprine (AZA) dose vs. full (2 to 2.5 mg/kg) AZA dose were analyzed statistically.

Results: Out of a total of 214 IBD patients treated with infliximab, there were 154 in remission at the time of the first assessment of infliximab trough levels. After excluding patients with previously intensified dose regimen, 125 patients were further analyzed. Among these 125 pts, 41 pts (33%) were on infliximab monotherapy, 58 pts (46%) were using combined immune suppression with a reduced dose of AZA and 26 (21%) were using the full AZA dose concomitantly with infliximab. Both groups, patients with infliximab monotherapy as well as patients using the reduced AZA dose had significantly lower percentage of patients with therapeutic levels of infliximab compared with the group using the full AZA dose co-medication (41% vs. 64% vs. 81%): infliximab monotherapy, reduced AZA dose and full AZA dose, respectively; p<0.001 for both comparisons, infliximab monotherapy (p=0.005) and reduced AZA dose vs. full AZA dose (p=0.003).

Conclusion: The proportion of patients with adequate infliximab trough levels is significantly higher in patients with full dose of concomitant azathioprine compared with the patients using a reduced dose of azathioprine. Thus, in order to maintain the clinical remission the infliximab maintenance treatment, the combined immune suppression should comprise full dose of azathioprine.

Introduction: Tacrolimus, a calcineurin inhibitor, has been shown to be safe and effective when used as salvage therapy for steroid-refractory ulcerative colitis (UC). Its pharmacological effect has been reported to be dependent on trough level in blood, though little is known regarding predictive factors in relation to the clinical efficacy of tacrolimus in UC patients.

Aims & Methods: The aim of this study was to identify factors related to prediction of short- and long-time efficacy of tacrolimus for UC. We retrospectively reviewed the medical records of patients with moderate to severe steroid-refractory ulcerative colitis who were treated with tacrolimus as induction therapy at Shimane University Hospital between January 2010 and March 2016. Oral tacrolimus was administered at a whole-blood trough level of 10-15 ng/mL to induce remission and then 5-10 ng/mL to maintain remission. Following tacrolimus therapy for 3 months, patients in clinical remission were given azathioprine for maintenance at an appropriate dosage. Using the Rachmilewitz clinical activity index (CAI), clinical remission was defined as a score of ≤4. Predictive factors associated with short- and long-term tacrolimus efficacy were analyzed by evaluating various clinical parameters.

Results: Thirty-six patients received oral tacrolimus for induction, of whom 22 (61.1%) and 27 (75%) experienced clinical remission at 2 and 12 weeks, respectively after starting therapy. Interestingly, there was no significant difference in the remission rate at 2 weeks which was significantly associated with CAI at 12 weeks. Interestingly, of the 22 patients in clinical remission within 2 weeks, 21 (95.5%) remained in remission at 12 weeks. In contrast, only 6 of 14 (42.9%) who did not achieve clinical remission at 2 weeks were not in clinical remission at 12 weeks. For evaluating the long-term efficacy of tacrolimus induction therapy, relapse-free periods were assessed using the Kaplan-Meier method. The relapse-free rate at 48 weeks was higher in patients who achieved clinical remission within 79.0% (vs. 60.0%).

Conclusion: Tacrolimus induction therapy was effective for patients with moderate to severe steroid-refractory UC. Our results clearly indicate that clinical remission achievement within 2 weeks is useful for predicting both short- and long-term outcome in UC patients treated with that therapy.

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colectomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn’s disease (CD), scheduled IFX infusions vs. episodic are associated with greater efficacy, less complications, and costs. In UC, historical difficulties of economic access had conditioned to our IBD center, to use IFX in moderate to severe UC as a bridge to thiopurines in 6mp/aza naïve. In UC, the mentioned strategy was insufficiently compared with a regimen of scheduled IFX treatment, that currently we use. Aim: To compare to scheduled in moderate to severe UC the results of induction with IFX (in thiopurine naïve pts) continuing with 6mp/aza maintenance vs. similar induction followed by scheduled IFX maintenance strategy.

We included a cohort of moderate to severe UC treated with IFX in an IBD center (2006 to 2015) comparing results between IFX bridge followed by thiopurines (re-induction when available for moderate to severe relapse) vs. scheduled IFX (n=135 pts, C6.2 wks and 8 wks interval infusions maintenance). Optimization (by frequency of intervals) was allowed in both modalities. Comparisons: Kaplan Meier/Log rank test: a) Cumulative incidence of colectomy; b) Cumulative incidence of colectomy/infliximab (induction 0,2,6 wks and 8 wks’ interval infusions maintenance). We identified 135 UC patients receiving IFX for moderate to severe UC. Results: more ‘consideration’ (β 1.18 (95%CI 0.10–2.27), p = 0.033) as well as the illness outcomes low physical (β = −7.22 (95%CI −9.68 –4.77), p < 0.001) and mental (β = −3.10 (95%CI −5.99 –2.03), p < 0.05) health and increased activity impairment (0.15 (95%CI 0.07–0.23), p < 0.01) were related with higher scores shift of biological drug compared with the scheduled strategy ‘pacing’ (p = 0.03) were found in IFX patients with arthropathies compared with baseline scores. Aims & Methods: Suffering from muscular arthropathies in IBD is strongly associated with different illiness perceptions, coping strategies and illness outcomes and changes of these factors over time. As a gastroenterologist, addressing the maladaptive illiness perceptions, coping strategies and related poor illness outcomes in these patients deals with an important field for behaviour modification in IBD patients including cognitive behavioural therapy (CBT) or physical exercise. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing mucosal healing in ulcerative colitis (UC) patients.

Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmoidoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin at weeks 14 and 54, concomitant use of steroid and azathioprine therapy at the time of inclusion were also recorded. At weeks 14 and 54, previous use of anti TNF drug and the need of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated. Results: Seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54 week treatment period. Mucosal healing was shown in 55.4% of the patients at week 14 and 61.7% at week 54 (p = 0.033). Complete mucosal healing was patient in 24.3% at week 14, but in none at week 54. The median values of CRP (p = 0.017), leukocytes (p = < 0.001), thrombocytes (p = < 0.001), and albumin (p = 0.002) showed significant difference at baseline and week 54. Mean trough level of CT-P13 was 5.02 µg/ml and 4.4 µg/ml at week 14 and 54. Serum antibody positivity was measured in 7.7% at week 14 and 26.2% of cases at week 14 and 54, respectively. Dose escalation was necessary in one third of patients. None of the patients need surgery who completed week 54, however 4 subjects who stopped CT-P13 therapy after induction regimen required colectomy. Conclusion: CT-P13 was related to two third of the patients during CT-P13 maintenance therapy. Our study confirmed the long-term efficacy of CT-P13 therapy on mucosal healing in UC. Disclosure of Interest: All authors have declared no conflicts of interest.

P1605 THE USE OF ANTI-TNFs IN INDUCING CLINICAL RESPONSE AND REMISSION IN UC PATIENTS: A COMPARATIVE ANALYSIS IN THE REAL-LIFE EXPERIENCE OF A SINGLE REFERRAL CENTER

Introduction: Anti-tumor necrosis factor (anti-TNF) agents, infliximab (IFX) and more recently adalimumab (ADA) and golimumb (GOL), have been shown effective and safe in the treatment of moderate-to-severe ulcerative colitis

United European Gastroenterology Journal 5(5S) A743
Aims & Methods: Our aim was to compare efficacy of IFX, ADA and GOL in inducing clinical response and remission in a prospective cohort of patients with moderate to severe UC. From June 2015 to October 2016, 61 consecutively UC patients were treated with anti-TNFs: 19 with IFX, 25 with ADA and 17 with GOL. Disease activity was assessed by Mayo Score. Clinical response and/or remission were evaluated at week 8 and at week 16. We also recorded: indications to biologic therapy, previous immunosuppressive or anti-TNF therapy and rate of anti-TNF discontinuation.

Results: Among the 61 patients, 36 were males; mean age was 43.6 ± 15; no significant difference was present in baseline characteristics (extent and disease activity): 59 patients were thiopurine failure; 38 were naive to anti-TNFs, most were treated with IFX (p = 0.001). ADA and GOL were more often used as a second-line or third-line. The principal indication for steroid resistance patients was IFX. No significant difference was observed between IFX and ADA both at week 16 (response: IFX vs ADA, p = 0.28; remission p = 0.001) and at week 16 (response p = 0.5; remission p = 0.97), though there was a trend towards a higher rate of response at week 8 with IFX (79% vs 64%). IFX and ADA were more effective than GOL at week 8 (response: IFX vs GOL p = 0.020; remission: ADA vs GOL p = 0.027). At week 16 only IFX seems to be more effective than GOL in inducing clinical response (p = 0.048) but not remission. No significant difference among the three drugs was observed in patients naive to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA because of persistent disease activity.

Conclusion: This single-center study shows that IFX is more effective than GOL both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC. IP is more preferred in steroid-resistant patients to get a faster response, ADA and GOL should be the first option in steroid-dependent patients naïve to anti-TNFs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Aims & Methods: non-polypoid dysplasia, only a few studies investigated the feasibility of ESD as a treatment for the resection of visible, non-polypoid dysplasia in UC. From August 2009 to January 2017, 19 UC patients with low grade dysplasia (LGD), high grade dysplasia (HGD) or synchronous dysplasia were included prior to first Infliximab infusion. Disease activity was measured by the use of Harvey-Bradshaw-Index (HBI) or partial Mayo Score, C-reactive protein (CRP) and ultrasound (Limberg Score). TNF-expression of LPS-stimulated monocytes was determined using a commercial kit. Adherence was estimated by infusions completed within seven days before or after the date prescribed. The reported date of administration should be indicated in the clinical history to identify patients who did not take the medicine as instructed. Aims & Methods: We aim to describe the adherence to infliximab in patients with IBD and identify causes and factors associated with poor adherence. We identified all IBD patients treated with infliximab in a single center since 2009. Results: in 139 of 140 courses of treatment, patients took more than 80% of infusions on time. In 89% of courses combo therapy with immunosuppressants was used. The prescribed regimens were: every 8 weeks (76.2%), every 4 weeks (77.5%), every 6 weeks (85.7%), every 12 weeks (54.1%) or other (4.5%). The mean duration of the courses was 23 months (range: 6-103). Only 69 out of 1714 infusions (4%), were not properly administered. The reported causes for that included: 36 “unknown” (52%), 18 “change requested by patient” (26%), 14 “due to logistic reasons” (20%) and 4 “other” (6%). Conclusion: the adherence to the scheduled infliximab regimen was very high and it would contribute to maintain the drug efficacy. The reasons for changing the date of administration should be indicated in the clinical history to identify associated factors and minimize the lack of adherence. Disclosure of Interest: All authors have declared no conflicts of interest.

P1697 COST-UTILITY ANALYSES OF BIOLOGICS FOR REFRACTORY ULCERATIVE COLITIS
S. Campbell Davies1, C. Inserra1, R. Saleron2, A. Cassinotti2, G. Muserra3, M. Piacenza3, E. Arzidonne3
1Pharmacy, ASST Fatebenefratelli Sacco, Milan, Italy
2Gastroenterology, ASST Fatebenefratelli Sacco, Milan, Italy

Contact E-mail Address: secampbelldavies@gmail.com

Introduction: Although many biologics (Bs) have been approved for the treatment of refractory-to-severe Ulcerative Colitis (UC) in patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not the most relevant.

Aims & Methods: The objective is to evaluate cost-utility of Bs for the treatment of refractory-to-severe UC both in Italy and in the Lombardy Region. A Markov model (considering 3 transition states: remission, clinical response, relapse) was constructed using the software R and markovchain-package to evaluate incremental cost-utility ratios (ICUR) of adalimumab (ADA), infliximab (IFX), infliximab biosimilar (IFX-B), golimumab (GOL) and vedolizumab (VED) of treatments of patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualised by -1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results: Costs per treatment were different from an N and R perspective (ADA: 10,182/QALY, IFX: 130,595, R: 103,081, E: 948/QALY). From a R perspective, ADA was dominating compared to all other treatments. The ICUR of VED/ADA was 103,081, R: 110,438, E: 68,314, E/C0 18.3%, VED (N: 18,665/QALY, E: 130,595, R: 103,081, E/C0 40.2%), IFX (N: 55%; IFX 14.3%, E: 28.6%), GOL (N: 3) or ECC (n E 15.4 years and mean duration 15.4 years and mean duration between UC diagnosis and dysplasia detection was 13.7±6.5 years. Nine were male. Five of 19 patients directly underwent colectomy without ESD trial due to the lesion size (n E 18.1±9.1 mm, respectively. The lesions were located at the rectum (n = 9), sigmoid colon (n = 2), descending colon (n = 1), and transverse colon (n = 1). The gross morphologic showed Paris IIa (n = 7), IIIb (n = 4), IIIc (n = 1), and Ib+ Is (n = 2). No lesions contained ulceraions. The borders were distinct in 6 and vague but endoscopically assumable in 8 cases. Mean UC endoscopic index of severity was 3.3 at the moment of the proceeding surgery. The mean resection time was 54.8±25.7 minutes. En bloc resection and R0 resection rates were 92.9% and 71.4%, respectively. There was no perforation or clinically significant bleeding.

Conclusion: According to our ESD series for dysplasia, ESD seems to be feasible for the resection of UC-associated dysplasia. However, meticulous surveillance colonoscopy is mandatory to monitor local recurrence and metachronous dysplasia. Non-lifting sign and surface ulceration are highly suggestive of invasive colitic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.
intracellular TNF-expression was analysed by flow cytometry. According to a cut-off point, patients were divided into low-producers and high-producers. Primary endpoint was clinical response, secondary endpoints were decrease in CRP and Limberg Score. Clinical response was defined as a decline in Score of ≥2 (HBI) or ≥5 (partial Mayo Score). A HBI ≤5 or a partial Mayo-Score ≤2 was defined as remission. Results were analysed using the Fisher’s exact test.

Results: Nine patients reached the endpoint at week 6 and were available for further analysis (5 patients with CD, 4 patients with UC). The median TNF-expression was defined as remission. Results were analysed using the Fisher’s exact test.

Aims & Methods: To further evaluate the impact of concomitant CS use on vedolizumab treatment persistence in patients with Crohn’s disease (CD) and ulcerative colitis (UC). We included 50 patients (mean age 45.5 y; male 56%) with Crohn’s disease (CD, n = 28) and Ulcerative colitis (UC, n = 22). 44 (88%) IBD patients had previous anti-TNF therapy. Baseline median HBI was 8 (5–16) and median pMayo was 6 (5–7). Median VTL (Interquartile range, IQR) at weeks 6, 10 and 14 were 38.6 (20.3–53.5), 25.4 (13.4–45.6) and 17.7 (10.1–33.7) ug/ml, respectively. VTL measured at week 6 were significantly higher in clinical responders as compared to non-responders: median (IQR) 38.3 (20.5–49.8) vs 13.4 (8.4–20.6) ug/ml, p = 0.006. Week 6 VTL were also higher in CRP responders (<5 mg/l): median (IQR) 48.1 (32.5–55.8) vs 32.8 (19.7–49.4) ug/ml, p = 0.004. Week 6 VTL were inversely correlated with CRP (rho = −0.39, p = 0.006). By ROC curve analysis, a cut off value of 44.3 ug/ml for clinical response was identified at week 6 (AUC 0.677, sensitivity 61.9%, specificity 79.3%, p = 0.006). However, remission rates after 6 weeks were significantly higher in high-producers compared to low-producers (high: 80% vs. low: 0% remission; p = 0.048). Secondary endpoints showed no significant difference in the two groups.

Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

Introduction: Corticosteroids (CS) are often used concomitantly with biologics in treatment of inflammatory bowel disease (IBD). However, their side-effect profile causes significant clinical and economic burden in long-term treatment. In this study, we investigated the impact of concomitant CS use on vedolizumab treatment persistence in patients with Crohn’s disease (CD) and ulcerative colitis (UC).

Aims & Methods: This was a nationwide (Finland), retrospective, non-interventional, multi-center chart review. From 27 centers, we included adult (≥18 years of age) IBD patients who received at least one vedolizumab infusion since 2014. Data were derived from patients charts in a standardized case report form. The key data collection points were at baseline, week 14 and month 6 of vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment persistence among IBD patients using CS in real-world clinical setting.

Results: 247 patients (CD 108, UC 139) were included. At baseline, 47 (43.5%) CD and 84 (60.4%) UC patients were using CS. Higher percentage of patients using CS at baseline discontinued vedolizumab during the 6-month follow-up compared to CS non-users (CD, 14/47 (29.8%) vs. 13/61 (21.3%); UC, 37/84 (44.1%) vs. 16/55 (29.1%). CS users had less vedolizumab discontinuations due to primary inefficacy (p = 0.04) and more discontinuations due to adverse events (p = 0.04). Over half of the patients on CS at baseline and who persisted on vedolizumab were able to discontinue CS before 6 months (p = 0.0035). VTL measured at week 6 were also higher in CRP responders (<5 mg/l): median (IQR) 38.6 (20.3–53.5) vs 13.4 (8.4–20.6) ug/ml, p = 0.005. The ROC curve analysis identified a cut off of 44.3 ug/ml for clinical response at week 6 (AUC 0.677, sensitivity 61.9%, specificity 79.3%, p = 0.02). Week 6 VTL were significantly higher in patients in clinical remission at their last follow-up (median (IQR) vs 80% vs. 14% at weeks 10 and then every 4 weeks were given to no-responders at week 6. Clinical activity was evaluated at baseline and week 6, 14 and 22 by Harvey Bradshaw Index (HBI) and partial Mayo score (pMayo). C-reactive protein (CRP) was measured at weeks 6, 14, 22. VTL and AVA were assayed by ELISA (Theraflag, Marne La Vallée, France) at weeks 6, 10 and 14. Limits of detection for VTL and AVA were 2 ug/ml and 35 ng/ml, respectively. Clinical response was defined as at least 30% reduction of activity scores from baseline and remission was defined as HBI <5 or pMayo <2. Statistics was performed by Mann Whitney test, Spearman’s rho, receiver operating characteristic (ROC) curve analysis.

Results: We included 50 patients (mean age 45.5 y; male 56%) with Crohn’s disease (CD, n = 28) and Ulcerative colitis (UC, n = 22). 44 (88%) IBD patients had previous anti-TNF therapy. Baseline median HBI was 8 (5–16) and median pMayo was 6 (5–7). Median VTL (Interquartile range, IQR) at weeks 6, 10 and 14 were 38.6 (20.3–53.5), 25.4 (13.4–45.6) and 17.7 (10.1–33.7) ug/ml, respectively. VTL measured at week 6 were significantly higher in clinical responders as compared to non-responders: median (IQR) 38.3 (20.5–49.8) vs 13.4 (8.4–20.6) ug/ml, p = 0.004. Week 6 VTL were also higher in CRP responders (<5 mg/l): median (IQR) 48.1 (32.5–55.8) vs 32.8 (19.7–49.4) ug/ml, p = 0.004. Week 6 VTL were inversely correlated with CRP (rho = −0.39, p = 0.006). By ROC curve analysis, a cut off value of 44.3 ug/ml for clinical response was identified at week 6 (AUC 0.677, sensitivity 61.9%, specificity 79.3%, p = 0.02). Week 6 VTL were significantly higher in patients in clinical remission at their last follow-up (median (IQR) vs 80% vs. 14% at weeks 10 and then every 4 weeks were given to no-responders: median (IQR) 38.3 (20.5–49.8) vs 13.4 (8.4–20.6) ug/ml, p = 0.005. The cut off identified by ROC curve analysis for this outcome was 16.4 ug/ml (AUC 0.820 sensitivity 100% specificity 63%, p = 0.0019). AVA were detected in 2% of patients at week 6, in 5.9% at week 10 and in 4.5% at week 14 and were not correlated with clinical response.

Conclusion: These preliminary data suggest that obtaining a VTL of 44.3 ug/ml after the first 2 Vedolizumab infusions is correlated with early clinical and biological (CRP) response and with clinical remission at a mean follow-up of 20 weeks. Week 14 VTL are correlated with clinical remission at week 22 and identified cut off is 16.4 ug/ml. Immunogenicity of Vedolizumab is low in these patients.

P1703  EFFICACY, SAFETY AND LONG-TERM OUTCOME OF ENDOSCOPIC BALLOON DILATION THERAPY (VDZ) IN ULCERATIVE COLITIS: IS THE ADHERENCE REALLY IMPORTANT?

Aims & Methods: The goal of maintenance therapy in Ulcerative Colitis (UC) is to keep clinical and endoscopic steroid-free remission. 5-aminosalicylate (5-ASA) represents the first line maintenance therapy. Non-adherence to 5-ASA is associated with increased risk of disease relapse, colorectal cancer and worsening of quality of life. Adherence rate has been analysed in several studies with controversial results. Adherence to 5-ASA in our population is low. Older patients that take other non-UC chronic drugs show higher adherence. With a one year treatment, 5-ASA properties (dose, administration regime, formulation), concomitant drugs, smoking habit, Montreal classification, extraintestinal manifestations, complications, disease course (moderate-severe relapse rate that require corticosteroid therapy), UC properties (dose, administration regime, formulation), consumption of other UC and non-UC chronic drugs. A multivariable logistic regression model was applied to discriminate the main factors including the risk factors of the univariable analysis. A Spearman’s rank coefficient analysis was performed to correlate percentage of adherence with relapse rate.

Results: The study cohort included 433 patients, 55% males with a median age at the first 5-ASA prescription of 49 years (IQR 39-61). 17% had a proctitis, 31% a left-side colitis and 52% an extended disease. 30% of patients required corticosteroid therapy when comparing both adherent and non-adherent groups. Multivariate analysis reached a predictive capacity of 65% outcomes of adherence. The aim of this study is to quantify the prevalence of adherence to 5-ASA, to identify risk factors to non-adherence and its correlation with the course of the disease. Observational, analytical, retrospective, single tertiary centre, cohort study of all UC patients followed-up in our IBD unit, until January 2016, with 5-ASA maintenance treatment prescribed by an electronic management program. Adherence was considered when 80% of the prescribed 5-ASA was dispensed at pharmacy. The first year (2016), assuming that dispensing of 5-ASA is equivalent to medication intake. The study analysed, according to the existence and degree of 5-ASA adherence, UC phenotypic expression (age, sex, smoking habit, Montreal classification, extraintestinal manifestations, complications), disease course (moderate-severe relapse rate that require corticosteroid therapy), 5-ASA properties (dose, administration regime, formulation), consumption of other UC and non-UC chronic drugs. A multivariable logistic regression model was applied to discriminate the main factors including the risk factors of the univariable analysis. A Spearman’s rank coefficient analysis was performed to correlate percentage of adherence with relapse rate. Results: The study cohort included 433 patients, 55% males with a median age at the first 5-ASA prescription of 49 years (IQR 39-61). 17% had a proctitis, 31% a left-side colitis and 52% an extended disease. 30% of patients suffered from extraintestinal manifestations and 8 from a complication. The mean dose of 5-ASA taken was 2.6 g/day (range 0.7-4.8) distributed in a daily dose regime. Adherence prevalence to 5-ASA was 65%. Adherent group had a higher median age (52 (±11) vs 43 (±13), p = 0.001) and received more non-UC chronic drugs (OR = 2.3, 95CI 1.5-3.4, p = 0.001). The independent variables, age and intake of other non-UC drugs, included in the multivariate analysis reached a predictive capacity of 65% outcomes of adherence. There was no significant reduction in the risk of moderate-severe flares that required corticosteroid therapy when comparing both adherent and non-adherent groups and rank correlation showed no relationship between adherence to 5-ASA and disease activity. Adherent group of patients treated with adjuvant maintenance therapy (bitherapy with thiopurines or anti-TNF or triple therapy with bithapy) both presented a significant reduction of flares (OR = 0.6, 95CI = 0.7-0.9, p = 0.019).

Introduction: Randomized controlled trials provide efficacy data of novel IBD drugs. The majority of patients included in these trials however, especially for novel biologics, are highly selected patients from referral centres and are included in a variety of countries with very different health care systems. Inclusion criteria and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practice in all centres. Aims & Methods: Here, we aim to test the feasibility of the web-based registry in patients starting vedolizumab. With a structured iterative process with IBD-specialist from the ICC, case report forms and lab-evaluation forms were developed to assess key elements of disease activity, safety and a PROM. Furthermore the ICC decided on a uniform follow-up protocol reflecting everyday practise. A web-based registry for capturing, managing and reporting follow-up data of IBD patients starting a new drug was developed (ICC-case series). The registry automatically reminds the treating physician or nurse prior to novel follow-up visits. Feasibility of the ICC-case series was assessed in 6 centres in the Netherlands in patients who started vedolizumab. To test data extraction and reporting, the baseline characteristics of the first cases were assessed. The characteristics were compared to baseline characteristics of subjects in the vedolizumab registration studies.

Results: A total of 230 IBD (4 IBD-U) patients starting vedolizumab were included. All users found the ICC-case series easy to use and received the reminder mails for follow-up visits. Baseline characteristics were successfully extracted and are reported in table 1.

Conclusion: The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlining the importance of country specific post-marketing data.

Introduction: Azathioprine (AZA) and thiopurines are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985-2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2-2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10-15 days for the first 3 months and then every 1-2 months following the institution of treatment.

Results: Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.3%) were affected by Crohn’s disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up <72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male...
and 115 (44.8%) female (average age of 35.68 ± 14.22 SD years, range 14–74 y.). Six years after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, p = 0.0017), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 24 UC, 20.3% and 36.5%, respectively, p = 0.0084), 56 (21.8%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%.

Conclusion: Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS—12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL

N. Jayasooriya, L. Everson, S. Mann
Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

Contact E-mail Address: nishani.jayasooriya@nhs.net

Introduction: Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

Aims & Methods: We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical and outcome were reviewed from Electronic Patient Records (EPR).

Results: Fourteen patients (F = 6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a starting dose of 0.1mg/kg/day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded after 10 months to have an elective subtotal colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 11 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n = 1 renal impairment; n = 1 started on infliximab; n = 3 referred for leucapharesis; n = 1 restarted on Azathioprine and n = 1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and immunogenicity than the young.

Disclosure of Interest: All authors have declared no conflicts of interest.

no adverse effects on maintenance treatment with Tacrolimus. 11 patients
(78.6%) have avoided a colectomy during the first 12-months of follow-up.
Conclusion: Tacrolimus should be considered as an alternative treatment for
patients with refractory UC in the out-patient setting. This is particularly
useful if the patient is unwilling to cosider a colectomy. With close monitoring
and adherence to protocols, it is safe and effective allowing patients an alternative immunosuppresant which may either avoid the need for a colectomy or, give
some time to adjust to its implications.
Disclosure of Interest: All authors have declared no conflicts of interest.

Larger prospective studies with longer follow up are warranted to confirm this
data.

Introduction: Adalimumab (ADA) and golimumab (GOL) are effective in the
induction and maintenance treatment of moderate-to-severe ulcerative colitis
(UC). No comparable data between the 2 drugs are available up to now.
Aims & Methods: We reported the Sicilian Network experience on the comparative efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC.
From June 2015 until April 2017, 197 consecutive pts with moderate to severe
UC were treated with ADA or GOL. The efficacy was evaluated at 8 week and at
the end of the follow up considering ‘‘clinical response’’ (reduction of at least 2
points of Partial Mayo Score with concomitant steroid reduction or discontinuation) and ‘‘clinical remission’’ (Partial Mayo Score 52 without steroids). The
presence of clinical response or clinical remission was defined as ‘‘clinical benefit’’. Endoscopic Mayo Score was evaluated at the end of the follow up in pts who
underwent colonoscopy.
Results: 118 pts were treated with ADA and 79 with GOL for a median
follow up of 40.21 [20.32, 69.14] weeks for ADA and 34.00 [17.43, 54.79]
weeks for GOL (p ¼ 0.08). Eighty-eight pts were naı̈ve to anti-TNF (59
ADA, 29 GOL, p ¼ 0.09). No difference in Mayo Score value was observed
between the 2 groups at the time of first drug injection (p ¼ 0.92). After 8
weeks clinical benefit was achieved in 93/118 (78.8%) pts treated with ADA
and 50/79 (63.3%) pts treated with GOL (p ¼ 0.026). Clinical remission was
achieved in 48/118 (40.7%) pts treated with ADA and 20/79 (25.3%) pts
treated with GOL (p ¼ 0.038). At the end of the follow up clinical benefit
was achieved in 79/118 (66.9%) pts treated with ADA and 37/79 (46.8%) pts
treated with GOL (p ¼ 0.008). Clinical remission was achieved in 50/118
(42.4%) pts treated with ADA and 23/79 (29.1%) pts treated with GOL
(p ¼ 0.082). No difference was observed in clinical outcomes at 8 weeks
and at the end of the follow up between naive and non naive pts
(p ¼ 0.187). At the end of the follow up the median Endoscopic Mayo
Score was 3.00 [0.00, 5.00] in pts treated with ADA and 4.00 [1.00, 7.00]
in pts treated with GOL (p ¼ 0.025). Univariable analysis revealed that
age 4 40 years at the time of first drug injection and age 5 40 years at the
diagnosis were associated with higher remission rate in pts treated with
ADA respect to pts treated with GOL at 8 weeks and at the end of the
follow up (p ¼ 0.034 and p ¼ 0.016 respectively). Disease duration 45 years
was associated with a higher remission rate in pts treated with ADA respect
to pts treated with GOL at 8 weeks and at the end of the follow up
(p ¼ 0.017).
Conclusion: This is the first study where the comparable efficacy of ADA and
GOL was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNF in the treatment of moderate to severe UC. ADA resulted
to be more effective than GOL in inducing and maintaining clinical benefit.

Introduction: The efficacy of golimumab for the induction and maintenance of
clinical remission in adult subjects moderately to severely active Ulcerative
Colitis (UC) has been studied in two completed clinical trials.1–2 However,
patients enrolled in clinical trials are not entirely representative of those encountered in the clinical practice setting. In Italy, golimumab is on the market for
treating UC from March 2015. The aim of our study is to evaluate the durability
and safety of golimumab in the context of real-life clinical practice.
Aims & Methods: An observational, multicenter, retrospective-prospective, phase
IV study, enrolling all patients starting golimumab from March to December
2015, from 21 IG-IBG centers. This study consists of two different parts: 1)
retrospective, regarding data until December 2016 and 2) a prospective one,
still ongoing, that will be concluded at the end of 2017. The co-primary outcomes
were the overall durability of treatment with golimumab, defined as persistence
on golimumab therapy because of sustained clinical benefit, and safety. Results
for the first 54-weeks period are reported.
Results: 121 patients (47% female), with mean age of 45.7 years (SD 14.3) and a
median duration of disease of 8 years, (range 0–28) were included. Sixty-seven
patients (55.4%) had severe endoscopic activity (Mayo 3). Clinical activity was
defined as moderate (Partial Mayo Score (PMS) 5–6) in 55 patients (45.5%) and
severe (PMS 7–9) in 66 patients (54.5%) Previous exposure to anti TNF- was
reported in 52% of patients (38 Infiximab, 4 Adalimumab, 21 both). Steroiddependence and refractoriness were reported in 78.5% and 16.5% of patients,
respectively. After 54 weeks, the cumulative persistence on golimumab therapy
was 31%. Seventy-seven patients withdrew from treatment, without significant
difference among anti TNF- naı̈ve vs exposed patients (55.2% vs 71.4%,
p ¼ 0.11 Chi-Square test). Among 90% of patients who completed week 8,
48% of patients were still on golimumab therapy at week 54. Thirty patients
(39%) withdrew within the first 14 weeks. Among the remaining patients, at
week 54 the persistence on golimumab therapy was 57.1%. Ten patients
reported an adverse event, but only 6 of them withdrew from treatment.
Four patients reported paradoxical skin lesions, unresponsive to topical therapies. Fifteen patients (12.4) underwent surgery within the first 54 weeks, with
a greater percentage among anti TNF- exposed (20.6% vs 3.4%, p ¼ 0.02
Chi-Square test).
Conclusion: This preliminary real-life data study endorses golimumab’s promising results, showing 57.1% of durability treatment at week 54 in those patients


who completed first 14 weeks of treatment and confirming it as a safe drug. Anti TNF-α treatment may be more likely to avoid colorectal cancer.

P1712 PREVALENCE OF CIPROFLOXACIN RESISTANCE IN INFLAMMATORY BOWEL DISEASE PATIENTS WITH GUT COLONIZATION WITH EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING ENTEROBACTERIA ACCORDING TO BACTERIAL PLASMID GENES

V. Skuja1, K. Pekarska1, H. Dauvarte1, E. Vasuka1, L. Dobenece1, J. Malina1, D. Raudznie1, E. Lavinovic2, L. Pekse1, A. Kalezna2, A. Krumina1, A. Lejnic1, A. Deroys1

Introduction: Ciprofloxacin is one of the most frequently used antibiotics in hospitalized inflammatory bowel disease (IBD) patients. Also discrepancies between clinical guidelines and real clinical situations are observed in terms of antibiotics use in patients with IBD. In the last few years an emerging resistance to ciprofloxacin, ranging from 43% to 82%, has been described in extended spectrum beta-lactamase producing bacteria (ESBL-E) colonizing the gut.1,2

Aims & Methods: The objective of this study was to evaluate the gut colonization with ESBL-E in IBD patients, determine the resistance to ciprofloxacin and bacterial plasmid genes associated with that. Rectal swabs were collected from all consecutive patients with confirmed ulcerative colitis (UC) and Crohn’s disease (CD) hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016). Enterobacteriaceae were cultured and subcultured to test for ESBL presence according to EUCAST guidelines, resistance to ciprofloxacin and bacterial plasmid genes CTX-M, TEM and SHV were detected.

Results: A total of 148 patients with confirmed IBD diagnosis were included in the study: UC (47% [32%] with CD. We found that 12 (12%) of the UC patients and 5 (11%) of the CD patients were colonized with ESBL-E. The isolated ESBL producing strains from UC patients included Escherichia coli (n = 10), Klebsiella oxytoca (n = 1) and Escherichia hermanii (n = 1). The isolated ESBL producing strains from CD patients included only Escherichia coli (n = 5). The isolated bacterial plasmid genes associated with ESBL production in UC included CTX-M (n = 11; 92%), TEM (n = 4; 33%), SHV (n = 1; 8%), in CD – CTX-M (n = 4; 80%) and TEM (n = 3; 60%). In UC (60%) and in CD (20%) of the patients the isolated ESBL producing strains were resistant to ciprofloxacin. In 1 case of the ciprofloxacin resistant CTX-M, TEM and SHV gene combination was observed, in 1 case CTX-M and TEM gene combination was observed, in 4 cases only CTX-M gene was present and in 1 case only TEM gene was present. 8 cases of ESBL colonization rate with TEM in IBD patients, mostly with E. coli, expressing CTX-M gene was found comparing with the literature. 2. Higher resistance to ciprofloxacin was found in ESBL-E isolated from UC patients, comparing to UC patients. 3. CTX-M and TEM genes are associated with resistance to ciprofloxacin.

Introduction: Ano-perineal fistulas (APF) are a common location of Crohn’s disease (CD). Their treatment is still disappointing. Identifying the predictive factors of response could guide the practitioner to adapt the anti-TNF α treatment of each patient.

Aims & Methods: We performed a descriptive, longitudinal and retrospective study over a period of 14 years. We included all patients with a definite diagnosis of complex APF of CD treated with anti-TNF α with a minimum follow-up of one year. Patients less than 16 years of age or over 70 years were excluded and non-observing patients were also excluded. A univariate and multivariate statistical analysis was then carried out using the SPSS software to identify the predictive factors of response to the treatment.

Results: A total of 49 patients had complex APF treated with anti-TNF α. 10% of the patients had also recto-vaginal fistulas. The mean age was 31 years. The sex ratio women/men was 1.35. All of the patients had an MRI at diagnosis. Patients had concomitant antibiotics and seton drainage in all cases. 76% of the patients received azathioprin. After the induction phase, 53% of the patients

Disclosure of Interest: E. Gilles: Travel expenses and fees from Astellas France. F. Coste-Desreux: Travel expenses from AbbVie France.
achieved clinical remission, 31% a partial clinical response and 12% a primary failure. Patients maintained a clinical remission after a year of maintenance therapy. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long term good response to anti-TNF therapy. Treatment remission after the induction phase was the only independent predictive factor of long-term remission under maintenance treatment after multivariate analysis. However, patients with a previous predictive of a clinical response as well as the presence of a recto-vaginal fistula and young age at diagnosis. Conclusion: According to our results, the type of response obtained after the induction phase seems to be closely related to the subsequent development of our prospective studies assessing early therapeutic adaptative strategies. We could better evaluate this perspective in the event of a partial clinical response. In addition, rectal involvement and recto-vaginal fistulas are factors of poor response for which aggressive and specific treatment is essential.

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs result that in a significant economic burden on the healthcare system, led to the development of biosimilar agents. The biosimilar IFX has been authorised for use in all the indications as the reference IFX. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. However, the role of biosimilar IFX, has not been proven in clinical trials. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab reference in inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out at 4 tertiary hospitals from 13 March to 3 December 2016. Inclusion criteria included consecutive cohorts of IBD patients. One cohort composed of patients who were started original IFX since 2013. The second cohort included patients who were treated from the introduction of biosimilar IFX. Adverse events (AEs), demographic, clinical, endoscopic and laboratory data were collected on all patients. Efficacy was assessed according to response and remission at 14th, 54th week. For CU, response was defined as a decrease in partial Mayo score of 2 or more from baseline and a partial Mayo score of 1 or less was used to remission. For CD, response was defined as a decrease in Harvey-Bradshaw score of 3 or more from baseline, and a Harvey-Bradshaw score of 4 or less was used to remission. We used Student’s t for independent samples and Chi-square test. Time to withdrawal due to adverse effects was estimated using Kaplan-Meier survival analysis, and the log rank test was used to test for treatment group differences.

Results: The analysis included 346 consecutive IBD patients, 104 treated with original IFX and 242 with biosimilar IFX. 103 patients were diagnosed with CU, 238 with CD and 5 with indeterminate colitis. Overall median follow-up was 21 months. Baseline clinical activity scores were not significantly different among the 2 groups. Frequency of concomitant azathioprine and systemic steroids were not different among both groups. Patients in biosimilar infliximab group were more likely to experience previous biologic treatment failure (29.2% versus 20.2% in the original IFX, p = 0.0163). There were no significant differences in patients achieving response and remission at weeks 14 and 54. There were no significant differences in rate of withdrawals among the 2 groups (37.1% versus 38.8% for biosimilar IFX, p = 0.811). There were no significant differences in cumulative discontinuation rate due to AEs in original IFX and biosimilar IFX (42.42, (95% CI 39.49–45.34) months versus 44.61 (95% CI 42.66–46.56) months, log-rank test p = 0.292).

Conclusion: All our experience showed similar efficacy and safety profile of biosimilar IFX compared to original IFX.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1716 DOES SEVERE ENDOSCOPIC COLITIS PREDICT STEROID REFRACTORY DISEASE IN ACUTE SEVERE COLITIS?
F. Er-Rahbi, S. Elmajboubi, E.M. Amine, W. Khannoussi, Z. Imsali, G. Kharrasse
Gastroenterology, Oujda University Hospital, Oujda/Morocco

Contact E-mail Address: fouda.errahbi@gmail.com

Introduction: Acute severe Colitis (ASC) is a severe complication of inflammatory bowel disease (IBD), for which there is no consensus definition. Its diagnosis is made based on clinico-biological and endoscopic criteria. Low endoscopy is essentially positive for the diagnostic of ASC as well as for the diagnosis of IBD

Aims & Methods: The objective of this study is to describe the endoscopic aspect of ASC and its interest in therapeutic management in our series of 48 cases it is a descriptive and analytic study of a series of 48 cases of acute severe colitis (ASC) collected during a period of 3 years (2014–2016) in the gastroenterology department.

Results: The average age of our patients was 39.8 years with extremes ranging from 14 to 69 years, a female predominance was found with a sex ratio of 0.77. The ASC was inaugural in 20 (41.66%), while 28 cases (58.33%) were known to have IBD, with 24 cases of UC (85.7%). Initial endoscopy was performed in all patients. The average time to perform endoscopy (from the onset of symptoms) was 37 days (2 to 75 days). Severe endoscopic aspects were present in 30 patients: deep ulcer (29 cases), spontaneous bleeding (4 cases), friability (4 cases). Other endoscopic lesions found were erythema (12 cases), erosions (5 cases), superficial ulcer (25 cases), pseudo polyps (14 cases), contact bleeding (27 cases). Biopsy was performed in all patients, histology was in favor of UC in 64.58% cases. CMV viral inclusions were found in 2.08% of cases. First-line medical treatment was based mainly on parenteral corticosteroid therapy, has been established in all cases. A second-line treatment has been anti-TNF agents used in 5 cases (10.41%) while surgical treatment was indicated in 15 cases (31.25%) of which 12 cases had severe endoscopic colitis. Steroid refractory disease was associated with endoscopic severe colitis (p = 0.04). In mono-varied analysis, endoscopic severe colitis was found in more men than females (53.5 vs 43.3). With a statistically significant difference p = 0.020

Conclusion: Endoscopy in ASC occupies an important place to specify the morphological severity and thus make the positive diagnosis, the severe endoscopic colitis constitutes one of the predictive elements of steroid refractory disease requiring the use of a second therapeutic palliatum.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1717 BASELINE CALPROTECTIN DOES NOT PREDICT RESPONSE TO BIOLOGICAL THERAPY IN ULCERATIVE COLITIS
D. Storey1, T. Skouras2, A. Bond1, S. Dodd1, S. Subramanian1
1Division Of Gastroenterology And Hepatology, Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool/United Kingdom 2Gastroenterology, Royal Liverpool University Hospital, Liverpool/United Kingdom

Contact E-mail Address: Thomas.skouras@nhs.net

Introduction: Response to biological drugs in ulcerative colitis (UC) is variable with induction response rates of 64.5% (vs 29.3% for placebo), 50.4% (vs 34.6% for placebo), 51.0% (vs 30.3% for placebo), 47.1% (vs 25.5% for placebo) for infliximab, adalimumab, golimumab and vedolizumab, respectively. Apart from prior exposure to anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological drugs have not been well defined. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Aims & Methods: Patients who were commenced on any biological therapy for UC and had a baseline FC at the time of commencement were included in this retrospective study. Disease activity was monitored serially by calculation of Simple Clinical Colitis Activity Index (SCCAI) or by Physician global assessment (PGA) or by treatment persistence. Clinical response was defined as decrease in SCCAI by 3 or a decrease in PGA by 1. Remission was defined as FC below 200. The ability of FC and fold change in FC to predict response and remission at 6 months was estimated using Mann-Whitney test.

Results: A total of 94 patients were commenced on biological therapy of who 70 (75%) commenced vedolizumab with a mean age of 41.8 (SD: ±18.2). Fifty-one (72%) and 39 (55%) patients commencing anti-TNF therapy had comparable calprotectin values at baseline, P=0.292. Fifty-one (72%) and non-responders (600 (107, 2100) [n=5]) to anti-TNF agents had comparable calprotectin values at baseline, P=0.039.

Conclusion: In a single-centre series of biologic treated UC patients, baseline FC did not predict clinical response at 6 months.

Introduction: The prevalence of Crohn’s disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient’s Registry in Poland was established to collect demographic and clinical data. Aims & Methods: The aim of the study was to assess the efficacy and tolerability of different medications in reference to demographic data and disease location and behaviour.

Results: 6030 of patients have been enrolled to the Polish National CD Patient’s Registry, conducted in 95 gastroenterology centers in Poland. Patient’s phenotype according to: Montreal classification, demographics, smoking, alcohol consumption, extraintestinal manifestation and medical treatment have been evaluated. The impact of demographic factors on the use of drugs from different groups (mesalamine, prednisone, azathioprine, methotrexate, anti-TNF), and medications efficacy and tolerance was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.

Conclusion: The first study comparing efficacy and tolerability of treatment methods used in ‘real-life’ practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect of casual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.

Aims & Methods: The aim of our non-interventional retrospective study was to assess the efficacy of induction VDZ therapy in patients with Crohn’s disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14. Results: 41 enrolled IBD patients were therapeutic failure or intolerant for infliximab and/or adalimumab therapy. The mean age was 38.6 years (range 18–67; median 40) and the average disease duration was 11.7 years (range 1–36; median 10). In 16 cases moderate and in 25 cases severe disease activity was observed. Extraintestinal manifestations occurred in patients, and in cases the IBD was associated with primary sclerosing cholangitis (PSC). Rate of the therapeutic responders for VDZ induction therapy was 80.49% (N = 33). Complete clinical remission was observed in 19 cases (46.34% 8 cases of whom were steroid-free remission. In one case VDZ therapy had to be interrupted due to development of IBD associated colorectal cancer and in one case due to MCV infection.

Conclusion: Our results suggest that induction VDZ therapy is effective and it is a safe therapeutic option in anti-tumor necrosis factor alpha failure or intolerant IBD patients with moderate or severe disease activity.

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. Despite the reduction of TB reactivation following treatment for LTBI the risk of reactivation still exists. The efficacy of LTBI treatment in IBD patients receiving biologic therapy and the timing of biologic therapy initiation has not been extensively studied.

Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. Patients were excluded including patients with active demographics, TB risk factors, chest x-ray findings, biologic agent used, prior and concomitant therapies, and LTBI treatment regimen. TB reactivation after completion of LTBI treatment was the primary outcome of the study. Risk of TB reactivation was calculated using McGill University’s ‘The Online TST/IGRA Interpreter’.

Results: A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included in the study. Their mean age was 38.3 ± 14.4 years and 68.6% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen was isoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to
starting biologic therapy. The median time from initiation of LTBI treatment to biologic was 43 days (4–3653). The mean duration of follow-up was 2.9 ± 3.3 years. The median calculated annual risk of developing active TB without treatment was 0.52% (0.08%–1.3%). Of the cohort studied, only one patient taking adalimumab monotherapy after completing 6 months of INH therapy developed reactivation of TB. The estimated TB reactivation rate in our cohort was 0.98 cases per 100 patient-years of follow up.

Conclusion: Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in our cohort. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

Introduction: Resection in Crohn’s disease (CD) intends to be a curative surgery, but sometimes it is not possible to remove completely the lesions of the damaged gut. The aim of our study was to describe the characteristics and management of patients with residual disease after surgery (RD) and to compare these with patients with curative surgery (CS) in post operative CD patients.

Aims & Methods: PRACTICROHN was a retrospective study that included adult patients from 26 Spanish hospitals who underwent CD-related ileorectal resection with ileocolonic or ileorectal anastomosis between January 2007 and December 2010. Clinical data was retrospectively collected from clinical charts. RD was defined when lesions were still present after surgical resection. Postoperative recurrence (POR) was defined by clinical symptoms (diarrhea, abdominal pain) and endoscopic Rutgeerts score ≥2, and/or CT or MRI confirmation of disease activity. Categorical variables were compared with the χ² test or Fisher’s exact test. Kaplan-Meier method was used to assess time to clinical recurrence and a log-rank test to obtain statistical significance.

Results: Three hundred and sixty-four patients were analyzed (mean age 40 years [SD 13], 50% men). Of these, 27 (7.5%) had RD after surgery. Median age at diagnosis was shorter in patients with RD than CS: 23 (IQR 19–34) years vs 29 (IQR 23–40), p = 0.02. At the time of resection B1(+p) behavior was more frequent in RD than in CS: 6 (22%) vs 26 (8%), p = 0.05; and location was mainly L1(±L4) in CS (19%, 57%) and L3(±L4) in RD (19.70%), p = 0.02. Four (16%) patients in RD were receiving immunomodulators at the time of surgery vs 132 (41%) of CS, p = 0.002. More patients in RD vs CS presented postoperative complications (12 (44%) vs 87 (26%), p = 0.06) as well as hospitalizations the first year after surgery (10 (37%) vs 42 (12%) p = 0.001). No differences in smoking habit, perianal disease or length of resection were found between the two groups. More patients were performed an endoscopy within the first year after surgery in the RD vs CS:16 (39%) vs 122 (36%), p = 0.03 but no difference in prophylactic treatment were found in RD vs CS groups. POR was more frequent among patients with RD (69% vs. 29%; p = 0.001). Median time to POR was longer in patients who received prophylaxis vs those who didn’t receive it (698 vs 392 days; p = 0.41, 81,275 (29%) in the CS presented POR with median time to POR being longer in patients who received prophylaxis (no median found vs 1529 days) p = 0.04. Conclusion: Residual disease is a rare situation after intestinal resection in CD. Patients with residual disease after surgery are more likely followed-up endoscopically within the first year. Conversely, similar prophylactic recurrence prevention was observed compared to curative surgery. In the case of residual disease although prophylactic treatment is useful, most of the patients will present POR. RD is a factor of poor prognosis in post-operative CD patients.

P1722 SEVERITY OF BILE ACID MALABSORPTION CORRELATES WITH LENGTH OF ILEAL RESECTION IN CROHN’S DISEASE

T. Skouras1, Y. Prasad2, S. Dodd3, S. Subramaniam4

1Gastroenterology, Royal Liverpool University Hospital, Liverpool/United Kingdom
2Royal Liverpool University Hospital, Liverpool/United Kingdom

Contact E-mail Address: Thomas.skouras@nhs.net

Introduction: Bile acid malabsorption (BAM) is a common cause of diarrhoea in Crohn’s disease (CD) patients with ileal resection and can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homotauricholic acid test (75SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain undiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.

Aims & Methods: We identified all CD patients with a prior surgical resection who underwent 75SeHCAT testing at our institute. Testing was based on the treating clinician’s discretion. The length of resected ileum was recorded from histopathology report. We conducted a Spearman’s correlation test to check for correlation between length of resected ileum and percentage retention on 75SeHCAT. Response to treatment with bile salt sequestrant and 75SeHCAT retention values was tested using Mann-Whitney test.

Results: A total of 97 patients were identified with a mean age of 46.4 (SD 14.5). The median length of resected ileum was 22.5 cms (range 1.5–95 cms) with a median of 1 resection (range 1–4). Overall, 90 patients (92.8%) had 75SeHCAT retention values of <5% and 5 (25.2%) patients between 5–10% and only 2 patients had values of >15%. There was moderate correlation between 75SeHCAT retention and length of ileal resection (Spearman’s rho: 0.4041, P < 0.001). Data on response to treatment was available for 60 patients, of whom 41 (42%) responded and 19 (19%) failed to respond to bile salt sequestrants. The 75SeHCAT retention values was comparable among responders (median 0.02%, range 0.1–6.6) and non-responders (median 0.02%, range 0.1–6.6, Mann-Whitney test, P = 0.72). Conclusion: There was moderate correlation between length of ileal resection and severity of BAM as defined by 75SeHCAT retention values. Response to bile salt sequestrant therapy was not dependent on 75SeHCAT retention values.

P1723 A MICROBIAL SIGNATURE OF PSYCHOLOGICAL DISTRESS IN IRRTIBLE BOWEL SYNDROME

H. Duboc

Introduction: Irritable Bowel Syndrome (IBS) is associated with alterations along the brain-gut-microbiota axis. Previous studies have suggested a parallel segregation of microbial features with psychological burden in IBS (1,2,3).

Aims & Methods: This increase is currently aimed at examining microbial correlates of psychological distress, anxiety, depression and stress perception. 16s rRNA fceal microbial analyses (illumina MiSeq, V1-2 amplified from total DNA) in 48 IBS patients (Rome-III criteria, mean age 42 years, 35 female subjects, 25 diarhoea-dominant, 5 constipation-dominant and 18 alternating-type IBS). Assessment of psychological and clinical variables with validated questionnaires, microbial analysis via QHIME, Machine learning to predict psychological distress through a composite model of bacterial features. Correlative analysis and comparisons in bacterial abundance among subgroups defined by thresholds in psychological variables.

Results: Thirty-one patients (65%) showed psychological distress, 22 (31%) anxiety, and 10 depression (21%). Psychological distress was uncorrelated with IBS severity (Spearman’s r = 0.05, p = 0.736). Microbial beta diversity was significantly associated with distress and depression (q = 0.044 each). A random forest model using 148 microbial estimators was able to correctly classify patients relative to their psychological distress (AUC = 0.98). Patients exceeding thresholds of distress, anxiety, depression and stress perception showed significantly higher abundances of Proteobacteria (LDA = 2.5). Patients with anxiety were characterized by higher abundances of Bacteroidetes (LDA = 3.0). Differently with Lachnospiraceae with Lachnospiraceae q = 0.013), anxiety positively with AnoBacterium (q = 0.65, q = 0.001).

Conclusion: A microbial signature accurately predicted the presence of psychological distress. Psychological variables significantly segregated gut microbial features, underscoring the role of brain-gut-microbiota interaction in IBS.

P1724 SACCHAROMYCIES BOULARDII CNCM I-745 LOWERS FECAL CHOLIC ACID CONCENTRATIONS DURING ANTIINFECTION THERAPY IN HEALTHY VOLUNTEERS: A NEW MECHANISMS STUDY IN THE PROTECTION AGAINST CLOSTRIDIUM DIFFICILE INFECTION

H. Duboc1, C. Chong Nguyen1, T. Kabbani2, D. Rainteau1, L. Humbert1, C. Kelly1, C. Chong Nguyen1

Introduction: Saccharomyces boulardii (SB) CNCM I-745 demonstrated clinical efficacy in the secondary prevention of post-antibiotic Clostridioides difficile infection (CDI), but the mechanism remains unclear. Cholic acid (CA) is a primary bile acid (BA), synthesized by the liver which triggers the germination of C. difficile spores in the intestine. Physiologically, the gut microbiota transforms primary BAs (cholic acid and chenodeoxycholic) into secondary (deoxycholic and lithocholic). CA loses its germinating properties after transformation and appears to become protective against CDI. The goals of this work in healthy volunteers (HV) were to: A) Describe the effect of SB on CA levels and the quantity of ‘pro-germination’ primary BA including CA in human stools B) Describe whether SB enhances transformation to ‘protective’ secondary BA in human.

Aims & Methods: This work was an ancillary of a previous study conducted in 4 groups of HV at Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, Massachusetts. The previous results of this work showed that SB CNCM I-745 can modulate shifts in the microbiota and reduces diarrhea during an antibiotic therapy. Group 1 (n = 12) received SB CNCM I-745 500 mg twice daily for 14 days. Group 2 (n = 12) received Amoxicillin-Clavulanate (AC) (875/125 mg, t.i.d) daily for 7 days. Group 3 (n = 12) received AC for 7 days and SB for 14 days. Group 4 (n = 12) did not receive any treatment. Group 1, 2, 3 had successive stool samples at D0-28, 0, 3, 7, 10, 13, 21. Group 4 had stool samples at D0, 7 and 21. The fecal concentrations of 28 BAs were measured by HPLC/MS, and expressed as % of total BAs.

Results: AC alone (group 2) significantly reduced the rate of fecal secondary BA at day 7 compared to control (group 4) (54.8 ± 10.1 vs 83.1 ± 7.4%, p = 0.017). In group 3 (AC plus SB), the decrease in secondary BA rate was significantly less than AC (71.23 ± 7.4% vs 54.70 ± 9%, p = 0.04), and this difference was prolonged over time. Similarly, the AC + SB group showed a significantly lower (and sustained) increase in CA than in the AC alone group.

Conclusion: Antibiotics alter the transformation of CA by microbial enzymes into secondary BA. SB administration reduces the transformation rate during antibiotic therapy. The concomitant administration of SB during AC treatment significantly reduces this CA peak. These results highlight new human data on a potential mechanism for post-antibiotic CA inhibition: alteration of the microbiota can encourage germination of C. difficile spores via increased CA concentrations and reduced concentrations of secondary BAs. The effectiveness of SB in preventing recurrent CDI may be explained, in part, through modulation of microbiota changes that influence the balance of pro- and anti-germination BA concentrations.

P1727 HUMAN MILK OLIGOSACCHARIDES: A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTRIDIUM DIFFICILE INFECTION?
L. K. Vigsnaes
Business Development, Glycom A/S, Horsholm/Denmark
Contact E-mail Address: louise.vigsnaes@glycom.com
Introduction: Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids, and the lowering of pH. Hence, the selective growth of bifidobacteria on HMOs can create an ecological niche that is more colonization resistant against pathogens. Bifidobacteria may also have a direct impact on microbial toxins by reducing their level and cytotoxic effect (3). Antibiotics, especially broad spectrum antibiotics, dramatically impact the microbiota and its balance, and have been implicated in the pathogenesis of many health conditions including gastrointestinal symptoms such as diarrhea (4). The most commonly cited mechanism for antibiotic-associated diarrhea is intestinal overgrowth of the pathogenic bacterium, Clostridium difficile.
Aims & Methods: The aim of this study is to investigate, in in vitro models of C. difficile infection, (i) the impact of HMOs on the microbial community and activity (e.g. bacterial metabolites and pH), and (ii) the anti-pathogenic activity of HMOs against C. difficile, with a focus on preventing recurrence of the infection. Two in vitro models, each using human faecal microbiota infected with C. difficile, were used to examine the impact of HMOs on bacterial metabolic production of Clostridium difficile. One model is a 48 hour batch fermentation model, while the other is a simulated gut model, run for 3 weeks post infection, which simulates the infection cycle of C. difficile after antibiotic treatment.
Results: The study revealed that the HMOs increase the level of bifidobacteria, in some models of beneficial bacterial growth, such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of C. difficile; in some cases completely eradicating C. difficile below detection limits. This antimicrobial effect of HMOs on C. difficile was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.
Conclusion: Conclusively, the results show that HMOs can impact C. difficile infection in an in vitro system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic C. difficile infection.

Introduction: It has been reported that the composition of human gut microbiota changes with aging, body mass index (BMI), diet and other environmental factors. In particular, the relationship between gut microbiota and obesity has been underlined frequently because intervention in the microbiota may reduce body fat. In this study, we investigated the relationship between obesity and composition of gut microbiota in healthy Japanese population.
Aims & Methods: Participants were 1,082 healthy Japanese adults (410 males, 672 females) who participated in the Iwaki Health Promotion Project in 2014. Faecal samples were analysed by 16S rRNA gene-targeted sequencing to determine family composition of gut microbiota. They were classified into obese group (BMI ≥ 25) and normal weight group (BMI < 25) according to Japanese standard and were stratified into 7 age groups, 19–29, 30–39, 40–49, 50–59, 60–69, 70–79 and 80–90. The family composition of gut microbiota in each age group was compared between obese and normal group.
Results: There were 235 obese participants, and 847 normal ones. The proportion of Bacteroides decreased substantially, and Ruminococcaceae increasing slightly with aging in obese group. The proportion of Bifidobacteriaceae, Lachnospiraceae and Porphyromonadaceae decreased gradually with aging in both groups.
Conclusion: Changes in composition of gut microbiota with aging were different between obese and normal group. Some previous researches observed differences of gut microbiota between obese and normal group but many of the researches did not take aging into consideration. Our study indicated that different intervention stratified with age could be needed.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1730 CARBOXYLIC AND AMINO ACIDS MIXTURE IDENTICAL TO THE METABOLITES OF THE PROBIOTIC ESCHERICHIA COLI N17 INDUCES BACTERIOCIN SYNTHESIS IN PROBIOTIC LACTOCOCCUS HELVETICUS D75 AND D76 STRAINS AND ENHANCES THEIR ANTIMICROBIAL ACTIVITY AGAINST TEST PATHOGENS

Introduction: The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonscopic in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 65±10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high grade dysplasia; 13 men, 18 women, mean age 68±10) and in the controls (average risk population with normal findings on colonscopic and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 66±10), all undergoing flexible fibre colonscopy.
Aims & Methods: The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonscopic in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 65±10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high grade dysplasia; 13 men, 18 women, mean age 68±10) and in the controls (average risk population with normal findings on colonscopic and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 66±10), all undergoing flexible fibre colonscopy.
Results: A total of 249 mucosal biopsies were taken (60 controls, 63 non-a-A, 60 a-A, 66 CRC) and samples were further investigated. Colcin producing strains were detected in 22% (13/60) controls, 59% (37/63) non-a-A, 55% (33/60) a-A and in 76% (50/66) CRC. Significantly higher production of colcins was observed in non-a-A, a-A and CRC group when compared to controls, p<0.001. Significantly higher production of colcins was confirmed in patients with CRC compared to patients with a-A, p=0.016. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in non-a-A compared to controls, p=0.002, in a-A and CRC group when compared to controls, p<0.001. Microcins were produced more frequently in patients with a-A compared to those with non-a-A, p=0.008.
Conclusion: Strains isolated from large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonscopic. We presume, that mucosal large intestinal microbiota with their products including bacteriocins play an important role during the development of colorectal neoplasia.
Disclosure of Interest: All authors have declared no conflicts of interest.

BMC Infect Dis 2014; 14: 733.
in DNA of both probiotic strains. Sequencing of these fragments showed a difference in their nucleotide sequence when compared to the reference DNA of DPC 4571 strain (A instead of G at position 46, C instead of T at position 249 and A instead of T at position 537), but all these replacements do not lead to changes in the amino acid sequence of a bacteriocin. For Lactobacillus acidophilus D76 another bacteriocin gene fragment of 283 bp was identified (in addition to 537 bp fragment). The latter had 95% homology with the helveticin J gene of Lactobacillus helveticus R0052 (R0052_09025 gene). In NCBI BLASTX database the sequences homologies to the helveticin gene of Lactobacillus helveticus DPC 4571 were found in 11.1% similarity to Lactobacillus paracasei, Lactobacillus casei and Lactobacillus crispatus, Lactobacillus gallinarum, Lactobacillus helveticus and Lactobacillus rhamnosus. The addition of the carboxylic and amino acids mixture (Actoflor®-S) results in 2-2.5-fold enhanced antimicrobial activity of both tested probiotics. Lactobacillus plantarum was the best pathogen Lactobacillus helveticus D75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

Conclusion: Study shows that there are at least two bacteriocins in Lactobacillus helveticus D76 and one bacteriocin in Lactobacillus helveticus D75. Carboxylic acid and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 probably induces bacteriocin synthesis in probiotic strains Lactobacillus helveticus D75 and Lactobacillus helveticus D76 and enhances their antimicrobial activity against test pathogens Escherichia coli O75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression. Discrimination of gut microbial metabolites mixture and identified probiotic bacteriocins for human health has yet to be realized.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal microbiota transplantation (FMT) has been shown to be effective treatment for recurrent Clostridium difficile infection. Concern has been raised about the long-term safety of FMT.

Aims & Methods: The aim of this study was to determine the long-term safety of fecal microbiota transplantation (FMT), and its effect on gastrointestinal symptoms (GI) in Clostridium difficile (CDI) patients. We studied 84 patients of which 45 received an FMT treatment via colonoscopy and 39 served as controls receiving antibiotic treatment (AB) for the recurrent CDI and followed their recovery for a mean period of 3.8 yrs. All together 130 patients (55 patients in the FMT group and 75 patients in the AB group) were sent a 45-item questionnaire collected anonymously. Treatment of recurrent CDI was 2.6 (1.5) vs. 2.0 (0.9) respectively, in the FMT and AB group respectively. The year with the highest incidence was 2015 (0.53%) but with a lower associated mortality rate. CDAD was mostly acquired at the hospital level (75.6%) and the mean length of hospital stay was 33 days. About 82.4% of the cases were first occurring and the remaining (18.6%) were recurrences of CDAD. The majority of the patients underwent study under performance of Proton Pump Inhibitors-IBP (52.8%) and antibiotic therapy (74.6%) (28.6% made a single antibiotic, and 23.6% 2 or more distinct antibiotics). Penicillin antibiotic class was the most used, followed by Cephalosporins (21.5%), Fluoroquinolones (11.4%) and Macrolides (10.1%).

Conclusion: A significant increase in the incidence of CDAD was observed in this study. This increase may be related to several factors, such as the improvement of laboratory diagnostic methods, increased antibiotic prescription, hospital contamination with Clostridium difficile spores or with the appearance of new and now virulent Ribotypes.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. Persistent bleeding or acute massive bleeding of presenting with hemodynamic disorders requires an interventiontreatment. The question of what is the best treatment for acute diverticular bleeding remains

Disclosure of Interest: All authors have declared no conflicts of interest.

References
The aim of this study is to clarify the efficacy of TAE for colonic diverticular bleeding. Retrospective study of transarterial embolization (TAE) for gastrointestinal bleeding was performed.

Aims & Methods: The aim of this study was to clarify the efficacy of TAE for colonic diverticular bleeding. 229 patients were diagnosed as diverticular bleeding from Jan 2010 to Dec 2016 in our institution. Bleeding stopped spontaneously in 126 patients. 103 patients were performed colonoscopy. Overt bleeding occurred in 8 patients after colonoscopy, and those were eligible for this study who underwent TAE. Conservative management or endoscopic procedure were not successful in all the patients. 7 patients were male and 1 was female with a median age of 62.6 years (range 39–85 years). The average opportunity for enhanced CT was 2.1, 7 patients were in shock, and all of the patients were treated with blood transfusion. Those who were extravasation-positive in enhanced CT underwent angiogram from celiac axis near the extravasation at least 3 times. In case radiopaque clips were placed at the bleeding site via colonoscopy to mark embolization site, regardless of whether or not active extravasation was identified on angiogram, coil embolization was performed using 0.018inch coils in vasa recta. Technical success and complications were evaluated. Technical success was defined as immediate complete cessation of bleeding confirmed by digital subtraction angiography showing no further contrast extravasation at the end of each TAE. Clinical success was defined as no recurrent bleeding in observation period.

Results: Technical success rate was 88%(7/8), and clinical success was also 88%(7/8). 6 patients were extravasation-positive in enhanced CT, and 5 patients were extravasation-positive in angiogram. Although 3 patients were extravasation-negative in angiogram, 2 patients underwent TAE. After TAE, no recurrence of bleeding was observed. Severe adverse events such as bowel infraction did not occur in all cases.

Conclusion: As the microcatheter technique has recently improved further, adverse events are rare. Therefore superselective coil embolization could be first choice for diverticular bleeding with extravasation-positive in enhanced CT.

### P1734 ACCURACY OF THE NASOGASTRIC TUBE AND THE BUN/CREATININE RATIO FOR DISTINGUISHING BETWEEN UPPER AND LOWER SOURCES OF GASTROINTESTINAL BLEEDING. A SYSTEMATIC REVIEW

Gastroenterology, Hospital Universitari Parc Tauli, Sabadell/Spain

Contact E-mail Address: stmachlab@tauli.cat

Introduction: The insertion of a nasogastric tube (NGT) and assessment of the BUN/creatinine ratio were recommended as initial measures to distinguish between upper and lower gastrointestinal bleeding (American College of Gastroenterology 2016). As the nasogastric tube is one of the most bothersome interventions for the patient, we evaluated the evidence supporting these recommendations.

Aims & Methods: The aim of the study was to identify the diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratios) of the NGT and the BUN/creatinine ratio for distinguishing between upper and lower sources of gastrointestinal (GI) bleeding. We conducted a systematic review of the literature in order to identify studies assessing the diagnostic accuracy of the NGT or BUN/creatinine in patients with melena, hematochezia or rectorrhagia without hematemesis. The search was performed in November 2016 in five data bases (PubMed, Scopus, Web of Science, Cochrane Plus Library and OpenGrey).

Results: Four studies met the selection criteria (two evaluating the NGT, one BUN/creat and one both). The two methods had a low sensitivity for detecting upper GI bleeding source. Both a positive NGT aspiration and BUN/creatinine ratio above 30 markedly increased the probability of an upper GI source with a positive likelihood ratio ranging from 2 to 11. Unfortunately, the sensitivity of both tests for upper GI bleeding was very low (negative likelihood ratios around 0.09). Characteristics and results of the studies selected are shown in table 1.

Conclusion: For patients with gastrointestinal bleeding without hematemesis, BUN/creat ≥30 indicates a high probability of an upper GI source. Nasogastric tube aspiration provides little additional information and so is not indicated. Neither test reliably rules out an upper GI source of bleeding.

2Surgery, University Hospital of Patras, Patras/Greece

Contact E-mail Address: geodiamiant@hotmail.com

Introduction: Acute lower gastrointestinal bleeding (ALGB) occurs in patients taking anticoagulants either warfarin or non Vitamin K oral anticoagulants (NOACs). The use of NOACs has been increasing compared with warfarin in recent years. We investigated patients with ALGIB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.

Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results: Out of 587 patients with ALGB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9 (range 61–88) and the average of polyp size was 11.6 (range 5–22) mm in diameter. The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between the two groups.

Conclusion: ALGB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGB on warfarin.
We conducted subgroup analyses according to the identity of FDRs affected, searched, assessed and extracted data from eligible studies. The relative risks family history of CRC in FDR were included. Two reviewers independently and grey literature were searched from their inception to December 2016, and all Aims & Methods: The present systematic review and meta-analysis examined the CRC risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and included all screening studies that investigated the three family history of CRC and incidence/prevalence of CRC. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects (<40 vs. ≥40; <50 vs. ≥50; <60 vs. ≥60 years). Statistical heterogeneity was assessed by the I² statistic. Publication bias was evaluated by an inverted funnel plot analysis with Begg's regression model.

Results: Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC (RR = 1.96, 95% CI = 1.57-1.97; p < .001, I² = 97.5%). Earlier age of onset of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR = 3.29, 95% CI = 1.67-6.49 for <40 years vs. RR = 1.42, 95% CI = 1.24-1.62 for ≥40 years, p = 0.017; RR = 2.81, 95% CI = 1.94-4.07 for ≤50 years vs. RR = 1.47, 95% CI = 1.28-1.69 for ≥50 years, p = 0.001). The Begg's test did not identify any publication bias (Kendall's t = 0.122, p = 0.159).

Conclusion: A family history of CRC in FDRs whose age of onset is earlier than or 40 or 50 years conferred a significantly higher risk of CRC in asymptomatic individuals, implying that age of onset could potentially enhance the discriminatory capability of CRC prediction scores.

Disclosure of Interest: N. Arber, J. L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, C. Yu, D. Fung, C. Y. Chinese University of Hong Kong, Hong Kong/Hong Kong Prc Contact E-mail Address: martin_wong@cuhk.edu.hk

text: 3.29, 95% C.I. 1.67–6.49 for <40 years vs. RR

5. Conclusion: Few studies compared the risk of colorectal cancer (CRC) among individuals with probands who were parents, siblings, and those with two or more probands.

Aims & Methods: This systematic review and meta-analysis tested the hypothesis that the risk of CRC conferred by family history of CRC in parents vs. siblings vs. ≥2 first-degree relatives (FDRs) was similar. The Ovid Medline, EMBASE and grey literature were searched from their inception to December 2016, and all screening studies that examined the association between detection of CRC and family history of CRC in FDR were included. Two reviewers independently searched, assessed and extracted data from eligible studies. The relative risks (RR) and odds ratios were pooled based on a random effects meta-analysis. We conducted subgroup analyses according to the identity of FDRs affected (parents vs. siblings vs. ≥2 FDRs), and examined statistical heterogeneity by the I² statistic. Potential publication bias was explored by funnel plot analysis with Begg's regression test.

Results: We identified 56 case-control and 7 cohort studies, consisting of 9.28 million subjects who were finally included in the meta-analysis. Asymptomatic individuals with siblings affected (RR = 2.44, 95% CI = 1.90–3.13); parents affected (RR = 2.18, 95% CI = 1.95–2.45) and ≥2 FDRs affected (RR = 2.68, 95% CI = 1.92–3.76) had statistically similar risk of CRC. We did not identify any publication bias based on the Begg’s regression test (p = 0.159).

Conclusion: The risk of CRC was similar among subjects whose siblings; parents or ≥2 FDRs were affected by CRC. Information on the identity of the FDRs affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1742 GILBERT SYNDROME IS NOT THAT INNOCENT
N. Arber1, N. Menachem1, L. Atri2, G. Lion1, B. Ezra1, H. Git1, H.G. Amir1, J. Mayerson1, S. Shapira2

2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Contact E-mail Address: nadira@tivme.gov.il

Introduction: Gilbert’s syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk among patients with Gilbert syndrome.

Aims & Methods: We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology, plastic surgery, OB/GYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24; blood count, TSH, CRP, PSA), vaginal, PSA and mammography (>40ys), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but to mild elevation in unconjugated bilirubin <3 mg/dl without any hemolysis. In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)17A in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome. Mortality data was obtained from the Israeli ministry of health and cancer incidence from the Israeli registry.

Results: A total of 6258 (49%) men and 6461 (51%) women, mean age 47.0±11.5 years, were included of which 1,019 had clinical Gilbert. Gilbert was significantly more common among men (11.5% versus 4.6% P < 0.001). The rate of Gilbert syndrome was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1,837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 1.23 (95% CI = 1.04-1.46 p = 0.017), and the prevalence of hypertension (OR 1.37 (95% CI = 1.12-1.68 p = 0.003) and CVA (1.1% versus 0.6% p = 0.06). Higher rate of kidney and bladder cancers (OR 2.64, 1.22-5.70, p = 0.019) was also observed in the Gilbert group. In contrast, the prevalence of breast cancer was much lower among patients with Gilberts (OR 0.39, 0.22-0.7, p = 0.034).

Conclusion: In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

P1743 CHARACTERISTICS AND PREDICTORS OF INTERVAL CANCER: A CASE-CONTROL STUDY
L. Lai1, J. Mizrachi2, F. Konikoff1
1Meir Medical Center, Kfar Saba/Israel
2Stony Brook University Hospital, New York/United States of America

Contact E-mail Address: ido.laihi@gmail.com

Introduction: Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions) in the post-polypectomy surveillance, or different polypologic factors that contribute to the development of the polyp (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports came from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

Aims & Methods: This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005–2014. Cases were included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative 13 indica or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since index colonoscopy (<3 years, 3-10 years). Positive controls were cancer patients without previous colonoscopy, and "negative" controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 1:3 ratio. Tumor characteristics (location, staging) and patient-related factors (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.

Multicenter study on hemorrhagic risk of heparin bridging therapy for periendo- scopic thoracopiphrenotomy ; Matsumoto et al. BMC Gastroenterology (2015) 15:89

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: 845 patients were diagnosed with a colon cancer within the study period, and 83 cases (9.8%) were found to have interval cancer. Among them, 51 patients (61.5%) had negative findings at index colonoscopy, while 22 (26.8%) had both non-advanced adenomas (12%) or advanced adenoma (26.5%). Compared to "positive" controls with primary cancer (575 patients with full data), patients with interval cancer were older (84% above 60 vs. 65%, p = 0.03) and had proximal (cecal to splenic flexure) tumor location (57% vs. 34%, p = 0.0001), but gender (47% vs. 53% males) and tumor staging (78% vs. 70% in stage 0–2, p = 0.12) were not different. Compared to "negative" healthy controls (255 participants), interval cancer and negative findings at index colonoscopy (51 patients) had higher prevalence of diabetes (33% vs. 15%, p = 0.002) but the same rate of family history, aspirin use and diverticulosis. There were no significant differences in all these characteristics between patients with interval cancer < or ≥ 65 years.

Conclusion: Patients with interval cancer tend to be older and have proximal tumor location than patients with primary colon cancer, and have higher prevalence of diabetes. A close surveillance or the use of better endoscopic techniques (e.g. use of NBI, longer retrieval time) should be considered for patients with these characteristics.

Disclosures of Interest: All authors have declared no conflicts of interest.

P1746 PREVALENCE OF SERRATED POLYPSYNDROME IN AVERAGE-RISK SCREENING COLORECTAL CANCER SCREENING

J. S. K. Schramm1, K. D. Janhsen2, J. Dinter1, F. Kuetting1, T. Goessler1, H. Steffen2
1University Hospital Cologne, Cologne/Germany
2St. Katharinen-Hospital, Prellen/ Germany

Introduction: Serrated polyps (SPs) have been recognized as precursors of colorectal cancer (CRC), accounting for up to 30% of CRCs via the serrated neoplasia pathway. SPs are classified into hyperplastic polyps (HPs), sessile serrated polyps (SSPs) with or without dysplasia and traditional serrated adenomas (TSAs). The serrated polyps syndrome (SPS) is characterised by multiple SPs throughout the colorectum. The current criteria for SPS is based on the presence of colorectal lesions at screening without knowing if colorectal neoplasia.

Aims & Methods: The aim of the study was to determine the prevalence of SPS in average-risk individuals participating in the German CRC screening programme. We retrospectively analyzed screening colorectal polyps performed by 11 gastroenterologists in 4 medical practices and 1 tertiary academic hospital between 01/01/2011 and 14/12/2016. Individuals <50 years, with a family history of CRC (i.e. first-degree relative with colorectal adenoma or CRC), or with other predictors of colorectal neoplasia were excluded. The significantly higher prevalence of both, non-advanced adenomas (51%, 95% CI 46–56%; p = 0.037) and advanced adenomas (22%, 95% CI 18–26%; p = 0.049) comparing to the individuals with isolated DM2. Advanced adenomas were more likely in patients aged 65–75 years.

Conclusion: Colorectal neoplasia is positively associated with metabolic syndrome. Cardiovascular risk factors (SCORE ≥10%) is a stronger risk factor than the presence of diabetes mellitus type 2. Individuals with SCORE ≥10% were considered as a risk group. Individuals with recent colorectal cancer screening program over the past five years. Newfoundland and Labrador selects patients for colonoscopy if one of two FIT values ≥100 ng/mL.

Disclosures of Interest: All authors have declared no conflicts of interest.

P1747 METABOLIC RISK FACTORS AND THEIR IMPACT ON COLORECTAL CANCER SCREENING: MULTICENTER PROSPECTIVE STUDY

T. Grega, S. Suchanek, O. Majek, O. Ngo, P. Minarikova, B. Seifert
1University Hospital Hradec Kralove, Hradec Kralove/Czech Republic
2St.-Katharinen-Hospital, Frechen/Germany
3Gastroenterology, University Clinic Kiel, Kiel/Germany
4Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine, Brno/Czech Republic
5Department Of General Practice, Department of GP First Faculty of Medicine Charles University, Prague/Czech Republic
6Department Of Internal Medicine, University Hospital Hradec Kralove, Hradec Kralove/Czech Republic
7Department Of Hepatogastroenterology, Institute For Clinical And Experimental Medicine, Prague/Czech Republic

Introduction: Screening for colorectal cancer is focused on the population with average risk of this disease. Individuals with metabolic syndrome represent a population with a higher risk of developing colorectal cancer, but they are not included in colorectal cancer screening standards. The aim of the study was to determine the prevalence of colorectal neoplasia (advanced adenomas and cancers) and evaluated their impact in colorectal cancer screening. Prospective, multicenter study was performed from January 2013 to December 2015 at eight high-quality colonoscopy centers. Patients with metabolic syndrome were identified from demographic measurements, current and past medical history and other risk factors, and colorectal pathologic findings were assessed in patients with metabolic syndrome (target group) who underwent preventive colonoscopy (FIT positive or screening colonoscopy). This data was compared with consecutive patients without metabolic syndrome (control group). The prevalence of colorectal neoplasia was estimated using the screening population criteria (asymptomatic, without family or personal history of colorectal neoplasia).

Results: 1,500 individuals were enrolled; 726 persons (494 men, 68%) had the target group (metabolic syndrome) and 774 persons (353 men, 46%) in the control group (without metabolic syndrome). The significantly higher prevalence of advanced adenomas was observed in the target group (18%, 95% CI 15–21%) comparing to the control group (9%, 95% CI 7–11%), OR 1.8, p = 0.02. Similarly, the prevalence of all adenomas was higher in the target group (48%; 95% CI 44–51%) than in the control group (35%, 95% CI 32–38%); however, the difference was not statistically significant (p = 0.179). Individuals with isolated DM2 (target group) and non-advanced adenomas (51%, 95% CI 46–56%; p = 0.037) and advanced adenomas (22%, 95% CI 18–26%; p = 0.049) comparing to the individuals with isolated DM2. Advanced adenomas were more likely in patients aged 65–75 years.

Conclusion: Colorectal neoplasia is positively associated with metabolic syndrome. Cardiovascular risk factors (SCORE ≥10%) is a stronger risk factor than the presence of diabetes mellitus type 2. Individuals with SCORE ≥10% were considered as a risk group. Individuals with recent colorectal cancer screening program over the past five years. Newfoundland and Labrador selects patients for colonoscopy if one of two FIT values ≥100 ng/mL.

Introduction: Early onset gastroenterological cancers lacking a positive family history are an increasingly worrisome entity. On one hand, early onset is the cornerstone of genetically determined oncological problems, but on the other negative family history does not support the suspect of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as ≤45 yrs. For the other cancers, the threshold was defined at 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed: 2 patients had MSH2 and MSH6 occurring de novo, given the absence of family history; 3 variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those <35 years (n = 4), 1 had MSH2 gene mutation and 3 were negative. In the 36–40 age group (n = 3), 1 had a MSH6 mutation and 2 were negative. In the age group 41–45 (n = 5), 2 MSH6 mutation and 2 VUS were found, alongside 2 negative results.

Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 25% had a VUS, and 58% were negative.

2 gastric diffuse cancer underwent NGS analysis (40 and 45 yrs, 1M and 1F), both negative.

Among 2 pancreatic cancer patients (< 50 yrs, 2 F), one tested negative and the other had a VUS on PMS2.

NGS analysis performed on 1 esophageal cancer (46 yrs, M) was negative.

1 duodenal cancer (46 yrs, F) has a MSH2 mutation and 2 VUS (MSH6 and PMS2).

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that the already known susceptibility genes seldom contribute to sporadic early onset cancers. Other genes and mechanisms may explain the early onset phenotype. Our data show that NGS is often non conclusive in early onset GI cancers, and further development is needed to better classify VUS (25%).

P1749 INVESTIGATING THE DIRECT INTERACTION BETWEEN CD24 AND β-CATENIN IN INTESTINAL TUMORIGENESIS

N. Arber, A. Fokra, S. Shapira, D. Kazanov, F. Bedny, B. Eli, C. Varol
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Gastroenterology, Tel-Aviv Sourasky Medical Center, Tel-Aviv/Israel

Contact E-mail Address: nadira@tlm.gov.il

Introduction: CD24 is a glycosylphosphatidylinositol-linked protein that functions as an adhesion molecule and is upexpressed at an early stage of CRC (Sagiv et al., 2006). The Wnt/β-catenin signaling pathway plays an important role in the CRC carcinogenesis process. C57BL/6.J mice carrying the ApmMin mutation develop ~24.3 ± 3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7 ± 1.7 polyps that ApmMin/CD24 -/- (Double KO) mice developed. Mice colonoscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApmMin mice displayed severe splenomegaly (355 ± 68 mg) compared (141 ± 49 mg) in double KO mice similar to WT mice. HB level in the ApmMin was 5.8 ± 2.5, significantly lower than in the double KO mice (8.2 ± 0.9) and their WT littermate.

Aims & Methods: We aimed to study the cellular interactions between CD24 and β-catenin, and effects of their interaction on intestinal tumorigenesis. CD24-inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transduced with CD24 (Naumov et al., 2014) were used to study this interaction in vitro. Co-immunoprecipitation and immunofluorescent staining were used to investigate the interaction between the two proteins. Far western blotting (FWB) analysis was used to confirm this direct interaction by probing the standard WB membrane with the purified CD24 protein.

Results: In vitro: Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of β-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the level of active β-catenin. Cytoplasmic/nuclear fractionation showed that more active β-catenin entered the nucleus in cells that expressed compared to control conditions (clone 4). In addition, in both cell lines, TOP/FOP luciferase reporter assay showed a significant increase in Luciferase activity upon CD24 expression induction. Co-immunoprecipitation studies of CD24 and β-catenin indicated that these two proteins might be interacting. In addition, in HEK-293T cells and SW480 cells, immunofluorescent staining of CD24 and β-catenin showed that these two proteins co-localize on the cellular membrane. Furthermore, far western blotting analysis suggests that a direct interaction between the proteins exist.

Conclusion: 1. CD24 plays a major role in intestinal tumorigenesis. 2. CD24 interacts with the Wnt pathway by activating β-catenin. 3. CD24 interacts directly with β-catenin. 4. Down-regulation of CD24 may be an important aim in the therapy of CRC.

Sagiv, E., Memeo, L., Karin, A., Kazanov, D., Jacob-Hirsch, J., Mansukhani, S., Sisakian, G., Rechavi, G., Hibshoosh, H. & Arber, N. 2006. CD24 plays a major role in intestinal tumorigenesis. C57BL/6.J mice carrying the ApcMin mutation develop ~24.3 ± 3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7 ± 1.7 polyps that ApmMin/CD24 -/- (Double KO) mice developed. Mice colonoscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApmMin mice displayed severe splenomegaly (355 ± 68 mg) compared (141 ± 49 mg) in double KO mice similar to WT mice. HB level in the ApmMin was 5.8 ± 2.5, significantly lower than in the double KO mice (8.2 ± 0.9) and their WT littermate.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing E. coli infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

Aims & Methods: Min mice were per os inoculated with a CRC-colibactin-producing E. coli strain (11G5), non pathogenic E. coli (K-12 MG1655) or PBS. Using optical in vivo imaging (IVIS spectrum), we evaluated oxidative stress induction with a bioluminescent inflammation probe in Min mice chronically infected. After 7 weeks, number and volume of polyps were evaluated and colonial scores were histologically analysed. Detection of immune cells was quantified by immunofluorescent labelling using a specific and innovative algorithm created with Image Studio software. Then, the density and localization of immune cells were performed in the three colon regions of interest: lymphoid follicle, mucosa and tumor.

Results: Using optical imaging, we detected a significant increase of luminescent signal in the gut of the infected group suggesting an increase of oxidative stress and inflammation. Histological analyses showed no difference about intra-tumoral immune infiltrate density on 11G5 and K12-infected mice. However, using our specific algorithm, we observed a significant increase of lymphoid follicle size in the gut of infected with the 11G5 strain compared to mice feeding with non-pathogenic K12 strain. Interestingly, follicle size was positively correlated with tumor volume, on the 11G5 infected group suggesting an association between pro-carcinogenic proprieties of this strain and gut immune response. In addition, we observed an increase of neutrophils (Ly6G+ cells) on mucosa and lymphoid follicle of mice infected with 11G5 compared to K12 and non-infected mice. These results can be linked with our in vivo optical imaging observations and our results about the increase of neutrophils chemotactants CXCL1 and CCL20 measured by qRT-PCR after infection. Analyses of T cells, macrophages, B cells and myeloid suppressive cells are in progress.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing E. coli infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

Several studies have demonstrated that the colorectal cancer (CRC) tumourspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HCT116 and A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models. We found that higher EGFR autophosphorylation (Y1068) in HCC827-, A549-, and HCT116-derived tumourspheres compared to the parental cells, which induced tumoursphere formation through activating G9α-mediated stemness property. YM155 was demonstrated to inhibit the tumoursphere formation by unexpectedly blocking the autophosphorylation of EGFR and G9α-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9α revealed the significant role of EGFR-G9α pathway in maintaining the cancer stemness property.

Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumourspheres through elevating the G9α-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumourspheres by simultaneously blocking autophosphorylation of EGFR and activity of G9α as a potent anti-stemness agent against EGFR-positive cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A cancer with a number of somatic mutations is defined as “hypermutator”, and shows therapeutic features, such as high sensitivity to immune checkpoint inhibitor. However, to date, analyses of hypermutator have not been done with a large number of cases.

Aims & Methods: The aim of this study is to analyze the incidences and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutations in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs., M:F = 755:390), those underwent surgery after full informed consent during 2014 to 2015. Genomic-wide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencer (Ion Torrent Proton sequencer and Ion AmpliSeq Exome RDY kit, Thermo Fisher Scientific). Hypermutator was defined when a tumor having > 500 mutations in the somatic DNA.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancer, 23 GISTS, 15 esophageal cancers and 14 neuroendocrine tumors, etc. Hypermutator was recognized in 66 cases (5.8%). Age and gender were not related to hypermutation. Associations with tumor location recognized in 6.2% (26 cases) of CRCs, 11.8% (27 cases) of gastric cancers, 2% (2 cases) of HCCs, and one case of small intestinal cancer. Within the hypermutator group, multiple cancers developed in 13.9% of CRC patients and 25.9% of GC patients. Mutations were restricted to 33.2% (22 cases), that of mismatch repair genes (either of MLH1, MSH2, MSH6, PMS2) in 13.6%, POLE in 9.1%, and POLD1 in 4.5%, respectively, in the hypermutator group.

Conclusion: Hypermutator was recognized in 5-10% of digestive system cancers, presenting similar characteristics in CRCs and GCs. Cases of hypermutator sometimes develops multiple cancers, associated with a somatic mutation of mismatch repair genes. Further research must be needed to clarify the characteristic of hypermutator of the digestive organs in the therapeutic aspects.

P1756 UNBIASED ANALYSIS OF REGULATION OF TRANSCRIPTION FACTORS UPON ER STRESS IN THE LS174T COLORECTAL CANCER CELL LINE EXPOSES CTBP2 AS A POTENTIAL REGULATOR OF STEMNESS

Introduction: In the intestinal epithelium, stem cells are located at the bottom of the crypt and their maintenance and differentiation is essential for sufficient organ function. Accumulation of mis- or unfolded proteins in the endoplasmic reticulum, so-called ER-stress, leads to an unfolded protein response (UPR) with a complex array of transcription factor (TF) responses. In human colorectal cancer cell lines (C-CRC) and GCs, cases of hypermutator sometimes develops multiple cancers, associated with a somatic mutation of mismatch repair genes. Further research must be needed to clarify the characteristic of hypermutator of the digestive organs in the therapeutic aspects.

Aims & Methods: Our aim is to identify transcription factors important for stem cell maintenance using a transcriptionomics approach. On thapsigargin treated LS174T-cells, a cell line with a transcriptional profile resembling intestinal stem cells, we performed a TF DNA-binding assay (CatTFRE) in which TFs present in the cell are bound to plasmid DNA, co-extracted and quantified using mass-spectrometry. We confirmed downregulation using immuno blot in colorectal cancer cell lines. Additionally, we examined CBT2 expression in mouse intestine using in situ hybridization, epithelial FACS sorting and immuno staining. To study CBT2 function, we transfected a LS174T cell line with shRNA CBT2 and analyzed stemcell and differentiation markers.

Results: By using the CatTFRE assay we quantified the binding activity for > 1000 transcription factors. Forty-three TFs showed significant downregulated binding upon thapsigargin treatment compared to controls compared to control. We confirmed downregulation of eight of these TFs on protein level, suggesting a loss of binding due to translation inhibition upon ER stress. We identified transcriptional corepressor CBT2 as the most significantly downregulated protein. Interestingly, in mouse small intestine, CBT2 is expressed in the proliferative compartment where stem cells reside. Additionally, mRNA expression analysis showed abundance of CBT2 in iECS. We next investigated the effect of CBT2 knockdown on stemness in the LS174T cell line. Three days upon shCBT2 transfection we showed a significant decrease in mRN A levels of stem cell markers Lgr5 and Olfm4 compared to control and an increase in differentiation markers Villin and P21, suggesting induced IESC differentiation.

Conclusion: Using an unbiased transcriptionomics approach we identified transcription factors that are lost on protein level upon ER stress. Furthermore, our data suggests that the significant loss of the transcriptional regulator CBT2 contributes to intestinal stem cell differentiation.

Aims & Methods: We aimed to identify epitogenic alterations associated with the development of TSAs and to clarify the associations between clinical, pathological and molecular characteristics in colorectal lesions. The genome-wide DNA methylation status in TSAs consisting of protruding and flat components were analyzed using an Infinium HumanMethylation450 BeadChip, and changes in DNA methylation during the development of TSAs were identified. Methylation of identified genes and CIMP markers (MINT1, -2, -12, -31, p16 and MLH1) and BRAF/KRAS mutations were analyzed in 847 colorectal lesions and 61 samples of normal colonic tissue. Effects of etopic expression on CRC cell growth in a panel of colorectal cell lines, and their expression in TSAs were evaluated. Results: Methylation of MINT1 was highly significantly associated with both normal colon and SSA/Ps, but is significantly downregulated in TSAs. Immunohistochemical analysis showed that SMOC1 was expressed in the epithelium of normal colonic tissues and SSA/Ps, but that expression is significantly reduced in TSAs. Methylation of SMOC1 was associated with progression, colony formation and in vivo tumor formation by CRC cells. Analysis of colorectal lesions revealed that SMOC1 is frequently methylated in TSAs and CRCs, and that SMOC1 methylation is strongly associated with KRAS mutation and CIMP-low.

Conclusion: Methylation of SMOC1 is associated with TSA development but is rarely observed in SSA/Ps. Immunohistochemical analysis of SMOC1 may be a useful marker to discriminate between SSA/Ps and TSAs. Our data suggests SMOC1 methylation may play a role in the neoplastic pathways arising in TSAs.

P1759 DEVELOPMENT AND VALIDATION OF PREDICTIVE MODEL FOR PARTICIPATION IN COLORECTAL CANCER SCREENING IN KOREA

J. Chung,1 J. Park,2 J.Y. Yoon1
1National Medical Center Division of Gastroenterology, Seoul/Korea, Republic of
2Department Of Internal Medicine, Gangnam Severance hospital, Seoul/Korea, Republic of

Aims & Methods: The Korean National Health and Nutrition Examination Survey (KNHANES) 2007 - 2010 datasets were used to develop a CRC screening participation screening score. 10,527 individuals aged ≥20 who completed the survey and not previously diagnosed with CRC were selected. Both logistic (LR) analysis and artificial neural network (ANN) were used to develop predictive models. Multilayer perceptron ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 (n = 9586) datasets and compared them with each other.

Results: Out of 10,527 individuals selected, 57.0% (n = 6005) responded unscreened for CRC. Among various demographic and socioeconomic factors, female gender, low education level, having a chronic disease, health insurance coverage, education level, private health insurance, self-reported depression, self-reported health status, and residence were found to be independently associated with CRC screening participation. LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥5.3 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Conclusion: The ANN produced better performing model than LR analysis based model in identifying population with low CRC screening participation. Sensible approaches should be implemented to encourage partaking in CRC screening in the identified individuals.

2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Background: CD24, a mucin-like cell surface molecule, highly expressed on solid tumors and hematological malignancies (HM) (Gastro 2006, Clin Can Res 2007, Can Res 2008). mAb to CD24 were used to inhibit the growth CD24 cancer cells (Gastro 2009). We have shown that a simple non-invasive blood test evaluating CD24 levels on PBL had good sensitivity and specificity for detecting colorectal neoplasia in subjects undergoing screening colonoscopy (Kraus et al., 2009).

Aims & Methods: We aimed to develop a simple, noninvasive blood test that could identify patients at risk for different types of cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic match healthy individuals served as controls. Hemoglobin levels were measured. Results: We undertook an extensive workflow at the Integrated Cancer prevention center at Tel Aviv Medical Center (Eur J Intern Med. 2013) All samples were collected and processed identically. An initial template data has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment which is uniformly applied to all the data collected in order to minimize fluorescence overlap among detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig.1a) (P < 0.013), PC (Fig.1b) (P < 0.018), biliary tract (P = 6.45E-12), breast (Fig.1c) (P = 2.93E-14), prostate (Fig.1d) (P = 0.013), MDS (P < 0.1) and Lymphoma (P < 2.1E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity for CRC were 79.2% and 74.7%, and for PC 70.6% and 75.9%, respectively.

The positive (PPV) and negative predictive (NPV) values of CD24 for the detection of CRC was 38% and 94.8%, and for PC 17.1% and 97.3%, respectively. Specificity and sensitivity for HM were also statistically significant (data not shown). The CD24 test could not discriminate between patients with cervical, stomach and lung cancers and healthy subjects.

Conclusion: Conclusions: CD24 expression in PBLs is a promising blood test for the early detection of CRC, PC and HM.

Introduction: Colonoscopy is considered the gold standard for prevention and early detection of colorectal cancer (CRC), however its effectiveness is directly related to quality of bowel preparation. Two of the quality measures of colonoscopy, cecal intubation rate and adenoma detection rate, are both associated with adequate bowel preparation. Data on factors associated with quality of preparation using Picolax® are limited.

Aims & Methods: We aimed to evaluate factors associated with a good bowel preparation using Picolax® (Sodium picosulfate/magnesium citrate) in the Israeli heterogeneous population. Consecutive outpatients referred for colonoscopy were prospectively assessed by a nurse practitioner filling out a questionnaire. Hemoglobin levels were measured prior to all 10 patients at 3 days before colonoscopy and split dose picolax. Demographics, medical history, Bisacodyl and water consumption, time of total preparation and time between end of prep to colonoscopy were evaluated. Quality was assessed using the Boston Bowel Preparation Score (BBPS). Bowel Prep was considered "good" if BBPS was ≥6 and ≥2 in each segment or "fair" if BBPS was < 6 or < 2 in any colonic segment.

Results: A total of 452 patients were included in the study (M = 54%, mean age 56.5 +/− 16.3 yrs), 366452 (81%) achieved a “good” bowel preparation, and 86 (19%) were classified as “not good.” No significant difference was observed between ethnicities and gender in terms of achieving a good bowel preparation (p = 0.77, p = 0.054). There was a significant difference among diabetics (n = 93, 20.6%) and non-diabetics (n = 359, 79.4%) in quality of the bowel prep. While 69.9% of diabetics achieved a good bowel preparation only 83.8% of non diabetics achieved a good bowel preparation (p = 0.004). In the univariate analysis, Bisacodyl did not have an effect on bowel preparation (p = 0.83) except in the diabetics, where the time who took an average of 2.1.3.1.9 (median 6) vs. 4.31 ± 1.5 (median = 4) tablets fared better (p = 0.018). Other chronic diseases had no effect on bowel preparation. Drinking 3-7 vs. 8-15 glasses of water achieved good preparation in 72.7% vs 83.8% of cases, respectively (p = 0.01). Time from end of preparation to colonoscopy -7% achieved significantly better prep vs >8 hrs (p = 0.002). In the multivariable model for prediction of quality of bowel preparation that included the time between sachets of picolax, number of water cups consumed, diabetes, gender, and age we found that all, excluding age, were good predictors of bowel preparation. Women had a better chance of achieving an adequate bowel preparation (OR1.68, p = 0.045, 95%CI = 1.01–2.79). Patients without diabetes had a better chance of achieving an adequate bowel preparation (OR = 2.05, p = 0.014, 95%CI = 1.16–3.63). Patients who had 5-9 hours between the 2 sachets of picolax had a lower chance of achieving an adequate bowel preparation as compared to those who had 9 to 24 hours between the 2 sachets (OR = 0.375, p = 0.009, 95%CI = 0.180–0.783). Lastly, drinking fewer than 8 cups lowers the chance of achieving an adequate bowel preparation (OR = 0.461, p = 0.003, 95%CI = 0.275–0.775).
Conclusion: Diabetics require a more intense bowel preparation aided by blood glucose control to help others. Time between bowel preparation and 8 hours and preparation should end no later than 8 hours prior to colonoscopy. Patients should be instructed to drink a minimum of 8 glasses of water with each dose of picolax.

Introduction: Colonoscopy is the gold standard method of colorectal cancer and polyp screening, but polyps are missed during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved with optimized endoscopic visualization methods. A recently developed new Fujinon endoscope system, Eluxeo carries a new function of electronic chroendoendoscopy, Linked Color Imaging (LCI), that enhances the coloring algorithm of epithelial membranes and helps to find lesions that are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colonic adenoma detection.

Aims & Methods: Up till now 247 eligible patients, elder than 45 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists (2000 hours) on 205 patients in the conventional high-definition Fujinon EC 590Z or a new EC 760Z VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist team. The minimum withdrawal time was defined as more than 6 minutes. All colonoscopies were routinely assisted with pure CO2 insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic technology.

Results: A total of 247 patients were randomized (mean age 58.7 years), 101 patients enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colorectal polyps and adenomas were detected more frequently in the LCI group than in the control group: 60.9% and 43.8% versus 55.4% and 33.6% respectively, however, this was not statistically significant (p = 0.32 and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 102, 55 vs. 55 vs. 102, respectively (p < 0.0001).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colorectal adenomas, which was mainly due to the ability of the more sensitive detection of minute (less than 5 mm) adenomas. Study was supported by ECT grant GINOP-2.1.1.1-15-2015-00128).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1763 COMPREHENSIVE ANALYSIS OF LONG NON-CODING RNAs WITH CHARACTERISTIC EXPRESSION LEVEL ALTERATION IN COLORECTAL ADENOMAS AND CANCERS

Introduction: Long non-coding RNAs (lncRNAs) play role in colorectal cancer (CRC) development, however, lncRNA expression profile in CRC and its relation to the epigenetic regulatory system still remain incomplete.

Aims & Methods: We aimed the perform whole genome lncRNA expression profiling and the analysis of underlying functional interactions of aberrantly expressed lncRNAs. lncRNA expression levels were analyzed on 60 colonic biopsy samples (60 CRCs, 20 adenomas, 20 normals) by Human miRNA microarray (Affymetrix). Expression alteration of certain candidates was verified by qPCR. Furthermore, in silico validation was performed on HGUC33 Plus 2.0 array data and also on TCGA COAD dataset. mRNA targets of lncRNAs were predicted with the mirCODE algorithm and mRNA expression was analyzed with miRNA microarray. Alternative transcriptional lncRNA-mRNA coexpression pattern analysis was also performed.

Results: According to HTA results in adenomas 12 lncRNAs (e.g. LINC00278) were upregulated and 6 lncRNAs (e.g. RP17_174D18.1) were downregulated compared to normals, while in CRC’s 1 lncRNA (UCA1) was overexpressed and 8 lncRNAs (e.g. LINC00350) were underexpressed compared to adenomas (p < 0.05; ≥2 fold). In CRC samples 8 lncRNAs (e.g. AC120231.1) were overexpressed and 9 lncRNAs (e.g. RP17-49k6.1) were downregulated compared to normals. 42% of lncRNAs upregulated in CRC samples showed moderate-high expression in adenomas (p < 0.05; ≥2 fold) while both downregulated and upregulated lncRNAs were found in adenomas.

Conclusion: The defined lncRNA sets (e.g. CCAT1, UCA1) may have a regulatory role in adenoma and CRC development and may direct tumor cell growth pathways. A subset of CRC-associated lncRNAs showed significant differential expression in the adenoma samples, which may give the possibility to develop biomarkers for colorectal adenoma specific markers and achieve early detection of colon lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Serine protease inhibitors (Serpins) play an important role in the regulation of enzymes involved in proteolytic cascades. Members of the family are: alpha-1-antitrypsin, alpha-1-antichymotrypsin, C1 inhibitor, antithrombin and neuroserpin. Kalikrein-related peptides (KLKs) are involved in proteolytic cascades of different tissues. KLK14, acting via PAR-2, represents an autocrine paracrine regulator of colorectal tumorigenesis and alpha-1-antitrypsin is a natural inhibitor of KLK14. Therefore its role in regulating the proteolytic cascade in colorectal tumorigenesis is of great importance.

Aims & Methods: The aim of this study was to analyze Alpha 1-antitrypsin (AAT) expression in tissue samples at different stages in the process of colorectal cancer development. We examined a total of 245 colon samples. Of those, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was demonstrated in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha-1-antitrypsin expression was found to be significantly associated with longer DFS (p = 0.026) in patients with colorectal cancer. Kaplan-Meier survival curves demonstrated that low alpha1-antitrypsin expression is significantly associated with longer DFS (p = 0.002) as well as OS (p = 0.021).

Conclusion: Our data suggests that alpha1-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Introduction: Real-time differentiation between neoplastic and non-neoplastic colorectal lesions may be crucial during colonoscopy. While adenomas are
neoplastic, and therefore should be resected, hyperplastic polyps never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomized study was to distinguish subcentimetric hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluxeo BLI electronic chromoendoscopy technology with and without optical magnification.

Aims & Methods: In order to create a video and digital picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10mm polyp were included as short (20sec) video-clip and at least one still picture of each polyp without and with 50x optical zoom at standard white-light (WLI), and with FICE-light or BLI-light were recorded with Fujinon EC 590Z and EC760Z endoscopes and stored in an anonymized database. Once the video-library was compiled, each of our 5 colonoscopic experts (ML, SZM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each case, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also assessed by Kudo classification. Finally, with the deficient confidence (low/medium/high on VAS), the histological prediction and the final decision has been clarified on each lesion as neoplastic or non-neoplastic (hyperplasia).

Results: Up till now 115 polyps were enrolled and recorded into our digital web-based library, 59 were assigned into the FICE and 56 into the BLI group. All of the detected 115 polyps were endoscopically removed and histologically analyzed and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI technology of the 5 experts without zoom and with 50x magnification difference to hyperplastic and adenomatous polyps were 77.62% and 84.51%, vs. 74.58% and 83.90%, vs. 88.84%, respectively. There was an excellent correlation between the histopathological results and our KUDO classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence ratio that was associated with a more precise histologically prediction as compared to non-zoom, WLI or FICE or BLI polyp assessment.

Conclusion: The new electronic chromoendoscopy technology with Eluxeo BLI significantly improved the reliability of the histology prediction as compared to FICE and WLI technology. High-confidence predictions for the differentiation of neoplastic and non-neoplastic polyps with Eluxeo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support ressect and discharge strategy. (Study was supported by ECT grant GINOP 2.1.1-15-2015-00128)

Contact E-mail Address: kudos@med.showa-u.ac.jp

Introduction: Till now, narrow-band imaging (NBI) could make it possible to analyze the surface microvascular patterns for colorectal lesions. However, the accuracy of the real-time diagnosis was not as high as ideal. EC (endocytoscopic vascular pattern) is the next generation of EC-V3 for diagnosis and classification of colorectal lesions.

Aims & Methods: The aim of this study was to evaluate the effectiveness of endocytoscopic vascular patterns for differentiating neoplastic lesions from inflammatory or non- neoplastic lesions and predicting the histopathological diagnosis of colorectal lesions. The sixty-eight patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and June 2015. A total of 576 lesions (45 Non-neoplastic polyps, 304 adenomas, 71 intransmucosal cancer, 21 slightly invasive submucosal cancer (SMs) and 135 massively invasive submucosal cancer) were retrospectively evaluated. We used the Kudo classification for the diagnosis of submucosal invasion and classified cancers accordingly. SMs cancer without vessel perfusion does not metastasize. In contrast, SMm lesions show a substantial proportion (~10%) of lymph node metastases. We named the ultra-magnified microvascular findings as endocytoscopic vascular pattern (EVP) pattern and classified into the following 3 groups: EVP-I, the surface microvascular structures were very fine and difficult to observe; EVP-II, the surface microvascular structures were very clearly seen and showed a regular vessel network, and their caliber and arrangement were uniform; and EVP-III, the surface microvascular structures were highly variable in caliber, their arrangement was early with to late vessel homogenization.

Results: The specificity, sensitivity and accuracy of EVP-I for diagnosis of hyperplastic polyp were 89.0%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of EVP-V3 for diagnosis of SMm were 82.2%, 98.0% and 94.3%, respectively.

Conclusion: Endocytoscopic vascular pattern was helpful in predicting the histopathology of colorectal lesions.

P1768 CONSIDERATION OF RECTAL NEUROENDOCRINE TUMOURS IN OUR HOSPITAL
M. Akita
Internal Medicine, Mito General Hospital, Kanonji City, Japan
Contact E-mail Address: m_akita1976@yahoo.co.jp

Introduction: Rectal neuroendocrine tumours (NETs) are recommended to undergo endoscopic therapy, those with a tumour diameter of ≤10mm and up to the deep submucosal layer. However, no clear guideline has been established on the radical criteria and additional treatment for rectal neuroendocrine tumours (NETs). The validity of the diagnosis and treatment recommended in the guideline for rectal NETs will be examined in the cases treated at our hospital.

Aims & Methods: We examined the microscopic features, pathological features, treatment methods, and prognosis of 22 patients diagnosed as having a rectal NET and treated at our hospital between 2007 and May 2016.

Results: The mean age of the patients was 65.2 years (range, 49–88 years); male-to-female ratio, 15:7; diagnosis opportunity, 21 asymptomatic cases and 1 and/or investigation. While miss rates for endoscopic and imaging modalities were low, 19% of missed cancer diagnosis were due to lack of appropriate investigations following outpatient or inpatient review for colorectal alarm symptoms or IDA; this might be improved by increasing specialist inpatient in-reach services and senior review of outpatient cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

symptomatic condition (lumbago); lesion site (Rs/Ra/Rb), 1/2/19 cases; mean tumor size: presence of biologically active enzymes: biopsy diagnosis rate, 11/14 (78.5%); presence/absence of endoscopic ulcers, 11/11 cases; and M/SM/MP, 1/19/1 cases. The TNM classification of the cases was as follows: T1a, 16 cases; T1b, 5 cases; T2, 1 case; N1, 1 case; and M1, 1 case. The treatment was successful in 20 cases with mucosal resection/endoscopic submucosal dissection/surgery/drug therapy in 5/7/2/1/1 case. Of 19 endoscopic treatment cases, 15 corresponded to a tumor diameter of ≤10 mm, with negative resection margin and vascular invasion as criteria for curative resection, and 3 cases of unknown stumps were recognised. In the EMRL group, all cases were negative. In all the cases except the case of other-disease death, it elapsed without recurrence. Both surgical cases showed a positive vascular invasion, and one case was a confirmed N1, but neither of the patients survived without a relapse. In the case with hepatic and bone metastases, medication was administered, and the effect was temporarily effective, but the patient died a year and a half later. Conclusion: Endoscopic treatments are considered appropriate for rectal NETs with a tumor diameter ≤10 mm or for depression or apparent metastasis, and not >10 mm in diameter. Among the treatment options, EMRL is considered useful and well tolerated. However, follow-up observation and case accumulation seem necessary to determine the long-term prognosis in NET, which may recur after years of follow-up.

Introduction: Inactivation of TP53 is the most frequent genetic damage in human cancer. In addition, hyperactivation of the RAS pathway is common in many human malignancies (Lung (LC)~40%, pancreatic (PC)~95%) and colorectal cancer (CRC)~50%). Despite multiple attempts, targeting these pathways for the treatment of cancer, for example through the development of RAS pathway inhibitors has not proven to be effective thus far. Herein, we propose to exploit the hyperactive RAS pathway and TP53 mutation status of human cancer to deliver targeted antitumor therapy. We had previously reported that a recombinant adenovirus, carrying a pro-apoptotic gene (PUMA) under the regulation of RAS-responsive elements (PY4) effectively suppressed the growth of human cancer cells harboring hyperactive RAS (Giladi et al, 2007). Furthermore, we had shown, both in vitro and in vivo, that replacing the pro-apoptotic gene with a bacterial toxin can improve the efficacy of this system (Shapira et al, 2015).

Aims & Methods: We aimed to establish a tight regulated dual system by expressing a toxin under PY4 elements in cancer cells, while sparing normal cells by expressing the anti-toxin under p53 responsive elements (RGC) specifically in non-malignant cells. Adenoviral vectors carrying the toxin (PY4-Maf-mcherry) and anti-toxin (PY4-E3) were designed. A specific inhibitor of interleukin enhancer binding factor 3 (ILF3), expressed specifically in cancer cells under the regulation of the IN derived peptides. Massive cell death was induced upon exposure of the infected cells to the IN peptide compared to the control peptide.

Conclusion: The use of IN derived peptides together with the CD242-targeted lentibehaviour of an in vivo, specifically to promote death of CD24-expressing cancer cells.

**P1711** ILF3 STABILIZES AND ACTIVATES EGF-R-MEDIATED G9A PATHWAY FOR MAINTAINING CANCER STEMNESS PROPERTY IN EGF-R-POSITIVE CANCERS

C. Cheng1, A. Ho2

1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Cheng Hsin General Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: A specific inhibitor of interleukin enhancer binding factor 3 (ILF3), MYC, suppresses EGF-R phosphorylation and signalling, inhibiting the formation of cancer stemness tumourspheres in vitro, suggesting that ILF3 as an oncogene participates in the maintaining of cancer stem cell property through stabilizing EGF-R-mediated stemness pathway. Since cancer stemness cell is the major driving force for cancer progression and recurrence under the regor of EGF-R, inhibition of ILF3 can potentially induce cell death and formation of double-strand breaks due to the action of the particles inte

Aims & Methods: The tumourspheres derived from EGF-R-wild-type and KRAS-mutant colorectal HCT116 and lung A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models in this study. RAS-mutant cells were utilized to search for putative growth factors involved in the formation of tumourspheres as the cancer stemness markers. Meanwhile, the differentiating stemness markers were also compared between ILF3-knockdowned and the control shLuc cells. Then, the protein level and phosphorylation of EGFR were investigated in the MMU-treated and ILF3-knockdowned A549-derived tumourspheres compared to the parental cells. The results of RNAseq evaluated that CD133 was a positive stemness marker, whereas MARCH4 as a negative marker. Knockdown of ILF3 reduced the cell proliferatio

Results: We found that higher EGF-R autophosphorylation (Y1088) in HCT116- and A549-derived tumourspheres compared to the parental cells. The results of RNAseq evaluated that CD133 was a positive stemness marker, whereas MARCH4 as a negative marker. Knockdown of ILF3 reduced the cell proliferatio

Conclusion: In conclusion, this study demonstrated that ILF3 played an impor

5. Liu S, Ye D, Guo W, Wu Y, He Y, et al. (2015) OA, 0.75 [95%CI, 0.57 to 0.98]. Subgroup analysis showed the highest preventive agents for recurrent colorectal adenomas.

6. Although various pharmacological agents have been trialed for prevention of colorectal adenomas, findings were significantly better for sulindac plus each metformin, ursodeoxycholic acid (UDCA), aspirin plus calcium with vitamin D, and difluoromethylornithine (DMFO) plus sulindac. For recurrent colorectal adenomas, findings were significantly better for sulindac plus difluoromethylornithine than other tested agents. Aspirin/NSAIDs was more effective than placebo in both pairwise (OR, 0.73 [95%CI, 0.59 to 0.90]) and NMA (OR, 0.75 [95%CrI, 0.57 to 0.98]). Subgroup analysis showed the highest probability of aspirin (≤100 mg/L) to be the most efficacious agent among all NSAIDs (SUCRA = 71.7%). For safety profiles, the top three ranked agents were metformin (86.7%), antioxidants (82.0%) and dietary supplements (65.9%), but none reached statistically significant when compared with placebo. Aspirin/NSAIDs performed the worst (16.4%) with significantly more serious adverse events than placebo (pairwise: OR, 1.25 [95%CI 1.14 to 1.38]; NMA (OR, 1.28 [95%CrI, 1.12 to 1.44]). Other regimens were not significantly different to each other in both pairwise and network comparisons, these agents include antioxidants, dietary supplements, calcium as well as folate acid.

Conclusion: For individuals with preserved increased risk of CRC, moderate-to-low dose aspirin among those under surveillance are both effective for recurrent colorectal adenomas. Future studies are required to provide more precise estimates of the optimal NSAIDs with an effective dose and low adverse events. We also suggest the further evaluation of NSAIDs-associated combination regimens and other novel agents (e.g.,melatonin) in the chemoprevention of CRC.

P1775 COST-EFFECTIVENESS OF THE FIRST SURVEILLANCE COLONOSCOPY IN POPULATION WITH ADVANCED COLORECTAL POLYPS OR MULTIPLE POLYPS FROM COLORECTAL CANCER SCREENING PROGRAM

L. Caroló, 1 M. González, 1 B. Battile, 1 A. Buroni, 2 X. Bessa Caserras, 2 M. Andreu Garcia, 1 A. Alvarez-Urturi 2 1Gastroenterology, Hospital del Mar, Barcelona/Spain; 2Hospital del Mar, Barcelona/Spain

Contact E-mail Address: l.caroló@parcelsalut.mar

Introduction: The implementation of the CRC screening program has generated an increase in surveillance colonoscopies. However, the intermediate-high risk group that included advanced lesions (size ≥10 mm, villous component or high grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Aims & Methods: We aimed to identify the cost effectiveness of the first surveillance colonoscopy and the predictive factors of metachronous lesions at 3 years in individuals with advanced lesions or ≥3 polyps detected at baseline screening colonoscopy. This was an analysis of all cases with advanced polyps and/or multiplicity from CRC screening program population of Barcelona detected at baseline colonoscopy during the years 2010–2011 and with a performed colonoscopy after 3 years. Epidemiological and clinical data of all individuals were collected as well as the morphological data of all polyps. For the statistical study, a bivariate analysis and logistic regression were performed.

Results: 638 cases were identified, with mean age of 64 years. 342 were men (62.6%). 23.8% required more than one colonoscopy for the complete removal of all the polypos. A complete surveillance colonoscopy at 3 years was performed in 518 cases (82%) with an average surveillance time of 38 months [15–75]. Mean fecal hemoglobin was 440 mg/mL. 51.8% suffered from hypertension, 15% from diabetes mellitus, 46.5% from dyslipidemia and 12.3% from chronic obstructive pulmonary disease. 45.8% of individuals were overweight (BMI ≥25) and 34.7% were obese (BMI ≥30). Surveillance colonoscopy was normal or with low-risk polypos in 420 cases (80.1%); and advanced polypos or multiplicity were identified in 98 cases (18.9%) 73 advanced adenoma in 59 cases (11.4%), ≥3 adenomas in 62 cases (11.4%), and others (11%) and/or serrated in 71 cases (13.7%). The presence of ≥3 adenomas and/or serrated polypos was the only variable that was associated with increased risk of the diagnosis of advanced adenomatous or serrated lesions in surveillance colonoscopy (p < 0.001).

Conclusion: In individuals with advanced polyps and/or multiplicity the incidence of metachronous risk lesions at 3 years is low. Assessment a baseline colonoscopy with complete removal of all the polyps could allow to increase the interval of surveillance, maintaining and ensuring the compliance of the surveillance, and thus in 3 years in the cases with multiplicity in the baseline colonoscopy.

P1777 POPULATION-BASED COLORECTAL CANCER SCREENING IN THE CZECH REPUBLIC—FIRST RESULTS OF THE NEW PROGRAM SETTINGS

S. Suchanek, 1 T. Grega, 1 O. Majek 2, O. Ngo, 1 B. Seifert, 1 L. Dusek, 2 M. Zavoral 3 1Department Of Gastroenterology, Military University Hospital, Prague/Czech Republic; 2Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine, Brno/Czech Republic; 3Department Of General Practice, Department of GP First Faculty of Medicine Charles University, Prague/Czech Republic

Contact E-mail Address: stepan.suchanek@uvv.cz

Introduction: The organized non-population based National Colorectal Cancer (CRC) Screening Program in the Czech Republic has been running since year 2000. In January 2014, the transition to population based setting has been implemented. Currently, the annual immunochromatographic FOBT (FIT) is offered in the age group 50–54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years’ interval.

Aims & Methods: Main aim was to assess the impact of the first 30 months of the population-based CRC screening program on the target population participation and colorectal neoplasia detection. The data from National Reference Center (health insurance companies database) and Preventive Colonoscopies Registry in years 2013 (non-population based settings) and 2014–2015 (population-based settings) were evaluated and compared. We did not find any adenoma recurrence at 3 and 5 years. No cancer recurrence occurred in the follow-up period.

Conclusion: FIT is a feasible strategy to manage superficial colorectal tumors. This study demonstrates favorable technical and short-term clinical outcome of colorectal ESD, but further studies are needed to confirm the long-term efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1776 OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL LESIONS: A SINGLE EUROPEAN CENTER EXPERIENCE

R. Maselli, 1 P.A. Galtieri, 1 L. Lamonaca, 1 M. Di Leo, 1 R. Semeraro, 1 L. Poliani, 1 F. Aurienma, 1 A. Fugazza, 2 G. Lollo, 2 G. Amvrosiadis, 2 E.C. Ferrara, 1 A. Anderloni, 2 S. Carrara, 1 A. Repici 1Humanitas Research Hospital, Milan, Italy; 2Rizzoni/Italy

Contact E-mail Address: roberta.maselli@humanitas.it

Introduction: Colorectal Endoscopic Submucosal Dissection (ESD) is recommended for superficial neoplastic lesions at high risk of submucosal invasion. ESD allows an en-bloc resection but ESD experience is still limited in Western countries.

Aims & Methods: The aim of this retrospective study was to evaluate technical and clinical outcomes of colorectal ESD, in a single tertiary European center. We retrospectively analyzed all consecutive patients treated by ESD for colorectal lesion at Humanitas Research Hospital (Milan, Italy) from January 2011 to September 2016. The primary outcomes were technical success, defined as en-bloc resection and clinical success, defined as curative resection (R0) without need for surgery. Secondary study outcomes were complication rate and adenoma/carcinoma recurrence. Complications were divided in early (≤24 hours) and delayed (>24 hours) and included bleeding and perforation. Recurrences were identified as the presence of adenoma or carcinoma at the endoscopic follow-up performed at 6 months, 1, 3 and 5 years. Data were analyzed by STATA 14 statistical software.

Results: A total of 185 lesions in 185 patients (M/F 79/107, mean age 67.6 ± 11.5). Lesions were located in the rectum (64.3%), left colon (9.7%), transverse (11.9%) and sigmoid (14%). Mean size of lesions was 39.3 ± 0.9 mm. A total of 140 (75.9%) were low-grade dysplasia (LGD) in 64 (34.6%), high-grade dysplasia (HGD) in 78 (42.2%) and adenocarcinoma in 42 (22.7%) cases. Only 1 NET (0.5%) was found. En bloc resection was achieved in 88% of lesions. Clinical success (R0) was obtained in 84.8% of lesions. No cancer recurrence occurred in the follow-up period.

Conclusion: ESD is a feasible strategy to manage superficial colorectal tumors.
P1778 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOUS DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM

P. Zhou1, T. Chen2
1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China
2Leeds Institute Of Biomedical & Clinical Sciences, St.James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: chentao66@yahoo.com

Introduction: Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasia, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dysplasia. We aimed to assess the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.

Aims & Methods: We performed a retrospective analysis of data collected from 5 consecutive patients with 520 colorectal early cancer and high-grade dysplasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.

Results: The overall rates of en bloc resection, complete resection, R0 resection, major complications were 94.4%, 91.5%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colon tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.

Conclusion: ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.

P1779 LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE

O. Craig1, C. Black2, L. Houghton3, A.C. Ford1
1Leeds Gastroenterology Institute, St. James’s University Hospital, Leeds/United Kingdom
2Leeds Institute Of Biomedical & Clinical Sciences, St.James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: ofcraig@gmail.com

Introduction: Patients with irritable bowel syndrome (IBS) often have co-existent mood disorder and psychological illness. Meta-analyses of randomised controlled trials consistently demonstrate that psychological therapies, such as cognitive behavioural therapy (CBT) and hypnotherapy, are effective treatments for IBS. In the UK the National Institute for Health and Care Excellence (NICE) recommends considering the use of these in patients with no response to pharmacological therapies, and for refractory symptoms.

Aims & Methods: We performed a cross-sectional survey to examine willingness of patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies as their first-choice treatment option than those with higher levels of anxiety and depression, somatoform-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

Conclusion: Qualitative and quantitative data were collected using a modified version of the Hospital Anxiety and Depression Scale (HADS), the Beck Depression Inventory (BDI), and the Beck Anxiety Inventory (BAI). Data were analysed using SPSS 21. A total of 63 patients (27 males) were recruited.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1780 GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON’S DISEASE ARE PAN-ENTERIC BUT NOT UBQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY

V. Passananti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: va.emmanuel@ucl.ac.uk

Introduction: Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson’s patients. These may involve muscles from the oropharynx to the anorectum, and the autonomic and enteric nervous system are often involved, resulting in secondary bowel dysmotility.

Aims & Methods: The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson’s disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table1) were included. PD severity were scored with the modified Hoehn and Yahr (H&Y) staging scale. GI symptom burden was identified by Wexner constipation score and Gastroparesis Cardinal Symptom Index (GCSI). Acidity, motility and transit data were obtained, standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the study. The WMC (600 mg) was swallowed and evaluated the long-term outcomes, including severe somatoform behaviour, versus 9.2% of those without (P = 0.10).

Results: One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic PD patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study. In the WMC, the use of constipation score correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and CTT in all patients (p < 0.01) but not GCSI and GET (p > 0.10). The results of Wireless Motility Capsule did not different between non-symptomatic PD and controls.

Conclusion: We have shown that Parkinson’s patients with gut symptoms have both upper and lower complaints. Symptomatic PD patients also have markedly delayed transit times throughout the whole gut compared to asymptomatic PD patients and controls. Whilst severity of constipation is related to delayed colonic transit no such relationship was present between gastroparesis symptoms and gastric emptying. The implication is that treating symptomatic Parkinson’s patients should address the whole gut, whether with prokinetics or dual therapy.

Introduction: Bloating and abdominal distension are common and bothersome symptoms and a frequent complaint of patients affected by functional gastrointestinal disorders (FGID). Recent studies demonstrated that an impairment in psychological therapies as their first-choice treatment option than those with mild or moderate symptoms (7.7% versus 21.7%, P = 0.10).

Conclusion: Despite high levels of psychological comorbidity and NICE recommendations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatoform-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

the handling of gas is a relevant underlining mechanism in FGID patients with bowel dysmotility. Identification of patients lacking these in patients are lacking.

**Aims & Methods:** Our aim is to study the relationship between the defecation pattern, the severity of bloating and the abdominal girth measurements in FGID patients consulting for bloating as primary complaint with/without visible abdominal distension. We propose a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 24 on a 0–100 mm scale) as primary complaint with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Consecutive patients aged ≥ 18 years and fulfilling Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth measurements. During the 2-week run-in period patients completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on adequate relief of bloating on a Likert scale and a further abdominal bloating 100-mm VAS score. ABM patients at standardization visit were provided assessment of abdominal girth two hours after a meal. All patients reporting insufficient adequate relief of abdominal bloating at the end of the run-in period underwent a standardized balloon expulsion test (BET) scored as either successful or failed. A straining questionnaire was also administered.

**Results:** 76 patients (66 female, 39.5±12.2 mean age, 6 IBS-D, 6 IBS-M, 30 IBS-C, 9 IBS-U, 6 FC, 16 FB, 3 FD) completed the 2-week run-in period. A significant negative correlation was found between adequate relief and both bloating and abdominal girth changes (r = -0.53 and -0.52, p < 0.001, respectively). 54/76 (70%) patients reported inadequate relief (worse or no improvement). Among the non-responders the vast majority (68%) failed the BET. Multiple regression analysis showed that BET (successful or failed) was the only dependent variable, that was significantly related to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire.

**Conclusion:** In this prospective, multicenter trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outcome dysfunction was prevalent and correlated with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

**Disclosure of interest:** S. Gallotta received research funding from Fondazione Torsio Premio Irene Habib.

**Introduction:** Faecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct cause of FI and selection the most appropriate therapy. Conventional and High Resolution (HR) Anorectal Manometry (ARM) is a useful tool to categorize anal and/or rectal dysfunctions in addition to provide physiological assessment of both anal sphincters and rectum.

**Aims & Methods:** To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female) and 23% men (M), mean age 63 range (22–92 year) referring to the outpatient unit of Digestive Pathophysiology of S. Giovanni-Addolorata Hospital, Rome from January 2006 to December 2016. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, balloon evacuation test) were analyzed. The manometric parameters obtained with conventional and HR-ARM were: resting pressure, squeeze pressure, rectal compliance, rectal sensibility and the anorectal pattern during the defeacatory maneuver.

**Results:** 114 out of 358 patients (32%) reported both FI and difficulty evacuating stool with/without incontinence UI (47%). Proctological surgery (n 122, 34%), pelvic surgery (n 77, 21%) and traumatic anal or vaginal injury (n 144, 40%) were statistically associated with FI (p < 0.05). Normal manometric parameters were found in 16 patients (4%). Manometric alterations observed were: internal anal sphincter (IAS) dysfunction: 228 (64%); isolated external anal sphincter dysfunction IAS and EAS, 198 (55%); isolated dyssynergic defecation: 100 (28%); rectal hypersensitivity: 130 (36%).
P1784 INTAKE OF FERMENTABLE Oligo-, Di- AND MONO-SACCHARIDES AND POLYOLS (FODMAPS) INCREASES THE RISK OF IRITABLE BOWEL SYNDROME (IBS) IN INDIVIDUALS EXPOSED TO PSYCHOSOCIAL STRESS IN THE COMMUNITY: RESULTS OF A LARGE, PROSPECTIVE, POPULATION BASED STUDY

Results: The cause of IBS is uncertain; however, food intolerance shares many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shephard 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in this patient group (Halmos 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2013) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015).

Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the etiology of IBS in the general community.

Aims & Methods: This population based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community.

Subjects aged 16–74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III), dietary intake (food frequency chart validated in Chinese population), psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

Results: From 1999/2115 (94.7%) members of the community that completed the study, 1221 (57.8%) had IBS by Rome III criteria. The IBS group ingested less lactose than the "No-IBS" group (P = 0.024). Intake of other FODMAPs was similar in both groups (P = 0.346). Compared to the "No-IBS" group, individuals with IBS had a greater likelihood of depression (OR 1.5 (0.97–2.32), p = 0.05), anxiety (2.48(1.84–4.39), p < 0.001), recent life event stress (1.5(1.03–2.20), P = 0.003) and medical or/and surgical co-morbidity (2.90(1.30–5.45), P < 0.001). The IBS group also had lower quality of life (P < 0.001). Joint risk analysis identified high intake of total FODMAP intake as a risk factors for IBS only in subjects with psychiatric disease and/or life event stress (table). Similar effects were seen for individual symptoms, in particular bloating (OR 2.4(1.25–4.60), p < 0.008). Increased risk of IBS was identified with ingestion of high intake of individual FODMAPs (e.g. fructose, lactose) in combination with psychosocial factors, but not with sucrose (control) in any group.

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive dysfunction (Zhu 2013). (ClinicalTrials: NCT0126597)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A large proportion of patients with irritable bowel syndrome (IBS) suffer from anxiety or depression, but the associations with pathophysiological findings and overall symptom reporting are not clear.

Aims & Methods: We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess anxiety and depression (HAD), overall IBS symptoms (IBS-SSS), bowel habits (BSF), quality of life (IBSQOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse.

Results: Based on validated HAD cut-off levels (≥8), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were anxious (p < 0.001), but for depression no gender differences were detected (p = 0.76). IBS patients with anxiety or depression were younger (p < 0.001), but more commonly reported sexual and/or physical abuse (p < 0.001) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit (p = 0.41, p = 0.18). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiological examinations, the findings were more inconsistent. OATT was similar between groups, as was stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge.

Table: Joint effects of psychiatric disease, life stress & total FODMAP intake on relative risk of IBS in community

*Adjusted variables: age, sex, marital status, education, job, income, smoking, drinking, and medical history.

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive dysfunction (Zhu 2013). (ClinicalTrials: NCT0126597)

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiologival findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1,2).

Aims & Methods: This study aimed to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Rome III criteria, as an effort to investigate the association between IBS and lactose intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Rome III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water within 5 minutes after 8 hours of fasting, in order to evaluate the lactose intolerance via hydrogen breath test (0, 15, 30, 60, 90, and 120 minutes). Additionally, symptoms arising during the test were assessed.

Results: Of the total 200 participants, 100 (50%) were in IBS and 100 (50.0%) were in control group. There were 133 females (66.5%), and the mean age was 40.5±12.3 years. Of the total 70 patients (35.0%) with lactose intolerance, 47 (47.0%) were in IBS and 23 (23.0%) were in control groups (p = 0.001). Symptoms related to IBS were more common in participants with lactose intolerance in both groups (p = 0.001, p = 0.001 respectively). A comparison of the two groups with regard to symptomatology after the test showed the presence of complaints in 35 (35.0%) patients in IBS group as compared to 24 (24.0%) subjects among controls (p = 0.092). The incidence of lactose intolerance in patients with IBS subtypes of diarrhea-predominant IBS, constipation-predominant IBS, mixed IBS, and unspecified IBS were 27 (57.4%), 7 (4.9%), 10 (21.3%), and 3 (6.4%), respectively, with no significant differences (p = 0.161, p = 0.124, p = 1.000, and p = 0.661 respectively).

Conclusion: A significantly increased frequency of lactose intolerance was found among IBS patients than in controls. In additional, symptoms associated with lactose intake occurred at a higher frequency in IBS patients, although the difference was insignificant.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Phases of the Study**

**Phase 1:** Baseline data collection from 2,450 IBS-C patients across three countries (US, UK, Canada) using validated questionnaires. Data collection began in 2014 and continued until 2019.

**Phase 2:** Longitudinal follow-up of 1,000 patients for up to 5 years, focusing on symptom severity and quality of life.

**Phase 3:** Evaluates the impact of symptom severity on healthcare utilization and quality of life.

**Conclusion:** Increased symptom severity is associated with higher healthcare utilization and lower QoL, emphasizing the importance of symptom management in IBS-C patients.

Ischaemic colitis (IC) is the most common vascular disease of the colon, although its exact pathophysiological mechanisms remain unclear.1

Aims & Methods: The aim of this study was to evaluate routine coagulation parameters associated with vitamin K in patients with IC and to compare them with a group of controls (individuals with known predisposing factors for IC but without evidence of the disease). This study was carried out in the context of a study evaluating thrombophilia among IC patients. The present study used the same study groups as the latter.2

Disclosure of Interest: Ischaemic colitis (IC) encompasses a number of clinical entities resulting in insufficient blood supply to the colon. The incidence of adverse outcome in patients with IC remains high.

Conclusion: Individuals fulfilling the Rome IV criteria for IBS in the general population have increased GI and non-GI healthcare utilization in primary and secondary care, excess non-GI symptom burden and impaired QOL.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1795 THE RISK PREDICTIVE VALUES OF ACG CLASSIFICATION IN A COHORT OF IRRITABLE BOWEL SYNDROME PATIENTS: DEFINING THE TERMINAL STATE OF DISEASE
V. Magno Pereira1, C. Simões2, M. Silva2, J. Carvão1, A. Oliveira1, C. Baldaia2, G. Serrão1, L. Jasmins1, J. Velosa3

Contact E-mail Address: carolinarobaptistamsoimoes@gmail.com
Introduction: Although most cases of colon ischemia (CI) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk patterns or the classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), to provide a management algorithm for these patients and select the level of care.
Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite CI (clinical, colonoscopy, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mm Hg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN > 20 mg/dl, Hgb < 12 g/dl, LDH > 350 U/l, serum sodium < 136 mEq/l, WBC > 15 x 109/cmm). Patients were then classified as mild (0 risk factors (RF)), moderate (1–3 RF), and severe (3 or more RF) or any of the following: peritonial signs, pneumatoasis or portal venous gas, gangrene on colonoscopy examination and pan-colonic or isolated right colon ischemia involving on imaging by colonoscopy or computed tomography.
Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of CI (62.7% females; mean age 72 years (±13). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intra-hospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only 1 patient with 2 RF died. The remaining 13 deaths were attributed to 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as the need for surgery (mean = 4.06, sd = 1.85). ACG classification presented high predictive accuracy for in-hospital and 1-month mortality with an AUROC of 0.82 respectively. For a cutoff of 2 ACG RF, the sensitivity (SE) for death was 100%, specificity (SP) 52%, with a positive predictive value (PPV) of 14% and negative predictive value (NPV) of 100%. For 3 ACG RF the results were: SE 93%, SP 61%, PPV 16% and NPV 99%, 3 or more risk factors had an odds ratio of 20.2 (confidence interval (CI) 2.59–158) for intra-hospital mortality and 18.42 for 1-month mortality (CI 2.34–144).
Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly in patients with at least 3 ACG RF.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1796 HOW COST AFFECTS THE TREATMENT CHOICE FOR IRRITABLE BOWEL SYNDROME WITH DIARRHEA PATIENTS: A COST-EFFECTIVENESS ANALYSIS OF TRICYCLIC AGENTS AND RIFAXIMIN
E. D. Shah, E. Andraska, J. Li, S. Zhang, W.D. Chey
Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America
Contact E-mail Address: ershah@med.umich.edu
Introduction: Drug pricing and third party payer coverage exert a profound effect on access to prescription therapies in patients with irritable bowel syndrome with diarrhea (IBS-D). We performed a cost-effectiveness analysis to assess the trade-offs associated with treating IBS-D patients with a tricyclic agent (TCA) or rifaximin.
Aims & Methods: We constructed a decision analytic model evaluating three treatment strategies for IBS-D in the United States healthcare system: first-line therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders. This model accounted for direct and indirect costs of therapy (Medicaid NADAC database and Healthcare Blue Book) and work-productivity loss (published literature and US Bureau of Labor) with a 3% per annum discount rate. Rifaximin was administered in 4-month treatment cycles based on published clinical experience. Responder and discontinuation rates were derived from clinical trial data, and validated health utility values were assigned to terminal health states. Base-case analysis was performed to determine incremental cost-effectiveness ratios (ICER) for both rifaximin strategies. Threshold analysis was performed to determine a range of willingness-to-pay (WTP) levels per quality adjusted life year (QALY). Appropriate sensitivity analyses were conducted. Analysis was performed with a 1-year time horizon from societal and payer perspectives.
Results: Based on the average acquisition cost of rifaximin ($US 29.78/pill), second-line rifaximin could be cost-effective from a societal perspective (Table 1). However, at contemporary WTP thresholds neither rifaximin strategy was cost-effective from a payer perspective despite greater effectiveness than TCA alone. On WTP, a 12–62% price reduction ($US 18.46–$26.34/pill) would enable the first-line TCA followed by second-line rifaximin to be more cost-effective than a TCA-only strategy. An 84–88% price reduction ($US 53.53–$4.71/pill) would enable first-line rifaximin followed by second-line TCA to be more cost-effective than TCA-only, though first-line TCA followed by second-line rifaximin would remain the cost-effective strategy. Our model was robust in tornado analysis and most influenced by rifaximin treatment interval. Sensitivity analysis on rifaximin retreatment interval suggests that current pricing may be based on longer retreatment intervals than those found in clinical literature (Fig 1a). Sensitivity analysis with a lower TCA responder rate could enable first-line rifaximin to be the preferred strategy, albeit at a reduced price (Fig 1b).
Conclusion: Rifaximin is an effective therapy for IBS but is less cost-effective than TCA as currently priced. We propose an evidence-based pricing strategy which would maximize the cost-effectiveness of rifaximin in IBS-D patients.

Introduction: Colonoscopy has been widely used for diagnostic and therapeutic purposes. Although the incidence is very low, perforation is one of the most serious complications. It is important to decide whether to try endoscopic clipping or to perform prompt surgical management.
Aims & Methods: We retrospectively reviewed charts of all patients who experienced colonoscopy-associated perforation in a single center between May 2009 and July 2015, and totally 45 patients were enrolled.
Table: The risk factors surgical treatment in colonoscopy-associated perforation
<table>

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping status were significantly more common in surgery group than conservative group (Table). Endoscopic clipping was performed in 31 cases (immediate; 23, delayed; 8), and immediate clipping group had significantly lower rate of operation (p = 0.013) and better clinical outcome (duration of antibiotic: p = 0.006, hospital stay: p = 0.001). Among 18 surgical cases, 13 patients had primary closure and 5 patients had complex surgery (2; segmental resection, 3; Hartmann’s procedure). The early (<24hr) surgical management significantly decreased the possibility of complex surgery (p = 0.002), as well as had better clinical outcomes such as duration of antibiotic use, fasting time and length of hospital stay (p = 0.003, p = 0.001, p = 0.005, respectively). In therapeutic cases, all five perforated patients who had surgery within 1 day could be managed by simple primary closure, but all four patients who had surgery after 1 day required complex surgery.
Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

Introduction: Despite diagnostic criteria and effective management options for functional gastrointestinal disorders (FGID), confidence in managing these disorders in primary care is low, and long waiting lists for specialist care are common. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

Aims & Methods: We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm-based approach to the diagnosis and management of FGID (ADAM-FGID). consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or the algorithm (2:1). Algorithm patients were screened for organic disease with a alarms-based questionnaire and panel of routine blood/stool tests. When patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All others were classified using Rome III criteria.

Results: 89 participants were screened (42 years [SD 14], 62% female). 35 had FGID (9 excluded). At 6 week follow up: 35/36 FGID respondents had read the feedback survey at study completion.

Conclusion: The discovery of a novel non-specialist-dependent algorithm-based clinical pathway for the diagnosis and management of FGID, in primary care is warranted.

Introduction: Colonoscopy every 5 years, starting at the age of 40 years, is considered the first-choice screening strategy in first degree relatives (FDR) of patients with colorectal cancer CRC, as these individuals are considered at higher risk of developing CRC than average-risk individuals. However, this practice has a low adherence and remains opportunistic. Recently, it has been suggested that annual fecal immunochromatographic testing (FIT) might be a valid alternative to colonoscopy in this setting. However, there are scarce data regarding cost-effectiveness of these strategies from the perspective of healthcare services.

Aims & Methods: This study was aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years, to reduce CRC mortality, in FDR of patients with CRC. A Markov model was constructed to simulate the efficacy and cost of annual FIT (cut-off 10 μg Hb/g feces) or colonoscopy every 5 years of
previously unscreened FDR, starting at age 40 years and ending at age 75. A 5% chance of a mutation in each strategy was assumed. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (http://dx.doi.org/10.1371/journal.pmed.1002008.g001). The main outcomes were quality-life-year (QALY) gained comparing colonoscopy, lifetime burden of colonoscopy, lifetime burden of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQual survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model. Results: In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years were cost-effective over no screening. Taking no screening as a reference, FIT for annual FIT and colonoscopy every 5 years was 1989 and 4472 euros/QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was associated with a number of complications compared to colonoscopy every 5 years. The results were robust in sensitivity analyses. Conclusion: Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

Introduction: Faecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in many countries. The use of sedation does, however, vary internationally and can present patient safety concerns. It has been questioned whether trials assessing patient safety in endoscopy can be generalized worldwide and how local sedation practices and adverse events rates can be compared. Objective: To investigate how current sedation practices in colonoscopy are related to adverse events and complications.

Aims & Methods: We conducted an international survey to examine procedural sedation practices and the incidence of adverse events (AEs) during procedural sedation in France, Germany, Italy, UK, and USA. Data collection from providers (nurses, physicians, and anesthesiologists) was via online surveys. Respondents were screened to assure that they had the expertise and experience to complete the survey. The survey covered topics such as guidelines, sedation agents, monitoring, patient throughput, and AE incidence, treatment, and outcomes as defined by World SIVA. Data analysis took a global approach with subgroup analysis by location.

Results: 101 providers completed the survey, with 20 responses per country, excepting the USA with 21. More than 62% of respondents were gastroenterologists and 38% were anesthesiologists. The main sedation agents used were midazolam (93 respondents), propofol (90), fentanyl (75), ketamine (57), and meperidine (15). Respondents from France reported higher ketamine and lower fentanyl use than other countries (p<0.003). Standard of care monitoring was generally reported to be comprised of pulse oximetry plus blood pressure and/or heart rate. Capnography use varied by country, and was standard of care for 46% of respondents (ranging from 15% in Italy to 67% in the US). The most desired property of a monitoring modality across all countries was one that “provides an early warning of patient compromise”. “Data displays and alarms relating to clinical events” was ranked second globally and in all countries apart from Italy. All respondents reported experience with patient safety issues in the last year, with hypotension the most common (67), followed by mild desaturation (63), bradycardia (63) and prolonged desaturation (52). AE incidence was influenced by monitoring modalities used. Among German respondents, for example, 7 of 11 who did not use capnography as standard of care reported severe oxygen desaturation events compared with versus 0 of 9 who routinely use it (p=0.005). Providers also differed in their reported adverse event incidence. Gastroenterologists most commonly reported mild oxygen desaturation to occur, while anesthesiologists and nurses reported hypotension to be the most common AE experienced during procedural sedation.

Conclusion: Clinical sedation practices are relatively consistent across countries, as are the occurrence of adverse events. Pulse oximetry monitoring is almost universally used during sedation, while capnography use is more variable. The most desired property of a monitoring modality across all countries was one that “provides an early warning of patient compromise”. “Data displays and alarms relating to clinical events” was ranked second globally and in all countries apart from Italy. All respondents reported experience with patient safety issues in the last year, with hypotension the most common (67), followed by mild desaturation (63), bradycardia (63) and prolonged desaturation (52). AE incidence was influenced by monitoring modalities used. Among German respondents, for example, 7 of 11 who did not use capnography as standard of care reported severe oxygen desaturation events compared with versus 0 of 9 who routinely use it (p=0.005). Providers also differed in their reported adverse event incidence. Gastroenterologists most commonly reported mild oxygen desaturation to occur, while anesthesiologists and nurses reported hypotension to be the most common AE experienced during procedural sedation.

This study aims to evaluate the performance of the Pure-Vu System in cleansing a poorly prepared colon, assess the system's usability, patient satisfaction and safety. Forty-seven cases were planned to be enrolled at three clinical sites, of which 32 had completed the study so far. Pure-Vu was used in subjects with a partially prep colon after 2x10 mg Bisacodyl, diet restrictions (no dried fruit, seeds or nuts) starting 2 days before the procedure and a 24-hour clear liquid diet prior to the colonoscopy. Study endpoints were: (1) Safety, (2) Improvement of colon cleansing level as per the Boston Bowel Preparation Scoring (BBPS) when comparing before and after Pure-Vu use, (3) Pure-Vu usability via questionnaire and (4) Patients' satisfaction via questionnaire.

Results: Thirty-two subjects (41% males), aged 31–74 years and with a mean BMI of 26 ± 3.9, were included in the analysis. Indications for colonoscopy included family history of CRC (56%) and poly surveillance (44%). No serious adverse events were reported. The Pure-Vu significantly increased the number of subjects with an adequate cleansing level (BBPS ≥ 2 for all 3 colon segments) from 25%; CI 95% [11%, 43%] at baseline to 100%; CI 95% [89%, 100%] after Pure-Vu and the cocum was reached and visualized in all study cases (i.e., 100%; CI 95% [89%, 100%]). Mean post-treatment BBPS score was 8.5 ± 0.8 vs. 3.38 ± 2.3 prior to Pure-Vu use. Physicians were satisfied with the device's general use of ease and found it in most cases acceptable to good or excellent to insert and to angulate the colonoscope. No major difficulties were experienced when performing polypectomy. Thirty of 32 (94%) patients reported that they would recommend Pure-Vu to theirs friends and family members who need a colono-

Conclusion: The Pure-Vu System was found to be safe and effective in cleaning inadequately prepared colons to an adequate level for a thorough exam. Based upon these early results it is expected that the device may play a role in patients with an inadequately prepared colon which may help to improve the overall quality of colonoscopy.

2Department Of Gastroenterology, Hepatology And Oncology, Medical Center for Postgraduate Education, Warsaw, Poland, Warsaw/Poland

Contact E-mail Address: marek.bugajski@gmail.com

Introduction: Recently, the European Society of Gastrointestinal Endoscopy (ESGE) published guidelines on key performance measures for colonoscopy (1). We analyzed feasibility of monitoring these measures and whether the proposed standards were met in the Polish Colonoscopy Screening Program (PCSP).

Aims & Methods: We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated Gastronet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–31.9%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality was 0.02% (9 cases). Gastronet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6%–81.8%), with painful colono-

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries.

PCSP meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter would improve the overall quality of colonoscopy.
is currently the biggest issue in PCSP and further training is needed to reach minimum standards for this performance indicator.

PI0105 VALIDATION OF THE “FAILURE TO PROVIDE ADEQUATE RELIEF” (F-PAR) SCALE IN A SPECIALIST CLINIC SETTING
V. Passananti, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Treatment of chronic idiopathic constipation is somewhat empiric, but based on step-wise approach[1]. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms sufficiently, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often dissatisfied with care[2] and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale[3] was developed to facilitate the recognition of when to move from one step to the next.

Aims & Methods: The aim of this study was to validate F-PAR in a tertiary clinic setting. We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to each face-to-face clinical assessment by one of 2 experienced physicians, participants completed the F-PAR scale; patients were seen blind to the F-PAR result. Standard clinic assessment was undertaken to identify efficacy of the current management as the gold standard.

Results: Of the 403 consultations, clinical assessment identified inadequate relief with current therapy was identified in 200. Neither duration nor type of treatment were correlated with relief. The table stratifies, by clinical gold standard, each item of the F-PAR and in the lower panel the total number of F-PAR items replied to positively.

Table: Positive F-PAR items correlated to clinical assessment of relief

</table>

Conclusion: Our findings showed that the F-PAR with only five questions can be considered sufficient to provide clinical evidence of treatment failure. The use of standardized process to investigate the efficacy of treatment may reduce the time and improve the quality of managing for the chronic constipation patients.

PI0106 ADHERENCE WITH TRANSMAL IRIGATION USING THE NAVINATM SYSTEM IS ASSOCIATED WITH PERSONALITY TRAITS EVEN WHEN THERE IS IMPAIRED HAND FUNCTION
V. Passananti, J. Storrie, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Transanal irrigation has become a key therapeutic modality in managing patients with neurological diseases who experience constipation and/ or on going fecal incontinence. Success and adherence to transanal irrigation (TAI) can be complicated over three quarters of patients with spinal cord injury (SCI) and multiple sclerosis (MS). Approximately 60% of patients who start TAI continue with long-term treatment. A common cause of treatment cessation is impaired hand function [3]. Training of the patient is a key aspect of TAI therapy and requires patients to be willing to manage their health themselves: self-efficacy.

Aims & Methods: We wished to study whether use of a novel TAI system, Navina™ Smart, which has an electronic pump component allows patients with impaired levels of hand function to adhere to TAI therapy. We also wished to identify if there were physiological or psychological correlates of adherence. Twenty-eight chronic constipation patients (19 SCI and 9 MS; mean age 42) were studied. All patients scored greater than 18 on the Ashon Hand Function Questionnaire and were completed to assess anxiety/depression and locus of control respectively. Anorectal physiology (manometry, sensation and rectal compliance) was undertaken at baseline. Training in TAI was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.4; CI 2.9 vs 6.9; CI 2.3; p=0.15) or HAD-depression (8.6; CI 3.9 vs 8.8; CI 4.2; p=0.46) and were similar in both who were and who were not using TAI (mean ± SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2 ± 6.7 vs 10.6 ± 5.9 respectively; p<0.0001). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression scores did not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

2Faculty Of Medicine, University of Queensland Translational Research Institute, Brisbane/Australia/QLD

1University of Queensland, Diamantina Institute, Microbial Biology and Metagenomics, Brisbane/Australia

Contact E-mail Address: e.shanahan@uq.edu.au

Introduction: The microbiota inhabiting the gastrointestinal (GI) tract plays an essential role in gut health. Although mucosal biopsies are increasingly used for microbiota studies, these are subject to variations introduced through sampling technique and patient preparation. The impact of bowel preparation on the mucosa-associated microbiota (MAM) is of particular interest given it results in complete emptying of bowel contents via laxative ingestion. Although bowel preparation does not appear to induce long term changes to stool microbiota [1], it can induce short-term changes to the colonic MAM [2]. While improvements in clearance of the small intestine after bowel preparation have been reported [3], the impact on the upper GI microbiota is currently unknown. Given patients may undergo both upper GI endoscopy and colonoscopy consecutively, a subset of endoscopy patients will have consumed bowel preparation prior to their procedure, representing a potential bias in MAM analyses. Therefore, this study aimed to assess the impact of bowel preparation on the duodenal MAM.

Aims & Methods: Individuals undergoing upper GI endoscopy, with or without concurrent colonoscopy, were recruited consecutively with ethical approval. Individuals undergoing upper GI endoscopy following overnight fast (n=58), or both upper endoscopy and colonoscopy following polyethylene glycol bowel preparation (n=48). Participants were undergoing screening for iron deficiency anaemia or GI symptoms with no evidence of mucosal disease/inflammation (n=58), or with diagnosed Crohn’s disease (n=18). Duodenal biopsies were obtained and gDNA extracted. Amplicon libraries of the 16S rRNA gene were sequenced (Illumina MiSeq). Sequencing of reagent controls enabled exclusion of
non-duodenal sequences. Bioinformatics and statistics were performed in QIIME and Calypso.

Results: A diverse microbiota was observed in duodenal mucosal samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbiota was dominated by the genus Streptococcus, followed by Prevotella, Veillonella and Neisseria. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric). Principal coordinates analysis (weighted UniFrac) revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Crohn’s disease population.

Conclusion: This study reveals a diverse duodenal MAM is retained following bowel preparation at EGD. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

Introduction: Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality. Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies. An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

Aims & Methods: The primary aim of this study was to compare the Glasgow-Blatchford score (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, reblooding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scores in correctly identifying low-risk patients that can be effectively discharged as outpatient. An EBPHAP prospective study was conducted at the Cancer Institute Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGIB were enrolled. Pre-endoscopic clinical parameters pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiographic or surgical intervention), reblooding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

Results: From April 2015 to May 2016, 394 cancer patients were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under curve) was significantly better than predicting ICU admission than GBS (AUC 0.79; p = 0.04), both the total and clinical RS (AUC 0.71 and 0.66; p < 0.001 for both). The GBS best predicted the need for blood transfusion (AUC 0.82, sensitivity 71% and specificity 80% for GBS ≥ 12) compared with the other prognostic scores. All scores performed poorly in predicting the need for hemostatic therapy and risk of reblooding. The AIMS65 score best predicted in-hospital mortality (AUC 0.84) compared to the GBS (AUC 0.75; p = 0.004), both the total and clinical RS (AUC 0.70 and 0.69; p < 0.001 for both). Among patients who bled at EGD, there was no difference in 30-day mortality if the etiology of bleeding was tumoral or non-tumoral disease (38.1% vs. 31.9%; p = 0.46). Identifying low-risk group: With GBS score of 0 as the cut-off value, its specificity was 100% with sensitivity of 5.8%. When GBS ≥ 2, its specificity was maintained at 100%, while sensitivity was increased to 23.5%. This change increased the proportion of the patients from 1% to 5% without erroneously discharging high-risk patients. In comparison, when an AIMS65 value of 0 was chosen as definition for low-risk, this tool misclassified 20 patients who needed hospital interventions (specificity of 53% and sensitivity of 89.5%). Finally, head-to-head comparison between GBS vs. RS, and GBS vs. AIMS65 scoring system revealed GBS to be superior to both the clinical RS (p < 0.001) and AIMS65 (p = 0.001) in correctly identifying low-risk patients.

</tr>
</tbody>
</table>

Conclusion: The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and reblooding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≤ 2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

Introduction: Endoscopists are more frequently performing endoscopic resection (ER) in patients on antplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PEB) rate in patients on anticoagulants.

Aims & Methods: This study aimed to evaluate the effect of anticoagulants on PEB rate. This was a retrospective study based on medical records from three centers. PEB was defined as bleeding that occurred 6 h to 10 days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included polypectomy, endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban. Warfarin was discontinued 4–5 days before ER, whereas the others were stopped 24–48 h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractionated heparin was administered after ceasing anticoagulants.

Results: Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivaroxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or
PEB rate. Overall, 57 patients (78%) in the warfarin group underwent HBT, and warfarin patients with PEB rate compared to the patients who did not undergo HBT in the warfarin group (36% vs. 0%, p < 0.05). Although there was no significant difference in the PEB rate between the group that did and did not undergo HBT in the DOAC group, the PEB rate was higher among rivaroxaban recipients (55% vs. 0%, p < 0.05). Multivariate analysis revealed that HBT, rivaroxaban, and anticoagulants plus antiplatelet therapy were associated with PEB (P < 0.05). Warfarin and DOAC were prescribed to 72 (57%) and 54 (35%) patients, respectively. Dagibartan was administered to 16 (13%), rivaroxaban to 18 (14%), apixaban to 18 (14%), edoxaban to 2 (1.6%) patients. Patients underwent polypectomy (n = 50), EMR (n = 62), or ESD (n = 10). PEB occurred in 5 (4.0%) patients (one polypectomy and four EMRs). Among them, warfarin was prescribed to one patient (1.4%) who also underwent polypectomy and apixaban was prescribed to two patients (11%) each. PEB rate was higher in the DOAC group than in the warfarin group (7.4% vs. 1.4%).

Conclusion: Patients on HBT, rivaroxaban, and anticoagulants plus antiplatelet therapy at an increased PEB risk after ESD for gastric tumors. We suggested that the PEB rate differs among DOACs because each drug has its own blood concentration and metabolism. Most clinicians have a limited knowledge on PEB during DOAC therapy because these are relatively new drugs, and because PEB has a low prevalence. Therefore, comparative data on larger patient series are needed to address this issue.

P1811 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS
Gastroenterology, Osaka General Medical Center, Osaka/Japan

Contact E-Mail Address: tatkatakkun@gmail.com

Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of post-polypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of bleeding in high-risk patients. High-risk patients are patients who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.

Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 2.7%, and 6.1%, respectively. Total 188 patients have taken oral antithrombotic drugs, and of them, 50 patients treated by gastric ESD under heparin bridge therapy. Tween-3 lesions were located in gastric body and median tumor size (range) was 15 (3–80) mm. En-bloc resection was achieved in 751 lesions (96.2%), and no uncontrollable bleeding occurred. Forty-nine patients (6.8%) experienced delayed bleeding after gastric ESD. Hospital stay was significantly longer in bleeding cases than in non-bleeding cases [median hospital stay (range) 11 (3–20) vs. 9 (2–5), p = 0.007]. A univariate and multivariate analysis were performed for heparin bridge therapy, antiplatelet therapy, and hemodialysis as a high-risk group for bleeding, and the remainder as a low-risk group. The incidence of delayed bleeding was significantly higher in the high-risk group than in the low-risk group (14.3% vs. 3.6%, p < 0.001). Severe bleeding requiring transfusion and recurrent bleeding were more often in the high-risk group than in the low-risk group. Median onset (range) of delayed bleeding was POD1 (0–16) in the high-risk group and POD6 (0–15) in high-risk group. No thromboembolism occurred in each group.

Conclusion: Bleeding high-risk patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis should be carefully observed after gastric ESD while early hospital discharge is acceptable for bleeding low-risk patients.

P1810 ENDOSCOPIC ALLPICATION OF MUCOADHESIVE POWDER (NEXPOWDER®) FOR HEMOSTASIS IN PATIENTS WITH GASTROINTESTINAL BLEEDING
B.W. Bang1, K.S. Kwon1, H.K. Kim2, Y.W. Shin2, S.J. Hong2, J. Park1, J.H. Moon2, J.J. Hwang2

2Digestive Disease And Research Institute, SoonChungHyang University School of Medicine, Bucheon/Korea, Republic of

Contact E-Mail Address: bangbyoung2@naver.com

Introduction: Although endoscopic hemostasis is usually effective in controlling gastrointestinal (GI) hemorrhage, some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. NEXPOWDER® (Next Biomedical, Incheon, South Korea) is a biocompatible and biodegradable powder and the hemostatic effects are accomplished by physical barrier when this powder immediately forms mucadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistency of gel on ulcer base. In addition, new powder delivering device was developed to reduce catheter clogging during endoscopic application.

Aims & Methods: The aims of this study were to confirm 1) success rate of hemostasis using NEXPOWDER® in acute GI bleeding from post-endoscopic procedure or various causes; 2) re-bleeding rate on second-endoscopy at 1 or 3 days after the procedure, 3) persistent rate of hydrogel on ulcer base at follow-up endoscopy, and 4) clogging rate of catheter during spraying powder. The NEXPOWDER® was delivered by newly developed spraying device through a catheter catheter and the initial hemostatic success as when the bleeding disappeared within 10 minutes. A second-look endoscopy was performed in one and three days after the procedure.

Results: A total of 57 patients were enrolled. The bleeding developed in 46 patients with post-endoscopic resection ulcers (41 ESUD induced ulcers and 5 EMR induced ulcers), 8 patients with peptic ulcers and 3 patients with other causes. 1) Success rates of hemostasis in acute bleeding were 96.5% (55/57) of NEXPOWDER® group, 2) Re-bleeding rates were 5.3% (3/57) of NEXPOWDER® group, 3) Persistent rate of NEXPODWER® on ulcer base was 70.3% (26/37) 1 day after the procedure, and 38.5% (13/34) 3 days after the procedure. 4) Clogging rate of spraying catheter was 3.5% (2/57).

Conclusion: The endoscopic application of NEXPOWDER® is effective for the several types of acute GI bleeding. This effective hemostatic action of NEXPOWDER® might be achieved by physical barrier of mucadhesive and persistent hydrogel on ulcer base. And new powder delivering device shows low rate of catheter clogging. In addition, a newly developed powder delivering device shows low clogging and targeted spraying properties onto bleeding site.

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year study of patients with acute GIB (anaemia with evident bleeding and/or hemodynamic instability) treated with FCM as part of our hospital’s habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥ 3 in 67.1% of cases (≥ 5 in 31.6%). 15.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was melena, in 76.7% of cases. 25.6% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 16.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/erosions, and 7.3% angiodysplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)

United European Gastroenterology Journal 5(5S) A783
with Charlson index 5

Conclusion: The increase in life expectancy and the increased use of antiplatelets, oral anticoagulants and nonsteroidal anti-inflammatory drugs (NSAIDs) while Forrest IIC and III were considered as low risk endoscopic stigmata.

comorbidities, (quantified by Charlson score), endoscopic aspect of ulcer bleeding. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding, who were hospitalized in a tertiary medical center over a

2

days (median: 4.0) after treatment with FCM, with an increase of 4.2 g/dL (SD 2.6). A mean Hb increase of 0.8 g/dL (SD 2.3) was observed in a mean period of 5.7 days (median: 4.0) after treatment with FCM, with an increase of 4.2 g/dL (SD 2.6) 30 days after acute GIB. After FCM administration, the mean Hb increased significantly (p = 0.0001) in patients ≥75 years (2.1 g/dL [SD 1.7]), in patients with Charlson index ≥3 (1.9 g/dL [SD 1.6]), and when Hb level during admission was <10 g/dL (2.0 g/dL [SD 1.7]). No adverse reactions were observed.

P1813 NOVEL EUS-GUIDED TREATMENT OF GASTRIC VARICES WITH A LIQUID NON-ADHESIVE NEUROVASCULAR EMBOLIZATION AGENT

Hospital de Clínicas Caracas, Caracas/Venezuela

Contact E-mail Address: albertogebaptista@gmail.com

Introduction: Endoscopic Injection of adhesive agents such as N-ButyI-2-Chloroethanol (NBC) is often accepted option for the management of gastric varices. Recently the combination of NBC and coils has been used with endoscopic ultrasound (EUS) assistance. Nevertheless adhesive properties of the polymer can cause blockage of instrumentation material and damage to endoscopes. Sometimes the ulcers, vascular wall necrosis, rebleeding and distal embolism. Ethylene-vinyl alcohol (EVOH) has been extensively used in interventional radiology to treat cerebral arteriovenous malformations and has the advantage of being radioopaque.

Aims & Methods: We aimed to demonstrate a novel gastric varices embolization therapy using EUS-guided injection of a composite non-adhesive endovascular liquid agent EVOH combined with Dimethylsulfoxide (DMSO) as a primer. Five cases of EUS-guided Injection under fluoroscopic vision with EVOH is described in 5 men and 2 women, aged 50-65 years with gastric fundus variae, portal hypertension, Child-B hepatic cirrhosis and previous episodes of bleeding. The procedure was well tolerated by EUS. Ceftriaxone was intravenously administered during the procedure. Patients were discharged on the same day. The mean follow-up was 6 months. Endoscopic and radiological control was performed at 1 and 3 months. The average procedure time was 20 min.

Results: All patients presented mild epigastric pain during the first 12 hours effectively managed with oral analgesics. The obliteration of variceal flow was achieved in all patients in a single session. There were no new episodes of bleeding or complications related to the technique.

Conclusion: EUS-guided embolization of gastric varices with EVOH can be considered as an efficient alternative. The procedure promises effective advantages in terms of number of sessions required, local or systemic adverse events and endoscopic contraindication. The technique is less invasive and it is a good alternative to TIPS as first-line treatment.

2Regional Institute of Gastroenterology and Hepatology Prof. Dr. Octavian Fodor, Cluj Napoca/Romania

Contact E-mail Address: dmatei68@gmail.com

Introduction: Peptic ulcers are the most frequent cause of upper gastrointestinal bleeding. In different population based surveys regarding all-cause UGIB, mortality ranges between 3% and 14%.

Aims & Methods: The aim of this study was to assess in-hospital mortality in patients with peptic ulcer bleeding and to evaluate the risk factors associated with mortality. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding and hospitalized in a medical center over a period of 24 months (January 2015- December 2016). Patients were divided into two groups - those who died and those who survived and the following parameters were compared: age, signs of hemodynamic instability (hypotension, tachycardia), prevalence of comorbidity indicated by Charlson score, Rockall score (overall mortality over 60 days). The type of ulcer (Forrest IA, IB, IIA, IIB were quantified as high risk endoscopic stigmata, while Forrest IIC and III were considered as low risk endoscopic stigmata), number of ulcers, Rockall score, Blatchford score, degree of anemia, coagulation disorders, renal function. We also analyzed comparatively rebleeding, the need of transfusion and need for surgery.

Results: The study included 431 patients. In-hospital mortality rate was 7.9%. The following differences have been observed by comparing patients who died and those who survived: age >75 years 41.2% vs 23.4% (p = 0.036); hypotension 17.6% vs 2.3% (p < 0.001); tachycardia 47.1% vs 21.4% (p = 0.001); one or more comorbidities 94.1% vs 63.5% (p = 0.001); high risk endoscopic stigmata 79.4% vs 62.2% (p = 0.070); multiple ulcers 41.2% vs 33.5% (p = 0.473); Rockall score ≥ 5 points 94.1% vs 46.9% (p = 0.001); Blatchford score ≥ 10 points 91.2% vs 66.2% (p = 0.005); hemoglobin < 9.5 g/dl 70.6% vs 41.1% (p = 0.002); INR ≥ 15.7% vs 5.8% (p = 0.022); creatinine ≥ 1.5 mg/dl 38.2% vs 10.8% (p = 0.001); rebleeding 20.6% vs 10.3% (p = 0.123); need for blood transfusion 82.4% vs 56.4% (p = 0.006); need for surgery 11.8% vs 3.5% (p = 0.003). In most cases (88.2%), the cause of death was other than hemorrhagic shock. Using multivariate analysis, three out of these factors were identified as representing independent factors significantly associated with the age over 75 years old: oral anticoagulants use (OR = 2.40, 95%CI:1.24–4.62, p = 0.009), antiplatelet use (OR = 2.33, 95%CI:1.43–3.81, p = 0.001) and in-hospital mortality (OR = 2.09, 95%CI:1.27–4.47, p = 0.048).

Conclusion: The use of oral anticoagulants and antiplatelet was significantly higher in older patients, compared to the younger group. Elderly patients with peptic ulcer bleeding do not have a different rebleeding, need for surgery, need of transfusion or hospitalization mortality compared to younger patients. In-hospital mortality was higher in elderly patients due to more frequent association of comorbidities.

Disclosure of Interest: All authors have declared no conflicts of interest.

Patient data over a period of up to 12 months post discharge was collected to restrict a restrictive approach to blood transfusions as well as the use of iron therapy for anemia [2].

EXPERIENCE

P1816 ANAEMIA AND UPPER GI BLEEDING: A LOCAL EXPERIENCE

M. Ding, R. Prawiradilaga, Z. Arastu, H. Sabri, M. Smith
Gastroenterology, Royal shrewsbury hospital, Shrewsbury/United Kingdom

Contact E-mail Address: micuddjw@gmail.com

Introduction: There has been significant research recently on the use of blood transfusions in upper GI bleeding (UGIB) [1] with recent evidence advocating a restrictive approach to blood transfusions as well as the use of iron therapy [2] for anemia. The aim of this study was to look at a retrospective analysis of patient admission with UGIB over a six month period and analysed the use of blood transfusions at our trust which consists of two District General Hospitals.

Patient data over a period of up to 12 months post discharge was collected to monitor their anemia.

Aims & Methods: Our aim was to monitor the appropriateness of transfusions in Upper GI Bleeding as well as monitoring the response to iron therapy following discharge. All inpatients that had an Upper GI endoscopy for UGIB were analysed. Electronic patient records were obtained from our endoscopy software and hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student’s T-Test was used to compare the average increase in haemoglobin (Hb) for patients discharged with iron therapy against those who were not.

Results: There were 148 patients, 81 male and 67 female. The mean age was 69.3, minimum 20 and maximum 98. The average Hb on admission was 103.6 g/L (min = 32 g/L, max = 178 g/L). 78 out of 148 (52.7%) patients presenting with UGIB received a blood transfusion. The mean amount of blood received for those transfused was 3.7 units. 48 out of 78 (61.5%) of blood transfusions were when Hb was below 70 g/L. 30 of 78 (38.5%) were transfused when Hb was below 70 g/L (36.7%, n =11) of those who were transfused with Hb above 70 had cardiac risk factors. The mortality rate in those transfused above Hb of 70 was 13.3% (n = 4) vs 10.4% (n = 5) 41.5% (n = 44) patients who were anemic post-UGIB were discharged with iron therapy. The average rise in Hb was 19.2 g/L with an SD of 9.3 g/L for those who did not. There was a statistically significant rise in Hb for those discharged with iron therapy (p < 0.005) on follow-up versus those who did not receive it (n = 62). The anaemia related readmission rates were similar for patients discharged on or not reaching an Hb of 70 g/L.

Conclusion: The data obtained supports a restrictive transfusion policy (mortality rate of 13.3% vs 10.4%). 58.5% of patients who were anaemic on discharge did not receive any iron therapy. On follow up, there was a statistically significant rise in Hb for the group discharged on iron compared to those who did not. There was an increase in Hb of 19.2 g/L with a SD of 9.3 g/L for those with anaemia. All the deaths were due to cardiac risk factors.

Introduction: Autoimmune gastritis (AIG) is an organ-specific autoimmune disease of the stomach marked by autoantibodies directed to hydrogen/potassium-ATPase and intrinsic factor. Gastric emptying of solids is delayed and autonomic nervous system dysfunction is detected in patients with autoimmune gastritis. As ghrelin and motilin are putative hormones produced in the stomach, ghrelin and motilin levels in patients with AIG are considered to be lower than in healthy controls. Forty-one patients with AIG were included into this study. Autoimmune gastritis is an organ-specific autoimmune disease of the stomach marked by autoantibodies directed to hydrogen/potassium-ATPase and intrinsic factor. The aim of this study was to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into enteroendocrine cells in the duodenum of patients with irritable bowel syndrome (IBS).

Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into enteroendocrine cells as detected by neurogenin 3, Musashi 1 and enteroendocrine cell densities in the duodenum of patients with IBS. The study included 16 IBS patients according to Rome III criteria and four patients were excluded. The remaining patients (n = 12, 4 females and 8 males, age range 20–44 years) were divided according to the cause of IBS into PI-IBS patients (n = 6) and idiopathic IBS (n = 6) and received FMT donated from their relatives. The patients underwent gastroscopy with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for neurogenin 3, Musashi 1 and all three enteroendocrine progenitors, but rather by changes in the differentiation progeny as detected by changes in the enteroendocrine cell density. The changes in the enteroendocrine cell density do not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

**P1819** THE EFFECT OF ESOPHAGEAL ACID EXPOSURE ON NMDA RECEPTOR SUBUNITs EXPRESSION AND D SERINE IN PREFRONTAL CORTEX AND HIPPOCAMPUS

W. Zhang1, L. Duan2, K. Wang2, X. Wang2
1Gastroenterology, Peking University Third Hospital, Beijing/China
2Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

**Aims & Methods:** This study aims to investigate the expression of NMDAR and the alteration of D-serine after neonatal and adult esophageal acid exposure. All rats were exposed to esophageal acid or saline at postnatal days 7–15 (P7–P15), and most rats underwent acute acid or saline exposure again as adult times (P60). All rats were randomly distributed to five groups, including P7S, P7H, P7H + P60H, P7S + P60H(P7: postnatal 7–15 days; P60: adult at postnatal 60 days; H: 0.1N HCL infusion; S: saline control). The tissue harvest was conducted at P60. We examined the expression of subunits of NMDAR (including NR1, NR2A, and NR2B, and D-serine), c-fos, and serine racemase in PFC, dorsal hippocampus (DH) and ventral hippocampus (VH). We also determined the D-serine and L-serine in PFC and hippocampus by LC-MS analysis. Statistical comparisons were performed by General Linear Model and one way ANOVA in SPSS.

**Results:** In PFC, compared with adult saline treatment (AS, including P7H and P7S + P60H group) and without adult treatment (A, including P7H and P7S group), adult acid exposure (AH) increased the expression of NR1 (P = 0.052, P = 0.298), NR2B (P = 0.035, P = 0.045), and serum racemase (P = 0.022, P = 0.017) significantly. In ventral hippocampus, compared with adult treatment absence, adult acid exposure caused increasing expression of NR2B (P = 0.012) and NR1 (P = 0.024) significantly. In PFC, the expression of serum racemase in the P7S + P60H group was obviously higher than that of other groups (P = 0.008). See Table1. In dorsal hippocampus, there was statistical significance on the level of c-fos between the P7S + P60H group and other groups (P = 0.008). Table1. In PFC, the LC-MS analysis results that D-serine (AH vs A-: P = 0.000, AS vs A-: P = 0.042, AH vs AS: P = 0.081) and L-serine (AH vs A-: P = 0.005, AS vs AS: P = 0.082) decreased in the AH and AS group, comparing with A- group.

**Conclusion:** Acute esophageal acid exposure may increase the expression of NMDAR in PFC and ventral hippocampus. We also found the first acid exposure at adult stage may enhance the expression of serine racemase in PFC and c-fos in ventral hippocampus, but this phenomenon may be absent in those rats having the experience of acid exposure in early life. Those long-term and transient molecular alterations may mediate the development of acid exposure related esophageal visceral hypersensitivity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

To the best of our knowledge, our findings are the first to establish an association between SLC6A4 gene polymorphism and globus pharyngeus.

**Aims & Methods:** 84 patients diagnosed with globus according to Rome III and 160 healthy controls were genotyped for 5-HTTLPR polymorphism by PCR amplification and agarose gel electrophoresis. All globus patients were studied with high-resolution manometry pre-therapy. Globus patients were randomized into paroxetine group; amitriptyline group for 6-week treatment, and were asked to complete the following questionnaires pre- and post-therapy: Glasgow Edinburgh Throat Scale (GETS), Pittsburgh Sleep Quality Index, Hamilton Rating Scale Anxiety, Depression. Treatment response was defined as a > 50% reduction in GETS scores.

**Results:** The significant difference was shown in globus performed S/S genotype with anxiety when compared to without (X² = 14.579, P = 0.006). The S/S genotype showed the difference between high upper esophageal sphincter pressure (≥104 mmHg) and non-high upper esophageal sphincter pressure patients (X² = 14.433, P = 0.006). There was significant association between the S/S genotype and the response to antidepressants treatment, while patients with sleep disorders or depression not.

**Conclusion:** A significant association was observed between S/S genotype of SLC6A4 polymorphism and globus pharyngeus, suggesting that SLC6A4 is a potential candidate gene involved in the pathogenesis of globus pharyngeus.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: The timed barium esophagogram (TBE) is an objective measurement of oesophageal (3 myotomy, 3 myotomy and emptying used in the assessment of achalasia. Post-thrapy correlation of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long-term prognostic implications. We hypothesize that the surface area (SA) of the barium column may be more accurate than height, firstly, by showing improvement in esophageal width that often occurs post-thrapy, but also by correcting for artificially higher height values due to esophageal (longitudinal) contraction occurring during a single image. We aimed to compare the correlation of TBE outcome measures of height and SA with symptom improvement post-thrapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent thrapy between August 2015-6 and had TBE and Eckardt score (ES) performed at baseline and 6 months separated by 6 months post-thrapy. With TBE upright single images were acquired at 1:2, 5 minutes following ingestion of 100-200 mL of low-density barium sulfate. Barium height was measured between the gastro-esophageal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES ≤ −3. On TBE, metrics of adequate emptying evaluated were i) post-thrapy column height <5cm, ii) >50% reduction in column height from pre to post-thrapy and iii) >50% reduction in column SA from pre to post-thrapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson’s correlation (R). Paired t-tests compared TBE measures before and after thrapy.

Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naive and 7 received (3 myotomy, 3 myotomy and emptying used in the assessment of achalasia. Mean resting LES pressure was 4.6 ± 4.7 mmHg. In all patients, mean and median IRP values for ten 5 mL water swallows were non-raised (mean 9.4 ± 4.3 and 8.7 ± 4.5 mmHg respectively). Of the 7 treatment-naive patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experienced patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance demonstrated during MWS and/or solid swallows. Mean height of the 5-minute column barium volume in patients with achalasia was 16.5 ± 8.9 mm; 8 patients have (so far) undergone therapy based on these findings; one per-oral endoscopic myotomy and 7 pneumatic dilatations. The median baseline ES was 7.5 (IQR 5-8). The median ES at 3 months (range 3-15 months) following treatment was 1 (IQR 0-3), and 5 patients (36.5%) experienced between 6 months post-thrapy. With TBE upright single images were acquired at 1:2, 5 minutes following ingestion of 100-200 mL of low-density barium sulfate. Barium height was measured between the gastro-esophageal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES ≤ −3. On TBE, metrics of adequate emptying evaluated were i) post-thrapy column height <5cm, ii) >50% reduction in column height from pre to post-thrapy and iii) >50% reduction in column SA from pre to post-thrapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson’s correlation (R). Paired t-tests compared TBE measures before and after thrapy.

Conclusion: TBE performed on achalasia patients post-thrapy, reduction in SA of the residual barium column compared with baseline values parallels symptomatic relief more closely than reduction of column height. All authors have declared no conflicts of interest.

Introduction: During meal intake, large volumes of gas can be ingested together with nutrients, and patients with gas-related abdominal symptoms often refer symptom exacerbation by meals. Previous studies have shown that under fasting conditions, gastric gas is rapidly cleared from the stomach and rarely emptied to the small bowel and colon, or via belching. Nutrients have several effects on gastric and intestinal motor function that could modulate gas transport and symptoms.

Aims & Methods: We aimed to determine the effect of gastric nutrients on transport of gastric gas, and its relationship with abdominal symptoms. In 7 healthy volunteers without gastrointestinal symptoms (4 women and 3 men, age-range 21–25 yrs), a mixture of non-absorbable gases was infused into the stomach, 5 cm caudal to the lower margin of the LES, at 25 mL/min during 60 min (Total gas infused: 1500 mL). In each subject two gas infusion tests were performed on separate days, with simultaneous infusion of nutrients (Nutridrink 1.5 Kcal/ml, total 315 Kcal) or saline. Belching, by an esophageal multimumidine manometry catheter, rectal gas evacuation, via a rectal tube connected to a barostat, and epigastric and abdominal symptoms, by specific questionnaires (from 0–6), were continuously recorded from the start of gas infusion until 30 min after gas infusion stopped. (Total recording time: 90 min).

Results: During saline infusion, participants evacuated via the rectum virtually all the infused gases (1613 ± 87 ml), with exceptional belching (1.1 ± 0.8 belches) and mild epigastric perception (score 1.7 ± 0.6 at the end of infusion), that decreased during the 30 min following infusion stop (score 1.1 ± 0.4; P = 0.051 vs infusion
P1827 MODIFICATIONS OF THE ECKARDT SCORE PARAMETERS AFTER PERORAL ENDSCOPY MOSOTOCY

Introduction: Peroral endoscopic myotomy (POEM) is a recently developed technique or the treatment of lower esophageal sphincter achalasia. POEM could be as effective as surgical Heller myotomy, while associated with lower morbidity. Currently, the Eckardt score is the clinical score that is the most widely used to assess the treatment of achalasia, clinical success being defined by a score below 4. However, POEM might not equally improve all four parameters of the Eckardt score.

Aims & Methods: All consecutive patients undergoing POEM for achalasia at our institution, performed by 3 operators with at least 6 months follow-up were prospectively included. Demographic, clinical, procedural, manometric and radiologic data were collected.

Results: Between March 2013 and July 2016, 62 POEM procedures were performed on 59 patients (Male/female 33/26; Median age ± SD range 47 ± 17, range (15–77)). Median (IQR) follow-up time was 8 (3–13) months. Achalasia was diagnosed for a median (IQR) of 24 (13–62) months, and 42% of the patients had received a previous treatment, by botulinum toxin injection (8%), pneumatic dilatation (32%), or Heller myotomy (7%). Achalasia subtypes were type I/III in 37%, IV in 15% of cases. Median Eckardt score and integrated resting pressure were 7 (6–8) and 21 (19–33) mmHg, respectively. An anterior myotomy was done in 60% of cases, and a posterior myotomy in 40% of cases. Median myotomy length (12.0 ± 1.0 cm) and hospital stay was 3 (2–4) days. Severe complications occurred in 5% of cases (1 pleural effusion requiring drainage, 2 pneumonias with more than 10 days of hospital stay). Success rates were similar between patients treated by anterior or posterior myotomy (92% vs 92%, p = 1), or between treatment-naive or pretreated patients (88% vs 96%, p = 0.32). Six treatment failures were treated by redo POEM in 3 cases, pneumodilatation in 2 cases, and esophagectomy in one case. Median Eckardt score varied from 7 (6–8) to 1 (0–0) at 3 months and 2 (0–3) at 12 months (p = 0.0001). Dysphagia score varied from 2 (1–3) to 0 (0–1) and 0 (0–0) (p = 0.0001), while regurgitations varied from 2 (1–3) to 0 (0–1) and 0 (0–0) (p = 0.0001), chest pain varied from 1 (0–2) to 0 (0–0) and 0 (0–0) (p = 0.0006), and weight loss from 2 (1–3) to 0 (0–0) and 0 (0–0) (p = 0.0006). At three months, median (range) drop of the integrated resting pressure was 16 (6–22) mmHg. Long-term follow-up visit, 86% of the patients still had clinical success, and 31% reported gastro-esophageal reflux symptoms.

Conclusion: Our results confirm the efficacy of the POEM as a first line or rescue treatment for achalasia, with a low complication rate. POEM is most effective on dysphagia and weight loss, while chest pain and regurgitations tend to persist after treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1829 THE TREATMENT OF ACHALASIA IN PATIENTS WITH GASTROESOPHAGEAL VARICES: AN INTERNATIONAL CASE SERIES

Introduction: Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller’s myotomy, Botox, pneumatic dilatation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Conomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.

Aims & Method: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ± 9 years. The median pre-therapy Eckardt score was 7 (IQR 6–9). 9/13 (69%) patients had a barium swallow and 12/13 (92%) had oesophageal physiology studies performed. There were 3 Type I, 6 Type II, 2 Type III achalasia and 2 with oesophage-gastric outflow obstruction. Varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 3 grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia. 4 were treated with Botox injections (1 with EUA), 4 had dilation alone, 3 received a POEM, another had POEM then dilation and 1 patient had Botox followed by Heller’s myotomy. 3 patients underwent variceal eradication in advance; all had banding first but in 2 patients superficial eradication was followed by a transjugular intrahepatic portosystemic shunt (TIPS) before endoscopic dilatation. All patients had symptomatic improvement with median Eckardt score post intervention of 1 (IQR 0–2) < 0.0001 compared to baseline. A matched group of 20 patients who underwent treatment for achalasia (all subtypes) but without varices had similar outcomes (p = 0.49) and patients who had received complications of bleeding or perforation; however both patients who had TIPS had temporary hepatic decompensation.

Conclusion: This reports 13 patients from international centres who have had interventions for achalasia on the background of oesophageal varices. None had bleeding complications despite only 3 having variceal eradication. Symptom response mirrored those who undergo standard achalasia therapy,
P1830 THE NATURAL HISTORY OF ACHALASIA: EVIDENCE OF A CONTINUUM—THE PATTERN-EVOLUTIVE STAGING THEORY
Dept. Of Surgical, Oncological And Gastroenterological Sciences, University Hospital of Padova, Padova/Italy

Contact E-mail Address: m.costantini@unipd.it

Introduction: Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

Aims & Methods: The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to 2015.

Results: Five-hundred and eleven consecutive achalasia patients (M:F = 283:228) represented the study population. Based on their manometric findings, 231 patients (45.2%) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern III cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet (p < 0.001). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%). The only predictor of final outcome was the preoperative manometric pattern (p < 0.001). All patients (42) whose surgical treatment failed underwent one or more endoscopic pneumatic dilations using Rigiflex balloons (30, 35 or 40 mm). The overall success rate of the combined treatment (LHD plus endoscopic dilations where necessary) was 98%. All patients with pattern I preoperatively had the same pattern after LHD, whereas more than 50% of patients with pre-treatment pattern III had patterns I or II after surgery. There were no cases showing the opposite trend (Table 1). Five patients showed signs of a partial recovery of peristalsis (all patients had a pattern II before LHD).

Table 1: Changing manometric patterns after LHD. *5 patients had a recovery of peristalsis (all patients had a pattern II before LHD).

<table>

Conclusion: The data of this study strongly support the hypothesis that the different manometric patterns of achalasia could represent different evolution stages of the disease - where pattern III is the earlier stage, pattern II an intermediate stage, and pattern I the end stage.

Introduction: The development of non-invasive methods to detect the presence of H. pylori, and to estimate the extent and severity of gastritis, have reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspeptic patients.

Aims & Methods: To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastroesophageal reflux disease (GERD), H. pylori (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6–95) was selected in a primary care population and examined with a panel of biomarkers (Pepinogen-I (PG-I) and -II (PG-II), atidated gastrin-17 (G-17), and HP IgG (Biohit, Finland). A standard questionsnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p < 0.0001). Table 1 shows the serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, CAG, and PPI therapy.

Conclusion: The combination of the data on the levels of PG-1, PG-2, G-17 and HP IgG allow to diagnose different pathological conditions such as HP- and non HP-related gastritis, the appropriateness of PPI administration, GERD and CAG, a precocious condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1832 SUSTAINED TREATMENT EFFECTS OF MENTHACARIN ON SYMPTOMS AND QUALITY OF LIFE IN PATIENTS WITH FUNCTIONAL DYSPESIA: 8 WEEKS AFTER THE END OF A 4-WEEK PLACEBO-CONTROLLED TRIAL

Introduction: Functional dyspepsia (FD) is one of the most common functional gastrointestinal disorders characterised by chronic or relapsing symptoms with or without structural or biochemical abnormalities that can be identified in the routine clinical setting. Thus, treatment targets symptoms. Very little is known about prolonged treatment for more than 4 weeks.

Aims & Methods: The aim of the additional data analysis of a previous randomised placebo-controlled trial was to explore post-treatment effects that occurred after continuation of therapy after a 4-week randomised placebo controlled trial using Menthacarin® with regard to disease-specific symptoms and QoL in FD patients. After the 4-week randomised placebo-controlled treatment period, patients were allowed to continue the treatment. The treatment was given in a double-blind fashion and allocation of treatment followed the initial randomisation. 114 adult FD outpatients were initially treated and received twice a day one enteric-coated Menthacarin capsule or a matched placebo capsule for 4 weeks. Fifty-four of them participated in the optional follow-up phase and received Menthacarin® (34) or placebo (20) for further 8 weeks according to their original randomization. The results of these 54 patients are presented here.

Outcomes were assessed utilising the self-rating Nepean Dyspepsia Index (NDI). Intra-individual differences between baseline and week 4/week 12 for NDI sub-scores for pain (sum of the NDI items “pain or ache in upper

Introduction: We recently reported that functional dyspepsia patients show impaired duodenal integrity, associated with low-grade inflammation (Vanheel, Gut 2014). A potential cause underlying this phenomenon may be the increased duodenal acid exposure that has been demonstrated in some of these patients.

Aims & Methods: Our aim was to evaluate the effect of duodenal acid perfusion on duodenal permeability in healthy volunteers and to investigate whether mast cell activation is required for acid-induced impairment of mucosal integrity. As it has already been shown that duodenal acid activates duodenogastrectomy reflux pathways, we also assessed intragastric pressure (IGP). This study consisted of 2 parts, each including 10 healthy volunteers. 1) An infusion tube was positioned in the second part of the duodenum and a high resolution manometry probe was positioned in the stomach to measure IGP. HCl 0.1N or saline was infused in the duodenum during 30 min (5ml/min) in a randomized, double-blind manner.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of Gastranol in relation to the appropriateness of PPI-therapy prescription. 2583 dyspeptic patients (male 36%, mean age of 44.0 yrs, range 6-95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I and II (PG-I and II) and Acid Permeability Testing (APT).

Results: 1015/2584 (39.3%) received PPI therapy up to three months before serum sampling and were included in the study. Among 1015 patients under PPI therapy, 294 (29.0%) received half-dose PPIs, 709 (69.8%) full-dose PPIs and 12 (1.2%) an exceeding-dose PPIs. Additionally, patients under PPI therapy (37.8%) showed a serological status compatible with body CAG (the definitive diagnosis was histologically confirmed). 68 (6.7%) presented HP infection. Table 1 shows the values of PG-I and G-I and G-I values according to the response to PPI therapy.

Conclusion: An appropriate prescription of PPI should be preceded by the assessment of gastric functional status. In particular, patients with HP infection should be eradicated before PPI therapy, while CAG patients should not receive PPI therapy. Additionally, patients with HP infection should be further investigated (compliance, diagnosis).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1836 THE PSYCHOLOGICAL CHARACTERISTICS OF REFUX HYPERSENSITIVITY:A PILOT STUDY BASED ON SCL-90 QUESTIONNAIRE AND 24 HOUR PH-IMPEDANCE MONITORING

K. Wang, Z. Xu, Z. Xia, Y. Ge, L. Duan
Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: duanlnp@bjmu.edu.cn

Introduction: Reflux hypersensitivity (RH) was lately defined as a functional esophageal disorder by the Rome IV workshop. The clinical and psychological characteristics are still unknown.

Aims & Methods: The aim of this study was to assess the reflux and psychological characteristics of RH. Patients who underwent 24 h pH-impedance monitoring were screened from Jan 1st 2011 to Nov 31st 2015. The patients with heartburn or chest pain ≥2 days/week for more than 6 months were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gastrointestinal diseases and underwent HRM test to exclude manotility disorders. The patients for esophageal mucosal but overload acid, weakly acid or non-acid reflux were diagnosed as non-erosive reflux disease (NERD). The patients with normal esophageal mucosal and normal reflux but positive symptom index (SI) or symptom association probability (SAP) were diagnosed as RH. The patients with normal mucosal, normal reflux, normal SI or SAP and negative PPI test results were enrolled in functional heartburn (FH) group.

Results: Total 231 patients were enrolled. 107 were NERD (48.25±3.18 yrs, M/F = 55:52), 92 were FH (48.30±1.27yrs, M/F = 98:83), 32 were RH (48.41±2.36yrs, M/F = 48:28). 28 HVs (47.21±2.27yrs, M/F = 82:20) were enrolled as controls. NERD presented significantly higher acid exposure time (pH < 4.2) than those of FH, RH and HV (6.55±0.71, 1.25±0.12, 1.90±0.33, 2.95±0.53, respectively, p < 0.005). The acid reflux and weakly acid reflux were both higher in NERD than that in FH, RH and HV (p < 0.001). The total scores of SCL-90 of RH group of patients were significantly higher than that of NERD, 133±5 ± 3.68 vs. 108.61 ± 4.51, p = 0.004. FH: pHHV, 133.15±3±0.68 vs. 108.61 ± 4.51, p = 0.003. RH: HVHV, 142.67±8.91 vs. 108.61 ± 4.51, p = 0.002.

Conclusions: The differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DICI and DILI) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new system or methodology of manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Introduction: High-Resolution Manometry (HRM) has recently became the gold standard for the evaluation of esophageal motility. A new classification of esophageal motility disorders (Chicago Classification, v. 3.0) has been developed, based on the findings from a given hardware and software. Different systems for HRM and new features of the existing ones have recently been developed.

Aims & Methods: In this study we aimed to evaluate a new solid-state HRM system and a new 3-D catheter and system for the study of lower esophageal sphincter (LES). Fifteen healthy volunteers (7 m, 8 f; median age 27) underwent two consecutive Esophageal HRM studies by using two different solid state systems (ManoScan, Medtronic, Minneapolis, USA and Medica SpA, Italy with Unisensor AG, Atikon, Switzerland catheter). The studies were performed in a random order using the standard protocol. Moreover, a new 3-D catheter for the study of sphincters was evaluated in 12/15 volunteers.

Results: Table 1 reports the findings obtained with the Medica system compared to the consolidated Medtronic system. The data of the 3-D evaluation are also reported. The data are expressed as medians (and 5th-95th percentiles).

Conclusions: Significant differences were recorded in most of the considered parameters obtained by the two HRM systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DICI and DILI) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new system or methodology of manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Introduction: Proton Pump Inhibition response esophageal eosinophilia (PPI-REE) is a condition characterised by symptoms of esophageal dysfunction in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of 5 weeks of PPI therapy. Recent data collected by using esophageal high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypotensive esophagogastric junction (EGJ). Data on the effect of PPIs in improving these motor abnormalities are lacking.

Aims & Methods: Aimed to prospectively compare HRM features of patients with PPI-REE before and after a course of PPI therapy, consecutive patients with symptoms suggestive of EsE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, therefore, enabled PPI treatment for at least 8 weeks. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of diagnosis (off-PPI) and after the course of PPIs (on-PPI). Patients with achalasia and absent peristalsis were excluded (Chicago Classification v.3).

Results: Twenty-eight patients (23M:5F; mean age 33 years) reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. After a course of PPIs, the majority of the patients reported complete resolution of esophageal symptoms directly linked to esophageal infiltration (p < 0.001), mainly dysphagia, bolus impaction and chest pain. Compared to HRM features at baseline, HRM after PPI therapy showed that patients with PPI-REE had higher median EGJ resting pressure [baseline 11 (3–34) vs. post-PPI 17 (3–34); p < 0.05], greater mean distal contraction integral [1094 (483–5281) vs. 2634 (495–6450); p < 0.01], and less frequent panesophageal pressurization [6 (21%) vs. 0 (0%); p = 0.02)]. No differences were observed in terms of distal latency and mean distal peristaltic velocity (p > ns). As to the manometric diagnoses, after PPI therapy patients with PPI-REE showed a reduced rate of ineffective motility or fragmented peristalsis [16 (57%) vs. 7 (25%); p = 0.02] and increased frequency of normal peristalsis [9 (32%) vs. 18 (64%); p = 0.03]. No differences were observed in terms of frequency of distal esophageal spasm and outflow obstruction diagnoses (p > ns).

Conclusion: In most PPI-REE patients, PPI therapy restores the impairment of esophageal motility assessed by ineffective or fragmented peristalsis, thus favouring the return to a normal motility pattern. This finding, paralleled with symptoms improvement in the same subjects, seems to emphasize the important role of inflammation linked to the eosinophilic infiltration of the esophageal wall in inducing motor dysfunction and related symptoms.

Introduction: Esophageal Eosinophilia (EoE) is a chronic immune disease of the esophageal wall causing localized inhomogeneous infiltration with histologically characterized by a predominant eosinophilic inflammation. EoE is mainly found in patients with atopic conditions. However, recently an association with IgG4 but not with IgE has been reported. Gastroesophageal reflux disease (GERD) is the most important diagnostic differential diagnosis of EoE. In this study we measured systemic serum IgG4 and IgE levels of EoE patients before and after a topic steroid therapy, correlated them to esophageal IgG4-positive plasma cells and compared them to GERD patients.

Results: In total, 119 patients were diagnosed with EoE and included in this study. The median age at onset of symptoms was 29 years (IQR 15–42) and the median age at diagnosis was 38 years (IQR 23–51 years), leading to a median diagnostic delay of 6.5 years (IQR 2–14 years). The median delay in diagnosis between first contact in the hospital and diagnosis was 1.0 year (IQR 2–14 years). The incidence of patients newly diagnosed with EoE increased steadily over a period of 11 years. Criteria for the microscopic diagnosis of EoE varied between pathologists in each hospital. Initial treatment included topical corticosteroids (30.3%), proton pump inhibitors (PPIs) (29.4%) or a combination of both (10.1%). A follow-up upper endoscopy was performed in 40.3% of patients. During follow-up, treatment included PPIs (76.0%), topical corticosteroids (59.6%) or a combination of both (45.4%).

Conclusion: Diagnostic and therapeutic discrepancies between daily clinical practice and recommendations for children and adults. Moreover, varying therapeutic strategies were utilized in the participating centers. Our results show that apart from developing guidelines, efforts should be undertaken to implement them in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims & Methods: Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group. Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as control group.

Results: Serum IgG4 levels of EoE patients were significantly higher than in GERD patients (mean: 121.0 mg/dL vs. 71.2 mg/dL, p = 0.034). In contrast, no significant difference of IgE levels in EoE and GERD patients was observed. In EoE patients, the number of eosinophils in histology was decreased at a significant level after topic steroid therapy (mean: 51.9 eosinophils/high power field (hpf) vs. 6.4 eosinophils/hpf p < 0.001). After therapy lower levels of IgG4-serum levels could be measured (mean: 121.0 mg/dL vs. 104.2 mg/dL p = 0.042). A significant difference could also be identified for IgE levels showing a significant decrease after therapy (mean: 13.9 kU/L vs. 8.8 kU/L p = 0.022).

Conclusions: EoE patients show higher systemic IgG4- but not IgE-immunological levels compared to GERD patients. These elevated levels normalize under effective topic steroid therapy. Additionally high local expression of IgG4-positive plasma cells can be seen in EoE patients. These findings might be further evidence for a possible IgG4-association of EoE.

P1841 SYSTEMATIC REVIEW: HEALTH-RELATED QUALITY OF LIFE IN CHILDREN AND ADULTS WITH EOSINOPHILIC ESOPHAGITIS: MEASURE INSTRUMENTS AND DETERMINANT FACTORS

Contact E-mail Address: alucendo@vodafone.es

Introduction: Measurement of Health-related quality of life (HRQoL) with generic or specific instruments has been increasingly used in patients suffering from EoE to support both research and clinical care. Generic instruments aim at measuring the overall HRQoL of patients across several conditions, being useful for comparing across different health states and evaluating health economics outcomes. Disease-specific instruments assess domains specific to a given disease and are considered more sensitive to changes in the patient’s health state. An up-to-date systematic review will provide a useful resource for researchers and EoE specialists to ensure they can select an appropriate HRQoL measure for patients in their practice in order to identify correctable factors determining an impaired perception and to improve treatment outcomes.

Aims & Methods: We aim to systematically review the current HRQoL measures for patients with EoE and to appraise their measurement properties using a robust evaluation methodology checklist. We also sought to identify disease-specific determinant factors for HRQoL in children and adults with EoE, and the effect of investigations and interventions on EoE on HRQoL. A search strategy was used to identify and retrieve all documents dealing with the relationship between HRQoL and EoE in children and adults. This systematic literature search was performed in 5 major databases (PubMed, EMBASE, Scopus, PsycINFO and Web of Science) for the period up to March 2017. The measurement properties of each specific EoE instrument identified and their performance properties were assessed using the quality properties checklist proposed by Terwee et al. Levels of the HRQoL measure establishment or use in literature: we used Cohen’s criteria. Cohort studies, case series and case reports were evaluated for the risk of bias with the aid of the Joanna Briggs Institute critical appraisal checklist. A descriptive summary with data tables was produced to summarize the literature. Quantitative pooling of data was not meaningful so a narrative synthesis with data tables was undertaken.

Results: Of the 596 references identified, data was collected from 34 studies including 1,142 individual patients. Three disease-specific HRQoL measures in EoE covering different aspects of patients’ lives and developed in EoE were scored positive regarding measurement properties. Respectively, the PedsQL inventory (including parent and child report forms) and the Peds-QoLÆ Esophageal module were the generic and specific instruments respectively used in children, while the SF-36 and EoE-QoL-A were the most used questionnaires in adults. Of the 596 references identified, data was collected from 34 studies (Table 1).

### P1844 GASTROESOPHAGEAL REFUX DISEASE PATIENTS REFUXATE TYPE INFLUENCE ON MACROPHAGE PHENOTYPE

S. Lyamina1, S. Kalish1, A. Parasekov2, O. Storonova2, S. Pirogov2, A. Ponomarev3, D. Rumyantseva2, A.S. Troukhmanov2, V. T. Ivashkin5, 1,3,4,5

**Introduction:** The modern understanding of gastroesophageal reflux disease (GERD) pathogenesis includes identification of the subepithelial layer: eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to eosinophils subepithelium in 62%, 75%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.331, p < 0.0001), endoscopic severity (rho 0.208, p = 0.003), and symptom severity (rho 0.179, p = 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of <15/hpf.

**Conclusion:** In one third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophil counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1845 THE LOCATION OF OESOPHAGEAL MUCOSAL AFFERENT NERVES ARE MORE SUPERFICIAL IN PATIENTS WITH NERD THAN IN HEALTHY VOLUNTEERS AND PATIENTS WITH BARRETT’S OESOPHAGUS

P. Woodland1, J.L.S. Ooi2, F. Grassi3, C. Lee4, J. Evans5, N. Koukias6, C. Triantos4, S. A.C. Mcdonald2, M. Peiris1, R. Aktar1, A. Blackshaw1, D. Sifrim1

**Introduction:** The pathophysiology of heartburn perception in gastro-esophageal reflux disease (GERD) remains unclear. The degree of reflux-induced epithelial change seldom predicts symptom severity, as evidenced by the greater symptom burden seen in non-erosive reflux disease (NERD) compared to patients with Barrett’s oesophagus (BE). Existing models of acid hypersensitivity are inadequate to explain this discordance.

**Aims & Methods:** To test the hypothesis that differences in peripheral esophageal nerve innervation may be relevant, we studied the distribution of mucosal nerve fibers in patients with NERD and BE and compared the results with that of healthy subjects. 13 patients with NERD undergoing reflux testing and 16 patients with BE undergoing endoscopic surveillance were prospectively recruited. Biopsies were obtained from the proximal and distal esophageal mucosa in NERD patients and the distalmost squamous epithelium in BE patients, then examined immunohistochemically for location and density of calcitonin gene-related peptide (CGRP)-immunoreactive nerve fibers. The results were compared with those from 10 healthy volunteers (HV) previously studied by our group.

**Results:** The distribution of mucosal CGRP-immunoreactive nerves is equidistant from the distal esophageal mucosa in HV and BE (median 25.5 cell layers to surface [IQR 21.4–28.8] vs 21.5 [16.1–27.5] respectively, p = 0.015). Mucosal innervation is significantly more superficial in NERD both distally (9.5 cell layers [1.5–13.3], p < 0.0001 vs both BE and HV) and proximally (5.0 [2.5–9.3], p = 0.0008 vs HV).

**Conclusion:** The acid hypersensitivity seen in NERD may be partially explained by the increased proximity of mucosal afferents to the esophageal lumen, and therefore greater exposure to noxious substances in refluxate. Conversely, the higher acid hypersensitivity in BE may be attributed to the deeper location of mucosal afferents.

P1846 BELCHING PATTERNS IN PATIENTS WITH ISOLATED PATHOLOGICAL UPRIGHT REFLUX AND PATHOLOGICAL BIPOSIONAL REFLUX
J.M. Conchillo, J. T. Snijkers, J. Santos Fernandez, A. A.m. Masleep
Gastroenterology, Maastricht UMC, Maastricht/Netherlands
Contact E-mail Address: j.conchillo@mumc.nl

Introduction: Belching is a commonly occurring symptom in patients with gastrointestinal reflux disease (GERD). Belching may reflect reflux. It is unknown whether GERD patients with isolated pathological upright reflux (UP) have belching patterns that are different from GERD patients with pathological bipositional reflux (BIP).

Aims & Methods: Aim of this study was to examine the belching patterns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who underwent 24-h pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded. A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22–77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18–77)) were enrolled. 24-h pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptom-assessment analysis was performed to assess a relationship between reported symptoms and reflux episodes.

Results: BIP patients showed higher acid reflux time (17.8 ± 2.4% vs. 7.3 ± 0.6%, p < 0.001) and higher number of total reflux episodes (121 ± 9 vs. 97 ± 8, p = 0.05) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients (51.7 ± 3.6% vs. 32.1 ± 3.7%, p < 0.001 and 27.3 ± 3.1% vs. 17.8 ± 2.9%, p = 0.03, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21 ± 6 vs. 12 ± 3, p = 0.16) and had more positive symptoms with belches (60.2 ± 7.1% vs. 39.0 ± 6.6%, p = 0.03) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were recorded in UP patients than in BIP patients (24.8 ± 6.4% vs. 11.1 ± 2.5%, p = 0.06).

Conclusion: In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological bipositional reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refractory to medical therapy.

P1847 IS REFLUX DURING NAPS WORSE THAN DURING NIGHT-TIME SLEEP?
C. Teruel Sánchez-Vegazo, M. J. De Higes Ruiz, A. Albillos
Gastroenterology, Hospital Ramón y Cajal, Madrid, Madrid/Spain
Contact E-mail Address: cteruelvegazo@yahoo.es

Introduction: Gastroesophageal reflux in the recumbent period is related to a higher risk of developing oesophageal lesions (severe esophagitis or Barrett oesophagus). The only study to date that analysed reflux during daytime naps suggests that it is worse than that which occurs during the night-time sleep. Our objective was to determine if reflux during naps is more severe than during night-time sleep.

Aims & Methods: Between February 2015 and November 2016 patients that underwent ambulatory 24-hour oesophageal pH monitoring at our motility unit were screened. Those who slept an afternoon nap in the recumbent position in the right-night-time sleep pattern and pathological acid exposure (deMeester score >14.72) were included. We excluded those patients with previous foregut surgery or sleep apnea, those taking sleeping medication and those who were in recumbent position more than twice during the study. All studies were analysed. Number of refluxes, number of refluxes per hour, reflux duration and oesophageal acid exposure (AET) time were compared between the two recumbent periods. Correlation between AET and meal-to-bed time was analysed, both for naps and night-time sleep.

Results: A total of 32 patients were selected (59.4% women, mean age 51.31 ± 14.59, median BMI 26.48 (range 21.63–38.71)). Indication was typical GERD symptoms in 68.8% and atypical symptoms in 32.3%. Oesophageal manometry revealed normal oesophageal body motility in 65.6%, inefficient peristalsis in 28.1%, and a median lower oesophageal sphincter pressure of 8 mmHg (range 1–24). Median nap duration was shorter than that of the night-time sleep: 108 mins (range 30–375) vs 454 mins (range 240–593) (p = 0.00). Median meal-to-bed time was also shorter for naps: 30.5 mins (range 4–185) vs 110.5 mins (range 9–247) (p = 0.00). Median number of refluxes per hour and median recumbent AET were similar in both periods: 1.71 (range 0–26.5) vs 1.85 (range 0–12.8) (p = 0.45) and 1.55 (range 0–61) vs 5.9 (range 36.1–36.1) (p = 0.57), respectively. 87% of total reflux recurrence took place during the night. Correlation between AET and meal-to-bed time trended to be significant for Spearman ρr = 0.33, p = 0.065), and was not significant for night-time sleep (Spearman ρr = 0.2, p = 0.94). All 5 patients who waited more than an hour after lunch to lay down had an AET during the nap of less than 1%.

Conclusion: Naps are not associated with a more severe acid reflux than night-time sleep, what does not support a specific recommendation against taking daytime naps for GERD patients. Avoiding short meal-to-bed time specifically for naps could be advisable.

P1848 TREATMENT WITH PROTON PUMP INHIBITORS (PPI) DOES NOT REDUCE ACID LARYNGOPHARYNGEAL REFLUX (LPR) DESPITE REDUCING DISTAL ACIDIC \nGASTROESOPHAGEAL REFLUX AND IMPROVING SYMPTOMS IN PATIENTS WITH LPR

Introduction: PPI improve LPR symptoms in many patients. It is implicitly assumed that this effect is due to reduction of acidic LPR by PPI. Here we tested this assumption. We evaluated LPR and distal gastroesophageal reflux by using simultaneous pH/impedance monitoring in laryngopharyngeal segment and in distal esophagus before and after PPI treatment.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux finding score (RFS > 7, determined by ENT physician) and/ or positive reflux symptom index (RSI > 13) at least one acidic LPR episode during 24-h pH-impedance study were enrolled. The RSI, RFS and dual pH/ impedance study of LPR and distal reflux were performed before and after 3 months therapy with PPI twice a day. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4–6 cm above LES. By definition each LPR event was preceded by reflux detection in the distal esophagus.

Results: 18 patients (11M/7F, 31 ± 10yrs) completed the study. In this group the PPI treatment substantially reduced the symptoms of LPR. Reflux finding score (RFS) was decreased by 40% from 9 ± 1 ± 3 ± 1 (P < 0.01). The number of distal acidic reflux episodes was reduced from 17 ± 2 to 3 ± 3 (P < 0.01). Surprisingly, acidic LPR was not decreased by PPI treatment. The number of LPR with pH < 5.0 was 2 ± 0.5 vs. 3 ± 1, P = NS, and the number of LPR episodes with pH < 4.0 was 0.7 ± 0.1 vs. 0.6 ± 0.2, P = NS.

Surprisingly, the number of acidic LPR episodes with pH = 5.0–6.0 was even increased (14 ± 2 vs. 21 ± 3, P < 0.05) leading to an increase in the overall number of LPR episodes by approximately 50% from 16 ± 2 to 24 ± 3 (p < 0.05). PPI treatment did not decrease laryngopharyngeal time the pH was <2 (P = NS) and did not alter the composition of acidic LPR reflux (RFS = NS).

Conclusion: Proton pump inhibitor treatment does not reduce acidic laryngopharyngeal reflux despite substantially improving symptoms in patients with objectively established LPR. This suggests that PPI treatment influences some aspects of pathogenesis of LPR symptoms that are not readily detected by laryngopharyngeal pH/impedance monitoring.

Before and after menthol infusion was 7.5/C6. Classification v3.0. Few volunteers reported only mild cold sensation during menthol 8 ml/min. was carried out and subsequently the water swallows in order to follow: after the baseline recording 10 water swallows of 15 ml and 3 water swallows of 10 and 15 ml. After that a 20 min. infusion challenge with 3 mM menthol on the esophageal peristalsis and LES tone.

Aims & Methods: The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers without out esophageal symptoms were enrolled. High-resolution manometry whether with a thin silicon tube attached was placed transnasally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: recording 10 with 5 ml swallows of 5 ml and 3 with 3 water swallows of 10 and 15 ml after. At that a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using Medical software and Parameters used into the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion. Paired test was used for statistical analysis.

Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during infusion presumed to be of the esophageal origin. The nadir LES pressure before and after menthol infusion was 7.5 ± 0.5 mmHg vs. 7.3 ± 0.7 mmHg, respectively (p < 0.7). IRP of 5 ml swallows was 2.8 ± 0.6 mmHg vs.2.1 ± 0.5 mmHg showed significance (p = 0.01). However, difference of IRP of 10 ml and 15 ml swallows was not significant (p > 0.1, p > 0.5, respectively). Average DCI of 5 ml swallows was 737.8 ± 126.3 mmHg and 814.2 ± 116.2 mmHg before and after menthol infusion, respectively (p > 0.5). We found no difference in DCI in 10 ml and 15 ml swallows before and after menthol infusion. Menthol seemed to have had only a marginal insignificant effect on IRP and DCI in rapid swallow wave.

Conclusion: We quantified the effect of menthol on the esophageal function and LES pressure in healthy volunteers using high-resolution manometry. The analysis of HRM tracings revealed that menthol has no effect on particular parameters of the peristalsis and esophageal motility.

**P1850** ANALYSIS OF THE RELATIONSHIP BETWEEN GLOBUS PERCEPTION AND ACIDIC LARYNGOPHARYNGEAL REFUX BY DUAL PHARYNGEAL AND ESOPHAGEAL 24-HOUR PH/ IMPEDANCE MONITORING

L. Bebrenková, M. Drůček, P. Banovcin, R. Hyrdeł Internal Gastroenterological Clinic, Jessenius Faculty of Medicine, Martin; Slovak Republic

Contact E-mail Address: lenka.bubernakova@gmail.com

Introduction: Globus is considered to be related to the gastroesophageal reflux disease/laryngopharyngeal reflux (LPR). However, a substantial part of subjectiveness and self-perception of globic sensation which is impossible to measure objectively makes this symptom difficult to study. Visceral hypersensitivity and/or altered functional state of the afferent nerve endings in the hypopharynx resulting from reflux have been suggested responsible for the development of globus. We hypothesized differences in the reflux burden and esophageal/pharyngeal symptoms between the patients with globus symptoms with globus compared to the patients with LPR symptoms without globus.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux symptom index (RSI > 15) and at least one acidic LPR episode during 24 h pH/impeance study were enrolled. We recruited patients that were at least 30 days without PPI treatment. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4-6 cm above LES. For each LPR event we determined the maximum drop of pH on the pH levels resulting from reflux below that pH level during 24h. According to the question 8 (sensations of sticking/lump in the throat) of self-evaluated RSI questionnaire the patients were divided into globus positive (tick 4-5 in the RSI) or globus negative (tick 0-1 in the RSI).

Results: 19 (13M/6F) completed the study. The number of globus positive and negative patients was 11 and 8, respectively. There were no major differences between groups. Disregarding the question about globus in the RSI, there was a significant difference of the RSI between the globus positive and negative group (25 ± 2 vs. 21 ± 2, respectively, p = NS). As for the reflux in distal esophagus, we observed no difference in the acid exposure time between the globus positive and negative patients (IRP 21.7% vs. 22.1%, respectively, p = NS). Therefore we assumed differences in the results from the hypopharyngeal pH sensor. However, the number of LPR events with pH drop to < 5.5 showed no significant difference between the globus positive and negative patients, either for the number of events (92 ± 6.5 vs. 93 ± 4.6, respectively, p = NS). We therefore speculated that more acidic LPR events (pH drop to < 5.5) might be of greater relevance. However, no significant difference was found between the globus positive and negative patients either in terms of the number of these LPR events (10 [2] vs. [1]–1, respectively, p = NS), or the pharyngeal acid exposure time (16 ± 6 s vs. 42 ± 3 s, respectively, p = NS).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without globus using 24 h dual channel pH/impedance. Other factors, e.g. visceral hypersensitivity might play a role in the development of globus symptoms, even in patients with objectively established LPR.

Introduction: Due to a negative feedback mechanism, gastrin-17 (G17) can be considered a mirror of acid secretion: the lower G17 values, the higher gastric acid secretion. Some studies suggest serum G17 low levels as a marker of acid-related conditions, like Gastroesophageal Reflux Disease (GERD). Aim of the study was to evaluate the properties of low levels of G17 in GERD diagnosis, compared with clinical and instrumental GERD gold-standards (typical symptoms, esophagitis at endoscopy, a positive Demester score at pH-metry).

Aims & Methods: We evaluated the demographic and clinical profile of patients with GERD diagnosed with low serum G17 levels; we determined the G17 levels in normal healthy controls. The study was a prospective study on sample of 777 consecutive patients.

Results: Out of 777 patients with non erosive reflux disease, 40 (5.1%) were found to have serum G17 levels lower than 20 pg/mL, the mean of this group was 10.8± 3.1 pg/mL, compared to the mean of 36.9± 14.6 pg/mL of normal healthy subjects. We therefore considered serum G17 low levels as a marker of acid-related conditions. By using low levels of G17 as a non-invasive marker of GERD, in clinical, endoscopical or functional accepted to support the diagnosis of functional dyspepsia. Only when severe symptoms are lacking or a NERD picture is find, GERD almost when typical symptoms are lacking or a NERD picture is found.

Conclusion: By using low levels of G17 as a non-invasive marker of GERD, in more than 90% (700 out of 777 pts) the diagnosis of reflux disease was confirmed, according with the current clinical or instrumental gold standard criteria, supporting the use of this simple method to identify subjects with suspected GERD almost when typical symptoms are lacking or a NERD picture is find.

Hiatal hernia (HRM) 33 (97.1%) 34 (70.8%) 16 (37.2%) 0

Hiatal hernia (X-ray) 34 (100%) 36 (75%) 17 (39.5%) 1 (3.8%)

Table I:

Contact E-mail Address: martinucci.irene@gmail.com

Introduction: Sliding hiatal hernia (HH) is a frequent diagnosis during upper endoscopy in patients with GERD-related symptoms. Recently, high resolution manometry (HRM) allowed an accurate evaluation of the esophagogastric junction (EGJ) and its sub-types (Chicago Classification V3.0; CCv3). Few data are available comparing the diagnostic accuracy of HRM and UE to detect HH.

Aims & Methods: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and MII-pH to investigate GERD. All tests were performed previous a 20-day wash-out from proton pump inhibitors. Erosive esophagitis (ERD) was diagnosed according to the Los Angeles Classification, and HH was diagnosed when the separation between the squamo-columnar junction and the diaphragmatic impression was greater than 2 cm. Patients with achalasia or major disorders of peristalsis or previous surgery were excluded. MII-pH monitoring allowed to sub-classify patients with non-erosive GERD in: NERD (abnormal AET), reflux events but positive symptom-reflux association, HE) and functional heartburn (FH), classified by means of upper GI endoscopy and reflux symptoms association analysis using both symptom association probability (SAP+ if ≥95%) and symptom index (SI+ if ≥50%).

Conclusion: HRM can be useful in detecting GERD, with a particular the role of the EGJ-CI in GERD pathophysiology has been recently acknowledged, the antireflux barrier function of EGJ can now be assessed evaluating the antireflux barrier in patients with non-erosive GERD in: NERD (abnormal AET), reflux events but positive symptom-reflux association, HE) and functional heartburn (FH). All patients underwent barium X-ray to measure HH. Recognition of two rings larger than 2 cm (re-occur position between EGJ and diaphragmatic hiatus was necessary to detect HH.

Results: We evaluated 151 patients (94 females) with mean age of 56.2 ± 15.4 yrs. ERD was diagnosed in 34 patients (22.5%). MII-pH allowed to subgroup patients in: 48 (31.8%) NERD, 43 (28.3%) HE, and 36 (27.2%) HH. As expected, HH showed a higher AET in ERD and NERD group (p < 0.001). HH was normal in 131/151 (86.8%) and 20/151 (13.2%) had ineffective motility. HH was confirmed in 83/151 patients (HRM 55% vs. UE 100%; p < 0.05) with barium X-ray and in 88/151 patients (barium 58.3% vs. UE 100%; p < 0.05) with barium X-ray. The mean length of HH during endoscopy (5.4 ± 2.6) was reported greater than that during HRM (3.9 ± 2.2) and Barium X-ray (4 ± 2.5) (p < 0.05). All details are reported in Table 1.

Table 1: Characteristic of the enrolled population stratified for GERD diagnosis

Conclusion: HRM and barium X-ray showed similar diagnostic accuracy to detect HH. Thus, HRM might be considered the test of choise during pre-surgical evaluation for laparoscopic antireflux surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: salvatore.tolomei@unica.it

Introduction: In patients with symptoms suggestive of gastroesophageal reflux disease (GERD) candidate to anti-reflux surgery, in order to objectively diagnose GERD, new metrics have been developed to investigate esophageal motor function, esophagogastric junction (EGJ) morphology and their function. In particular, the antireflux barrier function of EGJ can now be assessed evaluating the EGJ-CI in GERD pathophysiology has been recently acknowledged, the antireflux barrier function of EGJ can now be assessed evaluating the antireflux barrier function of EGJ in patients with non-erosive GERD in: NERD (abnormal AET), reflux events but positive symptom-reflux association, HE) and functional heartburn (FH). All patients underwent barium X-ray to measure HH. Recognition of two rings larger than 2 cm (re-occur position between EGJ and diaphragmatic hiatus was necessary to detect HH.

Aims & Methods: Our aim was to assess the differences in terms of HRM characteristics between patients with typical reflux symptoms with GERD and those with functional heartburn (FH), classified by means of upper GI endoscopy and impedance-pH (MII-pH) monitoring off-medication. We also aimed to develop a predictive model for distinguishing FH from GERD by using the prevalence of these HH features. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate esophageal peristalsis and HH function. Recognition of two rings larger than 2 cm (re-occur position between EGJ and diaphragmatic hiatus was necessary to detect HH.

All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate esophageal peristalsis and HH function. Recognition of two rings larger than 2 cm (re-occur position between EGJ and diaphragmatic hiatus was necessary to detect HH.

Results: Overall, 68 patients (39 F/29 M, median age 42.3) underwent HRM and MII-pH. HH findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistical parameters of cut-off were found in EGJ pressure, EGJ-CI, mean DCl, DCI, mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosmer’s purposeful selection of covariates, an optimal predictive model based on HRM variables was built by logistic regression analysis. The model was tested for discriminative performance by computing the area under ROC curve (AUROC), and calibration was assessed by Hosmer-Lemeshow goodness-of-fit test. The bootstrap resampling method was used to evaluate the internal validity of the model and to correct for over-fitting.

Results: Overall, 68 patients (39 F/29 M, median age 42.3) underwent HRM and MII-pH. HH findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistical parameters of cut-off were found in EGJ pressure, EGJ-CI, mean DCl, DCI, mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosmer’s purposeful selection of covariates, an optimal predictive model based on HRM variables was built by logistic regression analysis. The model was tested for discriminative performance by computing the area under ROC curve (AUROC), and calibration was assessed by Hosmer-Lemeshow goodness-of-fit test. The bootstrap resampling method was used to evaluate the internal validity of the model and to correct for over-fitting.

Introduction: In patients with symptoms suggestive of gastroesophageal reflux disease (GERD) candidate to anti-reflux surgery, in order to objectively diagnose GERD, new metrics have been developed to investigate esophageal motor function, esophagogastric junction (EGJ) morphology and their function. In particular, the antireflux barrier function of EGJ can now be assessed evaluating the EGJ-CI in GERD pathophysiology has been recently acknowledged, the antireflux barrier function of EGJ can now be assessed evaluating the antireflux barrier function of EGJ in patients with non-erosive GERD in: NERD (abnormal AET), reflux events but positive symptom-reflux association, HE) and functional heartburn (FH). All patients underwent barium X-ray to measure HH. Recognition of two rings larger than 2 cm (re-occur position between EGJ and diaphragmatic hiatus was necessary to detect HH.

Aims & Methods: Our aim was to assess the differences in terms of HRM characteristics between patients with typical reflux symptoms with GERD and those with functional heartburn (FH), classified by means of upper GI endoscopy and impedance-pH (MII-pH) monitoring off-medication. We also aimed to develop a predictive model for distinguishing FH from GERD by using the prevalence of these HH features. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate esophageal peristalsis and HH function. Recognition of two rings larger than 2 cm (re-occur position between EGJ and diaphragmatic hiatus was necessary to detect HH.

Results: Overall, 68 patients (39 F/29 M, median age 42.3) underwent HRM and MII-pH. HH findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistical parameters of cut-off were found in EGJ pressure, EGJ-CI, mean DCl, DCI, mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosmer’s purposeful selection of covariates, an optimal predictive model based on HRM variables was built by logistic regression analysis. The model was tested for discriminative performance by computing the area under ROC curve (AUROC), and calibration was assessed by Hosmer-Lemeshow goodness-of-fit test. The bootstrap resampling method was used to evaluate the internal validity of the model and to correct for over-fitting.

P1854 GORD PATIENTS ARE FREQUENTLY DISSATISFIED ON LONG-TERM ACID SUPPRESSION TREATMENT: DATA FROM THE LOPA II STUDY

J. Labenz1, G. Labenz7, M. Müller1, D. Stephan1, E. Wickle4

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked about their PPI therapy satisfaction with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consultation related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reasons for dissatisfaction with their current medication treatment. “Lost Patients” were defined as those with a satisfaction score of 1 or 2 on a 5-point Likert scale (1: very dissatisfied; 2: dissatisfied). GerdQ score at least 8, and have not previously received specialized GORD diagnostics.

Results: 510 consecutive patient responses were collected within one year. Patients suffered from GORD an average of 9.6 years and prescribed PPI therapy for an average duration of 7.9 years. 70% were dissatisfied or very dissatisfied on their current therapy (score of 1 or 2), 83% reported heartburn or regurgitation symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Aims & Methods: Our study was aimed to define the prevalence of reflux symptoms in mild GERD patients suffering from mild GERD. We considered 500 consecutive patients referred to the Division of Allergy and Clinical Immunology of Azienda-IST IRCCS San Martino di Genova for gastrointestinatal symptoms associated to food intake. Patients with a clinical and instrumental diagnosis of food allergy, food intolerance, Irritable Bowel Syndrome (IBS) and Small intestinal Bacterial Overgrowth (SIBO) were excluded. Patients with a diagnosis of GERD based on clinical history represented our study population. Basal metabolic rate and calories need of patients was assessed by means of Harry-Benedict equation corrected for their physical activity. Patients were asked to take antacids for one month. Subsequently patients discontinued medication consumption and followed an elimination diet of 1 month. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptomatic score was recorded.

P1855 PREVALENCE AND PATHOPHYSIOLOGY OF GASTROESOPHAGEAL REFUX DISEASE IN PATIENTS WITH AUTOIMMUNE GASTRITIS

G. Maddalo1, V. Pilotto1, E. Savarino1, C. Orlando1, M. Fassan2, D. Basso3, M. Rugge2, F. Farinati1

Introduction: Autoimmune gastritis (AIG) is characterized by corpus-predominant atrophy with consequent hypo-achlorhydria. In AIG patients dyspepsia is frequent but acid reflux symptoms not uncommon, with few data available regarding gastroesophageal reflux disease (GERD) in AIG.

Aims & Methods: We studied in order to define the prevalence of reflux symptoms in AIG patients, to evaluate the serological, histological and clinical differences in AIG patients with or without reflux symptoms and to investigate the pathophysiology behind these symptoms. One hundred and fifty AIG cases, with exclusion criteria are defined in the study: 29 AIG patients with reflux symptoms (AIG-R) and 58 without (controls), selected with similar age and gender distribution. AIG-R underwent pH-impedance (pH/I) and high resolution manometry (HRM), Serum biomarkers, EGDS, histology and anamnestic data were evaluated in both groups. Statistics was performed as indicated.

Results: AIG-R were 19% overall and 28% of them showed endoscopic esophageal lesions, with frequent hiatal hernia than in controls (p < 0.02). pH/I diagnosed acid reflux, esophageal hypersensitivity and a normal pattern in 7%, 28% and 66% patients, respectively. The number of non-acid reflux (NAR) was higher when compared with acid ones (p < 0.0001), moreover NAR and NAR proximal extension were associated with endoscopic lesions (p < 0.03 and p < 0.05, respectively). HRM revealed normal pattern in 62% of patients, minor periatal disorders in 24%, and outflow obstruction in 14%. According to the new Rome IV criteria, 55% of patients presented “functional esophageal disorders” (Rome IV-IN). No differences were detected in serological marker and clinical presentation. AIG-R presented lower antrum gastritis (p < 0.02) and a trend towards higher atrophy stages (p = 0.07) when compared with controls. The two patient with acid GERD were an OLGA 0 with mild gastrin increase and an OLGA I with short segment Barrett’s esophagus. Lower OLGA stages, lower corpus atrophy (p < 0.02) and more frequent response to PPI (p < 0.05) were associated with Rome IV-OUT status.

Conclusion: AIG-R patients are not uncommon despite the hypo-achlorhydria. Acid reflux is rare in AIG, while motility and “functional” disorders are frequent. Lower corpus atrophy and OLGA stage in Rome IV-OUT patients, with an intact corpus is likely relevant in the pathogenesis of symptoms. Treatment should consider use of proton pump inhibitor drugs only in specific patients.

P1856 DIET IS MORE EFFECTIVE THAN ANTACIDS IN RELIEVING REFUX SYMPTOMS IN MILD GERD

M. Furnari1, S. Cento1, S. Tolone1, M. Frazzoni1, E. Savarino2, L. Frazzoni2, E. Marabotto3, G. Bodini1, V. Savarino1, N. De Bortoli1, S. Marchi1, P. Minale3

Introduction: Gastroesophageal reflux disease (GERD) is a common disorder commonly overlapping with several functional or allergic/immunological disorders, whose symptoms are related to food intake. Awareness of health care costs and potential side effects of long-term acid suppression has increased the attention in non-pharmacologic treatment for alleviating reflux symptoms.

Aims & Methods: The aim of our prospective study was to evaluate the non-inferiority of a controlled diet compared to antacid compounds in relieving reflux symptoms in patients suffering from mild GERD. We considered 500 consecutive patients referred to the Division of Allergy and Clinical Immunology of Azienda-IST IRCCS San Martino di Genova for gastrointestinatal symptoms associated to food intake. Patients with a clinical and instrumental diagnosis of food allergy, food intolerance, Irritable Bowel Syndrome (IBS) and Small intestinal Bacterial Overgrowth (SIBO) were excluded. Patients with a diagnosis of GERD based on clinical history represented our study population. Basal metabolic rate and calories need of patients was assessed by means of Harry-Benedict equation corrected for their physical activity. Patients were asked to take antacids for one month. Subsequently patients discontinued medication consumption and followed an elimination diet of 1 month. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptomatic score was recorded.

Results: After investigations 261 patients out of 500 (52.2%) were excluded because of IBS (140), celiac disease (6), nickel allergy (25), lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 132F/107M; no erosive reflux disease) and were included in our interventional prospective study. After 1 month of elimination diet diet, there were noted a significantly associated in patients suffering from food related symptoms, based on their calories need. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptomatic score was recorded.

Introduction: Safety and efficacy of electrical stimulation of the lower esophageal sphincter (LES) using the EndoStim® LOS Stimulation System (Nijmegen, The Netherlands) has been demonstrated in clinical trials up to >5 years. Data on outcomes in routine clinical practice is growing.

Aims & Methods: An ongoing, prospective international multicenter web-based registry is collecting data in patients with refractory GORD symptoms, treated with ES-LOS in clinical practice. Data is collected at baseline and at routine follow-ups for 5 years. Demographics, adverse events, GORD symptoms, GORD health related quality of life (GORD-HRQL) scores, use of proton pump inhibitor (PPI), and psychological and physiopathological data (oesophageal pH, manometry) are collected when available.

Results: 180 patients at 31 sites in Europe and Latin America have been enrolled. Follow-up data up to 2 years is available. Median (IQR) age at the time of implant was 51 (41–60), 57% were male. All patients were taking prescription PPI at baseline. At their last follow-up between 6 and 24 months post op, 70% (84/121) were completely off PPI (p < 0.001). Median (IQR) composite GORD-HRQL score improved from 23 (17–29) preoperatively to 3 (4–15) at 6 months, 7 (2–12) at 12 months, and 8 (4–15) at 24 months (p < 0.001 at all time points. n = 154, 121, 66, 33 at baseline, M6, M12, M24, respectively). Oesophageal pH testing post-op was performed by a few sites either as standard of care or in in-person consultations. Median (IQR) 9-hour post-prandial oesophageal acid exposure improved from 8.2% (4.6–18.4) at baseline to 4.7% (1.4–14.5) at 6 months (p = 0.026) and 3.6% (1.0–5.8) at 12 months (p = 0.04) (n = 120, 39, 10 at baseline, M6, M12, respectively). The proportion of patients with moderate to severe regurgitation decreased from 64% at baseline to 22.5% after 6 and 13.4% after 12 months. Extra-oesophageal symptoms (recurrent cough, pneumonitis, shortness of breath) and sleep disturbances also decreased substantially. Overall, dysphagia and gas were less common at 12 months than preoperatively. Four severe adverse events were reported in the first year. One myocardial infarction related sudden death at 11-month post-op, not related to the device or procedure; 1 event of asymptomatic electrode erosion into the oesophagus detected during routine endoscopy and the device safely removed during laparoscopic fundoplication; and 2 events of gas leak were in 1 patient requiring hospitalization, possibly related to the device, were reported.

Conclusion: ES-LOS is safe and effective in treating patients with refractory GORD symptoms despite PPI in routine clinical practice. ES-LOS should be considered an appropriate treatment option for very difficult to treat patient cases.

P1859 EFFECTIVENESS OF SELECTIVE SEROTONIN REUPTAKE INHIBITORS IN THE TREATMENT OF NON-EROSSIVE REFLUX DISEASE: A RANDOMIZED TRIAL

I. Birichenko, N. Bondarenko, A. Svititskyi
National Medical University, Kyiv/Ukraine

Contact E-mail Address: doctor.gastro@yahoo.com

Introduction: To date a large quantity of 5-HT3 receptors were found in esophageal mucosa that indicates on an important role of this neuromediator in pathogenesis of non-erosive reflux disease (NERD) and gastroesophageal reflux disease (GERD). Antidepressants seems to be effective, as they have central and psychologically. Psychological testing was done using validated short-form version of the depression anxiety stress scales (DASS-21) and Toronto alexithymia scale (TAS). The patients were randomly divided into two arms: patients of the first arm received PPI (pantoprazole) 40 mg once a day plus escitalopram as follows: initial dose - 5 mg/day for the first two weeks of treatment; depending on individual response the dose was increased to 10 mg/day. The second arm received only PPI 40 mg once a day. Patients were assessed on the 4th and 8th week of treatment. The superiority was shown if there was more lasting decrease in heartburn severity, reduced anxiety (A), depression (D) and alexithymia levels.

Results: Of 75 randomized patients 39 were allocated to the first arm and 36 to the second one. The groups were statistically comparable in age and sex. Treatment results showed reduction of heartburn severity in both groups on the 8th week, however more significant in the first group (1group-89.7%, 2group-61.1%, P < 0.001). Also both A and D levels were much lower in the first group compared to the second one (P < 0.001). Comparing the alexithymia between two arms on the 8th week after the initiation of treatment we found that alexithymic type of personality prevailed in patients that received PPI only (P < 0.001).

Conclusion: The combination of PPI plus antidepressant demonstrates superiority to PPI therapy alone, showing more lasting symptoms regression and improved psychological and emotional condition of patients.

Introduction: The quality of histologic healing or inflammatory cytokine-related change in erosive reflux disease (ERD) had been verified in few studies. The aim of this study was to evaluate the healing rate of endoscopic erosions.

Aims & Methods: We conducted double-blinded comparative study to assess endoscopic, histologic quality of mucosal healing in ERD, following 4-week medical treatment with lansoprazole combined with rebamipide or not. The patients with ERD in modified LA classification grade A-D were enrolled via four referral institutes, regardless of GERD related symptoms. The enrolled subjects were randomly allocated to ingest 30 mg lansoprazole alone or ingest lansoprazole 30 mg with rebamipide 100 mg three times in a day for 4 weeks. The 4-weeks follow up endoscopic biopsies were performed to assess endoscopic healing (regressed into minimal change or normal), and to obtain esophageal biopsy specimens (at 3 o’clock direction, 3 cm proximal area from squamocolumnar junction). Additional tissue samples were obtained to measure tissue inflammatory cytokines (IL-8, PAF, at 9 o’clock direction, 3 cm proximal area from squamocolumnar junction).

Results: Overall 109 patients were enrolled and randomly allocated to lansoprazole group (N = 54) or combination group (N = 55). Demographic data, smoking or drinking habits were not significantly different between both groups. The endoscopic healing rate at 4-week was not different significantly (75.0% vs 87.9%; P = 0.686. Difference 3.95%, 95%CI [-15.24, 23.13]). The histologic changes of basal layer thickness, intraepithelial infiltration of inflammatory cells (eosinophils, neutrophils) were normalized in subsets of patients regardless of the fate of endoscopic healing, and were not different in both groups. In contrast, papillary length, intraepithelial infiltration of T lymphocyte and the dilated intercellular space (DIS) was normalized significantly in endoscopically
healed combination group. When both group were pooled in a group (proton pump inhibitor + endoscopic ablation), the papillary length and DIS was significantly improved in endoscopically healed patients. Tissue level of IL-8, but not Lyso-PAF, was significantly decreased in lansoprazole alone group.

Conclusion: Adjuvant therapy of rehampidine to lansoprazole failed to reveal additional esophageal healing effect by endoscopic or histologic evaluation. Papillary length and DIS was more evident parameter of quality of mucosal healing in patient of erosive reflux disease treated with proton pump inhibitor. Long term follow-up data are needed on whether these histologic parameters of mucosal healing can help predict the prognosis of gastroesophageal reflux disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1861 LONG-TERM RESULTS OF RADIOFREQUENCY ABLATION (RFA) IN PATIENTS WITH BARRETT’S ESOPHAGUS RELATED NEOPLASIA

J. Krajciova1, J. Maluskova2, M. Kollar2, Z. Vackova1, J. Spicka1, J. Martinek1
1Department of Gastroenterology, SCT Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: kraj@ikem.cz

Introduction: Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett’s esophagus (BE) related neoplasia (BORN). After successful treatment, follow-up is still required as recurrences may occur. The aim of this prospective single-center case series was to assess the long-term efficacy of endoscopic treatment (RFA with or without ER) for BORN. Main outcomes were complete remission of neoplasia (CR-N) and recurrent length (R-IM) and neoplasia (R-N).

Aims & Methods: A total of 99 consecutive patients with BORN have been treated from 2009 to 2013. 89 patients (75 men, mean age 64, range 22–91) completed the treatment and were included into this analysis. The patients had been followed up during 296 patient-years (mean 3.4 years, range 0.5–6). Thirty-three patients were diagnosed with adenocarcinoma (38%), 24 patients with high-grade dysplasia (28%) and 30 patients with low-grade dysplasia (34%). Prior to RFA, ER for visible lesions was performed in 57 patients (66%). Mean length of the Barrett’s esophagus (BE) was 4.6 cm (range 1–13 cm). After treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies. Recurrence: Complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) were achieved in 54 patients (54/3 pts, 65.1%; 95% CI 54.3–74.5) and 82 patients (98.8%; 95% CI 92.8–99.9), respectively. All patients who did not achieve CR-IM had macroscopically normal neo-Z-line without visible abnormality for at least one patient where macroscopic eradication of BE was not achieved due to giant hiatal hernia and who was referred for anti-reflux surgery. During the follow-up, 18 patients (13.3%, 18/54 pts) experienced a recurrence of IM and 3 patients (2.6%, 3/117 pts) had a recurrence of neoplasia (LGD 2x, HGD 1x). We did not encounter any patient with a submucosal neoplasia. All recurrences occurred at the level of neo-Z-line and 6 patients with recurrent IM had also macroscopic recurrence of BE. A total of 13 patients underwent endoscopic retreatment: 7x probe-based re-RFA, 5x escape argon plasma coagulation (APC) and 1x ER. After retreatment, we achieved 100% CR-N and 54% (7/13 pts) CR-IM. Treatment-related adverse events occurred in 22 patients (25%): 12x chest pain and 10x stricture. Two patients with a stricture had to undergo surgical resection - first patient due to perforation during balloon dilatation of a post-RFA stricture, the second because of refractory post-RFA stricture after 20 sessions of dilatation.

Conclusion: RFA combined with ER for patients with BORN achieves a high success rate of CR-N with durable results. Recurrence of IM occurs in approxi- mately one-third of patients and supports continuing endoscopic surveillance even after complete eradication. Nonetheless, the majority of recurrent IM occurs within a normally appearing neo-Z-line with questionable clinical relevance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1862 METHODS OF MEASURING BARRETT’S MACOSCOPIC THICKNESS WITH VOLUMETRIC LASER ENDOMICROSCOPY (VLE), AS A BIOMARKER TO GUIDE TO TREATMENT CHOICE

I. Levink1, G. Tearney2, H. C. Wolfsen3, S. Schlachter4, P.D. Siersema5, M. B. Wallace6
1Gastroenterology, Mayo Clinic, Jacksonville/United States of America/FL
2Harvard Center Of Photomedicine, Massachusetts general hospital, Boston/United States of America/MA

Contact E-mail Address: irislevink@gmail.com

Introduction: Barrett’s Esophagus (BE) is a premalignant condition, in which prolonged gastroesophageal reflux results in intestinal metaplasia, leading to an annual risk of adenocarcinoma 0.12%/year.1 The current standard of treatment is Endoscopic Resection (ER) of visible nodular lesions and Radiofrequency Ablation (RFA) of Barrett’s, which has a success rate of 92%2. For refractory cases, wide field ER, cryotherapy and other methods are used, but may have higher adverse events. We hypothesize that thicker Barrett’s tissue is less likely to respond to RFA and have developed methods to precisely measure the thickness with Volumetric Laser Endomicroscopy (VLE). These methods may facilitate future studies, correlating tissue thickness with response to therapy and prediction of optimal treatment.

Aims & Methods: We performed a nested cohort study from the U.S. VLE Registry (which comprises 1000 patients) of patients with BE, who had a baseline VLE scan, followed by RFA ablation and had at least one follow up exam. We excluded patients who had any ablative therapy prior to baseline VLE. The primary outcome was the percentage reduction of Prague length after the first treatment. Secondary outcomes were: 1. complete remission of intestinal metaplasia (CRIM) during 12 months after baseline procedure, 2. complete remission of dysplasia (CRD) during 12 months after baseline procedure, and 3. number of RFA treatments necessary for complete response of intestinal metaplasia. We estimated the thickness of BE mucosal layers, by measuring the distance between the esophageal surface to the deepest edge of the lamina propria. In order to do so, we developed an algorithm (ImageJ software; image.nih.gov/ji/) that automatically adjusts every clockwise image into a high-resolution vertical scan with enhanced contrast. We used two measurement protocols: subjective, by drawing a line from the surface to the edge of the lamina propria (LP) and by plotting a grayscale density plot at the same location, using the sharp drop off in density to indicate the boundary between the lamina propria and the esophageal surface. Results: We included 92 patients with BE (at least COM1), who had a baseline VLE scan, followed by RFA, and had no prior ablative therapy. These patients were divided in three patient groups: without prior EMR and treated with only RFA (n = 53, mean Prague length(M) = 5.399, SEM = 0.220), without prior EMR treated with combined EMR and RFA at baseline(n = 3, mean Prague length(M) = 6.67, SEM = 1.67), with prior EMR and RFA at baseline (n = 19, mean Prague length (M) = 3.816, SEM = 0.616). After determination of gastroesophageal junction (GEJ) location on VLE, we measured mucosal thickness in 8 segments at 0.5 cm intervals from GEJ to the top of the Barrett’s tissue. The mean amount of selected crossing sections as seen in the first 40 patients was 6.33 (SEM = 0.50; n = 40). The measurements of thickness, using the subjective and objective protocol in one patient is shown in Table 1.

Conclusion: We developed an algorithm, that automatically adjusts raw VLE images in order to recognize superficial layers of the esophageal wall and measure the thickness of these different layers in Barrett’s tissue. We performed both subjective and objective methods for thickness calculation. This is the first step to the production of a biomarker for the prediction of treatment response in patients with Barrett’s Esophagus. Further research is needed to demonstrate which of these two measurement protocols can predict the response to RFA and ER.

Disclosure of Interest: G. Tearney; Tearney G is the co-inventor of the VLE scan; he contributed VLE expertise to be able to do the measurements. The measurements itself were done by Iris Levink.

S. Schlachter: Schlachter, S is an employee at Ninepoint Medical and manages the data of the Ninepoint registry. Schlachter, S had no influence on the outcomes of the measurements. The measurements were done by Levink, I. All other authors have declared no conflicts of interest.

Contact E-mail Address: k.belghazi@amc.uva.nl

Introduction: Radiofrequency ablation (RFA) of Barrett’s oesophagus (BE), with or without prior endoscopic resection (ER) of focal lesions, results in complete eradication of intestinal metaplasia (CE-IM) and complete eradication of neoplastic tissue (CE-neo) in 93–100% and 96–100%, respectively.

Aims & Methods: The aim of this study was to assess if the excellent results after successful RFA for BE with high-grade dysplasia (HGD) or early cancer (EC) are sustained on the long term. We screened all patients treated with RFA, and ER for Barrett’s oesophagus, for BE with histologically proven HGD EC who were previously enrolled in 5 consecutive cohort studies in a tertiary referral center in the Netherlands. All patients who had reached endoscopic and histologically confirmed CE-neo and CE-IM after RFA were included for evaluation of long-term follow-up (FU). Primary outcome: recurrence of HGD EC; recurrence of endoscopically visible Barrett’s mucosa. Secondary outcomes: Buried Barrett’s glands; IM in biopsies obtained distal to a normal appearing neop squamocolumnar junction (neo-SCJ); need for retreatment; sustained CE-IM and CE-neo at last FU.

Results: 68 patients were included (55 men, median 64 yrs, median BE CSM6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD) (n=28), high-grade dysplasia (HGD) (n=27), or early cancer (EC) (n=2)). Worst pathology pre-RFA (after ER) was: non-dysplastic IM (n=9), LGD (n=27), HGD (n=32). Median FU was 85 months (IQR 50–96) with a median of 7 FU endoscopies per patient. Recurrence of HGD/EC was found in 2 patients (3%): one patient with a T1m2 EAC 3 cm (n=1), 34 months (IQR 58–96) with a median of 7 FU endoscopies per patient. Recurrence of HGD/EC was rare (3%). Recurrence of endoscopically visible Barrett’s mucosa was seen in 12 patients (17%), however it was not reproduced in 84%. In 2 patients LGD without IM was found in the neo-SCJ. Eleven patients required retreatment: APC for small areas of visible Barrett’s mucosa (n=5), six patients had additional ER (1x T1m2, 1x HGD, 2x LGD, 2x visible Barrett’s islands), RFA for LGD without IM in the neo-SCJ (n=1). CE-neo and CE-IM (excluding IM in the neo-z-line) at the last FU endoscopy were found in 32% of patients, however it was confined to small islands or tongues <1 cm in the vast majority of patients.

Conclusion: With 7-years of follow-up, this study presents the longest published follow-up data on RFA for BE with HGD/EC to date. Our long-term outcomes show that after successful RFA recurrence of HGD/EC is rare (3%). Recurrence of endoscopically visible BE was found in 32% of patients, however it was confined to small islands or tongues <1 cm in the vast majority of patients.

Introduction: Barrett’s oesophagus (BE) is the only identifiable pre-cursor condition for oesophageal adenocarcinoma. Endoscopic surveillance is performed in BE to detect dysplasia as it is likely to be amenable to curative therapy. There is dearth of evidence to suggest that a diagnosis of BE has a negative impact on the quality of life of patients. To our knowledge, no guidance exists on the counselling of patients about their diagnosis of BE and associated anxiety levels at a district general hospital.

Aims & Methods: An in-house database was used to identify patients with BE over a 10-year period (2006–17). A simple, 10-point based questionnaire was devised and answers obtained via a telephone consultation (Table 1).

Results: Of 618 patients BE were identified (417 male, 201 female) were recruited (13 deceased, 38 did not answer, 8 declined). 2 patients had previously undergone therapy for BE (1 RFA, 1 fundoplication). Results are displayed in Table 1. Less than a third of patients remembered meeting a clinician to discuss their diagnosis and the rationale for follow-up. Consequently, only 41% of patients understood their diagnosis and 44% the rationale for surveillance. Although almost all patients (92%) were on a regular proton pump inhibitor, less than half (48%) understood why. Only 11% of patients were aware of the overall cancer progression risk and even fewer (7%) of the treatment options that are currently available. Interestingly, half of all patients admitted feeling anxious about their diagnosis with the majority (82%) admitting that further counselling would benefit in this regard.

Table 1: A 10-point based questionnaire which was used to check the understanding amongst patients with Barrett’s Oesophagus (BE–Barrett’s Oesophagus, OAC–Oesophageal adenocarcinoma PPI–Proton pump inhibitor).

<tr>
<td>11. If yes, do you know when this indicated?</td>
<td>36(35)</td>
<td>68(65)</td>
</tr>
<tr>
<td>12. Does or has anyone in your family suffered with BE or OAC?</td>
<td>53(51)</td>
<td>51(49)</td>
</tr>
<tr>
<td>13. Do you feel or have you ever felt anxious about your diagnosis of BE?</td>
<td>82(79)</td>
<td>22(21)</td>
</tr>
</tbody>
</table>

Conclusion: We have demonstrated that patients with BE have a relatively poor understanding of their diagnosis and the treatment options that are available to them. Further efforts need to be made to address this and help empower a group of patients who are understandably anxious about their diagnosis.

P1865 BARRETT’S ESOPHAGUS IS ASSOCIATED WITH TOTAL SERUM ADIPONECTIN IN WOMEN, BUT NOT WITH OTHER INFLAMMATORY OR METABOLIC BIOMARKERS

Introduction: Data on the association between inflammatory and metabolic biomarkers and Barrett’s oesophagus (BE) are scant and conflicting.

Aims & Methods: We aimed to study the association between circulating inflammatory biomarkers (interleukin-6 [IL-6], high-resolution C-reactive protein [hrCRP], intra-cellular adhesion molecule [ICAM], tumor necrosis factor recep-
tor-2 [TNF-R2]) and metabolic biomarkers (leptin, adiponectin, C-peptide, insulin-like growth factor 1 [IGF-I], and insulin-like grow factor binding proteins -1, -2 and -3 [IGFBP-1, -2 and -3]) with BE. This was a case-control study, nested within two female-only prospective cohort studies (Nurses’ Health Study 1 and 2) and one male-only prospective cohort (Health Professional Follow-up Study). Participants of provided biennial detailed information on demographic, lifestyle, dietary and medical factors, including endoscopy use. Overall, 80,437 participants enrolled in these cohorts provided a prediagnostic blood specimen between 1989 and 1995. Among these participants, through 2012, we identified 283 cases of BE (163 females and 120 males). Two study physicians, blinded to biomarkers results, reviewed the medical records of patients reporting BE. We matched BE participants to participants without BE that underwent upper endoscopy during the same time period and did not have BE (361 females and 265 males) on year of birth, year of blood collection, month of blood collection, fasting status and “am or pm” blood draw. We used multivariable conditional logistic regression models, adjusted for known and putative risk factors for BE, to assess the association between each biomarker and the risk of BE. We used the lowest quintile as reference, and assessed linear trend across exposure categories using the median of each quintile as a continuous variable.

Results: In women, plasma adiponectin was significantly associated with BE (p-trend = 0.01). When compared to the lowest quintile (Q1), the the multivariate odds ratio (OR) for the highest quintile (Q5) of adiponectin was 0.39 (95%CI 0.17, 0.88). This association was not materially altered after further adjustment
Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early adenocarcinoma and related diseases. In this process, we diagnosed 10 superficial esophageal cancers. But there are few reports of endoscopic resection for superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and March 2017, forty-four patients were included in the study. EGD with narrow band imaging and endoscopocystoscopy were performed in these patients. During the procedure, the esophageal mucosa was stained with 0.5% methylene blue and then with crystal violet. The endoscopocystoscopy findings were graded from 1 to 5 according to the Inoue et al’s classification. The esophageal mucosa was also evaluated with narrow band imaging (NBI) and the findings were classified according to the Intrapapillary capillary loop (IPLC) pattern classification. These findings were compared against the gold standard of histopathological classification which was based on the Vienna classification.

**Contact E-mail Address:** xeroxalb@yahoo.it

**Introduction:** Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early adenocarcinoma and related diseases. This study aimed to improve the understanding on the outcomes of the EMR in patients, in whom the EMR’s histologic assessment identifies early-stage adenocarcinoma of the oesophagus with incipient submucosal invasion (pT1b sm1).

**Aims & Methods:** We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

**Results:** A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incipient invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMR’s 7 (28%) patients had a single piece, 7 (28%) patients 3 piece and 4 (16%) patients 4 piece EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2-4). We observed 6 (24%) intra-procedural bleedings and 2 (8%) patient needed admissions with post procedural bleeding and 1 (4%) of them required transfusion. Stricture was endoscopically detectable but not causing any symptoms in 1 (4%) patient and another patient (4%) had slight dysphagia post EMR, but did not need dilation. Histology showed lymphovascular invasion in 6 (25%) patients and vascular invasion in 1 (4%) patient. Of all 25 early adenocarcinomas 7 (28%) were reported as poorly differentiated, 11 (44%) as moderately differentiated and 3 (12%) as well differentiated. In 4 (16%) cases differentiation was not reported. All resection margins were reported as being clear from dysplasia or cancer in 9 (36%) cases, radial resection margins were reported with dysplasia in 3 (12%) cases and with cancer in 15 (60%) cases, but this included the multiple piece EMRs. The deep margin was reported as being clear in 18 (72%) cases, with dysplasia in 1 (4%) case and with cancer in 6 (24%) cases. There were 10 (40%) patients with cancer infiltration on the radial and/or deep margin of the EMR specimen, of these patients 9 (60%) had oesophagectomy and in the histologic assessment of these specimens, lymph node involvement was observed in 2 cases (22.2% of all oesophagectomies and 9.5% of all surviving and currently cancer-free patients). There was no residual cancer in 3 (33.3%) of the surgical specimens. Radical radio-chemotherapy was given in 1 (6.7%) patient and patient 3 (33.3%) patients did not have radical treatment for clinical reasons. There were 10 (40%) patients without cancer invasion of the EMR resection margins, of these 4 (40%) had oesophagectomy and 1 (10%) radical radio-chemotherapy. The histologic assessment of these surgical specimens showed residual cancer in 3 (30%) cases and high-grade dysplasia in 1 (10%) case. Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett’s oesophagus. Of the 13 (52%) patients who have had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the oesophagectomy, and sadly in this case the oesophagectomy specimen did not show residual cancer. Of the 12 (48%) patients who have not had oesophagectomy 3 (25%) died since their EMR, 1 (8.3%) of cardiac arrest, 1 (8.3%) of chronic obstructive pulmonary disease and 1 (8.3%) of advanced oesophageal cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all cancer free on follow up investigations, one after radical chemo/radiotherapy. The median survival of all 21 (84%) patients currently alive is 25 months (range: 2-68 months; SD: 22.2).

**Conclusion:** In this retrospective analysis we have found that the clinical outcomes are very difficult to predict for patients with early adenocarcinoma and incipient invasion of the submucosa. Clinical decision making remains very challenging and has to be individualised for all patient, until further in depth studies gives us more useful prognostic factors.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

67 months. Ectopic lesions were detected in 2 cases, and these patients underwent endoscopic treatment and survived. The patient treated with TAE for a nodule 1.5 cm. Conclusion: Endoscopic resection for achalasia-associated superficial esophageal cancer invasive to the MM on histopathology is safe and effective, and relatively long-term outcome is good.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI869 USEFULNESS OF TRIAMCINOLONE INJECTION TO PREVENT STRicture AFTER SEMICIRCUMFERENTIAL ESOPHAGEAL ENDOSCOPIC SUBMUCOSAL DISSECTION: A PRACTICAL STUDY

T. Oyama1, A. Takahashi2

1Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: oyama@cc.saku.or.jp

Introduction: ESD is a standard treatment for superficial esophageal cancer in Japan. Stricture is one of important complication of esophageal ESD, and it makes quality of life of the patient worse. Usefulness of Triamcinolone (TA) injection to prevent stricture after semi-circumferential ESD has been reported. However, usefulness of TA injection after circumferential esophageal ESD is still unclear.

Aims & Methods: The aim of this study is to clarify the usefulness of triamcinolone injection to prevent stricture after circumferential ESD. A total of forty-four patients treated by circumferential esophageal ESD from 2004 to 2016 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. The patients treated from 2004 to 2009 were followed up without TA injection (Non-TA group). TA injection was performed for the patients after 2009 (TA group). The number of patient in Non-TA and TA group was 16 and 28, respectively. Age of both groups was 65 (30–83) and 61 (42–82) years old. The length of circumferential resection was 75 (50–100) and 75 (55–111) mm, respectively. There was no significant difference in the background of both groups. Fifty mg TA was injected into submucosal layer just after ESD, and TA injection was repeated in two-weeks interval. Fifteen mm endoscopic balloon dilatation (EBD) was performed when the scope couldn’t pass the ESD ulcer. The primary endpoint was the number of balloon dilatation. The secondary endpoints were duration from ESD to ulcer healing, and the difference between Barrett’s esophageal adenocarcinoma (EAC) and squamous cell carcinoma (SCC).

Results: 1. Number of EBD in Non-TA and TA group were 20 (13–33) and 5.1 (0–23), respectively (p < 0.01). 2. Duration from ESD to ulcer healing were 10 (3–24) and 3 (1–24) months, respectively. (p = 0.47). 3. Complications (perforation rate due to ESD was 6.3% (1/16) and 3.6% (1/28). Both patients were treated by conservative therapy. 4. Difference between EAC and SCC: There were four EAC and 24 SCC patients in TA group. The number of EBD were 5.3 (5–11) and 2.4 (3–11), respectively. Duration of ulcer healing were 10 (6–14) and 6.5 (5–24), respectively. There was no significant difference between two groups.

Conclusion: Triamcinolone injection is safe and effective treatment to prevent stricture after circumferential ESD, not only for SCC but also for EAC.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for esophageal squamous cell carcinoma (ESCC), approximately 40% of patients develop local failure, resulting in poor long-term survival. However, there is no definitive biomarker which is useful to predict survival outcome after CRT for ESCC. Several studies have investigated the correlation of expression of CD24, cytokeratin 4 (CK4), podoplanin (PDPN) with prognosis of patients with various malignant tumours who underwent surgical resection. However, it remains unclear whether the expression of these proteins can predict the outcome of CRT for patients with ESCC. The aim of this study was to analyze the predictive values of expression of CD24, CK4, and PDPN for ESCC patients who received CRT. Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPE) as an initial treatment between 2005 and 2018, 75 patients were selected for analysis on the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0–1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDPN in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDPN expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDPN expression were statistically analyzed. OS was calculated from the date of CRT or OPE to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox’s proportional hazards model.

Results: 148 ESCC patients (CRT group, n = 83; OPE group, n = 65) were analyzed. In the CRT group, 40 patients had stage II and 43 patients had stage III, and the 5-year OS was 52%. In the OPE group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were significant variables for OS in differences between the CRT and OPE group. The cut-off value for CD24, CK4, and PDPN expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDPN, respectively. In the CRT group, the OS of patients with strong CD24 expression was significantly better than that of patients with weak CD24 expression (P = 0.015; strong/weak 5-year OS: 65%/43%). On the other hand, for CK4, the strong CD24 expression was poorer OS comparing with patients with weak expression in the OPE group, however there was no significant difference (P = 0.286; strong/weak 5-year OS: 77%/74%). As for patients with strong CD24 expression, there was no significant difference between CRT group (P = 0.448), however there was significant difference between CRT and OPE group in patients with weak CD24 expression (P = 0.009). There were also no significant differences of the OS based on expression of CK4 or PDPN between the CRT and OPE group, respectively. Moreover, the strong CD24 expression in CRT group (P = 0.012; HR = 2.787; 95%CI: 1.253–6.200) as an independent variable for favorable outcome.

Conclusion: CD24 expression was significantly associated with the survival outcome in ESCC patients with CRC when they were treated with CRT. Strong weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in ESCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P8174 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANIED BY EARLY ESOPHAGEAL CANCER

Y. Jie, L. Ying
Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, China

Contact Email Address: 13770755008@126.com

Introduction: Normally, restituted within the submucosal layer of esophagus, each submucosal gland duct will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue and muscula mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMDI) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. Since the 1990s, the esophageal lesions presumed to originate from ESMGDs had been described consistently in various case reports. Currently, in addition to the gold standard of histology, almost no useful modality could be up-to-date to this lesion. In our study, we considered that the ESMGD had a correlation with early esophageal cancer, and we noted that the ESMGD may have special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnosis ESMGD.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESMGD accompanied by early esophageal cancer, which were suggested by conventional endoscopy or not, this study retrospectively reviewed 48 consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and of them all had already underwent EUS combined with Endoscopic Submucosal Dissection(ESED). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5 ± 4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMGD by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMGD, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMGD were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intraepithelial neoplasia. One case was regarded as ESMGD by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMGD were 85.0% (34/40) and 99.8% (478/478) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (474/475).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMGD as well as high sensitivity and specificity.

Introduction: Preoperative Neutrophil to Lymphocyte Ratio (NLR) has been proposed as a prognostic marker in several solid tumors (Templeton 2014). A retrospective case-control study of 60 patients showed the prognostic relevance of NLR as a predictor of response in esophageal cancer patients treated with chemoradiotherapy. The aim of this study is to assess the NLR prognostic strength in a retrospective series of two high-volume centers.

Aims & Methods: A retrospective review of two prospective esophageal cancer database was conducted. Neutrophil to lymphocyte ratio was defined as the pre-chemoradiotherapy serum neutrophil count divided by lymphocyte count. We dichotomized the NLR data using as cut-off values 2.5 and 3 respectively. Univariable logistic regressions were performed to determine the effect of NLR on response after neoadjuvant treatment. Survival curves were constructed with Kaplan Meier method and compared with the long rank test.

Results: We included 280 patients. The analysis of NLR as predictor of pathological complete response (pCR) showed a OR of 0.93 (95% CI 0.531–1.746, p = 0.901) and 1.161 (95% CI 0.647–2.081, p = 0.671) considering as cut-off values 2.5 and 3 respectively. In our large series, NLR did not result as a predictive marker either in terms of Overall Survival nor in terms of Disease Free Survival (p = 0.997 and p = 0.672 respectively).

Conclusion: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as a post-treatment marker. The heterogeneity of treatments, the complexity of the disease, the absence of a validated and pre-defined NLR cut-off value in the available literature are the main limits to our analysis. Further studies are needed to assess the clinical relevance of NLR as a predictive marker of response to neoadjuvant treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Carbon monoxide (CO) is produced endogenously in the body as a by-product of heme degradation via activity of the enzyme heme oxygenase (HO-1). This gaseous mediator with multidirectional biological activity exerts anti-inflammatory, anti-fibrotic and immunomodulatory properties. Carbon monoxide recently gained consideration as a newly discovered class of compounds, named CO-releasing molecules (CORMs), is capable of releasing CO gaseous molecule that can be useful as a novel experimental tool to assess the physiological role of CO under experimental conditions. CORM-2 was implicated in gastroprotection against formation of acute gastric lesions but the contribution of CO to the mechanism of gastric ulcer healing has not been fully elucidated.

Aims & Methods: We determined the effect of daily treatment with vehicle or CORM-2, on healing of preexisting gastric ulcers induced by serosal application of acetic acid (ulcer area = 28 mm²) in rats. Our second goal was to examine the mechanism of CO released from its donor by the determination of the CORM-2-induced alterations in gastric blood flow (GBF) at ulcer margin, the parameters of oxidative stress and the gastric mucosal expression of pro-inflammatory and anti-inflammatory factors. Groups of seven rats with gastric ulcers (A-D) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 to 10 mg/kg i.g., C) the HO-1 inhibitor, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphyrin IX (ZnPPIX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were measured by ELISA and NF-κB, HO-1, TNF-α, HO-2, COX-1, COX-2, iNOS cDNA were analyzed by RT-PCR and Western blot.

Results: Treatment with CORM-2 significantly reduced the area of gastric ulcers and significantly raised GBF at ulcer margin. The dose accelerating ulcer healing by 50% (ID50) and significantly raising GBF was 5 mg/kg as compared with vehicle and ZnPPIX. None of the groups showed any significant difference in area of gastric ulcers and raised GBF at ulcer margin but the treatment with ZnPPIX significantly increased the area of gastric ulcers and significantly decreased the GBF at ulcer margin. There was no difference in gastric ulcer healing by CO alone compared to CO donors.

Conclusion: CORM-2 based on its anti-inflammatory properties has a potential to be developed as a new therapeutic approach for acute gastrointestinal hemorrhage.

P1878 PROTON PUMP INHIBITORS INAPPROPRIATE USE IN PATIENTS ADMITTED IN A TERTIARY GREEK HOSPITAL CREATES SIGNIFICANT DIRECT COSTS BURDEN AND EXPOSURE OF PATIENTS TO THE RISK OF UPPER GASTROINTESTINAL COMPLICATIONS

Contact E-mail Address: ktirian@med.uoa.gr

Introduction: There is evidence of proton pump inhibitors (PPIs) misuse in the community and in the hospitals causing significant direct and indirect costs burden for the health care system.

Aims & Methods: We aimed to evaluate the frequency of inappropriate PPIs administration in hospitalized patients, to measure the direct in-hospital costs of PPIs inpatients and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, cardiac, psychiatric, obstetrics and day clinic admission were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. We calculated the direct hospital costs of PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

Results: We included data from 470 patients aged 67 ± 19 yrs; 32.5% were previously admitted, 65.9% during hospitalization and 72.8% at discharge. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before, during and after the admission, while medications underutilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Admission at internal medicine and orthopedics clinics was associated with the highest unadjusted ORs (1.68 [95%CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse. 80% of the 193 over treated patients received PPIs (80% of them od, 20% bid) while the rest were treated with PPIs per os (80% of them od, 10% bid) during hospitalization. This accounts for 1460 PPI iv and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of our hospital in a year, we concluded that in case of PPI iv and per os preparations and assuming a similar to that of our sample case distribution for the next 12 months, we calculated the direct hospital costs burden of inappropriate PPIs use at 154940 euros per year. Using the same model, 1200 patients would be at risk of UGI complications annually, due to under prescription of PPIs at discharge.

Conclusion: Hospitalization does not represent an opportunity for optimization of PPIs utilization. On the contrary, the frequency of PPIs inappropriate use during hospitalization is higher than that during admission, causing significant direct costs for the hospital and exposing patients to the risks of UGI complications.

P1880 ENDOSCOPIC RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY

S. E. Van Der Wiel, J. W. Popey, M.J. Bruno, A.D. Koch

Contact E-mail Address: s.e.vanderwiel@erasmusmc.nl

Introduction: Adenomas of the ampulla of Vater are rare. Endoscopic ampullctomy has been recognized as a safe and reliable treatment of selective tumors of the ampulla of Vater and is associated with lower morbidity and mortality rates than surgical resection. However, the success rates for endoscopic ampullctomy are limited. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6mm (range 5–80) for patients with ACA, 34.8mm (range 23–50) for LSA and 16.3mm (range 10–20) for patients with an AIE (P = 0.039). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups (P = 0.775). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for AIE (P = 0.136). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor (P < 0.000). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients with a lateral spreading adenoma and 1 patient with an intraductal extended adenoma (P = 0.875).

Conclusion: Endoscopic ampullctomy is a safe and successful treatment in patients with an adenoma with or without a lateral spreading growth pattern. For an intraductal extended adenoma endoscopic success rates are significantly lower.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are few reports about the technical difficulty of gastric endoscopic submucosal dissection (ESD) which were investigated through the prospective trial.

Aims & Methods: The aim of this study was to evaluate the factors associated with the technical difficulty of ESD for early gastric cancer (GC) which met expanded indication criteria using data from JCOCG0067. The major inclusion criteria of this study were as follows: 1) histologically proven intestinal-type adenocarcinoma; 2) cT1aN0M0; 3) lesion without finding of ulcer (UL negative) and >2 cm in size, or UL positive and ≤3 cm in size; 4) age ≥70. ESD were performed by certified endoscopists or under the supervision of certified endoscopists. 130 cases were defined as difficult ESD cases. The aim of this study was to evaluate the factors associated with technical difficulty of ESD.

Results: From 1st of January 2007 to 30th of June 2010, a total of 470 patients (pts) (male/female: 385/85, median age 65-yo (range: 40–75)) were enrolled from 29 institutions. Tumor location was upper (U) of stomach in 71, middle in 255, and lower in 144 pts, respectively. The median tumor size was 2.5 cm (range: 0.5–13), and 207 lesions were judged as UL positive whereas the other 263 were assessed as UL negative. And, 152 of 263 UL negative lesions were 3 cm or less in size, and the other 111 of them were larger than 3 cm. Median procedure time was 79 min (range: 14–462), and it took 120 min or longer in 127 pts. 12 pts developed perforation during the procedure. Male: 385/85, median age 65y-o (range: 40–75)) were enrolled from 29 institutions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: During the study period 1487 EUS procedures were performed in our clinic. Thirty patients with gastric submucosal lesions were enrolled to participate in this study. The ratio of male to female was 66% to 34%, mean age was 62 years (range 31–88). Mean lesion size was 27 mm (range 12–60 mm). Twenty-two-gauge needles were used in 14 cases (55%) and twenty-five-gauge needles were used in 12 cases (45%). Overall diagnostic yield for 3 needle passes was higher for FNB vs. FNA for gastric submucosal lesions (78% [9/12] vs. 44% [4/9], P = 0.04). Among these 25 patients, 2 leakages were defined. The difference of the different passes, the diagnostic yield was: 61%, 67% and 78% with the first, second, and third FNB pass, respectively. In evaluation of tissue quantity and quality of FNB samples, the median tissue length was 7.3 ± 5.2 mm, with a median endoscopic tissue proportion between 10% and 25% of the total tissue procured (determined as the percent of the surface are occupied by lesion over the surface area of the entire tissue on one slide). No complications occurred during the study period.

Conclusions: FNB using a novel core needle system is safe and effective for diagnosis of gastric submucosal lesions. When performed without on-site cytologic evaluation, EUS-FNB has a higher diagnostic yield than FNA and may represent an advance for endoscopic ultrasound guided gastrointestinal biopsies.

P1885 SHORT-TERM OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER IN ELDERLY PATIENTS AND LONG-TERM OUTCOME AFTER NON-CURATIVE RESECTION
1 Division Of Gastroenterology, Department Of Internal Medicine, Graduate School of Medicine, Kobe University, Kobe/Japan
2 Endoscopy, Kobe University Hospital, Kobe/Japan
Contact E-mail Address: valencia.0001@gmail.com
Introduction: Endoscopic submucosal dissection (ESD) is widely used as a standard treatment for superficial tumors in the GI tract and its safety has been established. Opportunities for elderly patients to undergo ESD for gastric cancer is increasing due to the continued improvement in life expectancy. However, short-term and long-term outcome of ESD for elderly patients is still unclear due to the higher prevalence of comorbidities and possible increased risk of complications related to ESD in this population.
Methods: Therefore, we investigated the safety, efficacy and short-term outcome of gastric ESD for patients over 80 years old. Additionally, we evaluated the long-term outcome of non-curative resections according to both age groups. 1056 lesions in 886 patients treated with ESD between January 2011 and December 2015 in our hospital were retrospectively reviewed. They were classified into two groups; elderly group > 80 years old (n = 246 lesions in 201 patients) and non-elderly group - 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium, etc.), which were classified into two groups. Concerning the long-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed.
Results: The median age was 83 years old (range: 80–92) in the elderly group and 63 years old (range: 36–78) in the non-elderly group. The rate of female patients was significantly higher in the elderly group (30.9% vs. 17.0%: p < 0.0001). Comorbidities were significantly higher in the elderly group including heart disease (24.8% vs. 10.5%: p < 0.0001), lung disease (13.6% vs. 7.4%: p = 0.002) and dementia (3.3% vs. 1.0%: p = 0.04). Tumor location was not significantly different between the two groups. Median specimen and tumor size were the same in both groups with no significant difference: 43 mm and 15 mm, respectively. The en bloc resection rates (96.3% and 97.8%) and the curative resection rates (82.5% and 84.6%) were not significantly different. The perforation rates were not statistically different (2.44% and 3.21%). However, the postoperative bleeding rate (5.28% vs. 2.72%: p = 0.05), postoperative delirium (2.0% vs. 0.25%: p = 0.009) and pneumonia (2.0% vs. 0.25%: p = 0.009) were significantly higher in the elderly group. In multivariate analysis, age over 80 was not an independent risk factor for postoperative bleeding, however it was the independent risk factor for postoperative delirium and postoperative pneumonia. Nineteen elderly patients and 54 non-elderly patients with non-curative resections were followed-up for 3 years after ESD for the long-term outcome analysis. The percentage of patients who underwent additional surgery after ESD was 26.3% (5/19) and 51.85% (28/54) respectively (p = 0.05). Neither disease specific death nor progression to gastric cancer was observed in each age group. Overall ESD recurrence rate was 14.4% and 87.2% respectively (p < 0.001).
Conclusion: ESD is a safe and effective treatment for early gastric neoplasia even in patients over 80 years old. However, because postoperative delirium and postoperative pneumonia were observed more often in the elderly patients, more careful attention to these conditions during postoperative care may be necessary. Elderly patients over 80 years, with non-curative resections, underwent less frequent additional surgery without any impact on the disease specific death and global mortality.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adenocarcinoma of the stomach is the second leading cause of cancer related death in the world. Gastric intestinal metaplasia (GIM) is an important intermediate stage in the gastric cancer cascade through a series of well-defined precursor lesions including nonatrophic gastritis, multifocal atrophic gastritis, intestinal metaplasia, and dysplasia. The prevalence of GIM is unclear in many parts of the world and few studies have evaluated the rate of progression to gastric cancer in patients with GIM. There is a lack of clarity in

Continued
published guidelines regarding appropriate surveillance of patients with GIM and how is wide disparity in the management of this premalignant condition.

Aims & Methods: This study aimed to analyze surveillance practice and characterize the natural history of this premalignant condition by identifying all patients with GIM on an upper GI surveillance programme and reviewing follow-up data. This is a retrospective study of patients with GIM who are currently enrolled in an upper GI surveillance programme. Patients with a history of GIM identified at any time during an 18 year surveillance period (from 1998 to 2016) were included in the study. Patient characteristics, endoscopic data including histology, rates of Helicobacter pylori infection, Barrett’s oesophagus association and outcomes were reviewed.

Results: 160 patients (including those with Barrett’s oesophagus, GIM and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIM were identified–20 females (47.6%) and 22 males (52.3%). The mean age at which GIM was first diagnosed was 60.6 years (range from 17.9 to 71.5 years). 15/42 patients (35.7%) had co-existent Barrett’s oesophagus and Helicobacter pylori was identified in 6/42 (14.3%). The follow-up period ranged from 1 to 17.3 years. 27 patients had had previous gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. The average interval of follow-up gastroscopies was 3.3 years per person. 14/27 patients (51.8%) had no evidence of GIM on most recent gastroscopy, 7/27 patients (26%) had repeat findings of persistent focal GIM, 5/27 patients (18.5%) progressed to extensive GIM. No cases of dysplasia were recorded but 1 patient (3.7%) developed gastric cancer.

Conclusion: This study suggests a low apparent risk of progression of gastric intestinal metaplasia in a small western cohort. Further studies may be necessary to address if the applicability of published surveillance guidelines can be generalized to regions with low gastric cancer prevalence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: tsm3wa@naver.com

Introduction: Previously we reported that direct family history of gastric cancer (GDC) as a risk factor of gastric cancer is correlated with genetic polymorphisms of TGFBI (transforming growth factor-β1) which was associated with the development of GC in the first-degree relative of GC. The aim of this study is to investigate relationship between stage of gastric cancer and genetic polymorphism of TGFBI regarding first-degree relative of GC. Aims & Methods: From January 2006 to March 2017, 1090 gastric cancer patients were enrolled at Seoul National University Bundang Hospital in whom stage of GC was obtained from surgery, endoscopic submucosal dissection (ESD), endoscopy (EMR), and computed tomography (CT) and positron emission tomography (PET)-CT images. 203 patients (18.6%) had direct family history GC and 887 (81.4%) did not have. Genotype of TGFBI-509 was measured by the polymerase chain reaction restriction fragment length polymorphism. Relationship between TGFBI polymorphism and stage or GC issue type was analyzed.

Results: Proportion of stage 1 & 2 was statistically higher in the group with direct family history GC (170, 83.7%) than without direct family history (600, 74.4%). (P = 0.005). When GC stage was analyzed regarding direct family history and TGFBI genetic polymorphism the ratio of gastric cancer stage I to TGFBI-509 T carrier was significantly higher than that of stage II or higher (P = 0.008), only in male. However, this difference was not found in female. In addition no significant difference was found in GC patients without direct family history. Lauren classification and TGFBI genotype did not show any statistically significant results even in the group with direct family history.

Conclusion: Family history of GC affects the stage of GC and the genotype of TGFBI-509 could be underlying mechanism in case of male. Survival analysis is undergoing.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS) has to been described recently only in a few families worldwide (only one in Europe so far). Three different point mutations in promoter 1B of the APC gene were identified as causals (c.-191T > C, c.-192A > G, and c.-195A > C). We diagnosed GAPPS in the second Czech white family (not related to that one published previously-ref. 1).

Aims & Methods: We diagnosed GAPPS across 3 generations in a new Czech white family. A genetic analysis of the family was performed. Results: The Proband (a 43-year-old male) was endoscopically regularly surveyed from his 34 years of age because of fundic-gland polyposis with predominant involvement of the gastric fundus and body (with relative sparing of the lesser curve) and microcytic anaemia. Polyposis slowly progressed with the intestinal differentiated low-grade dysplasia in polypectomy specimens 10 years after the diagnosis. As the GAPPS criteria were fulfilled (ref. 2), he and his family underwent genetic testing and bi-directional Sanger sequencing of promoter 1B of the TGFB1-509 could be underlying mechanism in case of male. Survival analysis is undergoing. This study aimed to analyze surveillance practice and character-ize the natural history of this premalignant condition by identifying all patients with GIM on an upper GI surveillance programme and reviewing follow-up data. This is a retrospective study of patients with GIM who are currently enrolled in an upper GI surveillance programme. Patients with a history of GIM identified at any time during an 18 year surveillance period (from 1998 to 2016) were included in the study. Patient characteristics, endoscopic data including histology, rates of Helicobacter pylori infection, Barrett’s oesophagus association and outcomes were reviewed.

Results: 160 patients (including those with Barrett’s oesophagus, GIM and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIM were identified–20 females (47.6%) and 22 males (52.3%). The mean age at which GIM was first diagnosed was 60.6 years (range from 17.9 to 71.5 years). 15/42 patients (35.7%) had co-existent Barrett’s oesophagus and Helicobacter pylori was identified in 6/42 (14.3%). The follow-up period ranged from 1 to 17.3 years. 27 patients had had previous gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. Introduction: ESD is the one of the options of treatment even for lateral spreading (LS) esophageal squamous cell carcino (ESCC). Endoscopic diagnosis is developed by magnified endoscopy, however accuracy of diagnosis for lateral spreading ESCC is not high. Some patients have to undergo additional treatment because tumor is invaded to submucosal layer or lymphvascular invasion is observed. On the other hand, wide resection by ESD could cause the delay of additive treatment because of the treatment for esophageal stricture after ESD. Thus, treatment strategy for lateral spreading ESCC has to include additional treatment after ESD. Aim of this study is to evaluate our treatment strategy for lateral spreading superficial ESCC.

Aims & Methods: From January 2010 to December 2014, 49 cases of lateral spreading superficial ESCC were resected by surgery or ESD. Diagnosis, treatment methods and outcomes are evaluated. Our indications for additional treatment after ESD are the cases of over pT2 (SM2) or lymphvascular invasion.

Results: In 49 cases of lateral spreading superficial ESCC, 32 cases were treated by ESD and 17 case were treated by surgery. All lesions of 32 cases are completely resected by ESD. Average size of tumor treated by ESD is 59.4 mm (50-83 mm). Accuracy of estimated depth of invasion by ESD for ESCC cases is 65.7%. Four of 32 cases of ESD underwent additional therapy (3 for surgery and 1 for CRT) because of pT2 (SM2) or lymphvascular invasion, and one case has lymph-node metastasis. Rate of stricture after ESD is 20.0% for sub-circumferential endoscopy and 77.3% for circumferential one instead of steroid injection. Average time and duration for control of esophageal stricture by Baloon Bougie is 13.5 times and 18 weeks. In 17 surgical cases, all cases are treated by thoracoscopic esophagectomy. Average size of tumor treated by surgery is 76.5 mm (50-130 mm). Accuracy of estimated depth of invasion by esophagectomy for surgical cases is 47.1%. Seven cases in 17 (41.2%) have lymph node metastasis. Rate of lymph node metastasis is 42.9% for pT1a-MM, 100% for pT1b-SM1 and 42.9% for pT1b-SM2. One case died by recurrence after surgery and 48 cases are survived without any recurrences.

Conclusion: Accuracy of estimated depth of invasion by endoscopy for lateral spreading superficial ESCC is cute low compared to normal superficial ESCC. Most of circumferential lesion could be prevented from being injection. However control of strictures after circumferential esophagectomy is difficult. Thus, diagnostic ESD should not be performed for circumferential lesions of lateral spreading superficial ESCC for the patients who will select CRT for additional treatment, and CRT should be selected for first treatment of these cases. Long survival could be obtained by ESD or surgery for the patients of lateral spreading ESCC by our treatment strategy.

Introduction: Few major international guidelines consider pepsinogen tests as the best available non-invasive tests to detect precancerous lesions in particular, - corpus atrophy in the stomach mucosa. Gastrin-17 (G-17) has been suggested as an alternative marker for atrophic gastritis at European and Asia. Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.

Aims & Methods: Generally healthy 40–65 years aged participants of the GISTAR pilot study referred for upper endoscopy according to the pilot study protocol were enrolled. Pepsinogen (Pg) I and II were assessed from plasma samples by two methods-ELISA (Biohit Plc.) and latex-agglutination (Eiken Chemical Co.) test systems. G-17 and IgG group antibodies to H.pylori infection were assessed by Biohit Plc. ELISA test systems. The following cutoff values were compared with the results of postoperative pathology from ESD. Good sensitivity and specificity. Few major international guidelines consider pepsinogen tests as the best available non-invasive tests to detect precancerous lesions in particular, - corpus atrophy in the stomach mucosa. Gastrin-17 (G-17) has been suggested as an alternative marker for atrophic gastritis at European and Asia. P1890 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASOngROGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND Duct INVOLVEMENT ACCOMPANYED BY EARLHY ESOPHAGEAL CARCINOMA Y. Jie, L. Ying

Dietective Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, China, Nanjing/China

Contact E-mail Address: 13770755008@126.com

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGD) can traverse the subepithelial connective tissue from the muscularis mucosa, and deliver the secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGGD) and its precursor lesion have not been comprehensively evaluated so far, and the series focusing on endoscopic features of this lesion has not been reported widely. While since the 1990s, the esophageal lesions presumed to originate from ESMGDD had been described constantly in various case reports. Currently, in addition to the gold standard of histopathology, almost no more useful modality could be applied to this lesion. In our study, we considered that the ESMGDD had a correlation with esophageal cancer, and we noted that the ESMGGDD had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESMGDG.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing Gastroesophageal cancer, we performed a retrospective analysis of the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2010. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, 48 cases (371 patients, 286 males and 148 females, with a mean age of 67.5±4.5years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMGD by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMGDG, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMGDG were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intrapithelial neoplasia. One case was regarded as ESMGDD by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMGDG was 85.0% (34/40) and 99.8% (478/478) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/478).

Conclusion: The esophageal submucosal gland duct involvement is a kind of special esophageal sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMGDG as well as good sensitivity and specificity.

miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines by RT-PCR. Furthermore, we investigate the biological role of miR-211 in the development of gastric cancer. The expression level of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent gastric mucosa by RT-PCR. We found that miR-211-5p was upregulated in gastric cancer tissues compared to adjacent non-cancerous tissues. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility.

Aims & Methods: We aimed to investigate and characterize the biological roles of miR-211 in the development of gastric cancer. The expression level of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent gastric mucosa by RT-PCR. Furthermore, we investigated the biological role of miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro.

Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cell lines in vitro. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility.

Conclusion: We suggest that miR-211-5p acts as a tumor suppressor by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

associated in our series, with a higher incidence of residual/recurrent adenoma, when compared to other reports. These results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully retreated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 39 months (range 1-147).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: NSAIDs have demonstrated chemopreventive activity against gastroduodenal/colorectal cancers but their role on GC remains unexplored. Recently, we have now been postulated as possible adjuvants to surgery or chemotherapy in order to prevent the formation of new lesions and reduce disease progression. Cancer cells enhance their resistance to the cytotoxic action of antineoplastic drugs by inducing autophagy, which is responsible for the clearance of cytoplasmic organelles and damaged organelles in the lysosome. We previously showed that indomethacin inhibits autophagy in gastric cancer cells by acting at a late stage in this catabolic process.

Aims & Methods: The aim of this study is to analyze whether indomethacin modulates lysosomal function and oxaloplatin-induced cell death in these cells. Gastric AGS cells were treated with increasing concentrations of indomethacin for 2, 6 and 20 hours. Lysosomal pH was assessed by using Lysotracker Red and Acidine orange fluorescent probes (static cytometry). Cathepsin activity was determined by using Omnicathepsin fluorescence substrate. In cells treated with indomethacin for 2 hours LAMP2 immunostaining was also carried out. In another set of experiments AGS cells were treated with increasing doses of the autophagy drug oxaplatin and indomethacin. Cell viability was measured by using an MTT assay, the rate of apoptosis/necrosis was analyzed by means of the Apoptosis Detection Kit, and autophagy by p62 immunoblotting.

Results: Treatment of AGS cells with indomethacin decreased Lysotracker fluorescence in AGS cells after 2, 6 and 20 hours. Indomethacin also produces an acute reduction in lysosome-derived fluorescence of acidic orange after 2 and 6 hours of treatment. In addition, we observed a significant reduction of cathepsin enzymatic activity in cells treated with indomethacin for 6 or 20 hours. Furthermore, there was an altered distribution of LAMP2-positive dots from the perinuclear position observed in control cells to a peripheral position in cells treated with indomethacin. Taken together, these data suggest that indomethacin inhibits the autophagy process at the level of the lysosomal acidic enzymes by increasing lysosomal pH. On the other hand, oxaloplatin decreased cell viability in a dose-dependent manner after 48 hours of treatment, and treatment of cells with indomethacin during the last 24 hours further decreased cell viability. In addition, indomethacin also increased the rate of apoptosis and necrosis in AGS cells treated with oxaloplatin. Finally, indomethacin blocked the autophagic degradation of p62 protein induced by oxaloplatin.

Conclusion: Indomethacin inhibits lysosomal function in gastric cancer cells. This could explain an inhibitory action on autophagy and the resultant increase in susceptibility to cytotoxic drugs.

**Introduction:** The mechanisms of gastric carcinogenesis, especially of diffuse type of gastric cancer (GC) are poorly understood. The cancer stem cells (CSC) represent a particular fraction of cancer cells, considered at the origin of cancer and responsible for tumor development. The endogenous nervous system (ENS) is a newly recognized component of tumor microenvironment and its role in carcinogenesis has been recently suggested. In particular, the role of acetylcholine (ACh), a major neuromediator released by enteric nerves, has been suggested in gastric carcinogenesis but its effect on gastric CSC remains to be established.

**Aims & Methods:** Our aim was to study the effect of ACh on gastric cancer cells, and in particular its capacity to induce the stem cell phenotype, and to study the mechanisms involved. Adenocarcinoma gastric epithelial cells MKN-45 were first cultured in adherent conditions in the presence of ACh (0.1-10^(-8)M), before being cultured in non-adherent condition in order to favor expansion of CSC and formation of tumorspheres (T). The effect of ACh on T formation was studied over 7 days by quantifying the number and size of T using the System snapshot file in INCell analyzer 2200/6000. The involvement of different cholinergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. This protocol was used to study SNP (NO donor) and L-Name (nitric oxide synthesis inhibitor). Finally, the effect of ACh on the expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) was monitored by immunofluorescence, RT-qPCR and flow cytometry. Statistical analysis was performed using two-tailed t-test, Kruskal-Wallis test, or two-way non-parametric ANOVA test using SPSS16.0 F software.

**Results:** ACh at concentrations of 0.1 and 1 μM significantly increased the number and size of T as compared to control conditions (p < 0.001). Bethanecol, a selective muscarinic receptor agonist, increased the number and size of T, while hexamethonium (nitric oxide synthesis inhibitor) significantly inhibited stimulatory effect of ACh on T (p < 0.001 as compared to ACh-stimulated cells). Interestingly, L-Name, significantly inhibited the effects of ACh on the number of T. Conversely, SNP, at 0.1 and 1 μM, increased the number and size of T. Finally, ACh induced the expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) and Vimentin) on gastric cancer cells.

**Conclusion:** This study shows that ACh induces CSC properties of gastric cancer cells of diffuse type via activation of muscarinic and nicotinic pathways. It also shows that ACh effects are, at least in part, mediated by nitric pathway. These results suggest that ENS may be a new actor in gastric carcinogenesis.

**Introduction:** The BreathID® urea breath test (UBT) system provides several advantages over other 13C breath analyzers for the detection of Helicobacter pylori (H. pylori), including: higher accuracy, operator independence and immediate results. However, there are occasional cases when mailing or transporting saved breath samples may be preferable to real time analysis, especially in centers requiring a large quantity of automated analyses where continuous sampling from a single patient can provide a bottle neck preventing multiple other users from accessing the device.

**Aims & Methods:** To evaluate the sensitivity and specificity of a new BreathID® lab system using breath sample bags, for the diagnosis of H. pylori in a multicenter international clinical study. A total of 257 subjects with evaluable results for UBT and biopsy [rapid urease testing (RUT) and histology] were enrolled into two study groups: 189 naïve subjects with unknown H. pylori status were included in the pre-therapy group, and 68 subjects who had completed eradication therapy comprised the post-therapy group. To assess the stability of the breath samples in the breath sample bags, each pair of breath sample bags was analyzed at a different time point up to 14 days after collection. Analytical studies were conducted to evaluate the reproducibility and repeatability of the 13C-UBT results using a cut-off of 5 Delta Over Baseline (DOB).

**Results:** Among the pre-therapy subjects evaluated with the composite results from the two biopsy based methods (RUT and histology/immunohistochsmics), 162 (86.3%) positive and 37 (19.6%) matched those of the UBT resulting in an overall agreement of 98.3% (95% CI: 95.2%; 99.7%) with a sensitivity of 100% (95% CI: 90.6%; 100.00%) and specificity of 97.9% (95% CI: 94.0%; 99.3%). The overall agreement between the UBT and the biopsy diagnosis in the post-eradication therapy cohort was 98.5% (95% CI: 92.1%; 100.00%). The sensitivity of the UBT in this cohort was 92.3% (95% CI: 66.7%; 98.6%) and its specificity was 100.0% (95% CI: 93.5%; 100.0%). The overall sensitivity evaluated in samples of 191 (45 positive, 146 negative) subjects from the pre-therapy cohort was excellent, with positive agreement in 97.8% (95% CI: 89.8%; 99.3%) and negative agreement in 100.0% (95% CI: 97.44, 100.0). Similarly there was uniformly high overall reproducibility of the test results over different batches, when analyzed on different days and under different storage conditions.

**Conclusion:** The validation studies of the BreathID® lab system described above show it is a highly accurate and dependable method for the diagnosis of H. pylori infection. Based on the current study, BreathID® lab System received on November 2016 U.S. Food and Drug Administration (FDA) marketing clearance for H. pylori bacterium detection.

Aims and Methods: In this study, we investigated whether activation of gGlut-HMRG fluorescence detected a wild-type of H. pylori (WT) and a ggt gene disrupted mutant of H. pylori (ggt mutant). In addition, we investigated whether activation of gGlut-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGsTop). Furthermore, we applied gGlut-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in H. pylori positive patients (n = 13) and H. pylori negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland)27.

Results: Activation of gGlut-HMRG fluorescence was detected in WT strain, but was not in ggt mutant strain. Activation of gGlut-HMRG fluorescence was inhibited by GGsTop. There was significant difference of the increase of fluorescence intensity between H. pylori positive and negative both in antrum corpus of stomach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for H. pylori infection diagnosis.

P1901 MACHINE-LEARNING-BASED AUTOMATIC DIAGNOSIS SYSTEM FOR HELICOBACTER PYLORI INFECTION USING LINKED COLOR IMAGING

Introduction: Linking color imaging (LCI), a recently developed endoscopic technic, emphasizes diffuse redness, which is a characteristic of Helicobacter pylori (Hp) infection. However, the diagnosis of Hp infection does not have objective indicators; it depends on medical doctors’ experience. Therefore, it is necessary to construct objective indicators to diagnose Hp infection.

Aims and Methods: The aims of this study are to determine objective indicators for the presence or absence of Hp infection to support medical doctors’ diagnoses by constructing an automatic diagnostic system. In the proposed system, first, a region with a high hue in LCI images is defined as a region of interest (ROI). Images with a wide ROI and images with a narrow ROI are classified as high and low hue images, respectively. As a result, LCI images are classified into two types in which inflammation due to Hp infection presents as red and purple. Then, the presence or absence of Hp infection is learned by machine learning for each type of LCI image. The feature values used in the learning process are the ratio of the ROI, the average and median value of hue in low hue images, and the mode saturation value and the median and variance of the hue in low hue images. Then, the trained classifiers diagnose the presence or absence of Hp infection automatically. In this paper, the constructed system was evaluated using 128 images (32 patients) in which endoscopic examination (LCI observation) and Hp infection diagnosis were performed at Murakami Memorial Hospital of Asahi University. Furthermore, support vector machines were used as classify learners for diagnosis.

Results: In the previous system [1], 29 out of 32 cases were automatically diagnosed correctly. In contrast, all cases were automatically diagnosed correctly with the proposed system. This result demonstrates that Classifying LCI images into two types based on color improves the accuracy of this system.

Conclusion: The proposed system can automatically diagnose the presence or absence of Hp infection with the same precision as medical doctors with sufficient experience. Therefore, the proposed system can support the diagnosis of medical doctors with less experience.

P1902 HELICOBACTER PYLORI DETECTION BY γ'-GLUTAMYLTRANSPEPTIDASE-ACTIVATED FLUORESCENT PROBE

Introduction: γ-glutamyltranspeptidase (GGT) is a cell surface-associated enzyme that is not highly expressed in normal cell. However GGT is overexpressed in various type of human cancers. It is known that Helicobacter pylori (H. pylori) also produce GGT. Urano et al have developed an enzymatically activatable fluorescent probe, γ-glutamyl hydroxymethyl rhodamine green (gGlut-HMRG), which iscoupled to fluorescein under acid pH and normal cellular environment, but turns to be highly fluorescent upon reaction with GGT28. Aim of this study is to consider if gGlut-HMRG can be useful for diagnosing infection H. pylori.

Aims and Methods: In this study, we investigated whether activation of gGlut-HMRG fluorescence detects a wild-type of H. pylori (WT) and a ggt gene disrupted mutant of H. pylori (ggt mutant). In addition, we investigated whether activation of gGlut-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGsTop). Furthermore, we applied gGlut-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in H. pylori positive patients (n = 13) and H. pylori negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland)27.

Results: Activation of gGlut-HMRG fluorescence was detected in WT strain, but was not in ggt mutant strain. Activation of gGlut-HMRG fluorescence was inhibited by GGsTop. There was significant difference of the increase of fluorescence intensity between H. pylori positive and negative both in antrum corpus of stomach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for H. pylori infection diagnosis.

P1903 SEROLOGICAL CHANGES AFTER EQUIVOCAL HELICOBACTER PYLORI-SEROLOGY TEST FINDINGS DEPEND ON THE GASTRIC SECRETING ABILITY

Aims & Methods: The study aim was to evaluate the long-term, follow-up result after an equivocal test finding on the serum anti-H. pylori IgG assay. Koreans above 18 years-old with an equivocal serum anti-H. pylori IgG assay finding were included. Subjects were excluded if they did not undergo H. pylori serology test, serum PG assay, and upper gastrointestinal (UGI) endoscopy on the same day at our center. Annual test findings were followed up using the same methods.

Results: Of the 7,178 subjects who underwent the serum assay and UGI endoscopy on the same day, 274 (3.8%) subjects showed an equivocal H. pylori serology test finding. Of the 98 followed-up subjects, 58 (59.2%) showed sero-positive finding at the mean follow-up period of 30.6±12.4 months. Subjects with seroconversion showed a higher initial serum PG I (p = 0.023) and PG II (p = 0.036) levels than the subjects without seroconversion.

Conclusion: An equivocal H. pylori serology test finding is not rare (3.8%) in Korean adults, and 60% of the equivocal subjects show seroconversion within 3 years. Higher seroconversion rates in the subjects with high PG I and PG II levels suggest that intact gastric secreting ability play a role for the survival of H. pylori. Therefore, equivocal subjects with increased serum PG levels should be considered as a potential seropositive subjects.

Introduction: Several H. pylori (Hp) infection related cardiac findings (mucosal atrophy, metaplastic change, diffuse redness, spotty redness and nodular change of the antrum etc.) are so important sign of Hp infection on endoscopic examination. On the other hand, we have confused with various newly endoscopic findings (patchy redness and map-like redness etc.) were seen on all Hp-eradicated stomach. On this time, we have found out a new other ultimate useful finding showing Hp infection related gastritis at gastric cardia (EG junction) including present and post Hp infection. The endoscopic image of gastric cardiac is the first gastric view through the esophagus on each endoscopic examination.

Aims & Methods: Our aim of this study is to elucidate possibility of judgement with only this cardiac endoscopic view about presence or absence with Hp infection. We have found out so useful and specific cardiac image (We call Whale Shark Sign: WSS) closely related to Hp infection. We have examined the presence of WSS on 4, 268 cases that have been able to overviewed on their endoscopic profiles. We have judged the presence of Hp infection with serum Hp antibody titers on each case. The 3,233 cases their serum Hp antibody titer were measured were from Jan. 2012 to Oct. 2016. A total of 2,810 patients (Hp positive) were enrolled. Fisher's exact test was used in all statistical analyses. The judgement of Hp present or past infection was done more than serum Hp antibody 3 U/ml to avoid false negative results.

Results: Mean age of patients was 52.4 years old. In case of WSS positive, all their serum Hp antibody titer showed more than cut-off level (3 U/ml). This means that the presence of WSS closely related to Hp related gastritis. The positive predictive value (PPV) of WSS was surprisingly high (98%). According to this high PPV, we can think WSS positive cases are high risk of gastric carcinoma. This WSS mean that the presence of irregular gastric mucosal surface pattern and the presence of lymphoid hyperplasia, that showing Hp infection's stomach. Especially presence of lymphoid hyperplasia at gastric cardiac is most important specific sign of Hp related gastritis. This lymphoid hyperplasia at gastric cardia were recognized small round whitish nodules on white light endoscopy. And this was more emphasized with image-enhanced endoscopy (Narrow Band Imaging; NBI), it looks like Whale Shark. This WSS sign is very simple and easy for every gastroenterologist. It is so useful to know gastric cancer risk at gastric entrance (cardia) with the presence of very easy simple sign.

Conclusion: We have been able to judge the presence of Hp infection with only cardiac endoscopic images (WSS), we should take care of seeing the presence of WSS sign. Since this sign is very easy and simple, everyone will be able to judge the presence of Hp infection as gastric cancer risk.

Introduction: The diagnosis of Helicobacter pylori (Hp) infection is currently made by means of non-invasive (Urea Breath Test or HpSA) or invasive (gastric biopsy or culture) methods. Serological assessment of Hp infection by using levels of IgG is not recommended. Pepsinogen II (PGII) is validated in the literature as a non-invasive marker of gastric inflammation. Aim of the study was to assess in a population of dyspeptic patients the clinical availability of PGII determination in singling out subjects infected by Hp in comparison with non-infected ones.

Aims & Methods: A cohort of 880 consecutive dyspeptic patients (F 439; mean age 55.5 ys; range 29.83 ys) were enrolled in the study. Exclusion criteria: previous surgery, previous Hp eradication therapy, comitant PPI. In all patients the diagnosis of Hp infection was made by means of upper GI endoscopy and at least one of these two methods: UBT, HpSA. All patients underwent blood sample for determination of serum levels of PGII (Biohit Oyj; Finland; normal values: 2-15µg/l). In a group of 670 pts a course of antibiotics (triple, concomitant or sequential therapy) to cure Hp infection was performed and PGII levels determined at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of Hp infection was assessed by using the ROC curve method.

Results: 430 out of 660 dyspeptic patients (F 245;mean age 52.3 ys; range 32-69 ys) showed an Hp-related gastritis (group1) in comparison with 430 (F 261; mean age 57.3 ys; range 38-74 ys) resulting negative for Hp infection (group 2). The mean value of PGII in group 1 was 20.9 ± 6.1 opposite to 7.2 ± 1.7 in group 2; p<0.0001. 415 out of 670 patients treated with antibiotics schedules were cured from Hp infection, opposite with 255 non-eradicated ones. In the group of cured patients, the PGII values at T0 were 16.5. in comparison with 8.6 at T1; p<0.001. The cut-off for PGII in the diagnosis of Hp infection, by comparing the 430 Hp positive pts and the 430 negative ones with method of ROC curve identified the mean value of 10.6 µg/l; youden index J =0.997.

Conclusion: serum PGII levels seem able to perform diagnosis of Hp infection in dyspeptic patients, as well as the efficacy of antibiotics treatment for Hp eradication, being 10.6µg/l the best cut-off in singling out infected from non-infected subjects.

Introduction: The Urea Breath Test (UBT) is considered the gold standard non-invasive test for detection of Helicobacter pylori infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of H. pylori infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naïve adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of >2.4% was obtained. Positive patients were categorised into low (<16%), intermediate (16-35%) and high (>35%) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at least 1-3 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBTs assessed (mean age 43.5±14.9 years, 39% male), 22.0% were positive (mean age 43.1±14.9 years, 41.9% male) of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between groups (p=0.06 for age and 0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p=0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower (DOB value was 29.8% compared to 29.8% when eradication was unsuccessful (p=0.03, 95% CI 0.69 to 17.5). 46 (50.5%) patients were patients clarithromycin-based triple therapy for 7 days. When this subset of patients was categorised into low, intermediate and high UBT groups, eradication rates were 75.0%, 75.0% and 50.0% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0% compared to 30.2%. When eradication was unsuccessful (p=0.6). Similarly, when these DOB values were compared to respective values in those whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of H. pylori infections, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was successful (20.6% vs 29.8%, p=0.03). The DOB value could be a useful value in stratifying patients with H. pylori infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for H. pylori infection.

Introduction: Bismuth is a heavy metal which has antimicrobial activity through regulating iron uptake profile of bacteria. Helicobacter pylori (H. pylori) is also highly susceptible to bismuth. So the Korean guideline preferably recommends the regimen contains bismuth for the patients who failed on H. pylori eradication with the primary regimen consists of proton pump inhibitors, amoxicillin, and clarithromycin. Rifaximin is one of derivatives of rifamycin with antimicrobial activity against H. pylori. It can achieve high concentrations within the gastrointestinal tract and remains active in acidic environment. So rifaximim has been studied as a treatment for persistent H. pylori infection. Rifaximin has been prescribed for replacing the bismuth of the regimen concurrently uses PPI, metronidazole, and tetracycline in Soonchunhyang University Hospital, Seoul for a while. So we reviewed the clinical outcomes of the 2 different regimens.

Aims & Methods: From May 1st 2003 to October 31st 2015, six thousand and five hundred ninety-five patients were treated their H. pylori infection in Soonchunhyang University Hospital, Seoul. And their prescriptions and result of eradication were retrospectively reviewed on the medical records. The patients had clarified pre-and post-eradication result, which can be assured by the rapid urease test. So we reviewed the clinical outcomes of the 2 different regimens.

Results: During the periods over 12 years, two thousand and seven hundred patients were treated the rifaximin-containing regimen and 34 (97.14%) of them showed successful eradication result. Other 91 patients were treated with the rifaximin-containing regimen and showed 92.31% of eradication rate. The treatment success rates are not different significantly in statistics. (Fisher’s exact test, p-value=0.442)

Conclusion: Alternative rifaximin containing regimen of second-line H. pylori treatment didn’t showed inferiority on standard bismuth-containing one. This suggested that the use of rifaximim is possible in the patients who are not suitable to bismuth use and failed with primary eradication.

Introduction: Standard triple therapy (STT) has been widely used in Helicobacter pylori infection, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levofloxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%. Aims & Methods: We compared the efficacy and safety of STT group and LBT group for Koreans. Between April 2014 and April 2016, 49 patients in the STT group (amoxicillin 1 g bid, clarithromycin 500 mg bid and esomeprazole 20 mg bid for 10 days) and 48 in the LBT group(levofloxacin 500 mg bid, amoxicillin 1 g

**Contact E-mail Address:** dbrennan9@tcd.ie

**Introduction:** In Ireland, Helicobacter pylori infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment.

**Aims & Methods:** Aims of this study were to compare eradication rates of standard clarithromycin-based triple therapy with those of tailored therapy based on antimicrobial susceptibility as a first-line treatment for H. pylori infection. Treatment-naïve adult patients undergoing endoscopy were prospectively recruited. Biopsies from H. pylori-positive patients (assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored therapy based on antibiotic sensitivities, for 7/14 days. A follow-up breath test was performed at least 8 weeks post-treatment.

**Results:** To date 889 patients have undergone endoscopy and 186 (21%) were H. pylori positive. Infected patients were significantly younger (mean age 53 vs 49 years, p = 0.002) and tended to be male (43% vs 53%, p = 0.02). Of 186 H. pylori-positive patients, 112 (60%) were treatment naïve. Culture of H. pylori was successful in 57% (104/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (104/112) patients and 55% (61/114) strains were clarithromycin resistant. Thus far, 99 (85%) treatment naïve patients have been enrolled in the study. 92 (93%) have completed the study. Of these, 45 (46%) have received standard triple therapy and 54 (54%) have received tailored therapy. In the tailored arm, 25 (46%) patients received standard triple therapy, 14 (26%) received levofloxacin-based triple therapy, 13 (22%) received a PPI and combination of antibiotics based on their sensitivities (e.g. levofloxacin, clarithromycin, rifampicin, tetracycline or metronidazole), and 3 (6%) bismuth quadruple therapy. H. pylori eradication efficacy of tailored therapy by intention-to-treat analysis was higher at 74% (40/54) compared to 67% (n = 30/45) for standard therapy (p = 0.03). The eradication efficacy by per-protocol analysis was also higher, at 82% (40/49) for tailored versus 70% (30/43) for standard therapy (p = 0.02). Patients in each arm were further categorised by clarithromycin resistance status, phenotypically by E-test or genotypically by GenoType HelicoDR assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored therapy based on antibiotic sensitivities, for 7/14 days. A follow-up breath test was performed at least 8 weeks post-treatment.

**Conclusion:** In those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieves an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistant rate was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (57%, p = 0.09).
were assigned to one of the following groups: a control group receiving the... 14-day of quadruple therapy with PPI + amoxicillin + metronidazole + levofloxacin with success.

Conclusion: Co-adjuvant sequential therapy with probiotic Lactobacillus reuteri protectis, within previous two weeks to final of treatment, is associated with higher HpET rate, initially or after sequential failure therapy, and lower rate of diarrheal side effect.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1913 THE IMPACT OF CLOSTRIDIUM BUTYRICUM MIYAI-588 ON HELICOBACTER PYLORI ERADICATION THERAPY
Department Of Gastroenterology And Hepatology, Kyoto Prefectural University of Medicine, Kyoto Japan

Contact E-mail Address: shunt02@koto.kpu-n.ac.jp

Introduction: As a country with high incidence of gastric cancer, the elimination of Helicobacter pylori (HP) is useful strategy for the prevention of gastric cancer in Japan. And the eradication therapy for HP-infected gastritis was approved as an insurance indication since 2013, and virtually all HP-infected patients are started eradication therapy using proton pump inhibitor (PPI)/amoxicillin (AMPC)/clarithromycin (CAM) has been used as a regimen for the primary eradication therapy. Since HP has rapidly acquired the resistant character against CAM, the eradication rate has gradually been decreasing. Recently (2013), a novel potential competitive acid blocker, has been approved for HP eradication therapy. Recently, higher HP-eradication ratio by VPZ + AMPC + CAM than PPI based triple therapy has been reported. However, there might be some concern for the use of VPZ; higher serum gastrin, decrease in the diversity of intestinal microbiota and increase in colitis.

Therefore, PPI-based triple therapy is still used, and additive effect of probiotics has been reported in these therapy.

Aims & Methods: The aim of this study is to investigate the effect of probiotics, Clostridium butyricum Miyai-588 (MBM) on PPI-based triple therapy comparing the eradication rate and side effect with VPZ-based triple therapy. From January 2015 to December 2016, patients who received HP primary eradication therapy in our hospital were retrospectively evaluated. They were divided into 2 groups: 1) patients who received PPI + AMPC + CAM therapy (PPI group), and 2) patients who received VPZ + AMPC + CAM therapy (VPZ group), 3) patients who received PPI + AMPC + CAM + MBM therapy (PPI + MBM group), and the eradication rate and side effects were evaluated.

Results: The number of patients enrolled in this study were 468; 150 cases in the PPI group, 271 cases in the VPZ group and 47 cases in the PPI + MBM group. Successful rate of HP eradication was 81.7% in the PPI group, 89.8% in the VPZ group and 89.1% in the PPI + MBM group. The eradication rate in VPZ group was significantly higher than that of PPI + MBM group. The rate of side effect was 14.7% in the PPI group, 10.0% in the VPZ group and 19.1% in the PPI + MBM group, and there was no significant difference between 3 groups.

Conclusion: Clostridium butyricum Miyai-588 can have additive effects in PPI-based triple therapy for HP.

P1914 THE EFFECTS OF SACCHAROMYCES BOULARDI SUPPLEMENTATION ON HELICOBACTER PYLORI ERADICATION RATE AND SIDE EFFECTS DURING SEQUENTIAL THERAPY: A PROSPECTIVE RANDOMISED CONTROLLED STUDY
H. Boualloula1, H. Seddiki2, K. Loubairis3, F. Najjar3, S. Berrag4, I. Elktiti4, A. Benkiranre
1Gastro-enterology II, Military Hospital Mohamed V, Rabat/Morocco
2Gastroenterology, HMIMV RABAT, Rabat/Morocco

Contact E-mail Address: hanaeboalloula@gmail.com

Introduction: The eradication of Helicobacter Pylori remains crucial because of constantly evolving data. The recent recommendations of Maastricht V stipulate that the concomitant quadritherapy and the bismuth quadruple therapy are more efficient than the sequential therapy because of a higher rate of eradication (90% vs 82%), but with more important side effects. The aim of our study is to investigate the effects of the Saccharomyces boulardii supplementation to the sequential therapy on Helicobacter pylori eradication rate and associated therapy side effects.

Aims & Methods: One hundred ninety nine patients with Helicobacter pylori infection documented on a histological study of gastric biopsies were enrolled from May 2013 to May 2016, on a single center, prospective, controlled and randomized study, performed in the Gastro EnteroLOGY II department on the military hospital of Rabat. Using a permuted block randomization, our patients were assigned to one of the following groups: a control group receiving the standard sequential therapy, and an experimental group receiving in addition to the standard sequential therapy, probiotics at 10 billions of living cells per day concomitantly during the eradication therapy. Statistical analysis was performed by the software SPSS 20.0. A model of logistic regression was performed to analyse the effects of Saccharomyces boulardii supplementation on eradication rate and side effects.

Results: There was no significant difference between the two groups on age (middle age = 44.3+/-13.8years vs 43+/-13.2years), gender (Sex ratio M/F = 1.15 vs 1.05), medical antecedents, smoking, endoscopic and histological datas. In Intention To Treat ITT and Per Protocol PP analysis, the eradication rate was significantly higher in the experimental group (86.6% ITT, 87.5% PP), comparing to the control group (78.2% ITT 74.7% PP), p=0.02. Moreover, the Saccharomyces boulardii supplementation allowed a significant reduction of the incidence of overall side effects (RR = 0.26, IC95% [0.14-0.47], p<0.001), and with a reduction of the antibiotic-associated diarrhea (RR = 0.97, IC95% [0.58-2.08], p < 0.0001). The incidence of nausea and vomiting, dizziness, asthenia and metallic taste was also lower in the experimental group, although the differences were not statistically significant. In the multivariate analysis, the Saccharomyces boulardii supplementation is associated with an optimization of the eradication rate (RR = 2.4, IC95% = [0.19-1.09], p = 0.02), and with a reduction of the antibiotic-associated diarrhea AAD (RR = 0.07, IC95% = [0.02-0.26], p < 0.001).

Conclusion: Our study shows that the Saccharomyces boulardii treatment during sequential therapy in Helicobacter pylori regimen is associated with a significant reduction of side effects and particularly the antibiotic-associated diarrhea, and allows an optimization of the eradication rate of Helicobacter pylori.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1915 “CONCOMITANT” OR “SEQUENTIAL” THERAPY FOR THE ERADICATION OF HELICOBACTER PYLORI: WHICH REGIMEN COMES FIRST IN MOROCCO?
A. Ait Errami, Z. Samlani, S. Oubaha, K. Krati
Hepatogastroenterology, CHU Mohammed V, Marrakech/Morocco

Contact E-mail Address: adil.ae@hotmail.com

Introduction: As a country with high incidence of gastric cancer, the elimination of Helicobacter pylori (HP) infection markedly reduces relapse of peptic ulcers, bleeding, and gastric cancer. The destruction of Helicobacter pylori (H. pylori) eradication rates with standard triple therapy resulted in a search for novel therapies for first-line therapy of H pylori infection.

Aims & Methods: The objective of this study is to compare, in Morocco, an African country, the efficacy rates of the concomitant versus the sequential H pylori eradication therapy. Our prospective randomized study included 164 patients with newly diagnosed H. pylori infection, randomized to receive a 14-day concomitant or 10-day sequential therapy. Treatment outcome was assessed by 13C-urea breath test at least 4 weeks after therapy. Intention to treat (ITT) and per protocol (PP) analysis of the eradication rates were performed. Secondary end points included patient compliance and safety.

Results: The concomitant therapy group achieved statistically significant higher eradication rates when compared with the sequential treatment group, both in the ITT and in the PP analysis (86.6% versus 79.9%, p=0.002, and 90.6% versus 72.1%, p=0.001, respectively), after adjusting for age, gender, smoking status, and the presence or not of ulcer and/or non-ulcer dyspepsia. Both groups displayed excellent compliance rates (99.5% for the concomitant therapy group and 96.2% for the sequential therapy group, p=0.067). Regarding treatment safety, major adverse events that led to the discontinuation of both regimes were few, with no statistical difference between the two groups (6.2% for the concomitant therapy group and 3.1% for the sequential therapy group).

Conclusion: Concomitant therapy led to statistically significant higher eradication rates over sequential therapy. Both therapies showed excellent compliance and an acceptable safety profile. The concomitant quadruple therapy scheme should be the adopted for first-line H pylori eradication in Morocco.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1916 PROSPECTIVE COMPARATIVE STUDY OF TWO FIRST-LINE REGIMENS FOR HELICOBACTER PYLORI ERADICATION: 14-DAYS NON-BISMUTH QUADRUPLE OPTIMIZED CONCOMITANT THERAPY VERSUS 10-DAYS BISMUTH-CONTAINING QUADRUPLE THERAPY USING A THYME-CAPSULE
Hepatogastroenterology, CHU Mohammad V, Marrakech/Morocco

Contact E-mail Address: jaldcedo@telefonica.net

Introduction: The Maastricht V/Florence Report recommends bismuth- quadruple or non-bismuth quadruple concomitant therapies as first-line treatments for H pylori infection, in areas where clarithromycin resistance is high (>15%). Head-to-head studies between both therapies are needed.

Aims & Methods: We aimed to compare compliance, efficacy and adverse effects of two first-line H pylori eradication therapies in a high clarithromycin resistance
area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naïve adult patients, candidates to Helicobacter pylori eradication. Omeprazole 40mg, Clarithromycin 500mg, Amoxicillin 1g and Metronidazole 500mg, all drugs b.i.d, for 14 days (OCAM); or Omeprazole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg + Tetracycline 125mg + Metronidazole 125mg, 3 capsules q.i.d, for 10 days (3–1-OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (<80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student’s t, and Mann-Whitney U tests with significance level p < 0.05 were applied. The protocol was approved by the Ethics Committee.

Results: 216 patients (63.43% women; mean age 51.33-range: 19–84 years) were included. OCAM was prescribed in 103 and 3–1-OBMT in 113. No differences in age, sex and functional dyspepsia as indication to eradicate were observed between groups. Main indications for treatment were functional dyspepsia (39.35%), gastroduodenal ulcer (19.44%) and non-investigated dyspepsia (13.89%). Compliance was <80% in 11 patients and unknown in 7. The efficacy outcome was unavailable in 9 subjects. Compliance >80% was observed in 89% with OCAM and in 93.53% with 3–1-OBMT (p=0.06). The ITT rates were 82.52% vs 85.84% (p=0.63), and PP 89.47% vs 96.04% (p=0.13), for OCAM and 3–1-OBMT respectively. The outcomes of adverse effects (frequency, number, duration and intensity) are shown in the Table.

<table>

**P1917 MANAGEMENT OF HELICOBACTER PYLORI INFECTION AT PRIMARY CARE LEVEL. THE IMPLEMENTATION OF SPECIFIC COUNSELLING TO PCP IMPROVES THE ERADICATION RATES**

V. Laredo1, T. Arroyo Villarino2, E. Affaro3, C. Sostres4, A. Lanas5
1University Hospital Lozano Blesa, Zaragoza/Spain
2University of Zaragoza School of Medicine, Zaragoza/Spain
3Biosanitary Research Institute Aragón (IIS Aragón), Zaragoza/Spain

Contact E-mail Address: vlaredodelatorre@gmail.com

Introduction: We have detected a large increase of Hp breath test (UBT) requests for Helicobacter pylori (Hp) diagnosis by primary care physicians (PCP). In this way, most Hp-infected patients are now being managed at primary care level. However, little is known about outcomes of Hp infection by PCP.

Aims & Methods: 1. To evaluate and compare the eligibility of UBT indications, treatment regimens and eradication rates between PCP and gastroenterologist specialist (GS). 2. To evaluate the effect of introduction of specific counselling to PCP in the management profile of Hp infection. First, we prospectively included 500 consecutive UBT indicated by PCP (250) and GS. Appropriate UBT indications were considered those included in the 3rd Spanish Consensus Conference on Helicobacter pylori infection (1). Hp treatment prescribed and eradication rates were collected retrospectively. Finally, we analyzed another 216 patients (63.43% women; mean age 51.53-range: 19–84 years-) were included for the implementation of specific counselling based on national guidelines.

Conclusion: Hp infection management at primary care level is inappropriate with significant increase in the adherence to appropriate treatment regimens (71% vs 35%; p < 0.0001) and eradication rates (78% vs 57%; p < 0.0001) were observed in the PCP group after the implementation of specific counselling based on national guidelines. The introduction of a specific counselling to PCP has significantly improved these outcomes. These data should encourage the implementation of interventional strategies in order to reduce the actual increase in antibiotic resistance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Radiation-induced gastrointestinal syndrome (RIGS) stems from the clonogenic loss of crypt cells and vill depopulation and results in mucosal barrier disruption, bacterial inflammation, infiltration and sepsis. Valproate (VPA) is the one of the popular anti-convulsants, recently its Notch signal modulatory effect has been reported. Notch signal pathway is the essential to maintain intestinal stem cells and to differentiate to secretory cells such as goblet cell. Moreover, it has been reported that combination of VPA and CHIR 99021 (GSK3β inhibitor) has powerful proliferatory effect for intestinal stem cells, such as Lgr5+ cells. One of the major difficulties for RIGS studies is the fact that crypts are not easily accessed and cultured with traditional means. Ex vivo culture techniques for single crypt or a stem cell derived enteroid, with essential features of the in vivo tissue architecture, have been recently developed. Thus, we have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS.

Aims & Methods: We have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. To culture enteroid, ten centimeters segments of jejunum were procured from 9–13 week-old C57BL6 mice. Crypts were isolated by EDTA chelation, suspended in Matrigel and grown in culture media containing epidermal growth factor, noggin, R-spondin 1. After 1 day in culture, the enteroids were treated (or not) 3 mM CHIR 99021 (GSK3β inhibitor) and 1mM VPA. On day 3, the enteroids were irradiated as a dose dependent manner. The evaluation of irradiated enteroids was performed by measuring MTT assay, budding efficiency of enteroid, and EdU staining. On post-irradiation Day 2 and Day 7, RT-PCR was performed.

Results: Enteroid from mouse had multiple crypts (‘budding’) with well-differentiated goblet, Paneth cells, + stem cells (quiescence stem cells, BMI1 is expressed), Lgr5+ stem cells. In the response of radiation, irradiated enteroid decreased proliferation rate in a dose dependent manner, as measured by MTT assay. budding efficiency of enteroid. Irradiated enteroids with VPA+CHIR 99021 could maintain their + stem cells even in 10 Gy of irradiation, lethal dose of mouse intestinal epithelium, and they were able to proliferation. Combination of VPA + CHIR 99021 did not have an effect on paneth cells, enteroid, and goblet cells.

Conclusion: VPA and CHIR 99021 may ameliorate RIGS in ex-vivo mouse enteroid, through + reservoir stem cell preservation and stimulatory action for epithelial proliferation. Considering their clinical application such as safety, they could be possible strategy for prevention and treatment of RIGS.

Introduction: Celiac disease (CD) is an important health problem worldwide. It is characterized by high prevalence (1%), specific morbidity, long-term complications and epidemiological progression. However, mass screening is not recommended. Currently, the strategy of ‘Targeted screening,’ defined as screening of high-risk groups, is widely practiced and recommended by learned Societies, in particular in relatives of CD patients. In the world, targeted screening studies related to CD showed prevalence ranging from 4.2 to 10.3%.

Aims & Methods: The main aim of our study is to determine the prevalence of CD in the first degree relatives in Algerian population. This was a descriptive-transversal study with prospective recruiting. This is a screening of first-degree relatives of patients known and treated for CD. Relatives are screened by using antitransglutaminase (tTG) antibodies in the serum. Upper digestive endoscopy and duodenal biopsy are performed in all sero-positive relatives and graded as per Marsh modified by Oberhuber classification to confirm the diagnosis. The four first degree relatives of 107 families are included in our study.

Results: Among the 546 first-degree relatives, we have 18.5% of parents, 57.3% of brothers and 27.1% of sisters. The main parameters for the prevalence of CD among first-degree relatives is 8.1% with Confident Interval (CI) at 95% [5.8–10.4]. The prevalence of CD in first-degree relatives with positive serology and positive duodenal biopsy is 7.3% with CI at 95% [5.2–9.4]. The average age of screening cases is 31.8 years with CI at 95% [27.2 to 36.4] and extremes of [3–71] years. The mean duration of symptoms before diagnosis is 3.4 years, with CI at 95% [2.8 to 4.0] years. Among the 44 new cases detected by targeted screening, there was an incidence of 1.4% asymptomatic, 88.6% symptomatic. This is a classical form in one case and atypical form in 86.4% of cases.

Conclusion: The present work entitled “Prevalence of celiac disease in relatives” is the first screening study of CD in the first-degree relatives carried out in Algeria. Among the 546 first-degree relatives, it shows that 44 patients present positive serology which corresponds to the prevalence of CD in first degree relatives of 8.1% with CI at 95% [5.8–10.4]. Our investigation supports the idea that the development of an extensive screening approach is needed to promote early diagnosis and prevent complications of CD in first-degree relatives.

P1920 LONG-TERM HEALTH AND LIFESTYLE OUTCOMES IN ADULT CELIAC DISEASE PATIENTS DIAGNOSED IN CHILDHOOD BECAUSE OF CLINICAL SUSPICION OR BY SCREENING
L. Kivelä1, S. Alim2, S. Kröger3, K. Kaukinen4, K. Kurppa5
1Tampere Center For Child Health Research, University of Tampere and Tampere University Hospital, University of Tampere/Finland
2School Of Medicine, University of Tampere, Tampere/Finland

Contact E-mail Address: laura.kiveila@finnet.fi

Introduction: Celiac disease affects 1–2% of the population, but due to diverse presentation most patients remain unrecognized. Diagnostic efficiency could be improved by screening of at-risk groups, but long-term benefits of this approach are unclear. To shed light to this issue, we compared a variety of celiac disease-related and other parameters in large cohorts of adult patients diagnosed in childhood either because of clinical suspicion or by screening.

Aims & Methods: A questionnaire about current health and lifestyle, adherence to gluten-free diet (GFD) and follow-up of celiac disease was sent to 564 adults with a primary diagnosis. Further, the participants fulfilled validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for symptoms and quality of life. Clinical and histological presentation at diagnosis and other relevant medical data were confirmed from patient records. All variables were compared between screen-detected and clinically detected patients.

Results: Altogether 235 (42%) adults completed the questionnaires. At diagnosis, screen-detected patients (n = 49) were older (11.3 vs 8.8 yr, p = 0.016) and had lower gluten challenge prevalence (15%, p < 0.001) compared to clinically diagnosed patients (n = 186). They also had a trend to have less often total villous atrophy (18% vs 32%, p = 0.075) and anemia (18% vs 32%, p = 0.072). The groups did not differ in gender, current age (median 26.5 vs 23.8 yr, p = 0.2), or recorded symptoms at diagnosis from the GSRS and PGWB. In addition, screen-detected patients were less symptomatic (4% vs 15%, p = 0.037) and had more often celiac disease in relatives (78% vs 58%, p = 0.011).

Conclusion: Diagnostic approach and presentation of celiac disease in childhood do not seem to affect the long-term health outcomes or attitude towards the disease in adulthood. Lack of difference in the dietary adherence and lifestyle recommendations gives further support for active screening and early diagnosis of celiac disease.

P1921 REVIEW OF SERVICE PROVISION OF NATIONAL INSTITUTE FOR HEALTH AND CARE EXCELLENCE (NICE) RECOMMENDED QUALITY STANDARDS FOR COELIAC DISEASE AT A BIG DISTRICT GENERAL HOSPITAL
F.K. Shaikh, D. Vani, M. Sprakes, F. Greenhalgh
Gastroenterology, Mid Yorkshire Hospitals NHS Trust, Wakefield/United Kingdom

Contact E-mail Address: shaikh177@yahoo.com

Introduction: In the UK, 1 in 100 people are affected with coeliac disease. NICE published quality standards (QS134) for coeliac disease in October 2016 based on NICE guidelines NG20 (September 2015). This quality standard covers the recognition, assessment and management of coeliac disease in children, young people and adults. The quality standard is expected to contribute to improvements in the diagnosis of coeliac disease, growth in children and young people, health-related quality of life, incidence of osteoporosis, intestinal lymphoma, vitamin D deficiency, and iron deficiency.

Aims & Methods: We audited our departmental practices against NICE quality standards for coeliac disease. It is a retrospective data analysis of patients, 16 years and above, with positive coeliac serology from April 2016 to September 2018. For each patient, we recorded year of referral, value of tissue transglutaminase (tTG) antibodies, type of referral (new or follow-up), timing of OGD (less than or more than 6 weeks), whether or not seen by dietician, offer of annual review, and DEXA scan.

Results: Total of 95 cases were examined. The General Practitioner was the main source of referral for tTG antibody (76%) test followed by gastroenterology outpatients (OP) (13%), 2% each was shared by surgical OP and inpatient gastroenterology services. Other referrals contributed 3% each. 88% (84 out of 95) of patients had tTG results; the results were more than 20 U/ml. 53 out of 95 (56%) were new referrals, 30 (31%) were follow-up and 12 (13%) referrals had no further record on system. 11 of 53 (21%) new patients had OGD in less than 6 weeks; 30 of 53 (56%) had OGD in more than 6 weeks, 22 of 95 (23%) had no record of OGD on system. 56 of 95 (59%) patients had dietician review. 26 of 95 (27%) were offered or had annual review. 42 of 95 (44%) had DEXA scan to assess bone density.

Conclusion: The incidence and prevalence of coeliac disease in our study are 30.28 per 100,000 persons-years and 0.072). The groups did not differ in gender, current age (median 26.5 vs 23.8 yr, p = 0.2), or recorded symptoms at diagnosis from the GSRS and PGWB. In addition, screen-detected patients were less symptomatic (4% vs 15%, p = 0.037) and had more often celiac disease in relatives (78% vs 58%, p = 0.011).

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: liisa.viitasalo@uta.fi

Introduction: In nonresponsive celiac disease (NRCD) the symptoms and duodenal histopathology persist despite gluten-free diet (GFD). It is not known whether a persistent growth of microorganisms, in particular yeast (Saccharomyces cerevisiae), bacteria (Pseudomonas fluorescens) or fungi (Aspergillus fumigatus), may be associated with the development of local referral and management pathways to ensure that all coelicians are captured, investigated, and followed up appropriately.

Aims & Methods: Serum microbial markers in nonresponsive celiac disease.

### P1924 CIRCULATING EXTRACELLULAR VESICLES, A NOVEL MECHANISM OF ENDOCRINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS

Contact E-mail Address: efkn78@gmail.com

**Introduction:** Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and pathologic systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy, chiefly triggered by gluten ingestion in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature.

**Aims & Methods:** The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-tTG positive, biopsy proven CD patients. Circulating EVs were identified on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSverse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the whole EV compartment and different EVs subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test.

**Results:** We evaluated 12 CD patients (mean age 42.4 ± 19.1 vs. 40.8 ± 15.9 years, F/M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥B1 according to the Corazza-Villanacci classification. Mean anti-tTG levels at diagnosis were 6.9 ± 4.1 times ULN. Mean number of total circulating EVs was significantly higher in CD than in controls (5985 ± 72482 vs 14383 ± 10018 EV/microL, p = 0.035). Subgroup analysis showed that EpCAM + EVs, of epithelial origin, and CD41 + platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1610 respectively, p = 0.05). In the contrary, CD45 + EVs, of leucocyte origin, showed a significantly higher number in CD patients vs. controls (60 ± 492 vs. 119 ± 150 p = 0.026).

### Table 1: Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to dietary treatment.

* Significant compared to controls (p < 0.05)
Conclusion: Celiac disease patients at diagnosis show higher numbers of circulating inflammatory factors when compared to matched controls. Phenotypical assessment suggests that this increase is not primarily driven by epithelial or endothelial damage. On the contrary, the increased numbers of leucocyte-derived EVs, suggest their potential implication in systemic signaling.

P1925 COELIAC DISEASE AND REPRODUCTIVE DISORDERS: IS THERE ANY CORRELATION

H. Boutallaka, I. Benelbardadh, F.Z. Ajana
Medicine C, Ibn Sina University Hospital, Rabat-Morocco

Contact E-mail Address: haneboutallaka@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the ingestion of gluten in genetically predisposed individuals. It occurs in people who are genetically predisposed primarily affecting the small intestine inducing atrophic lesions, which are regressive with a gluten-free diet. The classic form is actually a minority of patients. The extradiagnostic forms are currently the most found, with varied manifestations including reproductive disorders. The aim of our study is to evaluate the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Aims & Methods: It's a single-center, retrospective and descriptive study including 241 patients with coeliac disease enrolled within period of 17 years from 1995 to 2016 in the department of Gastroenterology «Medecine C» in Ibn Sina University Hospital.

Results: About 241 patients suffering from coeliac disease, 58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10/6. The mean age was 32.25years ranging from 13 to 59years old. The diagnosis of coeliac disease was based on: Histology (severe or partial Villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antienzyme antibodies and/or anti-transglutaminase antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extradiagnostic signs at the time of the diagnosis of coeliac disease. These disorders were more frequent during puberty in 11 cases (19%), secondary amenorrhea in 13 cases (22.4%), Metrorrhagia in 12 cases (20.6%), absence of development of secondary sexual characters in 8 cases (12.5%), spontaneous abortion in 7 cases (10.9%), menometrorrhagia in 4 cases (13.8%), primary sterility in 3 cases (5%), premature labour and/or IUGR in 3 cases (5%), primary amenorrhea in 2 cases (3.4%), and intrauterine Fetal death IUFD in one case (1.7%). All our patients benefited from a gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients were lost to follow-up. Of the remaining patients, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases. The cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in one case. One patient leveled her cycle after primary amenorrhea, and one case was delivered a baby in term after a repeated premature deliveries. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrhea continued in 2 cases.

Conclusion: Reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet. The classic form is actually a minority of patients. The extradigestive forms are currently the most found, with varied manifestations including reproductive disorders. The aim of our study is to evaluate the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1926 SEVERITY OF MUCOSAL DAMAGE AND TISSUE TRANSGLUTAMINASE ANTIBODY LEVELS CORRELATE WELL IN ADULT CELIAC DISEASE IRRESPECTIVE OF CLINICAL FEATURES

R. Maxim1, A. Trifan2, A. Plesa3, S. C. Oana Cristina1, I. Ciortescu2, I. Girleanu2, C. Stanciu3

2Institute Of Gastroenterology And Hepatology, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi/Romania
3Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: ancatrifan@yahoo.com

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes range from classical gastrointestinal manifestations to only atypical signs, thus making the clinical diagnosis a challenge. The aim of our study was to investigate the relationship between duodenal histology, specific antibody levels and clinical presentation in adult CD Romanian patients.

Aims & Methods: Twenty-nine patients were enrolled. Fourteen patients (46%) were female, mean age 40.02 ± 12.14 years. A total of 48.1% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38yrs vs 47yrs). Marb-Obreuber classification was used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-tissue transglutaminase (IgA-tTG) antibody (61.45 ± 76.45 u/mL vs 162.02 ± 106.179 u/mL, P = 0.001) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83 ± 69.41u/mL vs 77.15 ± 71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3b and 3c) in CD patients by Spearman rank correlation. Among symptomatic, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels (r = -0.516, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-3c lesions (P = 0.004). Among biological markers included in the statistical analysis, low iron levels (cut off 30mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3b lesions (P = 0.008) and elevated IG-IgA titers (r = -0.384, P = 0.001).

Conclusion: IgA-tTG and AGA levels correlate with duodenal villous atrophy in adult CD patients. An IgA-tTG level >160 was nearly always associated with severe CD histopathology. GI and non-GI symptoms are not reliable predictors of CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1927 ASSOCIATION OF CELIAC DISEASE AND PATENT FORAMEN OVALE FORMS WITH OVALE: IS THERE ANY CORRELATION

M. Seziki1, G. Dindar1, D. Karacimen2, S.B. Ackigoz2
1Department Of Gastroenterology, Health Sciences University Koceri Derince Education and Research Hospital, Kocaeli/Turkey
2Department Of Cardiology, Izmit Seca State Hospital, Kocaeli/Turkey

Contact E-mail Address: drseziki@hotmail.com

Introduction: Celiac disease is an immunologically-mediated enteropathy that triggered by the intake of gluten-containing foods in genetically predisposed individuals. It causes intestinal and extraintestinal manifestations. Extraintestinal findings are observed in many systems. The prevalence of extraintestinal findings in CD is 5% in children, and in adults, the prevalence is twofold. Extraintestinal findings are observed in many systems. Extraintestinal manifestations include reproductive disorders. The aim of our study is to evaluate the frequency of patent foramen ovale in celiac disease patients.

Aims & Methods: Between May-June 2015, 65 patients who applied to the gastroenterology clinic of Derince Education and Research Hospital and followed up with celiac disease were identified. The sociodemographic characteristics, celiac disease diagnosis duration, symptoms and complaints, accompanying diseases, drug use histories, histogram and biochemical parameters of these patients were recorded. The patients underwent saline contrast transthoracic echocardiography in the cardiology clinic. Patients' data were recorded. The obtained data were evaluated with appropriate statistical methods.

Results: Sixty-five celiac patients were included in the study. 21 (32.3%) male and 44 (67.7%) female. The mean age of the study group was 41.5 ± 14.1 years. PFO was detected in 39 (60%) of the patients. There was no difference in the incidence of PFO in between female and male patients. (61.9% and 59.1% respectively, p=0.829). Compared with the frequency of PFO in the general population, the incidence of PFO in celiac patients was not statistically significant. (25% and 60% in general population and celiac patients respectively).

Conclusion: As a result, the incidence of PFO is more prevalent in celiac patients than in the general population. For this reason, the evaluation and treatment of the cardiovascular disease become crucial in the clinical follow-up of these patients. Because our patients did not undergo transesophageal echocardiography, this rate may be less than real exist. For this reason, further evaluation is required with a wider patient group and by transesophageal echocardiography.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1928 EFFECTIVENESS OF BULB BIOPSY SAMPLES IN CELIAC DISEASE DIAGNOSIS IN ADULTS

D.V. Balaban1, A. Popp2, J. Taavela2, K. Laurila2, M. Makki2, M. Jinga1
1"Carol Davila" University of Medicine and Pharmacy, Bucharest/Romania
2Center For Child Health Research, University of Tampere and Tampere University Hospital, Tampere/Finland

Contact E-mail Address: vbalaban@yahoo.com

Introduction: The bulb biopsy (BB) guidelines recommended sampling of both the bulb and distal duodenum for diagnostics. This has been reinforced by the recent data on ultra-short CD [1]. However, it has been previously shown in pediatric CD that bulb specimens are frequently of poor quality with low diagnostic yield [2]. In the absence of duodenal biopsies, non-celiac patients also, and it can lead to false-positive diagnoses [2]. Our aim was to address the same issue in adult CD, using the same validated morphometric methods [3].

Aims & Methods: We prospectively recruited cases of clinically recommended upper GI endoscopy; all patients also had signs and symptoms of CD and were checked for CD serology (serum tissue transglutaminase 2 antibodies and endomysial antibodies) and biopsy sampled according with current
recommendations. Paraffin embedded biopsy samples were assessed for villous height-to-width (CD) and VH:VH ratio. The corre-
sponding frozen duodenal samples were assessed for duodenal IgA deposits target-
ing transglutaminase 2 (TG-2-IgA), density of CD3 (cut-off 37 cells/mm² epithelium) and γδ T cell receptor bearing intraepithelial lymphocytes/IELs (cut-off 4.3 γδ T cells/mm² epithelium). The study was approved by the Local Ethical Committee.

Results: Altogether 41 patients, mean age 45.4 ± 14.6 years, 61% female, were recruited. Among these, 21 were finally diagnosed as adult CD (mean TG-156 U/L, mean CD3 ratio 81.87, and crypt hyperplastic mucosal lesion in distal duode-
num) and the rest 20 were non-CD controls (serum negative and normal on distal duodenal biopsy). All patients were on a gluten-containing diet. Quality of bulk biopsy samples was unsatisfactory and unreadable in 67% of CD cases and 50% of controls, even after reorientations and recuttings. All CD patients had, when measurable, VH:CrD < 2 in the anatomical bulb (average 0.31, range 0.02-0.61). On the other hand also non-CD controls had a crypt hyperplastic diseased bulk mucosa in 80% of patients (average VH:CrD 1.65, range 0.7-4.1), but the injury was much higher in CD patients (CD 0.7:00.006). The discrimination was significantly higher in CD compared to controls (CD3 1.87 vs. 34.05, p < 0.01; γδ IELs 29.12 vs. 6.44, p < 0.01). Bulk IgA deposits were positive in all CD patients and were able to discriminate CD cases from disease controls.

Conclusions: As reported in previous literature, bulk biopsy samples in adults are frequently of poor quality and not reliable for accurate histomorphological measurements. Also, interpretation of results from bulk samples should be done with caution, as non-
CD patients may have mild injury in the bulk lining and could be misinterpreted as CD. Assessment of bulb TG-2-IgA subepithelial deposits is a powerful tool to confirm CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Celiac disease (CD) is a chronic inflammatory disorder triggered by the genetically susceptible people. The prevalence varies between European countries and averages at 1% within whole Europe. It is anticipated that the number of undetected and therefore untreated cases is high. Since untreated CD is associated with a high morbidity, further diagnostic modalities to improve the diagnosis are currently explored. In this setting, we evaluate Simtomax™, a POCT detecting deamidated gliadin peptide anti-
bodies, with the goal to identify patients that need for duodenal biopsies prior to gastroscopy. Thus, the goal was to establish a test allowing to guide the endos-
copy in his decision to collect duodenal biopsies.

Aims & Methods: Prospective investigator-initiated multi-center study in six adult gastroscopy and two pediatric gastroscopy centers in Berlin and Brandenburg, Germany, approved by the local ethical committees. Finger prick blood of positive CD was collected for gastroscopy and eligible for the study (exclusion: defective coagulation, established celiac disease or on gluten-free diet) was analyzed by the POCT (IgA and IgG for deamidated gliadin peptides; Simtomax™ test, Tillotts, Switzerland). Test results were compared with duodenal histology (Marsh classification). In POCT-positive individuals transglutaminase-IgA serology was performed.

Results: Analysis was performed at n = 721 adult patients (average age: 48 yrs) and n = 108 pediatric patients (average age: 11 yrs). In the adult cohort 45 POCT-

POCTs were judged as “positive”. Within the POCT positives, 6 Marsh III cases were detected. None of the 676 POCT-negative individuals revealed CD. Therefore, the prevalence of CD in this population was 0.8%. The POCT-specificity in this group was 94% (95%CI 92-96%), the sensitivity was 100% (95%

Aims & Methods: We aimed to consider management of occult OGIB patients based on the long-term outcomes. A total of 357 consecutive occult OGIB patients (203 men; mean age: 59.7 years) who underwent CE at Hiroshima University Hospital before March 2016 and whose entire small-bowel could be observed and followed-up by CE for at least 12 months, were enrolled. We examined each patient to confirm the positive CE findings rate, the detection rate of bleeding source lesions, the details of bleeding source lesions, the overt POCT. However, the CD prevalence in this group was low. In the pediatric group we reported a positive sensitivity, either due to a sensitivity problem with this serology in the pediatric population or secondary to a suboptimal IgA band expression of the POCT.

Disclosure of Interest: All authors have declared no conflicts of interest.

bleeding rate with or without treatment, the rate of anaemia exacerbation (hemoglobin decreased by 0.5 g/dL), 5 year overall survival rate (DSS), Occult OGB was defined as recurrent or persistent iron deficiency anaemia with or without a positive faecal occult blood test and no bleeding findings by esophagogastroduodenoscopy and colonoscopy. Results: Results: The positive CE findings rate was 44% (157/357) and the detection rate of bleeding source lesions was 27% (98/357). All of the treated overt bleeding source lesions (Group A) were as follows: angioectasia 61 patients (Yano-Yamamoto classification Type 1a 37 patients, Type Ib 24 patients), non-specific ulcers 15 patients, duodenal anti-inflammatory drugs-induced ulcer 1 patient, hemangomas 5 patients, Crohn’s disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not regarded as bleeding source (without treatment (Group B)) were as follows: angiectasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B (Type 1a) that was not a bleeding source lesion, OGB in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B was 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Conclusion: Long-term outcomes with occult OGB patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGB patients without bleeding source lesions, including Type 1a angioectasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGB patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1932 A PILOT STUDY INVESTIGATING THE VALUE OF FAEAL IMMUNOCHEMICAL TEST (FIT) WHEN INVESTIGATING ANAEMIA OR OCCULT GASTROINTESTINAL BLEEDING WITH SMALL BOWEL CAPSULE ENDOSCOPY

D. Tighe1, C. Judge1, P. Walsh1, M. Kelly1, A. O’Connor1, N. Breslin1, B. Ryan1, G. Boran2, D. Menamara1

Contact E-mail Address: donaltighe83@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can detect the causes of anaemia or bleeding, such as angiodysplasia, small bowel Crohn’s disease, polypos, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochromical test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were patients referred for SBCE with the indication of anaemia or occult GI bleeding. Baseline patient characteristics were obtained including age, gender, history of relevant disease, transfusion requirements and use of anti-coagulants/anti-platelet agents. Patient haemoglobin (Hb) level was checked on the day of SBCE where possible. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was this the standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18–77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dL (range 7.8–15.9 g/dL). The average FIT reading was 459 ng/ml (range 0–4426 ng/ml). 30% of patients had a FIT level >50 ng/ml. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients with a FIT level >50 ng/ml had positive findings at capsule endoscopy, compared to 5/28 (17.8%) for FIT <50 ng/ml, p value = 0.002, 95% C.I 0.29–0.86 O.R. 0.16. These included 4/12 (33%) new cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-BHD enteritis, 1/12 (16.7%) small bowel tumours and 1/12 (16.7%) melanoma, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >90 ng/ml were anaemic (Hb <11.5 g/dL), compared to 17% with FIT <50 ng/ml, p value = 0.02 95% C.I 0.09–0.76 O.R 0.14. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology. 83% of patients, who were anaemic and had a FIT >50 ng/ml had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value = 0.05 95% C.I 0.22–0.3 O.R 0.05. Overall the sensitivity for a FIT >50 ng/ml for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56%-95%). Antiplatelet uptake was not predictive of a positive FIT, as 16.7% of patients with a FIT >50 ng/ml were on anti-platelet agents, compared to 83.3% who weren’t.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would benefit from referral.

Introduction: The features of the portal hypertension enteropathy (PHE) vary from mild mucosal changes to varices with or without bleeding. The prevalence and the correlation of factors that predict the development of PHE are not fully understood.

Aims & Methods: Our aim in this study is to examine the prevalence of the different manifestations portal hypertensive enteropathy and it’s correlation with the Child-Pugh score (CTP) in cirrhosis using video capsule endoscopy (CCE). At a single center, we performed a retrospective chart review study of patients between the age of 18 and 80 with cirrhosis, who had VCE study between January 2010 and January 2016. Based on the published literature we divided the portal hypertensive enteropathy lesions in our study into vascular lesions (arteriovenous malformation (AVM), red spots, bleeding or varices) and mucosal lesions (mild inflammatory changes or severe inflammatory changes which are a mosaic, congested and friable mucosa).

Results: 100 patients with cirrhosis had a VCE study. The mean age was 62.82 years. Male gender was predominant with a 64%, while the Caucasians represented 82% of the cohort. The most common etiologies of the cirrhosis were chronic alcohol abuse followed by chronic hepatitis C virus (HCV) and non-alcoholic steatohepatitis (NASH)Table 1A. The average MELD score was 13.86(±0.66). VCE detected small bowel lesions in 71% of the patients while the features of portal hypertensive enteropathy were found in 5% from the total cohort. AVMs and Inflammatory changes were the most common findings, followed by bleeding. 13 patients found to have two or more lesions by VCE. More than 50% of the lesions were vascular in nature (table1A). The percentage of the CTP A, CTP B and CTP C was 46%, 21% and 13% respectively. The odds of finding portal hypertensive enteropathy in decompensated cirrhosis is twice that in compensated cirrhosis (odd ratio of 2.0) table 1B. 45 patients had negative EGD exam for any active bleeding, esophageal varices (EV), portal hypertensive gastropathy(PHG) or gastric varices(GV). 31 of them (68%) had features of portal hypertensive enteropathy in their VCE. table 1B.

OFGIB (male/female: 678/374, age of onset: median of 51 years). We retrieved the database from 1997 to 2007 and estimated ORs using Mantel-Haenszel estimator in discordant cases. Drug adherence was classified into 4 groups: 1) 100%, 2) 50% or higher, 3) lower than 50%, and 4) 0%. Using a case-crossover design, we investigated patients with persistent overt SBB after negative DBE and the presence of enteric-coated aspirin (n = 148, 33%), drug injuries (n = 48, 11%: malignant 32, benign 16), diverticula (n = 13, 3%), etc. Data from 133 patients included 346 drugs which could be identified 24 weeks before overt SBB. ORs (95% CIs) of enteric-coated aspirin (n = 51), warfarin (n = 27), clopidogrel (n = 24), and loxoprofen (a propionic acid derivative, n = 21) were 5.1(1.3–24.3), 3.7(0.8–16.6), 3.1(0.2–45.3), and 15.8(2.3–139.6). Aspirin-associated SBB was caused by aspirin-induced injuries, angioedema, Meckel’s diverticula, and polyps. Laxoprofen-associated SBB was caused by mostly loxoprofen-induced injuries.

Conclusion: Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as drug injuries causing overt SBB during a relatively short period after administration.

P1936 META-ANALYSIS REVEALS SIMILAR REBLEEDING RATES AMONG EASTERN AND WESTERN Populations UP TO FIVE YEARS AFTER INDEX VIDEO CAPSULE ENDOSCOPY

EXAMINATION FOR OBSCURE GASTROINTESTINAL BLEEDING G. Tzitzios, P. Gkolfakis, G. D. Dimitriadis, K. Triantafyllos 2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: Video capsule endoscopy (VCE) is the first-line diagnostic modality for obscure gastrointestinal bleeding (OGBB). Investigation and different re-bleeding rates have been published among Western and Eastern studies.

Aims & Methods: Aim of this meta-analysis was to examine the differences in re-bleeding rates in patients with OGBB after index VCE, as measured in Western and Eastern studies. A comprehensive literature search in MEDLINE was conducted to identify all studies examining re-bleeding rate after VCE for OGBBB. Meta-analysis assessed the pooled proportion of re-bleeding events after VCE for OGBB according to study’s origin (Western vs. Eastern) as the primary endpoint. Point estimates and their 95% CI were calculated using the fixed and random effect model. Heterogeneity was measured using the I² statistic.

Results: Thirty-eight (14 Eastern and 24 Western) studies were included in the analysis with 5197 patients followed from 6 to 52 months. We detected significant heterogeneity with no evidence for publication bias in the meta-analyzed studies. While the overall, pooled rate of re-bleeding after VCE was 25.2(21–29)%, I² = 93%, similar re-bleeding rates were detected among Eastern and Western populations [22.16–28%], I² = 93% vs. 28.22–35%], I² = 95%. The re-bleeding rates after positive compared to negative VCE index examination was higher [1.89(1.10–3.24), I² = 72%] in Eastern populations, while a similar difference was not detected in the Western studies [1.46(0.72–2.94), I² = 88%]. When only studies with short-term follow-up were analyzed, the OR of re-bleeding after positive vs. negative VCE was 1.23(0.58–2.61), I² = 77% and 1.93(0.90–4.13), I² = 71% in Western and Eastern studies, respectively. For studies with long-term follow-up, no significant difference in the OR of re-bleeding after positive vs. negative VCE was detected either in the East [2.03(0.96–4.29), I² = 71%] or in the West [2.42(1.27–4.62), I² = 0%].

Conclusion: Our analysis shows that patients undergoing VCE for OGBB have similar re-bleeding rates in the East and in the West, regardless of the length of the follow-up. An increased re-bleeding risk after positive vs. negative index VCE was not noted only in studies originating from the East.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1934 MULTICENTER PROSPECTIVE CASE-CROSSOVER STUDY ON THE ASSOCIATION BETWEEN OVERT SMALL-BOWEL BLEEDING AND DRUGS USING CAPSULE ENDOSCOPY

Introduction: Small-bowel capsule endoscopy (SBCE) have been useful in managing obscure gastrointestinal bleeding. We previously reported that the use of oxicams and diclofenac was associated with an increased risk of nonsteroidal anti-inflammatory drug (NSAID)-induced small-bowel injury (Aliment Pharmacol Ther 2014). However, the etiology and temporal development of drug-associated small-bowel bleeding (SBB) has not been well characterized.

Aims & Methods: The aim of this study is to determine the risk of drugs associated with overt SBB using a case-crossover design. The Japanese Association for Capsule Endoscopy developed a prospectively recorded database of outpatients and inpatients who underwent SBCE at 18 medical centers in Japan, and data were collected from 1052 patients with obscure gastrointestinal bleeding (OGIB) between December 2010 and June 2016. This database includes patient characteristics, drugs used, SBCE findings, and final diagnosis. Drugs used were identified during a “case period” 4 weeks before the overt SBB, and a “control period” 24-5 weeks before the overt SBB. Drug adherence was classified into 4 groups: 1) 100%, 2) 50% or higher, 3) lower than 50%, and 4) 0%. Using conditional logistic regression, odds ratios (ORs) and 95% confidential intervals (CIs) were estimated using Mantel-Haenszel estimator in discordant cases.

Results: Of 1052 patients with OGIB (male/female: 678/374, age of onset: median of 51 years), 485 with SBB (male/female: 291/194, age of onset: median of 51 years) were enrolled. Final diagnoses were vascular lesions (n = 169, 37%), followed by inflammatory lesions (n = 148, 33%), drug injuries (n = 64, 14%: NSAID 47, aspirin 15, both 1, anticancer drug 1), tumors (n = 48, 11%: malignant 32, benign 16), diverticula (n = 13, 3%), etc. Data from 133 patients included 346 drugs which could be identified 24 weeks before overt SBB were analyzed. ORs (95% CIs) of enteric-coated aspirin (n = 51), warfarin (n = 27), clopidogrel (n = 24), and loxoprofen (a propionic acid derivative, n = 21) were 5.1(1.3–24.3), 3.7(0.8–16.6), 3.1(0.2–45.3), and 15.8(2.3–139.6). Aspirin-associated SBB was caused by aspirin-induced injuries, angioedema, Meckel’s diverticula, and polyps. Laxoprofen-associated SBB was caused by mostly loxoprofen-induced injuries.

Conclusion: VCE detected small bowel lesions in 71% in our cohort. There is a high prevalence of PHE in patients with decompensated cirrhosis. Vascular lesions are the most common finding in the small bowel of this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Department Of Inflammatory Bowel Disease, Division Of Internal Medicine, Hyogo College of Medicine, Nishinomiya/Japan

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: To examine the effect of discontinuation of antithrombotic agents on the diagnostic yield of capsule endoscopy in patients with obscure gastrointestinal bleeding. Use of antithrombotic agents including platelet anti-aggregants is associated with gastrointestinal bleeding. Antithrombotic users account for a large portion of patients with obscure GI bleeding, and those with the use of antithrombotics are often excluded CE. It should be noted that some patients with over antithrombotics could be referred for CE, which may affect the diagnostic yield. Aims & Methods: To examine the effect of discontinuation of antithrombotic agents on the diagnostic yield of CE in patients using antithrombotics who develop overt GI bleeding. Between March 2004 and December 2015, 130 consecutive patients (75 male; mean age 71.9 years) were referred for CE (for overt GI bleeding) and of these patients with antithrombotics were underwent for CE for overt GI bleeding, whereas patients who underwent double-balloon enteroscopy before CE were excluded. Findings were noted in the presence of observed lesions could explain the bleeding, while findings including isolated red spots and a single small polyp were considered false-negative. The primary endpoint was the rate of positive CE findings between patients who continued continued antithrombotic agents. Furthermore, a propensity score analysis was performed to reduce the effects of selection bias and potential confounding factors. The secondary endpoint was to assess the predictive factors for the positive CE findings by using multiple logistic regression.

Results: Of the 73 patients who discontinued antithrombotic agents, 36 (49.3%) patients had positive findings in the small intestine (ulcer/erosion [n = 24], angioectasia [n = 7], tumor [n = 4], and blood pooling [n = 1]), while of the 57 patients who discontinued these agents, 35 (61.4%) patients had positive findings (ulcer/erosion [n = 17], angioectasia [n = 11], tumor [n = 3], and blood pooling [n = 4]). The rates of positive CE findings did not differ between the two groups. Even after propensity score matching, discontinuation of antithrombotic agents did not increase the rate of positive CE findings. In multivariate analysis, the lowest hemoglobin level before CE examination was an independent predictive factor associated with positive CE findings. The odds ratio per 1 g/dL increase in the lowest hemoglobin level was 0.91 (95% confidence interval, 0.87-0.98). However, other factors, including sex, age, and discontinuation of antithrombotic agents, were not associated with positive CE findings.

Conclusion: Discontinuation of antithrombotic agents did not affect the diagnostic yield of CE with overt GI bleeding, and lowest hemoglobin level was associated with positive CE findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy allows high-quality imaging of the small bowel. Newer capsule with a panoramic viewing mode is available and might increase the detection rate of bleeding lesions in patients with obscure gastrointestinal bleeding. Furthermore, an improved patient acceptance rate is expected.

Aims & Methods: In a randomized prospective comparative multi-center study, patients with obscure gastrointestinal bleeding were included and examined either with Capsocam SV-1 or Pillcam SB 3. Different views of the bleeding lesions (interaction with blood and visualization of lesions; transit and evaluation time and adverse events were evaluated. Physicians were interviewed about their experience with both capsules and the evaluation software. A detailed subject questionnaire analyzed acceptance of each capsule system. Three months after initial capsule endoscopy follow-up procedures were documented.

Results: One hundred eighty-one patients with obscure gastrointestinal bleeding were recruited into the study. After exclusion of 28 patients 153 patients were randomized and Capsocam SV-1 (n=78) or PillCam SB 3 (n=75) was administered. Capsocam SV-1 detected more cases of bleeding (31/79, diagnostic yield 39.7%) compared to PillCam SB 3 (26/75, diagnostic yield 34.6%, n.s.). Transit time of both capsules was not different. Evaluation time with PillCam SB

Introduction: Chronic mesenteric ischemia (CMI) is the result of insufficient mucosal perfusion of the gastrointestinal tract, mostly caused by atherosclerotic stenosis of the mesenteric arteries. Other causes of CMI are vasculitis, median arcuate ligament syndrome or non-occlusive ischemia (NOIIM) due to decreased cardiac output or hypoxia-oxygenation. The diagnosis of CMI remains challenging as chronic abdominal pain is common and mesenteric artery stenoses are frequently observed in the general population but not necessarily related. Harki et al.1 designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50–70% celiac artery (CA) stenosis 1 pt, >70% CA stenosis 4 pts, 50–70% superior mesenteric artery (SMA) stenosis 1 pt and >70% SMA stenosis 3 pts). A total score of 0–2 pts predicts an absolute risk of CMI of 0–21%, 3–6 pts a 22–46% risk and ≥7 pts a risk of ≥79%. We aimed to validate this prediction model in a prospective large multicenter patient cohort.

Aims & Methods: Patients suspected of CMI referred to two Dutch specialized CMI referral centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography or MR-angiography, and a mucosal ischemia test (visible light spectroscopy or tonometry), all patients were discussed in a specialized CMI multidisciplinary meeting resulting in an expert based consensus diagnosis. All patients with a CMI consensus diagnosis were planned for treatment (revascularization for occlusive disease and medication for NOMI). A definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

Results: A total of 246 patients were included and consensus diagnosis of CMI was made in 108 (44%) patients, which resulted in 96 (39%) patients with a definitive diagnosis of CMI after a positive response therapy. A definite diagnosis of CMI was made in 9% of the patients with low risk, in 40% of the patients with intermediate risk and in 94% of the patients with high risk of CMI according to the score chart, respectively. Etiology and vascular lesions are summarized in the table. The discriminative ability of the score chart was strong (C-Statistic 0.87).

Conclusion: The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Isolated stenosis of the celiac artery (CA) or the superior mesenteric artery (SMA) is frequently detected in patients with abdominal complaints. These patients may suffer from chronic mesenteric ischemia (CMI) causing nonspecific abdominal complaints as postprandial pain, nausea or diarrhea. However, the existence of single artery mesenteric ischemia is a topic of continuous clinical debate and reports on the effectiveness of single mesenteric artery revascularization are scarce. We evaluated the long-term clinical success rates for single CA or SMA revascularization in patients with gastrointestinal symptoms and confirmed mucosal ischemia.

Aims & Methods: Data were collected from all 97 consecutive patients with gastrointestinal symptoms and a single mesenteric artery stenosis referred to the outpatient clinic of our tertiary care institution for analysis of CMI between January 2006 and October 2010. All patients underwent a standardized diagnostic work-up for CMI at baseline consisting of medical history taking and physical examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a vascular surgeon, interventionalist radiologist and gastroenterologist, all specialized in CMI, leading to an expert based consensus diagnosis. Patients with consensus diagnosis of CMI underwent surgical or endovascular revascularization. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

Results: Consensus diagnosis of CMI was obtained in 62/97 patients and all consensus patients were revascularized. Isolated CA stenosis was present in 55/ 62 patients (89%) (31 vascular disease; 24 median arcuate ligament syndrome, MALs) and isolated atherosclerotic SMA stenosis in 7 patients. After a mean follow-up of 5.5 ± 3.0 years, 42/62 patients (68%) experienced sustained symptomatic relief. Responders to revascularization had a BMI increase during follow-up in contrast to the non-responders (+0.43 ± 2.5 versus −1.06 ± 2.4 kg/m², p = 0.033). Response to revascularization was not related to lesion localization (CA 67% versus SMA 71%, p = 0.825) or lesion etiology (MALs 63% versus vascular disease 71%, p = 0.483). See table.

### P1942 UNDERUTILIZATION OF ENDOSCOPIC ARGON PLASMA COAGULATION FOR TREATMENT OF BLEEDING GASTROINTESTINAL ANGIODYPLASIAS: AN INTERNATIONAL MULTICENTRE COHORT STUDY

**K. Grooteman**1, M. Mathurewicz2, G. Hollerner2, E. Van Geenen1, D. Menasur1, L. Pebas3

2Department of Clinical Medicine, Trinity College, Dublin/Ireland

**Contact E-mail Address:** karinagrooteman@gmail.com

**Introduction:** Endoscopic argon plasma coagulation (APC) is the first-line treatment in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasias. In the minority of patients active bleeding angiodysplasias are seen during endoscopy, but in contrast non-bleeding angiodysplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodysplasias with APC difficult.

**Aims & Methods:** The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodysplasia patients.

**Results:** Patients and methods: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before intervention, vitamin D deficiency was present in 77.7% of patients. Patients with severe vitamin D deficiency (<20 ng/mL of serum 25(OH)D) were considered for vitamin D3 treatment (15 μg/day).

**Conclusion:** A substantial proportion of patients with clinical symptomatic angiodysplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** anam_vaz@hotmail.com

**Introduction:** An association between obesity and vitamin D deficiency has been reported in several studies. This may be explained, among other things by the sequestration of the fat-soluble vitamin D in the adipose tissue. Bariatric surgery, including Roux-en-Y gastric bypass (RYGB) is an effective treatment for more extreme cases of obesity, promoting significant weight loss and consequently reduction in some obesity-related health problems. However, the problem of vitamin D deficiency doesn’t seem to be solved after RYGB and can even be exacerbated by the changes in digestion and absorption of this nutrient after the surgery.

**Aims & Methods:** The aim of this study was to analyze the prevalence of vitamin D deficiency (VDD) and vitamin D insufficiency (VDI) in a population of obese patients, before and after being submitted to RYGB. We included patients patients selected to undergo RYGB for obesity. We measured anthropometric values and the levels of 25-hydroxy-vitamin D (25(OH)D) before and 1 year after the procedure. VDD was defined as serum 25(OH)D ≤ 20ng/mL and VDI as serum 25(OH)D concentrations between 20–30ng/mL. Levels of 25(OH)D > 30ng/mL were considered normal.

**Results:** We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before

### P1943 DIGESTIVE INVOLVEMENT IN SYSTEMIC DISEASES: A UNIVERSITY HOSPITAL EXPERIENCE

**W. Khamnoussi**1, K. Chitha1, H. Bachir1, G. Kharras2, A. El Mekkaoui1, S. Hamza2, H. B. Alaoù1, K. Serra1, Z. Ismaili1

1Hepato Gastroenterology, University Hospital Mohammed V, Oujda/Morocco
2Internal Medicine, Mohammed V University Hospital, Oujda/Morocco
3Hepatogastroenterology, CHU Med V Oujda, Oujda/Morocco

**Contact E-mail Address:** wkhhamnoussi@yahoo.com

**Introduction:** Digestive manifestations in systemic diseases including vasculitis and granulomatosis is broad and can affect any segment of the digestive tract and related organs. The clinical symptoms are not specific and it can be challenging for diagnosis. The other difficulty remains the interference of digestive side effects of medication used.

**Aims & Methods:** We aimed to review various digestive manifestations of systemic diseases. This was a retrospective study from Feb 2009 to Sep 2016 in internal medicine and gastroenterology departments. The exclusion criteria was incomplete data considering the diagnosis of the systemic disease.

**Results:** patients were included, sex ratio 0.38 (101 F/39 M), mean age at inclusion was 40 years old [13,79]. The following chart summarize the % of digestive manifestations by disease:

- Systemic Lupus erythematosus 49 (10.36%)
- Systemic sclerosis 27 (8.33%)
- Behcet’s disease 27 (4.39%)
- Celiac syndrome 14 (7.37%)
- Wegener’s granulomatosis 2 (21.60%)
- Antiphospholipid Anti body Syndrome 3 (22.58%)
- Amyloidosis 1 (4.56%)
- Churg-Strauss syndrome 2 (20.96%)
- Dermatomyositis 2 (25.80%)
- Microscopic Polyangiitis 1 (0%)
- Horton’s disease 2 (8.06%)
- Takayasu arteritis 3 (3.22%)
- Cryoglobulinaemic vasculitis 2 (0%)
- Henoch-Schönlein purpura 3 (30.10%)
- Leucocytoclastic vasculitis 2 (12.9%)

**Conclusion:** Revascularization of the CA or SMA provides long-term symptom relief in 68% of patients with chronic gastrointestinal symptoms and confirmed mucosal ischemia due to single mesenteric artery stenosis. This provides the opportunity to help patients with otherwise unexplained, refractory abdominal complaints.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After sur-
gery, the number of VDD increased to 71.1% (p = 0.0079). The mean levels of 25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery (p < 0.05). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

**Conclusion:** There is a high prevalence of vitamin D deficiency in obese patients eligible for bariatric surgery. The level of deficiency tends to increase after RYGB. This population of patients should, therefore, be offered an adequate level of vitamin D supplementation, especially after the procedure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ricfittipaldi@hotmail.com

**Introduction:** Bariatric surgery is established as an excellent therapy for obesity. However, lower degrees of overweight without surgical indication also impact on patients’ health and quality of life, and the intragastric balloon (IGB) may be a treatment option.

**Aims & Methods:** We aimed to assess the efficacy of excess weight treatment with an IGB in patients with overweight and grade I obesity at EndogastroRio Clinic. A total of 717 patients were analyzed. A liquid filled IGB was used. The patients had initial body mass index (BMI) between 27 and 34.9 kg/m². The level of significance was set at p < 0.05.

**Results:** Results 615 patients were women. 131 patients had overweight and 586 had grade I obesity. Mean age was 37.97 years (17-75). Weight loss results and treatment success rates are shown on table 1. Percent excess weight loss (%EWL) was higher in overweight group (p < 0.0001) and percent total body weight loss (%TBWL) was higher in the grade I obesity group (p = 0.0009). 96 (73.28%) overweight patients and 132 (22.52%) grade I obesity patients reached a normal BMI (≤25 kg/m²).

**Conclusion:** Endoscopic treatment of obesity with an IGB shows to be an excellent therapeutic option to non elective patients for bariatric surgery according to BMI criterion

**Disclosure of Interest:** M. Galvao Neto: I declare that I have received personal fees from FRACTYL LABS, GI WINDOWS, APOLLO ENDO SURGERY, GI DYNAMICS, ETHICON ENDO SURGERY, not related to the present study.

#### P1947 SPATZ3® ADJUSTABLE INTRAGASTRIC BALLOON TREATMENT: A BRAZILIAN MULTICENTRIC EXPERIENCE

**R.J.F. Fernandez**, 1 C.F. Diestel, 2 M. Galvao Neto 3, A. F. Teixeira, 1 E. Usuy, 3 S. Barrichello 1

1Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil

2Bariatric Endoscopy, Gastro Obeso Center, Sao Paulo/Brazil

3Dept. Of Gastroenterology, Ussy Clinic, Florianopolis/Brazil

**Contact E-mail Address:** ricfittipaldi@hotmail.com

**Introduction:** Intragastric balloons (IGB) are already used worldwide in the treatment of overweight and obesity, with established success. The Spatz3® adjustable balloon brings the possibility of balloon volume control during all the treatment, possibly reducing the risk of early removals due to intolerance and greater weight loss when compared to traditional IGBs.

**Aims & Methods:** We aimed to analyze the initial 25 months results regarding weight loss and complications with Spatz3® adjustable intragastric balloon in Brazil. In this retrospective longitudinal study were included patients submitted to Spatz3® adjustable IGB treatment between October 2014 to April 2017 in four private clinics in Brazil. The IGB Spatz3® was filled with a standard volume of 600 ml that was downward or upward adjusted when necessary. The patients presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the complications of Spatz3® treatment and BMI reduction, percent total body weight loss (%TBWL) and percent excess weight loss (%EWL). Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at p < 0.05.

**Results:** 422 patients underwent implant Spatz3® balloon in the period. The complications (14.28%) at the present study were: early balloon removal (6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%). There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume reduction: 162.86 mL) and all of them kept in the treatment (no early removals). 180 patients have completed the treatment (minimum 9 months of gastric balloon stay). The BMI decreased from 37.69 to 31.51 kg/m² (p < 0.0001), body weight decreased from 107.67 to 90.16 kg (p < 0.0001) and excess weight diminished from 36.79 to 19.27 kg (p < 0.0001). Eighty-six patients underwent upward adjust-ment. The adjustment resulted in a further mean weight loss of 4.2 kg (>9 to 20 kg), the range of upward volume was 281.73 to 66.58 ml (100-420 ml) and the moment of the procedure was 7.06 ± 1.64 months. The group of patients that did the upward adjustment don’t have a higher %TBWL, %EWL or a a higher BMI reduction, when compared to the group that did not (p = 0.4413, p = 0.9245, p = 0.2729, respectively).

**Conclusion:** This study shows that Spatz3® IGB treatment is an effective procedure for weight reduction, without mortality but with higher morbidity rates when compared to traditional IGBs. Even more, the downward adjustment treatment seems to be effective in preventing the early balloon removal. Although the upward adjustment does not show to be able in providing a greater weight loss.

**Disclosure of Interest:** M. Galvao Neto: I declare that I have received personal fees from FRACTYL LABS, GI WINDOWS, APOLLO ENDO SURGERY, GI DYNAMICS, ETHICON ENDO SURGERY, not related to the present study.

All other authors have declared no conflicts of interest.
Patients’ body mass distribution had a clear improvement, with a significant increase in the percentage of Fat-Free Mass. A significant reduction of the basal metabolic rate of 1893.24 to 1694.67 was noted. Endoscopic approach with gastric balloon provides a significant weight loss and helps patients acquiring healthy habits.

Disclosure of Interest: M. Galvao Neto: Apollo endosurgery consultant
All other authors have declared no conflicts of interest.

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.

Aims & Methods: We aimed to assess the efficacy and complications of excess weight treatment with a non-adjustable IGB.

A liquid-filled IGB with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m² and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist.

For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data were analyzed using descriptive statistical methods, the Student t-test, and analysis of variance followed by the Tukey post-test. The level of significance was set at p < 0.05.

Results: A total of 5874 patients were analyzed. The incidence of complications was 7.32% (n = 430), as listed below: 299 (5.09%) early IGB removal, 58 (0.98%) absence of weight loss or weight gain. The incidence of gas production inside the balloon was 0.20% (n = 54), and the incidence of leakage was 0.54% (n = 12) and the incidence of pancreatitis and esophagus perforation was 0.01% each (n = 1). Of the 5444 remaining patients, 4081 (74.9%) were women and 1363 (25.1%) were men. Mean age was approximately 38.8 years. The patients showed a significantly lower final BMI (mean: 30.08 ± 5.06 kg/m²) than the initial BMI (mean: 36.94 ± 5.67 kg/m²) (p < 0.0001). Mean BMI reduction was 6.85 ± 3.06 kg/m² (range: 0.25-29.79). Mean percent total body weight loss (TBWL) was 18.42 ± 7.25% and mean percent excess weight loss (EWL) was 65.66 ± 36.24% (range: 3.99-336.14). The weight loss in kilograms was 19.13 ± 8.86. The treatment success rate (%EWL > 25) was 93.0%, as follow: overweight was 99.0%, grade I obesity was 95.83%, grade II obesity 93.65% and grade III obesity was 86.09%. Percent EWL was higher in the overweight group (OW) (131.54% EWL), followed by grade I obesity (G1O) (76.67%), grade II obesity (G2O) (56.01%) and grade III obesity (G3O) (45.45%) sequentially (p < 0.000). Percent EWL was also higher in women (69.71% EWL) than in men (53.39% EWL) (p < 0.000). Results are better shown in table 01.
Disclosure of Interest: M. Galvao Neto: I received personal fees from FRACTYL Ltd. L.G. Introduction: Mechanisms contributing to the development of irritable bowel syndrome (IBS) including the altered visceral perception, intestinal low-grade inflammation and psychosocial factors. Recent research has revealed a relationship between intake of FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechanisms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) stress induced IBS mice model. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in this study. Mice were subjected to water avoidance stress (WAS) condition (1 h/10 days) or sham stress (basal condition; 1 h/day for 10 days) with an oral gavage of saline or gut solution containing FOS (8 g/kg) for 2 weeks. Then visceral sensitivity was measured by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) and histologic analyses were used to evaluate mucosal inflammation. Immunohistochemistry, reverse transcription, and qPCR were used to assess mucosal mast cell, levels of cytokines (IL-6, IL-23, TNF-α, IL-10, IL-1β) and SCFA, respectively.

Results: Changes in visceral hyperalgesia and low-grade inflammation in WAS mice as a model of IBS. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3±2.61 vs. 8.33±3.55, P<0.01) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression were mediated by FOS with increased IL-23 (3.17±2.11 fold, P<0.05) in ileum and IL-1β (2.45±1.55 fold, P<0.05) in colon compared with saline. In addition, the average concentrations of acetate (2.48±0.62 vs. 1.04±1.0, P<0.01), propionate (0.48±0.09 vs. 0.33±0.0 P<0.01), butyrate (0.70±0.09 vs. 0.19±0.003, P<0.05) and total SCFA (3.61±0.89 vs. 1.79±0.17, P<0.01) significantly increased in FOS administered mice compared with saline administered mice in WAS condition. In basal condition, no differences of visceral sensitivity, intestinal inflammation and SCFA were observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are linked with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immune activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several formulations consisting of live lactic acid bacteria, including bifidobacteria, are marketed as probiotic products. However, these products are often heterogeneous with respect to the composition of gastrointestinal diseases (e.g. bacteria, yeast, fungi). Hence, it is important for manufacturers to know the exact species content of their products in order to control the growth of harmful bacteria. In addition, to ensure the effectiveness of the probiotic product, the DNA was extracted from the superstrains that are members of the multispecies probiotic product VSL#3. VSL#3 is marketed globally for treating colitis ulcerosa, pouchitis, and ulcerative colitis. However, the exact species composition of this product was not yet established methods. The DNA was subject to paired-end Illumina sequencing using a HiSeq2000 platform, assembled and annotated as previously described (Douillard et al 2013).

Results: The next generation sequencing provided high quality genomes of all 8 strains that are components of the multispecies probiotic VSL#3. Detailed phylogenetic and genomic analysis confirmed the species composition to be as indicated in the VSL#3 product specification and showed the 8 strains of this multispecies product to be closely related to the species Lactobacillus acidophilus, Lactobacillus plantarum, Lactobacillus helveticus, Bifidobacterium breve and B. animalis subsp. lactis (this species included two strains). The species L. paracasei and L. casei were highly related and in need for further official taxonomic resolution. The annotated genes of the assembled genomes were used to identify genes involved in potential probiotic functions. Full sets of genes for the production of tight adherence pili were observed in the Bifidobacterium spp. and are known to produce adherence factor that is involved in adherence to mucosal surfaces and ornmote intestinal integrity, and influence host cell development (O’Connell Motherway et al 2011). Moreover, a series of signaling proteins were identified in the genomes of the Lactobacillus spp., including surface layer proteins and sortase-dependent pili proteins that we showed to interact with the mucosal surfaces and dendritic cells (Konstantinov et al 2008; Kankainen et al 2008; Tytgat et al 2016).

Conclusion: The genomic analysis of the VSL#3 strains confirmed the product specifications, defined the baseline genetic coding capacity, and predicted a number of probiotic mechanisms that could explain the efficacy of this multispecies product.

Introduction: Disease prevention and public health awareness are fundamental to reduce morbidity, mortality and health-related costs. Extensive research led to identification of causes of gastrointestinal (GI) diseases, but health problems are still difficult to get population involved. The goals of our pilot campaign are: (a) to raise awareness about GI diseases, risk factors, signs, symptoms, in order to convince people to change behavior and to prompt them with concerns to visit doctors as early as possible; (b) facilitate communication between healthcare providers and population; (c) to determine the knowledge of health personnel about the appropriate diagnostic investigations. Any information we can share may also benefit patients and their families, in recognition of the many people who suffer with the pain and discomfort caused by GI disorders.

Aims & Methods: We organized population-based events, out of health facilities during which: (a) giant inflatable anatomical models of GI organs that can be visited inside, were installed; (b) educational panels and brochures were set up and exhibited both inside and outside the model; (c) videos illustrating endoscopy exams and histopathology examinations were projected and discussed; (d) clinical cases, also mimicking patient encounter, were simulated.

Results: We started an innovative strategy focused on the keywords: multidisciplinary team, scientific rigor but simple words, people attraction, curiosity inducing communication, in Parma and neighbouring Cities. Specialists in Gastroenterology, Anatomic Pathology, Radiology, Surgery, Biochemistry, Nutrition, together with pre- and post-graduate Students, discussed various aspects of gastrointestinal diseases. Selected people were examined by ultrasound, computed tomography. Municipality and civil society were also involved to ensure organizational efficiency. The most discussed topics regarded dyspepsia, gastritis, helicobacter pylori infection, gastroesophageal reflux disease, alcohol abuse, cirrhosis, hepatitis, intestinal bowel syndrome, thyroid diseases, colorectal cancer, food allergy and intolerance, optimal nutrition in health and disease. The event performed in the main square of Parma lasted two full consecutive days and was attended by about 3,000 people, most of which also filled a questionnaire. A total of 120 ultrasound examinations were performed. In neighbouring Civic the events were organized for one day; as a consequence, the number of participants was lower in proportion, but very satisfactory.
Conclusion: The events were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

Introduction: Amino acids are essential metabolites which play a role as protein constituents. Moreover, amino acids and their metabolites feature in regulation of anabolic and catabolic metabolism, detoxification processes, and act as neurotransmitters. Concentration of circulating amino acids reflects about dietary protein intake and can be an indicative of malnutrition. Changes in the amino acid homeostasis are observed in coeliac disease (CD) [1] due to malabsorption caused by enteropathy but also because of the treatment with gluten-free diet (GFD) shown to be low in the important nutrients.

Aim & Methods: A randomized, placebo-controlled interventional trial was designed to assess the influence of an oligofructose-enriched inulin (OEI) as a supplement of GFD on plasma profile and urine excretion of amino acids in CD children strictly following GFD at least 1 year. We randomized 34 children diagnosed with CD into a group receiving 10 g of OEI daily and a placebo (maltodextrin) group during a 12-week nutritional intervention. Amino acid profiles in urine and plasma was analysed via EZ.Faas [2,3] derivatisation method followed by gas chromatography/mass spectrometry detection.

Results: At the baseline and after supplementation, 22 and 27 amino acids were identified in plasma and urine, respectively in both groups of children. Significantly higher levels (p < 0.05) of alanine, serine, asparagine, glutamine, threonine, proline, histidine, lysine, and ornithine were observed in the OEI group. The changes of glutamic acid, hydroxylysine and cystine were detected in urine of OEI group after intervention as compared to the baseline and placebo group. Analysis of amino acid profiles in plasma samples showed a significant increase (p < 0.05) of many amino acids in both OEI and placebo groups after intervention. However, the concentrations of glutamin and glutamic acid were significantly higher (p < 0.05) in the OEI supplemented group.

Conclusion: Our study showed that supplementation of GFD with OEI impacts the amino acid homeostasis in CD children. OEI in GFD increased a total concentration of amino acids in both urine and plasma. Higher excretion of amino acids in urine accompanied with increased amino acid content in plasma may indicate the improved absorption or/and stimulated de novo synthesis of proteins. Increase in the concentration of glutamic acid can stimulate recovery of the intestinal mucosa by itself or by the involvement in the synthesis of cytokine known as negatively correlated with intestinal mucosal damage [1], therefore we can suspect that OEI added to GFD can help in restoring of the intestinal barrier integrity.

Introduction: The quality of life and nutritional management after gastrectomy are major issues for gastric cancer patients, as is oncological surveillance. Weight loss usually follows gastric resection, with reported losses ranging from 10% to 30% of the preoperative weight. This loss has been attributed to inadequate oral intake, malabsorption, rapid intestinal transit time, and bacterial overgrowth. Timely, appropriate nutritional intervention can minimize diet intolerance, weight loss, and micronutrient deficiencies that often follow surgery.

Aim & Methods: This study investigated long-term trends in hematological and nutritional parameters after gastrectomy for gastric cancer and evaluated the influence of the reconstruction type on these trends. The medical records of 558 patients who underwent curative gastrectomy with standard lymph node dissection for stage I gastric cancer between January 2006 and December 2013 were reviewed. The hematological and nutritional parameters evaluated included hemoglobin, ferritin, vitamin B12, total protein, albumin, total cholesterol, triglyceride, and calcium. The patients were followed up for 6 months postoperatively and then annually until death, cancer recurrence, or follow-up loss.

Results: In the long term, ferritin and triglyceride gradually decreased after gastrectomy, while the other parameters decreased slightly or were stable. In the comparisons according to reconstruction type, the Roux-en-Y group had the lowest levels of hemoglobin, ferritin, vitamin B12, total protein, albumin, and total cholesterol beginning 6 months postoperatively compared with the Billroth I and II groups. However, only ferritin and vitamin B12 had significant differences in the 5-year cumulative incidences of deficiency according to the reconstruction type, whereas albumin, triglyceride, total cholesterol and calcium did not.

Conclusion: Although malabsorption and malnutrition are common in patients after a gastrectomy, most nutritional parameters were stable or decreased slightly in the long-term and were not markedly influenced by the reconstruction type or extent of gastrectomy. Therefore, for more accurate nutritional assessment after gastrectomy, multivariate analysis and further study should be considered rather than simply measuring biochemical parameters.

Introduction: Total gastrectomy can profoundly influence patients’ nutritional status and wound healing. The optimal route of nutrition is controversial and vaccination guidelines vary. The objective of this systematic review and meta-analysis is to determine if the optimal nutritional route after total gastrectomy can be identified.

Aims & Methods: Studies were identified via a systematic review of randomized controlled trials comparing various nutritional routes after total gastrectomy. The primary outcome measure was overall morbidity.

Results: Six studies involving 353 patients (median age 62 years, 217 males, 170 TPN, 96 NJ, 87 JEJ) who underwent total gastrectomy were analysed. Overall morbidity was significantly greater in patients after TPN compared with EN (p = 0.04). HFD rats were more anxious in OFT (p = 0.001) and showed increased faeces weight (p = 0.01), whereas VAD compromised spatial learning (p = 0.04). HFD rats were more anxious in OFT (p = 0.001) and showed increased faeces weight (p = 0.01), whereas VAD compromised spatial learning (p = 0.04).

Conclusion: HFD-induced alterations in memory and anxiety were not affected by VAD but impaired HFD on water intake and faeces weight, suggesting that their operating mechanisms are different. VAD by itself impaired spatial memory that requires further investigation.

Introduction: Patients on home parenteral nutrition (HPN) are exposed to a life-long risk of catheter-related bloodstream infections (CRBSI), which threaten catheter and patient survival. Both taurolidine 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurolidine as CLS is superior to saline in preventing CRBSI in HPN patients.

Aims & Methods: We hypothesized that taurolidine 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blinded trial randomly assigned HPN patients to use either the CLS taurolidine 2% or saline 0.9% for one year. Primary outcome was the number of CRBSI/1000 catheter days. Secondary outcomes included time to CRBSI or catheter removal due to CRBSI, number of catheter removals due to CRBSI, exit-site infections, catheter occlusions, and serious adverse events.

Results: Of 102 randomized patients were enrolled as modified intention-to-treat population. With taurolidine, 5 CRBSI occurred during 15318 catheter days. In the saline arm 18 CRBSI occurred over 12493 catheter days. CRBSI/1000 catheter days were 0.33 in the taurolidine group and saline groups, respectively. Relative risk, 0.25; 95% CI, 0.07 to 0.73; P = 0.003. The cumulative proportion of CRBSI-free patients after one year was 88% in the taurolidine group and 49% in the saline group (P = 0.002). The number of catheter removals due to CRBSI was two (4%) in the taurolidine group and eight (16%) in the saline arm (P = 0.049). The cumulative proportion of patients without a catheter removal due to CRBSI was higher in the taurolidine group (P = 0.025). Exit-site infection and catheter occlusion rates were similar in both groups. Except for occurrence of CRBSI (P = 0.002), there was no difference in (serious) adverse events between groups. Drug-related adverse events were rare and generally mild to moderate.

Conclusion: Taurolidine 2% decreased the risk for CRBSI by more than four fold in HPN patients compared to saline 0.9%. Given its favorable safety profile and lack of evidence for altering microbial susceptibility, taurolidine lock solution therefore seems a key strategy to prevent CRBSI.

P1960 REPAIR OF DAMAGED CENTRAL VENOUS CATHETERS SUBSTANTIALLY LONGS DELAY IN SURVIVAL IN PATIENTS ON HOME PARENTERAL NUTRITION

Y. Wouters1, R. Vissers2, W. Kiević2, G. Wanent1

1Radboudumc, Nijmegen/Netherlands
2Radboud University Medical Center, Nijmegen/Netherlands

Contact E-mail Address: Yannick.Wouters@radboudumc.nl

Introduction: Patients with severe intestinal failure depend on life-long home parenteral nutrition (HPN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients in the Radboud University Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (32%) were damaged at the distal end, near the screw thread of the catheter, 25 CVCs (50%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the flexible part of the catheter. The mean time to catheter repair after placement was 2.2 years (95% CI = 1.5–2.89). The mean catheter survival after repair was extended by 1.4 years to 3.6 years (95% CI = 2.69–4.46; p = 0.01). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients who maintain venous access. Catheter repair is a safe procedure.

P1961 LONG-TERM CLINICAL OUTCOMES OF PATIENTS ON HOME PARENTERAL NUTRITION USING TAUROLIDINE CATHETER LOCKS

Y. Wouters1, B. Roosenboom2, W. Kiević2, G. Wanent2

1Radboudumc, Nijmegen/Netherlands
2Department Of Gastroenterology And Hepatology, Radboud University Nijmegen, Nijmegen/Netherlands

Contact E-mail Address: Yannick.Wouters@radboudumc.nl

Introduction: Catheter-related complications (CRCs) in home parental nutrition (HPN) patients are a threat to both catheter and patient survival. Taurolidine 2%, an antimicrobial catheter lock solution (CLS), is an effective agent for the prevention of catheter-related bloodstream infections (CRBSI). Aim & Methods: The aim of this retrospective study was to evaluate long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) for HPN support were included in this study. CRC incidence rates/1000 catheter days were described. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunneled CVCs) were inserted, comprising 261252 catheter days. Median survival for Hickmans, PACs and non-tunneled catheters was 175 (43–544), 310 (61–827) and 246 (54–817) catheter days (5–2070). Numerically, but not significantly, CRBSI and CRO rates decreased over time. The sole use of intra-venous nutrition (IV) in PAC patients was placed as the only factor that could influence the CVC repair rate. Data obtained were filtered by quality and length and processed for alpha and beta diversity analyses using QIIME software package. SCFA profile was measured using solid phase microextraction (SPME) coupled to gas chromatography and high resolution mass spectrometry employing time of flight mass analyser (Pegasus GC-HRT; LECO, USA). D-lactate content was determined using Megazyme kit.

Conclusion: Weighted UniFrac analysis revealed significant differences between control and TPN subjects. In healthy controls, most abundant phylum was Firmicutes (64.2 ± 7.5%), followed by Bacteroidetes (22.5 ± 9.1%) and Actinobacteria (8.9 ± 4.5%). Proteobacteria were found in only one control sample. In TPN group, Firmicutes dominated 64–29% of microbiota but Bacteroidetes were absent and Actinobacteria significantly reduced (1.6–5.4%). Proteobacteria were found in all samples (23.6 ± 15%). The most abundant metabolites in control stool samples were short chain fatty acids (SCFA): acetate, propionate and butyrate. In the TPN group, lactate predominated significantly, while SCFA were absent in the intestinal content of these patients.

Introduction: Patients with short bowel syndrome (SBS) exhibit substantial disturbances in gut microbiota composition, which implicates significant alterations of intestinal metabolism.

Aims & Methods: The aim of this study was to perform genetic and metabolomic analysis of stool samples collected from SBS patients totally dependent on parenteral nutrition (TPN). We included 10 healthy individuals and 8 healthy individuals and 8 healthy individuals and 8 healthy individuals.

Results: Weighted UniFrac analysis revealed significant differences between control

Disclosure of Interest: All authors have declared no conflicts of interest.

P1963 COMPARING RISKS OF ADVERSE EVENTS ASSOCIATED WITH PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) PLACEMENT BETWEEN THE MODIFIED INTRODUCER TECHNIQUE AND THE OVERTUBE ASSISTED PULL TECHNIQUE

H. Matsui1, H. Inomata1, H. Horuiuchi1, N. Tama1, K. Sumiyama1

1Department Of Endoscopy, Jikei University School of Medicine, Tokyo/Japan

Contact E-mail Address: hiro24th@s10.yahoo.co.jp

Introduction: Techniques of percutaneous endoscopic gastrostomy (PEG) placement can be divided into two techniques, the pull technique or the introducer technique. Although the development of the pull technique has improved procedural safety for the gastrostomy placement, the pull technique, in which the PEG catheter is delivered through the oral cavity and the hypopharynx, inevitably contaminates the peristomal site. A series of studies directly comparing the newly developed modified introducer technique using a blunt cannula compared with the conventional pull technique demonstrated that the modified introducer technique was more preferable regarding procedure related adverse events. Meanwhile, use of an overtube while guiding the catheter into the stomach is performed in the reduction of the bacteria implantation. It is still unclear if the modified introducer technique or the overtube assisted pull technique would reduce risks of adverse events.

Aims & Methods: In this study, we retrospectively investigated risks of adverse events associated with the modified introducer technique and the overtube assisted pull method. Outcomes of patients who underwent the PEG placement from Jan 2013 to Oct 2016 at Jikei University Hospital were analyzed. The following data were collected from clinical records: age, gender, technique of PEG, reasons for PEG, lab tests and prognostic nutritional index (PNI).

Results: During the study period, 236 PEG placements were done in 234 patients. The average age was 69.3 ± 12.5. The modified introducer technique was applied in 167 procedures (70.8%) and the overtube assisted technique was applied in 69 procedures (29.2%). The nutrition the PEG was placed aiming for cancer patients in 132 procedures, cerebrovascular accident in 51 procedures, aspiration pneumonia in 32 procedures, and others such as infection and disuse atrophy in 21 procedures. Age (the overtube assisted pull technique > the modified introducer group) and the PNI level were significantly different between the two groups (p < 0.05). Overall, adverse events were observed in 19 (8.1%) procedures, although there was no procedure related mortality in the both groups. The risks of clinically significant adverse events were not different between the two groups. There was no significant difference in the types and the rate of adverse events between the two groups. However, severe peristomal bleedings were observed only in the modified introducer technique group. Four patients required suture placements and 3
patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events (p < 0.05) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events (p < 0.05). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events (p < 0.05). The types of the technique used were not relevant to risks of adverse events.

Clinical backgrounds of patients with and without adverse events.

Conclusion: There was no significant difference in overall risks of adverse events between the modified introducer technique group and the overtube assisted pull technique group. However, the modified introducer technique may be associated with higher risks of severer adverse events. Especially, special care should be taken in patients with lower serum platelet level.

Disclosure of Interest: All authors have declared no conflicts of interest.
